...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
                      action="store_false", dest="verbose")
    ...
    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print("reading %s..." % options.filename)
    ...

if __name__ == "__main__":
    main()
```

17.2.5 Reference Guide

Creating the parser

The first step in using *optparse* is to create an OptionParser instance.

class optparse.**OptionParser**(...)

The OptionParser constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

usage（預設值：`"%prog [options]"`）
The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

option_list（預設值：`[]`）
A list of Option objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by OptionParser subclasses), but before any version or help options. Deprecated; use *add_option()* after creating the parser instead.

option_class (default: optparse.Option)
Class to use when adding options to the parser in *add_option()*.

version（預設值：`None`）
A version string to print when the user supplies a version option. If you supply a true value for `version`, *optparse* automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for `usage`.

conflict_handler（預設值：`"error"`）
Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

description（預設值：**None**）
A paragraph of text giving a brief overview of your program. *optparse* reformats this paragraph to fit the current terminal width and prints it when the user requests help (after `usage`, but before the list of options).

formatter (default: a new **IndentedHelpFormatter**)
An instance of optparse.HelpFormatter that will be used for printing help text. *optparse* provides two concrete classes for this purpose: IndentedHelpFormatter and TitledHelpFormatter.

add_help_option（預設值：**True**）
If true, *optparse* will add a help option (with option strings `-h` and `--help`) to the parser.

prog
The string to use when expanding `%prog` in `usage` and `version` instead of `os.path.basename(sys.argv[0])`.

epilog（預設值：**None**）
A paragraph of help text to print after the option help.

Populating the parser

There are several ways to populate the parser with options. The preferred way is by using *OptionParser.add_option()*, as shown in section 教學. `add_option()` can be called in one of two ways:

- pass it an Option instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the Option constructor), and it will create the Option instance for you

The other alternative is to pass a list of pre-constructed Option instances to the OptionParser constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
    ]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating Option instances; currently it is an alias for the Option constructor. A future version of *optparse* may split Option into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate Option directly.)

定義選項

Each Option instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an *Option* instance is with the `add_option()` method of *OptionParser*.

`OptionParser.`**add_option**(*option*)

`OptionParser.`**add_option**(**opt_str*, *attr=value*, ...)

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new Option object. The most important option attribute is *action*, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, *optparse* raises an *OptionError* exception explaining your mistake.

An option's *action* determines what *optparse* does when it encounters this option on the command-line. The standard option actions hard-coded into *optparse* are:

"store"
store this option's argument (default)

"store_const"
store a constant value, pre-set via *Option.const*

"store_true"
store `True`

"store_false"
store `False`

"append"
append this option's argument to a list

"append_const"
append a constant value to a list, pre-set via *Option.const*

"count"
increment a counter by one

"callback"
call a specified function

"help"
print a usage message including all options and the documentation for them

(If you don't supply an action, the default is `"store"`. For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called `options`, which is an instance of *optparse.Values*.

class optparse.**Values**

An object holding parsed argument names and values as attributes. Normally created by calling when calling *OptionParser.parse_args()*, and can be overridden by a custom subclass passed to the *values* argument of *OptionParser.parse_args()* (as described in 剖析引數).

Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

例如🄵，當你呼叫：

```
parser.parse_args()
```

one of the first things *optparse* does is create the `options` object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following:

```
-ffoo
-f foo
--file=foo
--file foo
```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

選項屬性

class optparse.**Option**

A single command line argument, with various attributes passed by keyword to the constructor. Normally created with *OptionParser.add_option()* rather than directly, and can be overridden by a custom class via the *option_class* argument to *OptionParser*.

The following option attributes may be passed as keyword arguments to *OptionParser.add_option()*. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, *optparse* raises *OptionError*.

Option.**action**

(預設值: `"store"`)

Determines *optparse*'s behaviour when this option is seen on the command line; the available options are documented *here*.

Option.**type**

(預設值: `"string"`)

The argument type expected by this option (e.g., `"string"` or `"int"`); the available option types are documented *here*.

Option.**dest**

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells *optparse* where to write it: *dest* names an attribute of the `options` object that *optparse* builds as it parses the command line.

Option.**default**

The value to use for this option's destination if the option is not seen on the command line. See also *OptionParser.set_defaults()*.

Option.**nargs**

(預設值: 1)

How many arguments of type *type* should be consumed when this option is seen. If > 1, *optparse* will store a tuple of values to *dest*.

Option.**const**

For actions that store a constant value, the constant value to store.

Option.**choices**

For options of type `"choice"`, the list of strings the user may choose from.

Option.**callback**

For options with action `"callback"`, the callable to call when this option is seen. See section *Option Callbacks* for detail on the arguments passed to the callable.

Option.**callback_args**

Option.**callback_kwargs**

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

Option.**help**

Help text to print for this option when listing all available options after the user supplies a *help* option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

Option.**metavar**

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section 教學 for an example.

Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide *optparse*'s behaviour; a few have required attributes, which you must specify for any option using that action.

- `"store"` [relevant: *type*, *dest*, *nargs*, *choices*]

  The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the *Standard option types* section.

  If *choices* is supplied (a list or tuple of strings), the type defaults to `"choice"`.

  If *type* is not supplied, it defaults to `"string"`.

  If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., `-f` implies `f`).

  範例:

  ```
  parser.add_option("-f")
  parser.add_option("-p", type="float", nargs=3, dest="point")
  ```

  As it parses the command line

  ```
  -f foo.txt -p 1 -3.5 4 -fbar.txt
  ```

  optparse will set

  ```
  options.f = "foo.txt"
  options.point = (1.0, -3.5, 4.0)
  options.f = "bar.txt"
  ```

- `"store_const"` [required: *const*; relevant: *dest*]

  The value *const* is stored in *dest*.

  範例:

  ```
  parser.add_option("-q", "--quiet",
                    action="store_const", const=0, dest="verbose")
  parser.add_option("-v", "--verbose",
                    action="store_const", const=1, dest="verbose")
  parser.add_option("--noisy",
                    action="store_const", const=2, dest="verbose")
  ```

  If `--noisy` is seen, *optparse* will set

  ```
  options.verbose = 2
  ```

- `"store_true"` [relevant: *dest*]

  A special case of `"store_const"` that stores `True` to *dest*.

- `"store_false"` [relevant: *dest*]

  Like `"store_true"`, but stores `False`.

  範例:

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant: *type*, *dest*, *nargs*, *choices*]

  The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

  The defaults for *type* and *dest* are the same as for the "store" action.

  範例:

  ```
  parser.add_option("-t", "--tracks", action="append", type="int")
  ```

  If -t3 is seen on the command-line, *optparse* does the equivalent of:

  ```
  options.tracks = []
  options.tracks.append(int("3"))
  ```

  If, a little later on, --tracks=4 is seen, it does:

  ```
  options.tracks.append(int("4"))
  ```

  The append action calls the append method on the current value of the option. This means that any default value specified must have an append method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

  ```
  >>> parser.add_option("--files", action="append", default=['~/.mypkg/defaults'])
  >>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
  >>> opts.files
  ['~/.mypkg/defaults', 'overrides.mypkg']
  ```

- "append_const" [required: *const*; relevant: *dest*]

  Like "store_const", but the value *const* is appended to *dest*; as with "append", *dest* defaults to None, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: *dest*]

  Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.

  範例:

  ```
  parser.add_option("-v", action="count", dest="verbosity")
  ```

  The first time -v is seen on the command line, *optparse* does the equivalent of:

  ```
  options.verbosity = 0
  options.verbosity += 1
  ```

  Every subsequent occurrence of -v results in

  ```
  options.verbosity += 1
  ```

- "callback" [required: *callback*; relevant: *type*, *nargs*, *callback_args*, *callback_kwargs*]

  Call the function specified by *callback*, which is called as

  ```
  func(option, opt_str, value, parser, *args, **kwargs)
  ```

更多細節請見*Option Callbacks*。

- `"help"`

  Prints a complete help message for all the options in the current option parser. The help message is constructed from the `usage` string passed to OptionParser's constructor and the *`help`* string passed to every option.

  If no *`help`* string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

  `optparse` automatically adds a *`help`* option to all OptionParsers, so you do not normally need to create one.

  範例：

```
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

  If *`optparse`* sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```
Usage: foo.py [options]

Options:
  -h, --help        Show this help message and exit
  -v                Be moderately verbose
  --file=FILENAME   Input file to read data from
```

  After printing the help message, *`optparse`* terminates your process with `sys.exit(0)`.

- `"version"`

  Prints the version number supplied to the OptionParser to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of OptionParser. Generally only relevant if the `version` argument is supplied to the OptionParser constructor. As with *`help`* options, you will rarely create `version` options, since *`optparse`* automatically adds them when needed.

Standard option types

`optparse` has five built-in option types: `"string"`, `"int"`, `"choice"`, `"float"` and `"complex"`. If you need to add new option types, see section *Extending optparse*.

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type `"int"`) are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling *`int()`* with the appropriate base (2, 8, 10, or 16). If this fails, so will *`optparse`*, although with a more useful error message.

`"float"` and `"complex"` option arguments are converted directly with *float()* and *complex()*, with similar error-handling.

`"choice"` options are a subtype of `"string"` options. The *choices* option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises *OptionValueError* if an invalid string is given.

剖析引數

The whole point of creating and populating an OptionParser is to call its *parse_args()* method.

`OptionParser.`**`parse_args`**(*args=None*, *values=None*)

Parse the command-line options found in *args*.

The input parameters are

args
: the list of arguments to process (default: `sys.argv[1:]`)

values
: a *Values* object to store option arguments in (default: a new instance of *Values*) -- if you give an existing object, the option defaults will not be initialized on it

and the return value is a pair `(options, args)` where

options
: the same object that was passed in as *values*, or the `optparse.Values` instance created by *optparse*

args
: the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply `values`, it will be modified with repeated *setattr()* calls (roughly one for every option argument stored to an option destination) and returned by *parse_args()*.

If *parse_args()* encounters any errors in the argument list, it calls the OptionParser's `error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. OptionParser provides several methods to help you out:

`OptionParser.`**`disable_interspersed_args`**()

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, *optparse* normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call *disable_interspersed_args()*. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.`**`enable_interspersed_args`**()

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

OptionParser.**get_option**(*opt_str*)

Returns the Option instance with the option string *opt_str*, or `None` if no options have that option string.

OptionParser.**has_option**(*opt_str*)

Return `True` if the OptionParser has an option with option string *opt_str* (e.g., `-q` or `--verbose`).

OptionParser.**remove_option**(*opt_str*)

If the *OptionParser* has an option corresponding to *opt_str*, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If *opt_str* does not occur in any option belonging to this *OptionParser*, raises *ValueError*.

Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own OptionParser subclass with some standard options.)

Every time you add an option, *optparse* checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

"error" (default)
assume option conflicts are a programming error and raise *OptionConflictError*

"resolve"
resolve option conflicts intelligently (see below)

As an example, let's define an *OptionParser* that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, *optparse* detects that a previously added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run     do no harm
  ...
  -n, --noisy   be noisy
```

It's possible to whittle away the option strings for a previously added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, *optparse* removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing OptionParser:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n`/`--dry-run` option is no longer accessible, so *optparse* removes it, leaving this help text:

```
Options:
  ...
  -n, --noisy   be noisy
  --dry-run     new dry-run option
```

Cleanup

OptionParser instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your OptionParser once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your OptionParser.

其他方法

OptionParser supports several other public methods:

`OptionParser.`**`set_usage`**(*usage*)

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.`**`print_usage`**(*file=None*)

Print the usage message for the current program (`self.usage`) to *file* (default stdout). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.`**`get_usage`**()

Same as *`print_usage()`* but returns the usage string instead of printing it.

`OptionParser.`**`set_defaults`**(*dest=value*, ...)

Set default values for several option destinations at once. Using *`set_defaults()`* is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several "mode" options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice")    # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced")  # overrides above setting
```

To avoid this confusion, use *`set_defaults()`*:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

17.2.6 Option Callbacks

When *`optparse`*'s built-in actions and types aren't quite enough for your needs, you have two choices: extend *`optparse`* or define a callback option. Extending *`optparse`* is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the `"callback"` action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

Defining a callback option

As always, the easiest way to define a callback option is by using the *OptionParser.add_option()* method. Apart from *action*, the only option attribute you must specify is `callback`, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, *optparse* doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments---the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

optparse always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via *callback_args* and *callback_kwargs*. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

type
: has its usual meaning: as with the `"store"` or `"append"` actions, it instructs *optparse* to consume one argument and convert it to *type*. Rather than storing the converted value(s) anywhere, though, *optparse* passes it to your callback function.

nargs
: also has its usual meaning: if it is supplied and > 1, *optparse* will consume *nargs* arguments, each of which must be convertible to *type*. It then passes a tuple of converted values to your callback.

callback_args
: a tuple of extra positional arguments to pass to the callback

callback_kwargs
: a dictionary of extra keyword arguments to pass to the callback

How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

option
: is the Option instance that's calling the callback

opt_str
: is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string---e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `"--foobar"`.)

value
: is the argument to this option seen on the command-line. *optparse* will only expect an argument if *type* is set; the type of `value` will be the type implied by the option's type. If *type* for this option is `None` (no argument expected), then `value` will be `None`. If *nargs* > 1, `value` will be a tuple of values of the appropriate type.

parser
: is the OptionParser instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

  parser.largs
  : the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor

option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of *parse_args()*.)

parser.rargs
the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

parser.values
the object where option values are by default stored (an instance of optparse.OptionValues). This lets callbacks use the same mechanism as the rest of *optparse* for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

args
is a tuple of arbitrary positional arguments supplied via the *callback_args* option attribute.

kwargs
is a dictionary of arbitrary keyword arguments supplied via *callback_kwargs*.

Raising errors in a callback

The callback function should raise *OptionValueError* if there are any problems with the option or its argument(s). *optparse* catches this and terminates the program, printing the error message you supply to stderr. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the `"store_true"` action.

Callback example 2: check option order

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

Callback example 3: check option order (generalized)

If you want to reuse this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
```

(繼續下一頁)

(繼續上一頁)

```
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

Callback example 4: check arbitrary condition

Of course, you could put any condition in there---you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                               % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon, dest="foo")
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a `"store"` or `"append"` option: if you define *type*, then the option takes one argument that must be convertible to that type; if you further define *nargs*, then the option takes *nargs* arguments.

Here's an example that just emulates the standard `"store"` action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that *optparse* takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as *optparse* doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that *optparse* normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why *optparse* doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []
```

(繼續下一頁)

(繼續上一頁)

```
    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)
```

17.2.7 Extending `optparse`

Since the two major controlling factors in how *optparse* interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

Adding new types

To add new types, you need to define your own subclass of *optparse*'s *Option* class. This class has a couple of attributes that define *optparse*'s types: *TYPES* and *TYPE_CHECKER*.

`Option.`**`TYPES`**

A tuple of type names; in your subclass, simply define a new tuple *TYPES* that builds on the standard one.

`Option.`**`TYPE_CHECKER`**

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where `option` is an *Option* instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the OptionValues instance returned by *OptionParser.parse_args()*, or be passed to a callback as the `value` parameter.

Your type-checking function should raise *OptionValueError* if it encounters any problems. *OptionValueError* takes a single string argument, which is passed as-is to *OptionParser*'s `error()` method, which in turn prepends the program name and the string `"error:"` and prints everything to stderr before terminating the process.

Here's a silly example that demonstrates adding a `"complex"` option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because *optparse* 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the *TYPE_CHECKER* class attribute of your Option subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the Option subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a *copy()* of *Option.TYPE_CHECKER*, we would end up modifying the *TYPE_CHECKER* attribute of *optparse*'s Option class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other *optparse*-based script, except you have to instruct your OptionParser to use MyOption instead of Option:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to OptionParser; if you don't use `add_option()` in the above way, you don't need to tell OptionParser which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

Adding new actions

Adding new actions is a bit trickier, because you have to understand that *optparse* has a couple of classifications for actions:

"store" actions
: actions that result in *optparse* storing a value to an attribute of the current OptionValues instance; these options require a *dest* attribute to be supplied to the Option constructor.

"typed" actions
: actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a *type* attribute to the Option constructor.

These are overlapping sets: some default "store" actions are `"store"`, `"store_const"`, `"append"`, and `"count"`, while the default "typed" actions are `"store"`, `"append"`, and `"callback"`.

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of Option (all are lists of strings):

`Option.`**`ACTIONS`**
: All actions must be listed in ACTIONS.

`Option.`**`STORE_ACTIONS`**
: "store" actions are additionally listed here.

Option.**TYPED_ACTIONS**

”typed” actions are additionally listed here.

Option.**ALWAYS_TYPED_ACTIONS**

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that *optparse* assigns the default type, `"string"`, to options with no explicit type whose action is listed in *ALWAYS_TYPED_ACTIONS*.

In order to actually implement your new action, you must override Option's `take_action()` method and add a case that recognizes your action.

For example, let's add an `"extend"` action. This is similar to the standard `"append"` action, but instead of taking a single value from the command-line and appending it to an existing list, `"extend"` will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an `"extend"` option of type `"string"`, the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of Option:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
            Option.take_action(
                self, action, dest, opt, value, values, parser)
```

Features of note:

- `"extend"` both expects a value on the command-line and stores that value somewhere, so it goes in both *STORE_ACTIONS* and *TYPED_ACTIONS*.
- to ensure that *optparse* assigns the default type of `"string"` to `"extend"` actions, we put the `"extend"` action in *ALWAYS_TYPED_ACTIONS* as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard *optparse* actions.
- `values` is an instance of the optparse_parser.Values class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially *getattr()* with a safety valve; it is called as

  ```
  values.ensure_value(attr, value)
  ```

  If the `attr` attribute of `values` doesn't exist or is `None`, then ensure_value() first sets it to `value`, and then returns `value`. This is very handy for actions like `"extend"`, `"append"`, and `"count"`, all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

17.2.8 例外

exception optparse.**OptionError**

Raised if an *Option* instance is created with invalid or inconsistent arguments.

exception optparse.**OptionConflictError**

Raised if conflicting options are added to an *OptionParser*.

exception optparse.**OptionValueError**

Raised if an invalid option value is encountered on the command line.

exception optparse.**BadOptionError**

Raised if an invalid option is passed on the command line.

exception optparse.**AmbiguousOptionError**

Raised if an ambiguous option is passed on the command line.

17.3 getpass --- 可🄵式密碼輸入工具

原始碼： Lib/getpass.py

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

getpass 模組 (module) 提供了兩個函式：

getpass.**getpass**(*prompt='Password: '*, *stream=None*, ***, *echo_char=None*)

提示使用者輸入一個密碼且不會有回音 (echo)。使用者會看到字串 *prompt* 作🄵提示，其預設值🄵 `'Password: '`。在 Unix 上，如有必要的話會使用替🄵錯誤處理函式 (replace error handler) 寫入到類檔案物件 (file-like object) *stream* 中。*stream* 預設🄵主控終端機 (controlling terminal) (`/dev/tty`)，如果不可用則🄵 `sys.stderr` (此引數在 Windows 上會被忽略)。

The *echo_char* argument controls how user input is displayed while typing. If *echo_char* is `None` (default), input remains hidden. Otherwise, *echo_char* must be a single printable ASCII character and each typed character is replaced by it. For example, `echo_char='*'` will display asterisks instead of the actual input.

如果無回音輸入 (echo-free input) 無法使用則 getpass() 將回退🄵印出一條警告訊息到 *stream*，🄵從 `sys.stdin` 讀取且同時發出*GetPassWarning*。

> **備🄵**
>
> 如果你從 IDLE 🄵部呼叫 getpass，輸入可能會在你🄵動 IDLE 的終端機中完成，而非在 IDLE 視窗中。

> **備🄵**
>
> On Unix systems, when *echo_char* is set, the terminal will be configured to operate in *noncanonical mode*. In particular, this means that line editing shortcuts such as `Ctrl+U` will not work and may insert unexpected characters into the input.

在 3.14 版的變更: Added the *echo_char* parameter for keyboard feedback.

exception getpass.**GetPassWarning**

當密碼輸入可能被回音時會發出的*UserWarning* 子類🄵。

getpass.**getuser**()

回傳使用者的" 登入名稱"。

此函式會按順序檢查環境變數 LOGNAME、USER、LNAME 和 USERNAME，🄵回傳其中第一個被設定成非空字串的值。如果均未設定，則在支援*pwd* 模組的系統上將會回傳來自密碼資料庫的登入名稱，否則將引發一個*OSError* 例外。

大部分情🄵下，此函式應該要比*os.getlogin()* 優先使用。

在 3.13 版的變更: 在過去，除了*OSError* 外還會引發各種例外。

17.4 fileinput --- 逐列🄵代多個輸入串流

原始碼： Lib/fileinput.py

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see *open()*.

The typical use is:

```
import fileinput
for line in fileinput.input(encoding="utf-8"):
    process(line)
```

This iterates over the lines of all files listed in sys.argv[1:], defaulting to sys.stdin if the list is empty. If a filename is '-', it is also replaced by sys.stdin and the optional arguments *mode* and *openhook* are ignored. To specify an alternative list of filenames, pass it as the first argument to *input()*. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the *mode* parameter in the call to *input()* or *FileInput*. If an I/O error occurs during opening or reading a file, *OSError* is raised.

在 3.3 版的變更: *IOError* 曾經被引發；現在它是一個*OSError* 的🄵名。

If sys.stdin is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using sys.stdin.seek(0)).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the *openhook* parameter to *fileinput.input()* or *FileInput()*. The hook must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. If *encoding* and/or *errors* are specified, they will be passed to the hook as additional keyword arguments. This module provides a *hook_compressed()* to support compressed files.

The following function is the primary interface of this module:

fileinput.**input**(*files=None*, *inplace=False*, *backup=''*, ***, *mode='r'*, *openhook=None*, *encoding=None*, *errors=None*)

Create an instance of the *FileInput* class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the *FileInput* class.

The *FileInput* instance can be used as a context manager in the with statement. In this example, *input* is closed after the with statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt'), encoding="utf-8") as f:
    for line in f:
        process(line)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameters *mode* and *openhook* are now keyword-only.

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

`fileinput.`**`filename`**`()`

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.`**`fileno`**`()`

Return the integer "file descriptor" for the current file. When no file is opened (before the first line and between files), returns `-1`.

`fileinput.`**`lineno`**`()`

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

`fileinput.`**`filelineno`**`()`

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

`fileinput.`**`isfirstline`**`()`

Return `True` if the line just read is the first line of its file, otherwise return `False`.

`fileinput.`**`isstdin`**`()`

Return `True` if the last line was read from `sys.stdin`, otherwise return `False`.

`fileinput.`**`nextfile`**`()`

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

`fileinput.`**`close`**`()`

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

`class` `fileinput.`**`FileInput`**`(`*files=None*, *inplace=False*, *backup=''*, ***, *mode='r'*, *openhook=None*, *encoding=None*, *errors=None*`)`

Class `FileInput` is the implementation; its methods `filename()`, `fileno()`, `lineno()`, `filelineno()`, `isfirstline()`, `isstdin()`, `nextfile()` and `close()` correspond to the functions of the same name in the module. In addition it is *iterable* and has a `readline()` method which returns the next input line. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With *mode* you can specify which file mode will be passed to `open()`. It must be one of `'r'` and `'rb'`.

The *openhook*, when given, must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. You cannot use *inplace* and *openhook* together.

You can specify *encoding* and *errors* that is passed to `open()` or *openhook*.

A `FileInput` instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as input:
    process(input)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameter *mode* and *openhook* are now keyword-only.

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

在 3.11 版的變更: The `'rU'` and `'U'` modes and the `__getitem__()` method have been removed.

Optional in-place filtering: if the keyword argument `inplace=True` is passed to *`fileinput.input()`* or to the *`FileInput`* constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the *backup* parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

`fileinput.`**`hook_compressed`**(*filename*, *mode*, *, *encoding=None*, *errors=None*)

Transparently opens files compressed with gzip and bzip2 (recognized by the extensions `'.gz'` and `'.bz2'`) using the *`gzip`* and *`bz2`* modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using *`open()`* without any decompression).

The *encoding* and *errors* values are passed to *`io.TextIOWrapper`* for compressed files and open for normal files.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed, encoding="utf-8")`

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

`fileinput.`**`hook_encoded`**(*encoding*, *errors=None*)

Returns a hook which opens each file with *`open()`*, using the given *encoding* and *errors* to read the file.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("utf-8", "surrogateescape"))`

在 3.6 版的變更: 新增可選參數 *errors*。

在 3.10 版之後被🄵用: This function is deprecated since *`fileinput.input()`* and *`FileInput`* now have *encoding* and *errors* parameters.

17.5 `curses` --- 字元儲存格顯示的終端處理

原始碼： Lib/curses

The *`curses`* module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

可用性: not Android, not iOS, not WASI.

此模組在行動平台或*WebAssembly* 平台上不支援。

備🄵

Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

17.5.1 函式

curses 模組定義了以下例外：

exception curses.**error**

Exception raised when a curses library function returns an error.

> **備🄵**
>
> Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to *A_NORMAL*.

curses 模組定義了以下函式：

curses.**assume_default_colors**(*fg*, *bg*, /)

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application.

- Assign terminal default foreground/background colors to color number `-1`. So `init_pair(x, COLOR_RED, -1)` will initialize pair *x* as red on default background and `init_pair(x, -1, COLOR_BLUE)` will initialize pair *x* as default foreground on blue.
- Change the definition of the color-pair `0` to `(fg, bg)`.

在 3.14 版被加入.

curses.**baudrate**()

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

curses.**beep**()

Emit a short attention sound.

curses.**can_change_color**()

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

curses.**cbreak**()

Enter cbreak mode. In cbreak mode (sometimes called "rare" mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first *raw()* then *cbreak()* leaves the terminal in cbreak mode.

curses.**color_content**(*color_number*)

Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between `0` and `COLORS - 1`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between `0` (no component) and `1000` (maximum amount of component).

curses.**color_pair**(*pair_number*)

Return the attribute value for displaying text in the specified color pair. Only the first 256 color pairs are supported. This attribute value can be combined with *A_STANDOUT*, *A_REVERSE*, and the other A_* attributes. *pair_number()* is the counterpart to this function.

curses.**curs_set**(*visibility*)

Set the cursor state. *visibility* can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the "visible" mode is an underline cursor and the "very visible" mode is a block cursor.

curses.**def_prog_mode**()

Save the current terminal mode as the "program" mode, the mode when the running program is using curses. (Its counterpart is the "shell" mode, for when the program is not in curses.) Subsequent calls to *reset_prog_mode()* will restore this mode.

curses.**def_shell_mode**()

Save the current terminal mode as the "shell" mode, the mode when the running program is not using curses. (Its counterpart is the "program" mode, when the program is using curses capabilities.) Subsequent calls to *reset_shell_mode()* will restore this mode.

curses.**delay_output**(*ms*)

Insert an *ms* millisecond pause in output.

curses.**doupdate**()

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The *doupdate()* ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a *noutrefresh()* call after write operations such as *addstr()* have been performed on a window. The normal *refresh()* call is simply noutrefresh() followed by doupdate(); if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing noutrefresh() calls on all windows, followed by a single doupdate().

curses.**echo**()

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

curses.**endwin**()

De-initialize the library, and return terminal to normal status.

curses.**erasechar**()

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.**filter**()

The *filter()* routine, if used, must be called before *initscr()* is called. The effect is that, during those calls, LINES is set to 1; the capabilities clear, cup, cud, cud1, cuu1, cuu, vpa are disabled; and the home string is set to the value of cr. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

curses.**flash**()

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by *beep()*.

curses.**flushinp**()

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

curses.**getmouse**()

After *getch()* returns *KEY_MOUSE* to signal a mouse event, this method should be called to retrieve the queued mouse event, represented as a 5-tuple (id, x, y, z, bstate). *id* is an ID value used to distinguish multiple devices, and *x*, *y*, *z* are the event's coordinates. (*z* is currently unused.) *bstate* is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of

one or more of the following constants, where *n* is the button number from 1 to 5: *BUTTONn_PRESSED*, *BUTTONn_RELEASED*, *BUTTONn_CLICKED*, *BUTTONn_DOUBLE_CLICKED*, *BUTTONn_TRIPLE_CLICKED*, *BUTTON_SHIFT*, *BUTTON_CTRL*, *BUTTON_ALT*.

在 3.10 版的變更: The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

`curses.`**`getsyx`**`()`

Return the current coordinates of the virtual screen cursor as a tuple `(y, x)`. If *leaveok* is currently `True`, then return `(-1, -1)`.

`curses.`**`getwin`**`(`*file*`)`

Read window related data stored in the file by an earlier *window.putwin()* call. The routine then creates and initializes a new window using that data, returning the new window object.

`curses.`**`has_colors`**`()`

Return `True` if the terminal can display colors; otherwise, return `False`.

`curses.`**`has_extended_color_support`**`()`

Return `True` if the module supports extended colors; otherwise, return `False`. Extended color support allows more than 256 color pairs for terminals that support more than 16 colors (e.g. xterm-256color).

Extended color support requires ncurses version 6.1 or later.

在 3.10 版被加入.

`curses.`**`has_ic`**`()`

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.`**`has_il`**`()`

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

`curses.`**`has_key`**`(`*ch*`)`

Take a key value *ch*, and return `True` if the current terminal type recognizes a key with that value.

`curses.`**`halfdelay`**`(`*tenths*`)`

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between `1` and `255`. Use *nocbreak()* to leave half-delay mode.

`curses.`**`init_color`**`(`*color_number*, *r*, *g*, *b*`)`

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between `0` and `COLORS - 1`. Each of *r*, *g*, *b*, must be a value between `0` and `1000`. When *init_color()* is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if *can_change_color()* returns `True`.

`curses.`**`init_pair`**`(`*pair_number*, *fg*, *bg*`)`

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between `1` and `COLOR_PAIRS - 1` (the `0` color pair can only be changed by *use_default_colors()* and *assume_default_colors()*). The value of *fg* and *bg* arguments must be between `0` and `COLORS - 1`, or, after calling `use_default_colors()` or `assume_default_colors()`, `-1`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

`curses.`**`initscr`**`()`

Initialize the library. Return a *window* object which represents the whole screen.

> **備𝔽**
>
> If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

curses.**is_term_resized**(*nlines*, *ncols*)

Return `True` if *resize_term()* would modify the window structure, `False` otherwise.

curses.**isendwin**()

Return `True` if *endwin()* has been called (that is, the curses library has been deinitialized).

curses.**keyname**(*k*)

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (`b'^'`) followed by the corresponding printable ASCII character. The name of an alt-key combination (128--255) is a bytes object consisting of the prefix `b'M-'` followed by the name of the corresponding ASCII character.

curses.**killchar**()

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.**longname**()

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to *initscr()*.

curses.**meta**(*flag*)

If *flag* is `True`, allow 8-bit characters to be input. If *flag* is `False`, allow only 7-bit chars.

curses.**mouseinterval**(*interval*)

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 milliseconds, or one fifth of a second.

curses.**mousemask**(*mousemask*)

Set the mouse events to be reported, and return a tuple `(availmask, oldmask)`. *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns `0`. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

curses.**napms**(*ms*)

Sleep for *ms* milliseconds.

curses.**newpad**(*nlines*, *ncols*)

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The *refresh()* and *noutrefresh()* methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

curses.**newwin**(*nlines*, *ncols*)

curses.**newwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a new *window*, whose left-upper corner is at `(begin_y, begin_x)`, and whose height/width is *nlines*/*ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

curses.**nl**()

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

curses.**nocbreak**()

Leave cbreak mode. Return to normal "cooked" mode with line buffering.

curses.**noecho**()

Leave echo mode. Echoing of input characters is turned off.

curses.**nonl**()

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

curses.**noqiflush**()

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

curses.**noraw**()

Leave raw mode. Return to normal "cooked" mode with line buffering.

curses.**pair_content**(*pair_number*)

Return a tuple `(fg, bg)` containing the colors for the requested color pair. The value of *pair_number* must be between `0` and `COLOR_PAIRS - 1`.

curses.**pair_number**(*attr*)

Return the number of the color-pair set by the attribute value *attr*. *color_pair()* is the counterpart to this function.

curses.**putp**(*str*)

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of *putp()* always goes to standard output.

curses.**qiflush**([*flag*])

If *flag* is `False`, the effect is the same as calling *noqiflush()*. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

curses.**raw**()

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

curses.**reset_prog_mode**()

Restore the terminal to "program" mode, as previously saved by *def_prog_mode()*.

curses.**reset_shell_mode**()

Restore the terminal to "shell" mode, as previously saved by *def_shell_mode()*.

curses.**resetty**()

Restore the state of the terminal modes to what it was at the last call to *savetty()*.

curses.**resize_term**(*nlines*, *ncols*)

Backend function used by *resizeterm()*, performing most of the work; when resizing the windows, *resize_term()* blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The `resize_term()` function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

curses.**resizeterm**(*nlines*, *ncols*)

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

curses.**savetty**()

Save the current state of the terminal modes in a buffer, usable by *resetty()*.

curses.**get_escdelay**()

Retrieves the value set by *set_escdelay()*.

在 3.9 版被加入.

curses.**set_escdelay**(*ms*)

Sets the number of milliseconds to wait after reading an escape character, to distinguish between an individual escape character entered on the keyboard from escape sequences sent by cursor and function keys.

在 3.9 版被加入.

curses.**get_tabsize**()

Retrieves the value set by *set_tabsize()*.

在 3.9 版被加入.

curses.**set_tabsize**(*size*)

Sets the number of columns used by the curses library when converting a tab character to spaces as it adds the tab to a window.

在 3.9 版被加入.

curses.**setsyx**(*y*, *x*)

Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both `-1`, then *leaveok* is set `True`.

curses.**setupterm**(*term=None*, *fd=-1*)

Initialize the terminal. *term* is a string giving the terminal name, or `None`; if omitted or `None`, the value of the `TERM` environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

curses.**start_color**()

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after *initscr()*.

start_color() initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the *curses* module, *COLORS* and *COLOR_PAIRS*, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

curses.**termattrs**()

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

curses.**termname**()

Return the value of the environment variable `TERM`, as a bytes object, truncated to 14 characters.

curses.**tigetflag**(*capname*)

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

curses.**tigetnum**(*capname*)

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

curses.**tigetstr**(*capname*)

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return `None` if *capname* is not a terminfo ”string capability”, or is canceled or absent from the terminal description.

curses.**tparm**(*str*[, ...])

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

curses.**typeahead**(*fd*)

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does "line-breakout optimization" by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until refresh or doupdate is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

curses.**unctrl**(*ch*)

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

curses.**ungetch**(*ch*)

Push *ch* so the next *getch()* will return it.

> **備🄵**
>
> Only one *ch* can be pushed before `getch()` is called.

curses.**update_lines_cols**()

Update the *LINES* and *COLS* module variables. Useful for detecting manual screen resize.

在 3.5 版被加入.

curses.**unget_wch**(*ch*)

Push *ch* so the next *get_wch()* will return it.

> **備🄵**
>
> Only one *ch* can be pushed before `get_wch()` is called.

在 3.3 版被加入.

curses.**ungetmouse**(*id*, *x*, *y*, *z*, *bstate*)

Push a *KEY_MOUSE* event onto the input queue, associating the given state data with it.

curses.**use_env**(*flag*)

If used, this function should be called before *initscr()* or newterm are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

curses.**use_default_colors**()

Equivalent to `assume_default_colors(-1, -1)`.

curses.**wrapper**(*func*, */*, **args*, ***kwargs*)

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to `wrapper()`. Before calling *func*, `wrapper()` turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

17.5.2 Window Objects

class curses.**window**

Window objects, as returned by *initscr()* and *newwin()* above, have the following methods and attributes:

window.**addch**(*ch*[, *attr*])

window.**addch**(*y*, *x*, *ch*[, *attr*])

Paint character *ch* at `(y, x)` with attributes *attr*, overwriting any character previously painted at that location. By default, the character position and attributes are the current settings for the window object.

> **備🄵**
>
> Writing outside the window, subwindow, or pad raises a *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

window.**addnstr**(*str*, *n*[, *attr*])

window.**addnstr**(*y*, *x*, *str*, *n*[, *attr*])

Paint at most *n* characters of the character string *str* at `(y, x)` with attributes *attr*, overwriting anything previously on the display.

window.**addstr**(*str*[, *attr*])

window.**addstr**(*y*, *x*, *str*[, *attr*])

Paint the character string *str* at `(y, x)` with attributes *attr*, overwriting anything previously on the display.

> **備🄵**
>
> - Writing outside the window, subwindow, or pad raises *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.
> - A bug in ncurses, the backend for this Python module, can cause SegFaults when resizing windows. This is fixed in ncurses-6.1-20190511. If you are stuck with an earlier ncurses, you can avoid triggering this if you do not call *addstr()* with a *str* that has embedded newlines. Instead, call *addstr()* separately for each line.

window.**attroff**(*attr*)

Remove attribute *attr* from the ”background” set applied to all writes to the current window.

window.**attron**(*attr*)

Add attribute *attr* from the ”background” set applied to all writes to the current window.

window.**attrset**(*attr*)

Set the ”background” set of attributes to *attr*. This set is initially `0` (no attributes).

window.**bkgd**(*ch*[, *attr*])

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

window.**bkgdset**(*ch*[, *attr*])

Set the window’s background. A window’s background consists of a character and any combination of attributes. The attribute part of the background is combined (OR’ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the

blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.`**`border`**`(`[*ls*[, *rs*[, *ts*[, *bs*[, *tl*[, *tr*[, *bl*[, *br*]]]]]]]]`)`

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

> **備🄵**
>
> A `0` value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

參數	描述	Default value
ls	Left side	*ACS_VLINE*
rs	Right side	*ACS_VLINE*
ts	Top	*ACS_HLINE*
bs	Bottom	*ACS_HLINE*
tl	Upper-left corner	*ACS_ULCORNER*
tr	Upper-right corner	*ACS_URCORNER*
bl	Bottom-left corner	*ACS_LLCORNER*
br	Bottom-right corner	*ACS_LRCORNER*

`window.`**`box`**`(`[*vertch*, *horch*]`)`

Similar to *border()*, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.`**`chgat`**`(`*attr*`)`

`window.`**`chgat`**`(`*num*, *attr*`)`

`window.`**`chgat`**`(`*y*, *x*, *attr*`)`

`window.`**`chgat`**`(`*y*, *x*, *num*, *attr*`)`

Set the attributes of *num* characters at the current cursor position, or at position `(y, x)` if supplied. If *num* is not given or is `-1`, the attribute will be set on all the characters to the end of the line. This function moves cursor to position `(y, x)` if supplied. The changed line will be touched using the *touchline()* method so that the contents will be redisplayed by the next window refresh.

`window.`**`clear`**`()`

Like *erase()*, but also cause the whole window to be repainted upon next call to *refresh()*.

`window.`**`clearok`**`(`*flag*`)`

If *flag* is `True`, the next call to *refresh()* will clear the window completely.

`window.`**`clrtobot`**`()`

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of *clrtoeol()* is performed.

`window.`**`clrtoeol`**`()`

Erase from cursor to the end of the line.

`window.`**`cursyncup`**`()`

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

`window.`**`delch`**`(`[*y*, *x*]`)`

Delete any character at `(y, x)`.

window.**deleteln**()

Delete the line under the cursor. All following lines are moved up by one line.

window.**derwin**(*begin_y*, *begin_x*)

window.**derwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

An abbreviation for "derive window", *derwin()* is the same as calling *subwin()*, except that *begin_y* and *begin_x* are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

window.**echochar**(*ch*[, *attr*])

Add character *ch* with attribute *attr*, and immediately call *refresh()* on the window.

window.**enclose**(*y*, *x*)

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

在 3.10 版的變更: Previously it returned `1` or `0` instead of `True` or `False`.

window.**encoding**

Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with *window.subwin()*. By default, current locale encoding is used (see *locale.getencoding()*).

在 3.3 版被加入.

window.**erase**()

Clear the window.

window.**getbegyx**()

Return a tuple `(y, x)` of coordinates of upper-left corner.

window.**getbkgd**()

Return the given window's current background character/attribute pair.

window.**getch**([*y*, *x*])

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

window.**get_wch**([*y*, *x*])

Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

在 3.3 版被加入.

window.**getkey**([*y*, *x*])

Get a character, returning a string instead of an integer, as *getch()* does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

window.**getmaxyx**()

Return a tuple `(y, x)` of the height and width of the window.

window.**getparyx**()

Return the beginning coordinates of this window relative to its parent window as a tuple `(y, x)`. Return `(-1, -1)` if this window has no parent.

window.**getstr**()

window.**getstr**(*n*)

window.**getstr**(*y*, *x*)

window.**getstr**(*y*, *x*, *n*)

Read a bytes object from the user, with primitive line editing capacity. The maximum value for *n* is 2047.

在 3.14 版的變更: The maximum value for *n* was increased from 1023 to 2047.

window.**getyx**()

Return a tuple `(y, x)` of current cursor position relative to the window's upper-left corner.

window.**hline**(*ch*, *n*)

window.**hline**(*y*, *x*, *ch*, *n*)

Display a horizontal line starting at `(y, x)` with length *n* consisting of the character *ch*.

window.**idcok**(*flag*)

If *flag* is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if *flag* is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

window.**idlok**(*flag*)

If *flag* is `True`, *curses* will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

window.**immedok**(*flag*)

If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call *refresh()* yourself. However, it may degrade performance considerably, due to repeated calls to wrefresh. This option is disabled by default.

window.**inch**(*y*, *x*)

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

window.**insch**(*ch*, *attr*)

window.**insch**(*y*, *x*, *ch*, *attr*)

Paint character *ch* at `(y, x)` with attributes *attr*, moving the line from position *x* right by one character.

window.**insdelln**(*nlines*)

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

window.**insertln**()

Insert a blank line under the cursor. All following lines are moved down by one line.

window.**insnstr**(*str*, *n*, *attr*)

window.**insnstr**(*y*, *x*, *str*, *n*, *attr*)

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.**insstr**(*str*, *attr*)

window.**insstr**(*y*, *x*, *str*, *attr*)

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.**instr**(*n*)

window.**instr**(*y*, *x*, *n*)

Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, *instr()* returns a string at most *n* characters long (exclusive of the trailing NUL). The maximum value for *n* is 2047.

在 3.14 版的變更: The maximum value for *n* was increased from 1023 to 2047.

window.**is_linetouched**(*line*)

Return `True` if the specified line was modified since the last call to *refresh()*; otherwise return `False`. Raise a *curses.error* exception if *line* is not valid for the given window.

window.**is_wintouched**()

Return `True` if the specified window was modified since the last call to *refresh()*; otherwise return `False`.

window.**keypad**(*flag*)

If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by *curses*. If *flag* is `False`, escape sequences will be left as is in the input stream.

window.**leaveok**(*flag*)

If *flag* is `True`, cursor is left where it is on update, instead of being at "cursor position." This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at "cursor position" after an update.

window.**move**(*new_y*, *new_x*)

Move cursor to `(new_y, new_x)`.

window.**mvderwin**(*y*, *x*)

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

window.**mvwin**(*new_y*, *new_x*)

Move the window so its upper-left corner is at `(new_y, new_x)`.

window.**nodelay**(*flag*)

If *flag* is `True`, *getch()* will be non-blocking.

window.**notimeout**(*flag*)

If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

window.**noutrefresh**()

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call *doupdate()*.

window.**overlay**(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overlay()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

window.**overwrite**(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overwrite()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

window.**putwin**(*file*)

Write all data associated with the window into the provided file object. This information can be later retrieved using the *getwin()* function.

window.**redrawln**(*beg*, *num*)

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next `refresh()` call.

window.**redrawwin**()

Touch the entire window, causing it to be completely redrawn on the next `refresh()` call.

window.**refresh**([*pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*])

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with `newpad()`. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

window.**resize**(*nlines*, *ncols*)

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by `bkgdset()`) merged into them.

window.**scroll**([*lines=1*])

Scroll the screen or scrolling region upward by *lines* lines.

window.**scrollok**(*flag*)

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.

window.**setscrreg**(*top*, *bottom*)

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window.**standend**()

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window.**standout**()

Turn on attribute *A_STANDOUT*.

window.**subpad**(*begin_y*, *begin_x*)

window.**subpad**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

window.**subwin**(*begin_y*, *begin_x*)

window.**subwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

window.**syncdown**()

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by `refresh()`, so it should almost never be necessary to call it manually.

window.**syncok**(*flag*)

If *flag* is `True`, then `syncup()` is called automatically whenever there is a change in the window.

window.**syncup**()

Touch all locations in ancestors of the window that have been changed in the window.

window.**timeout**(*delay*)

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and *getch()* will return -1 if no input is waiting. If *delay* is positive, then *getch()* will block for *delay* milliseconds, and return -1 if there is still no input at the end of that time.

window.**touchline**(*start*, *count*[, *changed*])

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=True) or unchanged (*changed*=False).

window.**touchwin**()

Pretend the whole window has been changed, for purposes of drawing optimizations.

window.**untouchwin**()

Mark all lines in the window as unchanged since the last call to *refresh()*.

window.**vline**(*ch*, *n*[, *attr*])

window.**vline**(*y*, *x*, *ch*, *n*[, *attr*])

Display a vertical line starting at (y, x) with length *n* consisting of the character *ch* with attributes *attr*.

17.5.3 Constants

curses 模組定義了以下資料成員：

curses.**ERR**

Some curses routines that return an integer, such as *getch()*, return *ERR* upon failure.

curses.**OK**

Some curses routines that return an integer, such as *napms()*, return *OK* upon success.

curses.**version**

curses.**__version__**

A bytes object representing the current version of the module.

curses.**ncurses_version**

A named tuple containing the three components of the ncurses library version: *major*, *minor*, and *patch*. All values are integers. The components can also be accessed by name, so curses.ncurses_version[0] is equivalent to curses.ncurses_version.major and so on.

Availability: if the ncurses library is used.

在 3.8 版被加入.

curses.**COLORS**

The maximum number of colors the terminal can support. It is defined only after the call to *start_color()*.

curses.**COLOR_PAIRS**

The maximum number of color pairs the terminal can support. It is defined only after the call to *start_color()*.

curses.**COLS**

The width of the screen, i.e., the number of columns. It is defined only after the call to *initscr()*. Updated by *update_lines_cols()*, *resizeterm()* and *resize_term()*.

curses.**LINES**

The height of the screen, i.e., the number of lines. It is defined only after the call to *initscr()*. Updated by *update_lines_cols()*, *resizeterm()* and *resize_term()*.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

Attribute	含義
curses.**A_ALTCHARSET**	Alternate character set mode
curses.**A_BLINK**	Blink mode
curses.**A_BOLD**	Bold mode
curses.**A_DIM**	Dim mode
curses.**A_INVIS**	Invisible or blank mode
curses.**A_ITALIC**	Italic mode
curses.**A_NORMAL**	Normal attribute
curses.**A_PROTECT**	Protected mode
curses.**A_REVERSE**	Reverse background and foreground colors
curses.**A_STANDOUT**	Standout mode
curses.**A_UNDERLINE**	Underline mode
curses.**A_HORIZONTAL**	Horizontal highlight
curses.**A_LEFT**	Left highlight
curses.**A_LOW**	Low highlight
curses.**A_RIGHT**	Right highlight
curses.**A_TOP**	Top highlight
curses.**A_VERTICAL**	Vertical highlight

在 3.7 版被加入: A_ITALIC was added.

Several constants are available to extract corresponding attributes returned by some methods.

Bit-mask	含義
curses.**A_ATTRIBUTES**	Bit-mask to extract attributes
curses.**A_CHARTEXT**	Bit-mask to extract a character
curses.**A_COLOR**	Bit-mask to extract color-pair field information

Keys are referred to by integer constants with names starting with KEY_. The exact keycaps available are system dependent.

Key constant	Key
curses.**KEY_MIN**	Minimum key value
curses.**KEY_BREAK**	Break key (unreliable)
curses.**KEY_DOWN**	Down-arrow
curses.**KEY_UP**	Up-arrow
curses.**KEY_LEFT**	Left-arrow
curses.**KEY_RIGHT**	Right-arrow
curses.**KEY_HOME**	Home key (upward+left arrow)
curses.**KEY_BACKSPACE**	Backspace (unreliable)
curses.**KEY_F0**	Function keys. Up to 64 function keys are supported.
curses.**KEY_Fn**	Value of function key *n*
curses.**KEY_DL**	Delete line
curses.**KEY_IL**	Insert line
curses.**KEY_DC**	Delete character

curses.**KEY_SUSPEND**	Suspend
curses.**KEY_UNDO**	Undo
curses.**KEY_MOUSE**	Mouse event has occurred
curses.**KEY_RESIZE**	Terminal resize event
curses.**KEY_MAX**	Maximum key value

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (*KEY_F1*, *KEY_F2*, *KEY_F3*, *KEY_F4*) available, and the arrow keys mapped to *KEY_UP*, *KEY_DOWN*, *KEY_LEFT* and *KEY_RIGHT* in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

Keycap	Constant
Insert	KEY_IC
Delete	KEY_DC
Home	KEY_HOME
End	KEY_END
Page Up	KEY_PPAGE
Page Down	KEY_NPAGE

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

> **備🄵**
>
> These are available only after *initscr()* has been called.

ACS code	含義
curses.**ACS_BBSS**	alternate name for upper right corner
curses.**ACS_BLOCK**	solid square block

The following table lists mouse button constants used by *getmouse()*:

Mouse button constant	含義
curses.**BUTTONn_PRESSED**	Mouse button *n* pressed
curses.**BUTTONn_RELEASED**	Mouse button *n* released
curses.**BUTTONn_CLICKED**	Mouse button *n* clicked
curses.**BUTTONn_DOUBLE_CLICKED**	Mouse button *n* double clicked
curses.**BUTTONn_TRIPLE_CLICKED**	Mouse button *n* triple clicked
curses.**BUTTON_SHIFT**	Shift was down during button state change
curses.**BUTTON_CTRL**	Control was down during button state change
curses.**BUTTON_ALT**	Control was down during button state change

在 3.10 版的變更: The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

The following table lists the predefined colors:

Constant	🄵色
curses.**COLOR_BLACK**	黑
curses.**COLOR_BLUE**	藍
curses.**COLOR_CYAN**	Cyan (light greenish blue)
curses.**COLOR_GREEN**	🄵
curses.**COLOR_MAGENTA**	Magenta (purplish red)
curses.**COLOR_RED**	紅
curses.**COLOR_WHITE**	白
curses.**COLOR_YELLOW**	Yellow

17.6 curses.textpad --- Text input widget for curses programs

The *curses.textpad* module provides a *Textbox* class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

curses.textpad 模組定義了以下函式：

curses.textpad.**rectangle**(*win*, *uly*, *ulx*, *lry*, *lrx*)

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

17.6.1 Textbox objects

You can instantiate a *Textbox* object as follows:

class curses.textpad.**Textbox**(*win*)

Return a textbox widget object. The *win* argument should be a curses *window* object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates `(0, 0)`. The instance's *stripspaces* flag is initially on.

Textbox objects have the following methods:

edit([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke

entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

do_command(*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

Keystroke	Action
Control-A	Go to left edge of window.
Control-B	Cursor left, wrapping to previous line if appropriate.
Control-D	Delete character under cursor.
Control-E	Go to right edge (stripspaces off) or end of line (stripspaces on).
Control-F	Cursor right, wrapping to next line when appropriate.
Control-G	Terminate, returning the window contents.
Control-H	Delete character backward.
Control-J	Terminate if the window is 1 line, otherwise insert newline.
Control-K	If line is blank, delete it, otherwise clear to end of line.
Control-L	Refresh screen.
Control-N	Cursor down; move down one line.
Control-O	Insert a blank line at cursor location.
Control-P	Cursor up; move up one line.

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

Constant	Keystroke
KEY_LEFT	Control-B
KEY_RIGHT	Control-F
KEY_UP	Control-P
KEY_DOWN	Control-N
KEY_BACKSPACE	Control-h

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

17.7 curses.ascii --- ASCII 字元的工具程式

原始碼： Lib/curses/ascii.py

The *curses.ascii* module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

名懲	含義
curses.ascii.**NUL**	
curses.ascii.**SOH**	Start of heading, console interrupt
curses.ascii.**STX**	Start of text
curses.ascii.**ETX**	End of text
curses.ascii.**EOT**	End of transmission
curses.ascii.**ENQ**	Enquiry, goes with *ACK* flow control
curses.ascii.**ACK**	Acknowledgement
curses.ascii.**BEL**	Bell
curses.ascii.**BS**	Backspace
curses.ascii.**TAB**	Tab
curses.ascii.**HT**	Alias for *TAB*: ”Horizontal tab”
curses.ascii.**LF**	Line feed
curses.ascii.**NL**	Alias for *LF*: ”New line”
curses.ascii.**VT**	Vertical tab
curses.ascii.**FF**	Form feed
curses.ascii.**CR**	Carriage return
curses.ascii.**SO**	Shift-out, begin alternate character set
curses.ascii.**SI**	Shift-in, resume default character set

繼續下一頁

表格 3 – 繼續上一頁

名懲	含義
curses.ascii.**DLE**	Data-link escape
curses.ascii.**DC1**	XON, for flow control
curses.ascii.**DC2**	Device control 2, block-mode flow control
curses.ascii.**DC3**	XOFF, for flow control
curses.ascii.**DC4**	Device control 4
curses.ascii.**NAK**	Negative acknowledgement
curses.ascii.**SYN**	Synchronous idle
curses.ascii.**ETB**	End transmission block
curses.ascii.**CAN**	Cancel
curses.ascii.**EM**	End of medium
curses.ascii.**SUB**	Substitute
curses.ascii.**ESC**	Escape
curses.ascii.**FS**	File separator
curses.ascii.**GS**	Group separator
curses.ascii.**RS**	Record separator, block-mode terminator
curses.ascii.**US**	Unit separator
curses.ascii.**SP**	Space
curses.ascii.**DEL**	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter

conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

curses.ascii.**isalnum**(*c*)

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c) or isdigit(c)`.

curses.ascii.**isalpha**(*c*)

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c) or islower(c)`.

curses.ascii.**isascii**(*c*)

Checks for a character value that fits in the 7-bit ASCII set.

curses.ascii.**isblank**(*c*)

Checks for an ASCII whitespace character; space or horizontal tab.

curses.ascii.**iscntrl**(*c*)

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

curses.ascii.**isdigit**(*c*)

Checks for an ASCII decimal digit, `'0'` through `'9'`. This is equivalent to `c in string.digits`.

curses.ascii.**isgraph**(*c*)

Checks for ASCII any printable character except space.

curses.ascii.**islower**(*c*)

Checks for an ASCII lower-case character.

curses.ascii.**isprint**(*c*)

Checks for any ASCII printable character including space.

curses.ascii.**ispunct**(*c*)

Checks for any printable ASCII character which is not a space or an alphanumeric character.

curses.ascii.**isspace**(*c*)

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

curses.ascii.**isupper**(*c*)

Checks for an ASCII uppercase letter.

curses.ascii.**isxdigit**(*c*)

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

curses.ascii.**isctrl**(*c*)

Checks for an ASCII control character (ordinal values 0 to 31).

curses.ascii.**ismeta**(*c*)

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function *ord()*.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

curses.ascii.**ascii**(*c*)

Return the ASCII value corresponding to the low 7 bits of *c*.

curses.ascii.**ctrl**(*c*)

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

curses.ascii.**alt**(*c*)

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

curses.ascii.**unctrl**(*c*)

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00--0x1f) the string consists of a caret (`'^'`) followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is `'^?'`. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and `'!'` prepended to the result.

curses.ascii.**controlnames**

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

17.8 `curses.panel` --- curses 的面板堆🄵擴充

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

17.8.1 函式

curses.panel 模組定義了以下函式：

curses.panel.**bottom_panel**()

Returns the bottom panel in the panel stack.

curses.panel.**new_panel**(*win*)

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

curses.panel.**top_panel**()

Returns the top panel in the panel stack.

curses.panel.**update_panels**()

Updates the virtual screen after changes in the panel stack. This does not call *curses.doupdate()*, so you'll have to do this yourself.

17.8.2 Panel Objects

Panel objects, as returned by *new_panel()* above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

Panel.**above**()

Returns the panel above the current panel.

Panel.**below**()

Returns the panel below the current panel.

Panel.**bottom**()

Push the panel to the bottom of the stack.

Panel.**hidden**()

Returns `True` if the panel is hidden (not visible), `False` otherwise.

Panel.**hide**()

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

Panel.**move**(*y*, *x*)

Move the panel to the screen coordinates `(y, x)`.

Panel.**replace**(*win*)

Change the window associated with the panel to the window *win*.

Panel.**set_userptr**(*obj*)

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

Panel.**show**()

Display the panel (which might have been hidden).

Panel.**top**()

Push panel to the top of the stack.

Panel.**userptr**()

Returns the user pointer for the panel. This might be any Python object.

Panel.**window**()

Returns the window object associated with the panel.

17.9 cmd --- 以列🄵導向的命令直譯器支援

原始碼： Lib/cmd.py

Cmd 類🄵提供了一個簡單的架構，用於撰寫列導向的命令直譯器。這類直譯器常用於測試控制工具、管理工具以及日後將包裝於更高階介面的原型中。

class cmd.**Cmd**(*completekey='tab'*, *stdin=None*, *stdout=None*)

Cmd 實例或其子類🄵實例是一種列導向的直譯器架構。通常🄵有必要直接實例化*Cmd* 本身；它更適合作🄵你自定義的直譯器類🄵的父類🄵，讓你能繼承*Cmd* 的方法，🄵封裝動作方法。

可選引數 *completekey* 是*readline* 模組中用於自動完成的按鍵名稱；預設🄵 `Tab`。若 *completekey* 不🄵*None* 且*readline* 可用，則會自動🄴用命令自動完成功能。

預設值 `'tab'` 會被特殊處理，使其在所有的*readline.backend* 中皆代表 `Tab` 鍵。具體來🄵，若*readline.backend* 🄵 `editline`，則 `Cmd` 會改用 `'^I'` 取代 `'tab'`。請注意，其他值不會有此處理方式，且可能僅能在特定的後端中適用。

可選引數 *stdin* 與 *stdout* 用來指定 Cmd 實例或其子類🄵實例所使用的輸入與輸出檔案物件。若未指定，預設🄵*sys.stdin* 與*sys.stdout*。

若你希望使用指定的 *stdin*，請務必將該實例的*use_rawinput* 屬性設🄵 `False`，否則 *stdin* 會被忽略。

在 3.13 版的變更: 對於 `editline`，`completekey='tab'` 會被替🄵🄵 `'^I'`。

17.9.1 Cmd 物件

Cmd 實例具有以下方法：

Cmd.**cmdloop**(*intro=None*)

重🄵顯示提示字元、接收輸入、剖析接收到的輸入字串前綴，🄵派發給動作方法，將其余部分作🄵引數傳遞給它們

此可選引數🄵🄵幅或導言字串，會在首次顯示提示字元前輸出（此值會覆寫*intro* 類🄵屬性）。

如果已載入*readline* 模組，輸入將自動繼承類似 **bash** 的歷史紀🄵編輯功能（例如 Control-P 可向上🄵動至上一個命令，Control-N 向下🄵動至下一個命令，Control-F 非破壞性地將游標向右移動，Control-B 非破壞性地將游標向左移動等）。

當輸入🄵檔案結尾（EOF）時，會傳回字串 'EOF'。

直譯器實例僅當存在 do_foo() 方法時，才會識🄵命令名稱 foo。作🄵特殊情🄵，以字元 '?' 開頭的列會被派發至*do_help()* 方法；另一個特殊情🄵是，以字元 '!' 開頭的列會被派發至 do_shell() 方法（若該方法已定義）。

當*postcmd()* 方法回傳真值時，此方法將會結束。傳遞給*postcmd()* 的 *stop* 引數是該命令對應的 do_*() 方法的回傳值。

如果🄵用了自動完成，命令的自動完成將會自動執行，而命令引數的自動完成則是透過呼叫 complete_foo() 方法🄵傳入 *text*、*line*、*begidx* 和 *endidx* 引數來處理。*text* 是要比對的字串前綴：所有回傳的符合項都必須以此字串開頭。*line* 是目前的輸入列（前置空白會被移除），*begidx* 和 *endidx* 則分🄵是前綴字串的起始與結束索引，可用來根據引數所在的位置提供不同的自動完成結果。

Cmd.**do_help**(*arg*)

所有*Cmd* 的子類🄵都會繼承預先定義的 do_help() 方法。當此方法接收到引數 'bar' 時，會呼叫對應的 help_bar() 方法；若該方法不存在，則會列印 do_bar() 的🄵明字串（若有的話）。若未提供任何引數，do_help() 會列出所有可用的🄵明主題（也就是所有具有對應 help_*() 方法或有🄵明字串的命令），🄵且也會列出所有尚未記🄵的命令。

Cmd.**onecmd**(*str*)

將引數視🄵在回應提示字元時所輸入的🄵容來直譯。這個方法可以被覆寫，但通常不需要這🄵做；參見*precmd()* 與*postcmd()* 方法，它們提供實用的執行勾點（hook）。此方法的回傳值是一個旗標，用來指出是否應該停止直譯器對命令的直譯。若有對應 *str* 命令的 do_*() 方法，則會回傳該方法的回傳值；否則，回傳值將來自*default()* 方法。

Cmd.**emptyline**()

在回應提示字元時輸入空白列，會呼叫此方法。若此方法未被覆寫，則會重復上一次輸入的非空命令。

Cmd.**default**(*line*)

當輸入列中的命令前綴無法辨識時，會呼叫此方法。若此方法未被覆寫，則會輸出🄵回傳錯誤訊息。

Cmd.**completedefault**(*text*, *line*, *begidx*, *endidx*)

當🄵有對應特定命令的 complete_*() 方法時，會呼叫此方法以完成輸入列。預設會回傳空串列。

Cmd.**columnize**(*list*, *displaywidth=80*)

此方法用來將字串串列顯示🄵緊🄵的欄集合。每一欄的寬度僅足以容納其🄵容，各欄之間以兩個空格分隔，以提高可讀性。

Cmd.**precmd**(*line*)

勾點方法會在直譯命令列 *line* 前執行，但會在提示字元🄵生🄵顯示後才觸發。這個方法在*Cmd* 類🄵中🄵 stub，預期由子類🄵覆寫。回傳值會作🄵*onecmd()* 方法所執行的命令；*precmd()* 的實作可以重寫該命令，或直接回傳未變更的 *line*。

Cmd.**postcmd**(*stop*, *line*)

勾點方法會在命令派發完成後執行。這個方法在*Cmd* 類🄵中🄵 stub，預期由子類🄵覆寫。*line* 是剛剛執行的命令列，而 *stop* 是一個旗標，用來指出在呼叫*postcmd()* 後是否應終止執行；該值即

🄵*onecmd()* 方法的回傳值。本方法的回傳值將會更新🄵部的 *stop* 旗標；若回傳 false，則會繼續進行直譯。

Cmd.**preloop**()

當*cmdloop()* 被呼叫時，此勾點方法會執行一次。這個方法在*Cmd* 類🄵中🄵 stub，預期由子類🄵覆寫。

Cmd.**postloop**()

當*cmdloop()* 即將回傳時，此勾點方法會執行一次。這個方法在*Cmd* 類🄵中🄵 stub，預期由子類🄵覆寫。

Cmd 子類🄵的實例包含一些公開的實例變數:

Cmd.**prompt**

用來請求輸入的提示字元。

Cmd.**identchars**

可作🄵命令前綴的字元字串

Cmd.**lastcmd**

最後一個遇到的非空命令前綴

Cmd.**cmdqueue**

排入🄵列的輸入列串列。當*cmdloop()* 需要新輸入時，會檢查 cmdqueue 串列；若不🄵空，其元素將依序處理，就如同它們是在提示字元中輸入的一樣。

Cmd.**intro**

作🄵簡介或🄵幅的字串。可透過🄵*cmdloop()* 方法提供引數來覆寫此🄵容。

Cmd.**doc_header**

若🄵明輸出包含已記🄵命令的區段，則會顯示的標頭字串。

Cmd.**misc_header**

若🄵明輸出包含雜項🄵明主題的區段（也就是存在 `help_*()` 方法但🄵有對應的 `do_*()` 方法），則會顯示的標頭字串。

Cmd.**undoc_header**

若🄵明輸出包含未記🄵命令的區段（也就是存在 `do_*()` 方法但🄵有對應的 `help_*()` 方法），則會顯示的標頭字串。

Cmd.**ruler**

用於在🄵明訊息的標頭下方繪🄵分隔🄵的字元。若🄵空，則不會繪🄵分隔🄵。預設🄵 `'='`。

Cmd.**use_rawinput**

一個旗標，預設🄵 true。若🄵 true，*cmdloop()* 會使用*input()* 來顯示提示字元🄵讀取下一個命令；若🄵 false，則會改用*sys.stdout.write()* 和*sys.stdin.readline()*。（這表示在支援的系統中，透過 import *readline* module，直譯器將自動支援類似 **Emacs** 的列編輯與命令歷史快捷鍵。）

17.9.2 Cmd 范例

cmd module 主要用於建構自訂 shell，讓使用者能以互動方式操作程式。

本節將示範如何以*turtle* module 中的幾個命令🄵基礎，建立一個簡單的 shell。

像是*forward()* 這樣的基本 turtle 命令，可透過新增名🄵 `do_forward()` 的方法加入至*Cmd* 子類🄵中。傳入的引數會轉🄵🄵數值，🄵傳送給 turtle 模組。該方法的🄵明字串會用於 shell 所提供的🄵明功能中。

此範例同時包含一個簡單的🄵🄵與重播功能，其實作方式是透過*precmd()* 方法，負責將輸入轉🄵小寫🄵寫入檔案。`do_playback()` 方法則會讀取該檔案，🄵將🄵🄵的命令加入*cmdqueue* 中以供立即重播:

```
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = '歡迎來到 turtle shell。輸入 help 或 ? 來列出命令。\n'
    prompt = '(turtle) '
    file = None

    # ----- 基本烏龜命令 -----
    def do_forward(self, arg):
        '將烏龜向前移動指定的距離: FORWARD 10'
        forward(*parse(arg))
    def do_right(self, arg):
        '將烏龜右轉指定的角度: RIGHT 20'
        right(*parse(arg))
    def do_left(self, arg):
        '將烏龜左轉指定的角度: LEFT 90'
        left(*parse(arg))
    def do_goto(self, arg):
        '將烏龜移動到指定的🄵對位置🄵改變方向。 GOTO 100 200'
        goto(*parse(arg))
    def do_home(self, arg):
        '將烏龜返回起始位置: HOME'
        home()
    def do_circle(self, arg):
        '畫出指定半徑、範圍和步數的圓: CIRCLE 50'
        circle(*parse(arg))
    def do_position(self, arg):
        '顯示當前烏龜位置: POSITION'
        print('當前位置是 %d %d\n' % position())
    def do_heading(self, arg):
        '顯示當前烏龜方向角度: HEADING'
        print('當前方向是 %d\n' % (heading(),))
    def do_color(self, arg):
        '設定🄵色: COLOR BLUE'
        color(arg.lower())
    def do_undo(self, arg):
        '撤銷 (重🄵) 最後一次烏龜動作: UNDO'
    def do_reset(self, arg):
        '清除畫面🄵將烏龜返回到中心: RESET'
        reset()
    def do_bye(self, arg):
        '停止🄵🄵、關閉烏龜視窗🄵退出: BYE'
        print('感謝使用 Turtle')
        self.close()
        bye()
        return True

    # ----- 🄵🄵與回放 -----
    def do_record(self, arg):
        '將未來命令儲存至檔案: RECORD rose.cmd'
        self.file = open(arg, 'w')
    def do_playback(self, arg):
        '從檔案回放命令: PLAYBACK rose.cmd'
        self.close()
        with open(arg) as f:
            self.cmdqueue.extend(f.read().splitlines())
    def precmd(self, line):
        line = line.lower()
        if self.file and 'playback' not in line:
            print(line, file=self.file)
        return line
```

(繼續下一頁)

(繼續上一頁)

```
    def close(self):
        if self.file:
            self.file.close()
            self.file = None

def parse(arg):
    '將一串零個或多個數字轉🄵🄵引數 tuple'
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()
```

以下是與 turtle shell 的一段範例互動，展示了🄵明功能、使用空白列重🄵執行命令，以及簡單的🄵🄵與重播功能：

```
歡迎來到 turtle shell。輸入 help 或 ? 來列出命令。

(turtle) ?

已記🄵的命令（輸入 help <主題>）：
=========================================
bye     color    goto     home  playback  record  right
circle  forward  heading  left  position  reset   undo

(turtle) help forward
將烏龜向前移動指定的距離： FORWARD 10
(turtle) record spiral.cmd
(turtle) position
當前位置是 0 0

(turtle) heading
當前方向是 0

(turtle) reset
(turtle) circle 20
(turtle) right 30
(turtle) circle 40
(turtle) right 30
(turtle) circle 60
(turtle) right 30
(turtle) circle 80
(turtle) right 30
(turtle) circle 100
(turtle) right 30
(turtle) circle 120
(turtle) right 30
(turtle) circle 120
(turtle) heading
當前方向是 180

(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 500
(turtle) right 90
(turtle) forward 400
```

(繼續下一頁)

(繼續上一頁)

```
(turtle) right 90
(turtle) forward 300
(turtle) playback spiral.cmd
當前位置是 0 0

當前方向是 0

當前方向是 180

(turtle) bye
感謝使用 Turtle
```

CHAPTER 18

🄵行執行 (Concurrent Execution)

本章節描述的模組在程式的🄵行執行上提供支援。選擇要使用哪一個工具則取🄵於是執行什🄵樣的任務（CPU 密集或 IO 密集）與偏好的開發風格（事件驅動協作式多工處理或搶占式多工處理）。以下🄵此章節總覽：

18.1 `threading` --- 基於執行緒的平行性

原始碼： Lib/threading.py

This module constructs higher-level threading interfaces on top of the lower level *`_thread`* module.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

18.1.1 Introduction

The `threading` module provides a way to run multiple threads (smaller units of a process) concurrently within a single process. It allows for the creation and management of threads, making it possible to execute tasks in parallel, sharing memory space. Threads are particularly useful when tasks are I/O bound, such as file operations or making network requests, where much of the time is spent waiting for external resources.

A typical use case for `threading` includes managing a pool of worker threads that can process multiple tasks concurrently. Here's a basic example of creating and starting threads using *`Thread`*:

```
import threading
import time

def crawl(link, delay=3):
    print(f"crawl started for {link}")
    time.sleep(delay)  # Blocking I/O (simulating a network request)
    print(f"crawl ended for {link}")

links = [
    "https://python.org",
    "https://docs.python.org",
    "https://peps.python.org",
```

(繼續下一頁)

(繼續上一頁)

```
]

# Start threads for each link
threads = []
for link in links:
    # Using `args` to pass positional arguments and `kwargs` for keyword arguments
    t = threading.Thread(target=crawl, args=(link,), kwargs={"delay": 2})
    threads.append(t)

# Start each thread
for t in threads:
    t.start()

# Wait for all threads to finish
for t in threads:
    t.join()
```

在 3.7 版的變更: This module used to be optional, it is now always available.

也參考

concurrent.futures.ThreadPoolExecutor offers a higher level interface to push tasks to a background thread without blocking execution of the calling thread, while still being able to retrieve their results when needed.

queue provides a thread-safe interface for exchanging data between running threads.

asyncio offers an alternative approach to achieving task level concurrency without requiring the use of multiple operating system threads.

備🄵

In the Python 2.x series, this module contained `camelCase` names for some methods and functions. These are deprecated as of Python 3.10, but they are still supported for compatibility with Python 2.5 and lower.

CPython 實作細節： In CPython, due to the *Global Interpreter Lock*, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use *multiprocessing* or *concurrent.futures.ProcessPoolExecutor*. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

18.1.2 GIL and performance considerations

Unlike the *multiprocessing* module, which uses separate processes to bypass the *global interpreter lock* (GIL), the threading module operates within a single process, meaning that all threads share the same memory space. However, the GIL limits the performance gains of threading when it comes to CPU-bound tasks, as only one thread can execute Python bytecode at a time. Despite this, threads remain a useful tool for achieving concurrency in many scenarios.

As of Python 3.13, *free-threaded* builds can disable the GIL, enabling true parallel execution of threads, but this feature is not available by default (see **PEP 703**).

18.1.3 Reference

此模組定義了以下函式：

`threading.`**`active_count`**`()`

Return the number of *Thread* objects currently alive. The returned count is equal to the length of the list returned by *enumerate()*.

The function `activeCount` is a deprecated alias for this function.

`threading.`**`current_thread`**`()`

Return the current *Thread* object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the `threading` module, a dummy thread object with limited functionality is returned.

`currentThread` 函式是此函式的已🄵用🄵名。

`threading.`**`excepthook`**`(`*args*, /`)`

處理由*Thread.run()* 引發且未被捕捉到的例外。

args 引數有下列屬性：

- *exc_type*：例外型🄵。
- *exc_value*: Exception value, can be `None`.
- *exc_traceback*: Exception traceback, can be `None`.
- *thread*：引發例外的執行緒，可以是 `None`。

If *exc_type* is *SystemExit*, the exception is silently ignored. Otherwise, the exception is printed out on *sys.stderr*.

如果這個函式引發例外，則會呼叫*sys.excepthook()* 來處理它。

threading.excepthook() can be overridden to control how uncaught exceptions raised by *Thread.run()* are handled.

Storing *exc_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *thread* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *thread* after the custom hook completes to avoid resurrecting objects.

也參考

sys.excepthook() 處理未被捕捉到的例外。

在 3.8 版被加入.

`threading.`**`__excepthook__`**

Holds the original value of *threading.excepthook()*. It is saved so that the original value can be restored in case they happen to get replaced with broken or alternative objects.

在 3.10 版被加入.

`threading.`**`get_ident`**`()`

Return the 'thread identifier' of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

在 3.3 版被加入.

`threading.`**`get_native_id`**`()`

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

可用性: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD, GNU/kFreeBSD.

在 3.8 版被加入.

在 3.13 版的變更: 新增對 GNU/kFreeBSD 的支援。

threading.**enumerate**()

Return a list of all *Thread* objects currently active. The list includes daemonic threads and dummy thread objects created by *current_thread()*. It excludes terminated threads and threads that have not yet been started. However, the main thread is always part of the result, even when terminated.

threading.**main_thread**()

Return the main *Thread* object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

在 3.4 版被加入.

threading.**settrace**(*func*)

Set a trace function for all threads started from the `threading` module. The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

threading.**settrace_all_threads**(*func*)

Set a trace function for all threads started from the `threading` module and all Python threads that are currently executing.

The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

在 3.12 版被加入.

threading.**gettrace**()

Get the trace function as set by *settrace()*.

在 3.10 版被加入.

threading.**setprofile**(*func*)

Set a profile function for all threads started from the `threading` module. The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

threading.**setprofile_all_threads**(*func*)

Set a profile function for all threads started from the `threading` module and all Python threads that are currently executing.

The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

在 3.12 版被加入.

threading.**getprofile**()

Get the profiler function as set by *setprofile()*.

在 3.10 版被加入.

threading.**stack_size**([*size*])

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a *RuntimeError* is raised. If the specified stack size is invalid, a *ValueError* is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information).

可用性: Windows, pthreads.

Unix platforms with POSIX threads support.

此模組也定義了以下常數:

threading.**TIMEOUT_MAX**

The maximum value allowed for the *timeout* parameter of blocking functions (*Lock.acquire()*, *RLock.acquire()*, *Condition.wait()*, etc.). Specifying a timeout greater than this value will raise an *OverflowError*.

在 3.2 版被加入.

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's *Thread* class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

Thread-local data

Thread-local data is data whose values are thread specific. If you have data that you want to be local to a thread, create a *local* object and use its attributes:

```
>>> mydata = local()
>>> mydata.number = 42
>>> mydata.number
42
```

You can also access the *local*-object's dictionary:

```
>>> mydata.__dict__
{'number': 42}
>>> mydata.__dict__.setdefault('widgets', [])
[]
>>> mydata.widgets
[]
```

If we access the data in a different thread:

```
>>> log = []
>>> def f():
...     items = sorted(mydata.__dict__.items())
...     log.append(items)
...     mydata.number = 11
...     log.append(mydata.number)

>>> import threading
>>> thread = threading.Thread(target=f)
>>> thread.start()
>>> thread.join()
>>> log
[[], 11]
```

we get different data. Furthermore, changes made in the other thread don't affect data seen in this thread:

```
>>> mydata.number
42
```

Of course, values you get from a *local* object, including their `__dict__` attribute, are for whatever thread was current at the time the attribute was read. For that reason, you generally don't want to save these values across threads, as they apply only to the thread they came from.

You can create custom *local* objects by subclassing the *local* class:

```
>>> class MyLocal(local):
...     number = 2
...     def __init__(self, /, **kw):
...         self.__dict__.update(kw)
...     def squared(self):
...         return self.number ** 2
```

This can be useful to support default values, methods and initialization. Note that if you define an `__init__()` method, it will be called each time the *local* object is used in a separate thread. This is necessary to initialize each thread's dictionary.

現在如果我們建立一個*local* 物件：

```
>>> mydata = MyLocal(color='red')
```

會有一個預設的數字：

```
>>> mydata.number
2
```

和一個初始𝔽色：

```
>>> mydata.color
'red'
>>> del mydata.color
```

和一個操作資料的方法：

```
>>> mydata.squared()
4
```

As before, we can access the data in a separate thread:

```
>>> log = []
>>> thread = threading.Thread(target=f)
>>> thread.start()
>>> thread.join()
>>> log
[[('color', 'red')], 11]
```

without affecting this thread's data:

```
>>> mydata.number
2
>>> mydata.color
Traceback (most recent call last):
...
AttributeError: 'MyLocal' object has no attribute 'color'
```

Note that subclasses can define *__slots__*, but they are not thread local. They are shared across threads:

```
>>> class MyLocal(local):
...     __slots__ = 'number'

>>> mydata = MyLocal()
>>> mydata.number = 42
>>> mydata.color = 'red'
```

So, the separate thread:

```
>>> thread = threading.Thread(target=f)
>>> thread.start()
>>> thread.join()
```

affects what we see:

```
>>> mydata.number
11
```

class threading.**local**

A class that represents thread-local data.

Thread 物件

The *Thread* class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the *run()* method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and *run()* methods of this class.

Once a thread object is created, its activity must be started by calling the thread's *start()* method. This invokes the *run()* method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its *run()* method terminates -- either normally, or by raising an unhandled exception. The *is_alive()* method tests whether the thread is alive.

Other threads can call a thread's *join()* method. This blocks the calling thread until the thread whose *join()* method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the *name* attribute.

If the *run()* method raises an exception, *threading.excepthook()* is called to handle it. By default, *threading.excepthook()* ignores silently *SystemExit*.

A thread can be flagged as a "daemon thread". The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the *daemon* property or the *daemon* constructor argument.

> **備🄵**
>
> Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an *Event*.

There is a "main thread" object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that "dummy thread objects" are created. These are thread objects corresponding to "alien threads", which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be *joined*. They are never deleted, since it is impossible to detect the termination of alien threads.

class threading.**Thread**(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*, ***, *daemon=None*, *context=None*)

This constructor should always be called with keyword arguments. Arguments are:

group should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

target is the callable object to be invoked by the *run()* method. Defaults to `None`, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form "Thread-*N*" where *N* is a small decimal number, or "Thread-*N* (target)" where "target" is `target.__name__` if the *target* argument is specified.

args is a list or tuple of arguments for the target invocation. Defaults to `()`.

kwargs is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If not `None`, *daemon* explicitly sets whether the thread is daemonic. If `None` (the default), the daemonic property is inherited from the current thread.

context is the *`Context`* value to use when starting the thread. The default value is `None` which indicates that the *`sys.flags.thread_inherit_context`* flag controls the behaviour. If the flag is true, threads will start with a copy of the context of the caller of *`start()`*. If false, they will start with an empty context. To explicitly start with an empty context, pass a new instance of *`Context()`*. To explicitly start with a copy of the current context, pass the value from *`copy_context()`*. The flag defaults true on free-threaded builds and false otherwise.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

在 3.3 版的變更: 新增 *daemon* 參數。

在 3.10 版的變更: Use the *target* name if *name* argument is omitted.

在 3.14 版的變更: 新增 *context* 參數。

start()

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's *`run()`* method to be invoked in a separate thread of control.

This method will raise a *`RuntimeError`* if called more than once on the same thread object.

If supported, set the operating system thread name to *`threading.Thread.name`*. The name can be truncated depending on the operating system thread name limits.

在 3.14 版的變更: Set the operating system thread name.

run()

Method representing the thread's activity.

You may override this method in a subclass. The standard *`run()`* method invokes the callable object passed to the object's constructor as the *target* argument, if any, with positional and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

Using list or tuple as the *args* argument which passed to the *`Thread`* could achieve the same effect.

舉例來🄵:

```
>>> from threading import Thread
>>> t = Thread(target=print, args=[1])
>>> t.run()
1
>>> t = Thread(target=print, args=(1,))
>>> t.run()
1
```

join(*timeout=None*)

Wait until the thread terminates. This blocks the calling thread until the thread whose *`join()`* method is called terminates -- either normally or through an unhandled exception -- or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating-point number specifying a timeout for the operation in seconds (or fractions thereof). As *`join()`* always returns `None`, you must call *`is_alive()`* after *`join()`* to decide whether a timeout happened -- if the thread is still alive, the *`join()`* call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be joined many times.

join() raises a *RuntimeError* if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to *join()* a thread before it has been started and attempts to do so raise the same exception.

If an attempt is made to join a running daemonic thread in late stages of *Python finalization* `join()` raises a *PythonFinalizationError*.

在 3.14 版的變更: May raise *PythonFinalizationError*.

name

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

On some platforms, the thread name is set at the operating system level when the thread starts, so that it is visible in task managers. This name may be truncated to fit in a system-specific limit (for example, 15 bytes on Linux or 63 bytes on macOS).

Changes to *name* are only reflected at the OS level when the currently running thread is renamed. (Setting the *name* attribute of a different thread only updates the Python Thread object.)

getName()

setName()

Deprecated getter/setter API for *name*; use it directly as a property instead.

在 3.10 版之後被🄵用.

ident

The 'thread identifier' of this thread or `None` if the thread has not been started. This is a nonzero integer. See the *get_ident()* function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

native_id

The Thread ID (`TID`) of this thread, as assigned by the OS (kernel). This is a non-negative integer, or `None` if the thread has not been started. See the *get_native_id()* function. This value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

> **備🄵**
>
> Similar to Process IDs, Thread IDs are only valid (guaranteed unique system-wide) from the time the thread is created until the thread has been terminated.

可用性: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD.

在 3.8 版被加入.

is_alive()

Return whether the thread is alive.

This method returns `True` just before the *run()* method starts until just after the *run()* method terminates. The module function *enumerate()* returns a list of all alive threads.

daemon

A boolean value indicating whether this thread is a daemon thread (`True`) or not (`False`). This must be set before *start()* is called, otherwise *RuntimeError* is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to *daemon* = `False`.

The entire Python program exits when no alive non-daemon threads are left.

isDaemon()

setDaemon()

Deprecated getter/setter API for *daemon*; use it directly as a property instead.

在 3.10 版之後被🄵用.

Lock 物件

原始鎖 (primitive lock) 是一種同步原語 (synchronization primitive)，在鎖定時不屬於特定執行緒。在 Python 中，它是目前可用的最低階同步原語，直接由*_thread* 擴充模組實作。

原始鎖會處於兩種狀態之一：「鎖定 (locked)」或「未鎖定 (unclocked)」，建立時會處於未鎖定狀態。它有兩個基本方法*acquire()* 和*release()*。當狀態🄵未鎖定時，*acquire()* 會將狀態變更🄵鎖定🄵立即回傳。當狀態被鎖定時，*acquire()* 會阻塞 (block)，直到另一個執行緒中對*release()* 的呼叫將其更改🄵未鎖定狀態，然後*acquire()* 呼叫會將其重置🄵鎖定🄵回傳。*release()* 方法只能在鎖定狀態下呼叫；它將狀態更改🄵未鎖定🄵立即回傳。如果嘗試釋放未鎖定的鎖，則會引發*RuntimeError*。

鎖也支援情境管理協定。

當多個執行緒阻塞在*acquire()* 中等待狀態轉變🄵未鎖定，此時若呼叫*release()* 將狀態重置🄵未鎖定，則只會有一個執行緒繼續進行；哪一個等待執行緒會繼續進行是未定義的，🄵且可能因實作而🄵。

所有方法均以最小不可分割的操作方式 (atomically) 執行。

class threading.**Lock**

實作原始鎖物件的類🄵。一旦執行緒獲得了鎖，後續再嘗試獲得它就會被阻塞，直到鎖被釋放；任何執行緒都可以去釋放它。

在 3.13 版的變更: `Lock` 現在是一個類🄵。在早期的 Python 中，`Lock` 是一個會回傳底層私有鎖型🄵實例的工廠函式。

acquire(*blocking=True*, *timeout=-1*)

阻塞或非阻塞地取得鎖。

當以 *blocking* 引數設🄵 `True`（預設值）來叫用，將會阻塞直到鎖被解鎖，然後將其設🄵鎖定🄵回傳 `True`。

當以 *blocking* 引數設🄵 `False` 叫用則不會阻塞。如果 *blocking* 設定🄵 `True` 的呼叫會阻塞，則立即回傳 `False`；否則將鎖設🄵鎖定🄵回傳 `True`。

當使用設定🄵正值的浮點 *timeout* 引數進行叫用，只要持續無法取得鎖，最多會阻塞 *timeout* 指定的秒數。`-1` 的 *timeout* 引數代表指定🄵不會停止的等待。當 *blocking* 🄵 `False` 時禁止指定 *timeout*。

如果成功取得鎖，則回傳值🄵 `True`，否則回傳值🄵 `False`（例如像是 *timeout* 已逾期）。

在 3.2 版的變更: 新的 *timeout* 參數。

在 3.2 版的變更: 如果底層執行緒實作支援的話，鎖的取得現在可以被 POSIX 上的訊號中斷。

在 3.14 版的變更: Lock acquisition can now be interrupted by signals on Windows.

release()

釋放鎖。這可以從任何執行緒呼叫，而不是只有獲得鎖的執行緒。

當鎖被鎖定時，將其重置🄵未鎖定然後回傳。如果任何其他執行緒在等待鎖被解鎖時被阻塞，只允許其中一個執行緒繼續進行。

當在未鎖定的鎖上叫用時，會引發*RuntimeError*

🄵有回傳值。

locked()

如果有取得了鎖，則回傳 `True`。

RLock 物件

可重入鎖 (reentrant lock) 是一種同步原語，同一執行緒可以多次取得它。在🄵部，除了原始鎖使用的鎖定/未鎖定狀態之外，它還使用「所屬執行緒 (owning thread)」和「遞🄵等級 (recursion level)」的概念。在鎖定狀態下，某個執行緒會擁有鎖；在未鎖定狀態下則🄵有執行緒擁有它。

執行緒呼叫鎖的*acquire()* 方法來鎖定它，🄵呼叫它的*release()* 方法來解鎖它。

備🄵

可重入鎖支援*情境管理協定*，因此建議使用 `with` 而不是手動呼叫*acquire()* 和*release()* 來對程式碼區塊處理鎖的獲得和釋放。

RLock 的*acquire()*/*release()* 呼叫成對組合可以嵌套使用，這與 Lock 的*acquire()*/*release()* 不同。只有最後一個*release()*（最外面一對的*release()*）會將鎖重置🄵未鎖定狀態，🄵允許在*acquire()* 中阻塞的另一個執行緒繼續進行。

acquire()/*release()* 必須成對使用：每次獲得都必須在已獲得鎖的執行緒中有一個釋放。如果鎖釋放的次數不能和取得的次數一樣的話，可能會導致死鎖 (deadlock)。

class threading.**RLock**

此類🄵實作了可重入鎖物件。可重入鎖必須由獲得它的執行緒釋放。一旦一個執行緒獲得了可重入鎖，同一個執行緒可以再次獲得它而不會阻塞；執行緒每次獲得它也都必須釋放它一次。

請注意，`RLock` 實際上是一個工廠函式，它會回傳平台有支援的特定 RLock 類🄵的最高效率版本的實例。

acquire(*blocking=True*, *timeout=-1*)

阻塞或非阻塞地取得鎖。

也參考

將 RLock 用作🄴情境管理器
若是使用場景合理，和手動呼叫 `acquire()` 和*release()* 相比，會是更🄵推薦的使用方式。

當以 *blocking* 引數設🄵 `True`（預設值）來呼叫：

- 如果🄵有執行緒擁有鎖，則獲得鎖🄵立即回傳。
- 如果另一個執行緒擁有鎖，則阻塞直到能🄵取得鎖，或者達到 *timeout*（如果設定🄵正浮點值）。
- 如果同一個執行緒擁有鎖，則再次取得鎖，🄵立即回傳。這就是*Lock* 和 `RLock` 之間的差🄵；*Lock* 處理方式與上一種情🄵相同，會阻塞直到能🄵取得鎖。

當以 *blocking* 引數設🄵 `False` 來呼叫：

- 如果🄵有執行緒擁有鎖，則獲得鎖🄵立即回傳。
- 如果另一個執行緒擁有該鎖，則立即回傳。
- 如果同一個執行緒擁有鎖，則再次取得鎖🄵立即回傳。

在所有情🄵下，如果執行緒能🄵取得鎖則回傳 `True`。如果執行緒無法取得鎖（即🄵有阻塞或已達超時限制）則回傳 `False`。

如果多次呼叫，又未能呼叫相同次數的*release()*，則可能會導致死鎖。考慮將 `RLock` 作🄵情境管理器使用，而不是直接呼叫 acquire/release。

在 3.2 版的變更: 新的 *timeout* 參數。

release()

釋放鎖🄵🄵少遞🄵等級。如果被🄵至零，則將鎖重置🄵未鎖定（不屬於任何執行緒），🄵且如果任何其他執行緒被阻塞以等待鎖變成未鎖定狀態，則僅允許其中一個執行緒繼續進行。如果遞🄵後遞🄵等級仍然非零，則鎖會保持鎖定🄵由呼叫它的執行緒所擁有。

僅當呼叫的執行緒擁有鎖時才能呼叫此方法。如果在未取得鎖時呼叫此方法則會引發*RuntimeError*。

🄵有回傳值。

locked()

Return a boolean indicating whether this object is locked right now.

在 3.14 版被加入.

Condition objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. Passing one in is useful when several condition variables must share the same lock. The lock is part of the condition object: you don't have to track it separately.

A condition variable obeys the *context management protocol*: using the `with` statement acquires the associated lock for the duration of the enclosed block. The *acquire()* and *release()* methods also call the corresponding methods of the associated lock.

Other methods must be called with the associated lock held. The *wait()* method releases the lock, and then blocks until another thread awakens it by calling *notify()* or *notify_all()*. Once awakened, *wait()* re-acquires the lock and returns. It is also possible to specify a timeout.

The *notify()* method wakes up one of the threads waiting for the condition variable, if any are waiting. The *notify_all()* method wakes up all threads waiting for the condition variable.

Note: the *notify()* and *notify_all()* methods don't release the lock; this means that the thread or threads awakened will not return from their *wait()* call immediately, but only when the thread that called *notify()* or *notify_all()* finally relinquishes ownership of the lock.

The typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call *wait()* repeatedly until they see the desired state, while threads that modify the state call *notify()* or *notify_all()* when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

```
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
    get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
```

The `while` loop checking for the application's condition is necessary because *wait()* can return after an arbitrary long time, and the condition which prompted the *notify()* call may no longer hold true. This is inherent to multi-threaded programming. The *wait_for()* method can be used to automate the condition checking, and eases the computation of timeouts:

```
# Consume an item
with cv:
    cv.wait_for(an_item_is_available)
    get_an_available_item()
```

To choose between *notify()* and *notify_all()*, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

class threading.**Condition**(*lock=None*)

This class implements condition variable objects. A condition variable allows one or more threads to wait until they are notified by another thread.

If the *lock* argument is given and not `None`, it must be a *Lock* or *RLock* object, and it is used as the underlying lock. Otherwise, a new *RLock* object is created and used as the underlying lock.

在 3.3 版的變更: changed from a factory function to a class.

acquire(**args*)

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

release()

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

locked()

Return a boolean indicating whether this object is locked right now.

在 3.14 版被加入.

wait(*timeout=None*)

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method releases the underlying lock, and then blocks until it is awakened by a *notify()* or *notify_all()* call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the *timeout* argument is present and not `None`, it should be a floating-point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an *RLock*, it is not released using its *release()* method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the *RLock* class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

The return value is `True` unless a given *timeout* expired, in which case it is `False`.

在 3.2 版的變更: Previously, the method always returned `None`.

wait_for(*predicate*, *timeout=None*)

Wait until a condition evaluates to true. *predicate* should be a callable which result will be interpreted as a boolean value. A *timeout* may be provided giving the maximum time to wait.

This utility method may call *wait()* repeatedly until the predicate is satisfied, or until a timeout occurs. The return value is the last return value of the predicate and will evaluate to `False` if the method timed out.

Ignoring the timeout feature, calling this method is roughly equivalent to writing:

```
while not predicate():
    cv.wait()
```

Therefore, the same rules apply as with *wait()*: The lock must be held when called and is re-acquired on return. The predicate is evaluated with the lock held.

在 3.2 版被加入.

notify(*n=1*)

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method wakes up at most *n* of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly *n* threads, if at least *n* threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than *n* threads.

Note: an awakened thread does not actually return from its *wait()* call until it can reacquire the lock. Since *notify()* does not release the lock, its caller should.

notify_all()

Wake up all threads waiting on this condition. This method acts like *notify()*, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

The method `notifyAll` is a deprecated alias for this method.

Semaphore 物件

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used the names `P()` and `V()` instead of *acquire()* and *release()*).

A semaphore manages an internal counter which is decremented by each *acquire()* call and incremented by each *release()* call. The counter can never go below zero; when *acquire()* finds that it is zero, it blocks, waiting until some other thread calls *release()*.

Semaphores also support the *context management protocol*.

class threading.**Semaphore**(*value=1*)

This class implements semaphore objects. A semaphore manages an atomic counter representing the number of *release()* calls minus the number of *acquire()* calls, plus an initial value. The *acquire()* method blocks if necessary until it can return without making the counter negative. If not given, *value* defaults to 1.

The optional argument gives the initial *value* for the internal counter; it defaults to `1`. If the *value* given is less than 0, *ValueError* is raised.

在 3.3 版的變更: changed from a factory function to a class.

acquire(*blocking=True*, *timeout=None*)

Acquire a semaphore.

When invoked without arguments:

- If the internal counter is larger than zero on entry, decrement it by one and return `True` immediately.
- If the internal counter is zero on entry, block until awoken by a call to *release()*. Once awoken (and the counter is greater than 0), decrement the counter by 1 and return `True`. Exactly one thread will be awoken by each call to *release()*. The order in which threads are awoken should not be relied on.

When invoked with *blocking* set to `False`, do not block. If a call without an argument would block, return `False` immediately; otherwise, do the same thing as when called without arguments, and return `True`.

When invoked with a *timeout* other than `None`, it will block for at most *timeout* seconds. If acquire does not complete successfully in that interval, return `False`. Return `True` otherwise.

在 3.2 版的變更: 新的 *timeout* 參數。

release(*n=1*)

Release a semaphore, incrementing the internal counter by *n*. When it was zero on entry and other threads are waiting for it to become larger than zero again, wake up *n* of those threads.

在 3.9 版的變更: Added the *n* parameter to release multiple waiting threads at once.

class threading.**BoundedSemaphore**(*value=1*)

Class implementing bounded semaphore objects. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, *ValueError* is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

在 3.3 版的變更: changed from a factory function to a class.

Semaphore 范例

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```
maxconnections = 5
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's acquire and release methods when they need to connect to the server:

```
with pool_sema:
    conn = connectdb()
    try:
        # ... 使用該連🄵 ...
    finally:
        conn.close()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

Event objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true.

class threading.**Event**

Class implementing event objects. An event manages a flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true. The flag is initially false.

在 3.3 版的變更: changed from a factory function to a class.

is_set()

Return `True` if and only if the internal flag is true.

The method `isSet` is a deprecated alias for this method.

set()

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call *wait()* once the flag is true will not block at all.

clear()

Reset the internal flag to false. Subsequently, threads calling *wait()* will block until *set()* is called to set the internal flag to true again.

wait(*timeout=None*)

Block as long as the internal flag is false and the timeout, if given, has not expired. The return value represents the reason that this blocking method returned; `True` if returning because the internal flag is set to true, or `False` if a timeout is given and the internal flag did not become true within the given wait time.

When the timeout argument is present and not `None`, it should be a floating-point number specifying a timeout for the operation in seconds, or fractions thereof.

在 3.1 版的變更: Previously, the method always returned `None`.

Timer 物件

This class represents an action that should be run only after a certain amount of time has passed --- a timer. *Timer* is a subclass of *Thread* and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their *Timer.start* method. The timer can be stopped (before its action has begun) by calling the *cancel()* method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

舉例來🄵:

```
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start()  # 30 秒後會印出 "hello, world"
```

class threading.**Timer**(*interval*, *function*, *args=None*, *kwargs=None*)

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed. If *args* is `None` (the default) then an empty list will be used. If *kwargs* is `None` (the default) then an empty dict will be used.

在 3.3 版的變更: changed from a factory function to a class.

cancel()

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

Barrier 物件

在 3.2 版被加入.

This class provides a simple synchronization primitive for use by a fixed number of threads that need to wait for each other. Each of the threads tries to pass the barrier by calling the *wait()* method and will block until all of the threads have made their *wait()* calls. At this point, the threads are released simultaneously.

The barrier can be reused any number of times for the same number of threads.

As an example, here is a simple way to synchronize a client and server thread:

```
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)
```

(繼續下一頁)

(繼續上一頁)

```
def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

class threading.**Barrier**(*parties*, *action=None*, *timeout=None*)

Create a barrier object for *parties* number of threads. An *action*, when provided, is a callable to be called by one of the threads when they are released. *timeout* is the default timeout value if none is specified for the *wait()* method.

wait(*timeout=None*)

Pass the barrier. When all the threads party to the barrier have called this function, they are all released simultaneously. If a *timeout* is provided, it is used in preference to any that was supplied to the class constructor.

The return value is an integer in the range 0 to *parties* -- 1, different for each thread. This can be used to select a thread to do some special housekeeping, e.g.:

```
i = barrier.wait()
if i == 0:
    # 只會有一個執行緒會印出這個
    print("passed the barrier")
```

If an *action* was provided to the constructor, one of the threads will have called it prior to being released. Should this call raise an error, the barrier is put into the broken state.

If the call times out, the barrier is put into the broken state.

This method may raise a *BrokenBarrierError* exception if the barrier is broken or reset while a thread is waiting.

reset()

Return the barrier to the default, empty state. Any threads waiting on it will receive the *BrokenBarrierError* exception.

Note that using this function may require some external synchronization if there are other threads whose state is unknown. If a barrier is broken it may be better to just leave it and create a new one.

abort()

Put the barrier into a broken state. This causes any active or future calls to *wait()* to fail with the *BrokenBarrierError*. Use this for example if one of the threads needs to abort, to avoid deadlocking the application.

It may be preferable to simply create the barrier with a sensible *timeout* value to automatically guard against one of the threads going awry.

parties

The number of threads required to pass the barrier.

n_waiting

The number of threads currently waiting in the barrier.

broken

A boolean that is `True` if the barrier is in the broken state.

exception threading.**BrokenBarrierError**

This exception, a subclass of *RuntimeError*, is raised when the *Barrier* object is reset or broken.

18.1.4 Using locks, conditions, and semaphores in the `with` statement

All of the objects provided by this module that have `acquire` and `release` methods can be used as context managers for a `with` statement. The `acquire` method will be called when the block is entered, and `release` will be called when the block is exited. Hence, the following snippet:

```
with some_lock:
    # 做某些事情...
```

is equivalent to:

```
some_lock.acquire()
try:
    # 做某些事情...
finally:
    some_lock.release()
```

Currently, *Lock*, *RLock*, *Condition*, *Semaphore*, and *BoundedSemaphore* objects may be used as `with` statement context managers.

18.2 `multiprocessing` --- 以行程🄵基礎的平行性

原始碼： Lib/multiprocessing/

可用性: not Android, not iOS, not WASI.

此模組在行動平台或*WebAssembly* 平台上不支援。

18.2.1 簡介

multiprocessing is a package that supports spawning processes using an API similar to the *threading* module. The *multiprocessing* package offers both local and remote concurrency, effectively side-stepping the *Global Interpreter Lock* by using subprocesses instead of threads. Due to this, the *multiprocessing* module allows the programmer to fully leverage multiple processors on a given machine. It runs on both POSIX and Windows.

The *multiprocessing* module also introduces APIs which do not have analogs in the *threading* module. A prime example of this is the *Pool* object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using *Pool*,

```
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```

也參考

concurrent.futures.ProcessPoolExecutor offers a higher level interface to push tasks to a background process without blocking execution of the calling process. Compared to using the *Pool* interface directly, the

concurrent.futures API more readily allows the submission of work to the underlying process pool to be separated from waiting for the results.

Process 類🄵

In *multiprocessing*, processes are spawned by creating a *Process* object and then calling its *start()* method. *Process* follows the API of *threading.Thread*. A trivial example of a multiprocess program is

```
from multiprocessing import Process

def f(name):
    print('hello', name)

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

For an explanation of why the `if __name__ == '__main__'` part is necessary, see *Programming guidelines*.

The arguments to *Process* usually need to be unpickleable from within the child process. If you tried typing the above example directly into a REPL it could lead to an *AttributeError* in the child process trying to locate the *f* function in the __main__ module.

Contexts and start methods

Depending on the platform, *multiprocessing* supports three ways to start a process. These *start methods* are

spawn
: The parent process starts a fresh Python interpreter process. The child process will only inherit those resources necessary to run the process object's *run()* method. In particular, unnecessary file descriptors and handles from the parent process will not be inherited. Starting a process using this method is rather slow compared to using *fork* or *forkserver*.

  Available on POSIX and Windows platforms. The default on Windows and macOS.

fork
: The parent process uses *os.fork()* to fork the Python interpreter. The child process, when it begins, is effectively identical to the parent process. All resources of the parent are inherited by the child process. Note that safely forking a multithreaded process is problematic.

  Available on POSIX systems.

在 3.14 版的變更: This is no longer the default start method on any platform. Code that requires *fork* must explicitly specify that via `get_context()` or `set_start_method()`.

在 3.12 版的變更: If Python is able to detect that your process has multiple threads, the `os.fork()` function that this start method calls internally will raise a `DeprecationWarning`. Use a different start method. See the `os.fork()` documentation for further explanation.

forkserver

When the program starts and selects the *forkserver* start method, a server process is spawned. From then on, whenever a new process is needed, the parent process connects to the server and requests that it fork a new process. The fork server process is single threaded unless system libraries or preloaded imports spawn threads as a side-effect so it is generally safe for it to use `os.fork()`. No unnecessary resources are inherited.

Available on POSIX platforms which support passing file descriptors over Unix pipes such as Linux. The default on those.

在 3.14 版的變更: This became the default start method on POSIX platforms.

在 3.4 版的變更: *spawn* added on all POSIX platforms, and *forkserver* added for some POSIX platforms. Child processes no longer inherit all of the parents inheritable handles on Windows.

在 3.8 版的變更: On macOS, the *spawn* start method is now the default. The *fork* start method should be considered unsafe as it can lead to crashes of the subprocess as macOS system libraries may start threads. See bpo-33725.

在 3.14 版的變更: On POSIX platforms the default start method was changed from *fork* to *forkserver* to retain the performance but avoid common multithreaded process incompatibilities. See gh-84559.

On POSIX using the *spawn* or *forkserver* start methods will also start a *resource tracker* process which tracks the unlinked named system resources (such as named semaphores or `SharedMemory` objects) created by processes of the program. When all processes have exited the resource tracker unlinks any remaining tracked object. Usually there should be none, but if a process was killed by a signal there may be some "leaked" resources. (Neither leaked semaphores nor shared memory segments will be automatically unlinked until the next reboot. This is problematic for both objects because the system allows only a limited number of named semaphores, and shared memory segments occupy some space in the main memory.)

To select a start method you use the `set_start_method()` in the `if __name__ == '__main__'` clause of the main module. For example:

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    mp.set_start_method('spawn')
    q = mp.Queue()
    p = mp.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

`set_start_method()` should not be used more than once in the program.

Alternatively, you can use `get_context()` to obtain a context object. Context objects have the same API as the multiprocessing module, and allow one to use multiple start methods in the same program.

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    ctx = mp.get_context('spawn')
```

(繼續下一頁)

(繼續上一頁)

```
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

Note that objects related to one context may not be compatible with processes for a different context. In particular, locks created using the *fork* context cannot be passed to processes started using the *spawn* or *forkserver* start methods.

Libraries using *multiprocessing* or *ProcessPoolExecutor* should be designed to allow their users to provide their own multiprocessing context. Using a specific context of your own within a library can lead to incompatibilities with the rest of the library user's application. Always document if your library requires a specific start method.

⚠ 警告

The `'spawn'` and `'forkserver'` start methods generally cannot be used with "frozen" executables (i.e., binaries produced by packages like **PyInstaller** and **cx_Freeze**) on POSIX systems. The `'fork'` start method may work if code does not use threads.

Exchanging objects between processes

multiprocessing supports two types of communication channel between processes:

Queues

The *Queue* class is a near clone of *queue.Queue*. For example:

```
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())    # 印出 "[42, None, 'hello']"
    p.join()
```

Queues are thread and process safe. Any object put into a *multiprocessing* queue will be serialized.

Pipes

The *Pipe()* function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())   # 印出 "[42, None, 'hello']"
    p.join()
```

The two connection objects returned by *Pipe()* represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted

if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

The `send()` method serializes the object and `recv()` re-creates the object.

Synchronization between processes

multiprocessing contains equivalents of all the synchronization primitives from *threading*. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.

Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then *multiprocessing* provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using *Value* or *Array*. For example, the following code

```
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print(num.value)
    print(arr[:])
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The `'d'` and `'i'` arguments used when creating `num` and `arr` are typecodes of the kind used by the *array* module: `'d'` indicates a double precision float and `'i'` indicates a signed integer. These shared

objects will be process and thread-safe.

For more flexibility in using shared memory one can use the *multiprocessing.sharedctypes* module which supports the creation of arbitrary ctypes objects allocated from shared memory.

Server process

A manager object returned by *Manager()* controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by *Manager()* will support types *list*, *dict*, *set*, *Namespace*, *Lock*, *RLock*, *Semaphore*, *BoundedSemaphore*, *Condition*, *Event*, *Barrier*, *Queue*, *Value* and *Array*. For example,

```
from multiprocessing import Process, Manager

def f(d, l, s):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()
    s.add('a')
    s.add('b')

if __name__ == '__main__':
    with Manager() as manager:
        d = manager.dict()
        l = manager.list(range(10))
        s = manager.set()

        p = Process(target=f, args=(d, l, s))
        p.start()
        p.join()

        print(d)
        print(l)
        print(s)
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
{'a', 'b'}
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

Using a pool of workers

The *Pool* class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

舉例來🄵:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
```

(繼續下一頁)

(繼續上一頁)

```
    with Pool(processes=4) as pool:

        # print "[0, 1, 4,..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,))      # runs in *only* one process
        print(res.get(timeout=1))             # prints "400"

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ()) # runs in *only* one process
        print(res.get(timeout=1))             # prints the PID of that process

        # launching multiple evaluations asynchronously *may* use more processes
        multiple_results = [pool.apply_async(os.getpid, ()) for i in range(4)]
        print([res.get(timeout=1) for res in multiple_results])

        # make a single worker sleep for 10 seconds
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a multiprocessing.TimeoutError")

        print("For the moment, the pool remains available for more work")

    # exiting the 'with'-block has stopped the pool
    print("Now the pool is closed and no longer available")
```

Note that the methods of a pool should only ever be used by the process which created it.

備𝔽

Functionality within this package requires that the `__main__` module be importable by the children. This is covered in *Programming guidelines* however it is worth pointing out here. This means that some examples, such as the *`multiprocessing.pool.Pool`* examples will not work in the interactive interpreter. For example:

```
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> with p:
...     p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
Traceback (most recent call last):
Traceback (most recent call last):
AttributeError: Can't get attribute 'f' on <module '__main__' (<class '_frozen_importlib.
↪BuiltinImporter'>)>
AttributeError: Can't get attribute 'f' on <module '__main__' (<class '_frozen_importlib.
↪BuiltinImporter'>)>
AttributeError: Can't get attribute 'f' on <module '__main__' (<class '_frozen_importlib.
↪BuiltinImporter'>)>
```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the parent process somehow.)

18.2.2 Reference

The *multiprocessing* package mostly replicates the API of the *threading* module.

Process 與例外

class multiprocessing.**Process**(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*, ***, *daemon=None*)

Process objects represent activity that is run in a separate process. The *Process* class has equivalents of all the methods of *threading.Thread*.

The constructor should always be called with keyword arguments. *group* should always be None; it exists solely for compatibility with *threading.Thread*. *target* is the callable object to be invoked by the *run()* method. It defaults to None, meaning nothing is called. *name* is the process name (see *name* for more details). *args* is the argument tuple for the target invocation. *kwargs* is a dictionary of keyword arguments for the target invocation. If provided, the keyword-only *daemon* argument sets the process *daemon* flag to True or False. If None (the default), this flag will be inherited from the creating process.

By default, no arguments are passed to *target*. The *args* argument, which defaults to (), can be used to specify a list or tuple of the arguments to pass to *target*.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (super().__init__()) before doing anything else to the process.

備🄵

In general, all arguments to *Process* must be picklable. This is frequently observed when trying to create a *Process* or use a *concurrent.futures.ProcessPoolExecutor* from a REPL with a locally defined *target* function.

Passing a callable object defined in the current REPL session causes the child process to die via an uncaught *AttributeError* exception when starting as *target* must have been defined within an importable module in order to be loaded during unpickling.

Example of this uncatchable error from the child:

```
>>> import multiprocessing as mp
>>> def knigit():
...     print("Ni!")
...
>>> process = mp.Process(target=knigit)
>>> process.start()
>>> Traceback (most recent call last):
  File ".../multiprocessing/spawn.py", line ..., in spawn_main
  File ".../multiprocessing/spawn.py", line ..., in _main
AttributeError: module '__main__' has no attribute 'knigit'
>>> process
<SpawnProcess name='SpawnProcess-1' pid=379473 parent=378707 stopped exitcode=1>
```

See *The spawn and forkserver start methods*. While this restriction is not true if using the "fork" start method, as of Python 3.14 that is no longer the default on any platform. See *Contexts and start methods*. See also gh-132898.

在 3.3 版的變更: 新增 *daemon* 參數。

run()

Method representing the process's activity.

You may override this method in a subclass. The standard *run()* method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

Using a list or tuple as the *args* argument passed to *Process* achieves the same effect.

範例:

```
>>> from multiprocessing import Process
>>> p = Process(target=print, args=[1])
>>> p.run()
1
>>> p = Process(target=print, args=(1,))
>>> p.run()
1
```

start()

Start the process's activity.

This must be called at most once per process object. It arranges for the object's *run()* method to be invoked in a separate process.

join([*timeout*])

If the optional argument *timeout* is `None` (the default), the method blocks until the process whose *join()* method is called terminates. If *timeout* is a positive number, it blocks at most *timeout* seconds. Note that the method returns `None` if its process terminates or if the method times out. Check the process's *exitcode* to determine if it terminated.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

name

The process's name. The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name.

The initial name is set by the constructor. If no explicit name is provided to the constructor, a name of the form 'Process-N_1:N_2:...:N_k' is constructed, where each N_k is the N-th child of its parent.

is_alive()

Return whether the process is alive.

Roughly, a process object is alive from the moment the *start()* method returns until the child process terminates.

daemon

The process's daemon flag, a Boolean value. This must be set before *start()* is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemonic child processes.

Note that a daemonic process is not allowed to create child processes. Otherwise a daemonic process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemonic processes have exited.

In addition to the *threading.Thread* API, *Process* objects also support the following attributes and methods:

pid

Return the process ID. Before the process is spawned, this will be `None`.

exitcode

The child's exit code. This will be `None` if the process has not yet terminated.

If the child's *run()* method returned normally, the exit code will be 0. If it terminated via *sys.exit()* with an integer argument *N*, the exit code will be *N*.

If the child terminated due to an exception not caught within *run()*, the exit code will be 1. If it was terminated by signal *N*, the exit code will be the negative value *-N*.

authkey

The process's authentication key (a byte string).

When *multiprocessing* is initialized the main process is assigned a random string using *os.urandom()*.

When a *Process* object is created, it will inherit the authentication key of its parent process, although this may be changed by setting *authkey* to another byte string.

參🄵*Authentication keys*。

sentinel

A numeric handle of a system object which will become "ready" when the process ends.

You can use this value if you want to wait on several events at once using *multiprocessing.connection.wait()*. Otherwise calling *join()* is simpler.

On Windows, this is an OS handle usable with the `WaitForSingleObject` and `WaitForMultipleObjects` family of API calls. On POSIX, this is a file descriptor usable with primitives from the *select* module.

在 3.3 版被加入.

interrupt()

Terminate the process. Works on POSIX using the *SIGINT* signal. Behavior on Windows is undefined.

By default, this terminates the child process by raising *KeyboardInterrupt*. This behavior can be altered by setting the respective signal handler in the child process *signal.signal()* for *SIGINT*.

Note: if the child process catches and discards *KeyboardInterrupt*, the process will not be terminated.

Note: the default behavior will also set *exitcode* to `1` as if an uncaught exception was raised in the child process. To have a different *exitcode* you may simply catch *KeyboardInterrupt* and call `exit(your_code)`.

在 3.14 版被加入.

terminate()

Terminate the process. On POSIX this is done using the *SIGTERM* signal; on Windows `TerminateProcess()` is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated -- they will simply become orphaned.

> **⚠ 警告**
>
> If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

kill()

Same as *terminate()* but using the `SIGKILL` signal on POSIX.

在 3.7 版被加入.

close()

Close the *Process* object, releasing all resources associated with it. *ValueError* is raised if the underlying process is still running. Once *close()* returns successfully, most other methods and attributes of the *Process* object will raise *ValueError*.

在 3.7 版被加入.

Note that the *start()*, *join()*, *is_alive()*, *terminate()* and *exitcode* methods should only be called by the process that created the process object.

Example usage of some of the methods of *Process*:

```
>>> import multiprocessing, time, signal
>>> mp_context = multiprocessing.get_context('spawn')
>>> p = mp_context.Process(target=time.sleep, args=(1000,))
>>> print(p, p.is_alive())
<...Process ... initial> False
>>> p.start()
>>> print(p, p.is_alive())
<...Process ... started> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<...Process ... stopped exitcode=-SIGTERM> False
>>> p.exitcode == -signal.SIGTERM
True
```

exception multiprocessing.**ProcessError**

The base class of all *multiprocessing* exceptions.

exception multiprocessing.**BufferTooShort**

Exception raised by `Connection.recv_bytes_into()` when the supplied buffer object is too small for the message read.

If `e` is an instance of *BufferTooShort* then `e.args[0]` will give the message as a byte string.

exception multiprocessing.**AuthenticationError**

Raised when there is an authentication error.

exception multiprocessing.**TimeoutError**

Raised by methods with a timeout when the timeout expires.

Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use *Pipe()* (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The *Queue*, *SimpleQueue* and *JoinableQueue* types are multi-producer, multi-consumer FIFO queues modelled on the *queue.Queue* class in the standard library. They differ in that *Queue* lacks the *task_done()* and *join()* methods introduced into Python 2.5's *queue.Queue* class.

If you use *JoinableQueue* then you **must** call *JoinableQueue.task_done()* for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

One difference from other Python queue implementations, is that *multiprocessing* queues serializes all objects that are put into them using *pickle*. The object return by the get method is a re-created object that does not share memory with the original object.

Note that one can also create a shared queue by using a manager object -- see *Managers*.

備🄵

multiprocessing uses the usual *queue.Empty* and *queue.Full* exceptions to signal a timeout. They are not available in the *multiprocessing* namespace so you need to import them from *queue*.

備🄵

When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties -- if they really bother you then you can instead use a queue created with a *manager*.

(1) After putting an object on an empty queue there may be an infinitesimal delay before the queue's *empty()* method returns *False* and *get_nowait()* can return without raising *queue.Empty*.

(2) If multiple processes are enqueuing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.

警告

If a process is killed using *Process.terminate()* or *os.kill()* while it is trying to use a *Queue*, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

警告

As mentioned above, if a child process has put items on a queue (and it has not used *JoinableQueue.cancel_join_thread*), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See *Programming guidelines*.

For an example of the usage of queues for interprocess communication see 範例.

`multiprocessing.`**`Pipe`**`(`[*duplex*]`)`

Returns a pair `(conn1, conn2)` of *Connection* objects representing the ends of a pipe.

If *duplex* is `True` (the default) then the pipe is bidirectional. If *duplex* is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

The `send()` method serializes the object using *pickle* and the `recv()` re-creates the object.

`class` `multiprocessing.`**`Queue`**`(`[*maxsize*]`)`

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual *queue.Empty* and *queue.Full* exceptions from the standard library's *queue* module are raised to signal timeouts.

Queue implements all the methods of *queue.Queue* except for *task_done()* and *join()*.

qsize()

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise *NotImplementedError* on platforms like macOS where `sem_getvalue()` is not implemented.

empty()

Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

May raise an *OSError* on closed queues. (not guaranteed)

full()

Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

put(*obj*[, *block*[, *timeout*]])

Put obj into the queue. If the optional argument *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *queue.Full* exception if no free slot was available within that time. Otherwise (*block* is `False`), put an item on the queue if a free slot is immediately available, else raise the *queue.Full* exception (*timeout* is ignored in that case).

在 3.8 版的變更: If the queue is closed, *ValueError* is raised instead of *AssertionError*.

put_nowait(*obj*)

Equivalent to `put(obj, False)`.

get([*block*[, *timeout*]])

Remove and return an item from the queue. If optional args *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *queue.Empty* exception if no item was available within that time. Otherwise (block is `False`), return an item if one is immediately available, else raise the *queue.Empty* exception (*timeout* is ignored in that case).

在 3.8 版的變更: If the queue is closed, *ValueError* is raised instead of *OSError*.

get_nowait()

Equivalent to `get(False)`.

multiprocessing.Queue has a few additional methods not found in *queue.Queue*. These methods are usually unnecessary for most code:

close()

Close the queue: release internal resources.

A queue must not be used anymore after it is closed. For example, *get()*, *put()* and *empty()* methods must no longer be called.

The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

join_thread()

Join the background thread. This can only be used after *close()* has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call *cancel_join_thread()* to make *join_thread()* do nothing.

cancel_join_thread()

Prevent *join_thread()* from blocking. In particular, this prevents the background thread from being joined automatically when the process exits -- see *join_thread()*.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to be lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

備🄵

This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a *Queue* will result in an *ImportError*. See bpo-3770 for additional information. The same holds true for any of the specialized queue types listed below.

class multiprocessing.**SimpleQueue**

It is a simplified *Queue* type, very close to a locked *Pipe*.

close()

Close the queue: release internal resources.

A queue must not be used anymore after it is closed. For example, *get()*, *put()* and *empty()* methods must no longer be called.

在 3.9 版被加入.

empty()

Return `True` if the queue is empty, `False` otherwise.

Always raises an *OSError* if the SimpleQueue is closed.

get()

Remove and return an item from the queue.

put(*item*)

Put *item* into the queue.

class multiprocessing.**JoinableQueue**([*maxsize*])

JoinableQueue, a *Queue* subclass, is a queue which additionally has *task_done()* and *join()* methods.

task_done()

Indicate that a formerly enqueued task is complete. Used by queue consumers. For each *get()* used to fetch a task, a subsequent call to *task_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task_done()* call was received for every item that had been *put()* into the queue).

Raises a *ValueError* if called more times than there were items placed in the queue.

join()

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer calls *task_done()* to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, *join()* unblocks.

Miscellaneous

multiprocessing.**active_children**()

Return list of all live children of the current process.

Calling this has the side effect of "joining" any processes which have already finished.

multiprocessing.**cpu_count**()

Return the number of CPUs in the system.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with *os.process_cpu_count()* (or `len(os.sched_getaffinity(0))`).

When the number of CPUs cannot be determined a *NotImplementedError* is raised.

> **也參考**
>
> *os.cpu_count()* *os.process_cpu_count()*

在 3.13 版的變更: The return value can also be overridden using the `-X cpu_count` flag or `PYTHON_CPU_COUNT` as this is merely a wrapper around the *os* cpu count APIs.

multiprocessing.**current_process**()

Return the *Process* object corresponding to the current process.

An analogue of *threading.current_thread()*.

multiprocessing.**parent_process**()

Return the *Process* object corresponding to the parent process of the *current_process()*. For the main process, `parent_process` will be `None`.

在 3.8 版被加入.

multiprocessing.**freeze_support**()

Add support for when a program which uses *multiprocessing* has been frozen to produce an executable. (Has been tested with **py2exe**, **PyInstaller** and **cx_Freeze**.)

One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:

```
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise *RuntimeError*.

Calling `freeze_support()` has no effect when the start method is not *spawn*. In addition, if the module is being run normally by the Python interpreter (the program has not been frozen), then `freeze_support()` has no effect.

multiprocessing.**get_all_start_methods**()

Returns a list of the supported start methods, the first of which is the default. The possible start methods are `'fork'`, `'spawn'` and `'forkserver'`. Not all platforms support all methods. See *Contexts and start methods*.

在 3.4 版被加入.

multiprocessing.**get_context**(*method=None*)

Return a context object which has the same attributes as the *multiprocessing* module.

If *method* is `None` then the default context is returned. Note that if the global start method has not been set, this will set it to the default method. Otherwise *method* should be `'fork'`, `'spawn'`, `'forkserver'`. *ValueError* is raised if the specified start method is not available. See *Contexts and start methods*.

在 3.4 版被加入.

multiprocessing.**get_start_method**(*allow_none=False*)

Return the name of start method used for starting processes.

If the global start method has not been set and *allow_none* is `False`, then the start method is set to the default and the name is returned. If the start method has not been set and *allow_none* is `True` then `None` is returned.

The return value can be `'fork'`, `'spawn'`, `'forkserver'` or `None`. See *Contexts and start methods*.

在 3.4 版被加入.

在 3.8 版的變更: On macOS, the *spawn* start method is now the default. The *fork* start method should be considered unsafe as it can lead to crashes of the subprocess. See bpo-33725.

multiprocessing.**set_executable**(*executable*)

Set the path of the Python interpreter to use when starting a child process. (By default *sys.executable* is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes.

在 3.4 版的變更: Now supported on POSIX when the `'spawn'` start method is used.

在 3.11 版的變更: 接受一個類路徑物件。

multiprocessing.**set_forkserver_preload**(*module_names*)

Set a list of module names for the forkserver main process to attempt to import so that their already imported state is inherited by forked processes. Any *ImportError* when doing so is silently ignored. This can be used as a performance enhancement to avoid repeated work in every process.

For this to work, it must be called before the forkserver process has been launched (before creating a `Pool` or starting a *Process*).

Only meaningful when using the `'forkserver'` start method. See *Contexts and start methods*.

在 3.4 版被加入.

multiprocessing.**set_start_method**(*method*, *force=False*)

Set the method which should be used to start child processes. The *method* argument can be `'fork'`, `'spawn'` or `'forkserver'`. Raises *RuntimeError* if the start method has already been set and *force* is not `True`. If *method* is `None` and *force* is `True` then the start method is set to `None`. If *method* is `None` and *force* is `False` then the context is set to the default context.

Note that this should be called at most once, and it should be protected inside the `if __name__ == '__main__'` clause of the main module.

參🄵*Contexts and start methods*。

在 3.4 版被加入.

備🄵

multiprocessing contains no analogues of *threading.active_count()*, *threading.enumerate()*, *threading.settrace()*, *threading.setprofile()*, *threading.Timer*, or *threading.local*.

Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using *Pipe* -- see also *Listeners and Clients*.

class multiprocessing.connection.**Connection**

send(*obj*)

Send an object to the other end of the connection which should be read using *recv()*.

The object must be picklable. Very large pickles (approximately 32 MiB+, though it depends on the OS) may raise a *ValueError* exception.

recv()

Return an object sent from the other end of the connection using *send()*. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

fileno()

Return the file descriptor or handle used by the connection.

close()

Close the connection.

This is called automatically when the connection is garbage collected.

poll([*timeout*])

Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

Note that multiple connection objects may be polled at once by using *multiprocessing.connection.wait()*.

send_bytes(*buffer*[, *offset*[, *size*]])

Send byte data from a *bytes-like object* as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MiB+, though it depends on the OS) may raise a *ValueError* exception

recv_bytes([*maxlength*])

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then *OSError* is raised and the connection will no longer be readable.

在 3.3 版的變更: This function used to raise *IOError*, which is now an alias of *OSError*.

recv_bytes_into(*buffer*[, *offset*])

Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

buffer must be a writable *bytes-like object*. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a `BufferTooShort` exception is raised and the complete message is available as `e.args[0]` where `e` is the exception instance.

在 3.3 版的變更: Connection objects themselves can now be transferred between processes using *Connection.send()* and *Connection.recv()*.

Connection objects also now support the context management protocol -- see 情境管理器型🄵. *__enter__()* returns the connection object, and *__exit__()* calls *close()*.

舉例來🄵:

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

警告

The *Connection.recv()* method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using `Pipe()` you should only use the *recv()* and *send()* methods after performing some sort of authentication. See *Authentication keys*.

警告

If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for *threading* module.

Note that one can also create synchronization primitives by using a manager object -- see *Managers*.

class multiprocessing.**Barrier**(*parties*[, *action*[, *timeout*]])

A barrier object: a clone of *threading.Barrier*.

在 3.3 版被加入.

class multiprocessing.**BoundedSemaphore**([*value*])

A bounded semaphore object: a close analog of *threading.BoundedSemaphore*.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with *Lock.acquire()*.

備🄵

On macOS, this is indistinguishable from *Semaphore* because `sem_getvalue()` is not implemented on that platform.

class multiprocessing.**Condition**([*lock*])

A condition variable: an alias for *threading.Condition*.

If *lock* is specified then it should be a *Lock* or *RLock* object from *multiprocessing*.

在 3.3 版的變更: The *wait_for()* method was added.

class multiprocessing.**Event**

A clone of *threading.Event*.

class multiprocessing.**Lock**

A non-recursive lock object: a close analog of *threading.Lock*. Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of *threading.Lock* as it applies to threads are replicated here in *multiprocessing.Lock* as it applies to either processes or threads, except as noted.

Note that *Lock* is actually a factory function which returns an instance of multiprocessing.synchronize.Lock initialized with a default context.

Lock supports the *context manager* protocol and thus may be used in with statements.

acquire(*block=True*, *timeout=None*)

Acquire a lock, blocking or non-blocking.

With the *block* argument set to True (the default), the method call will block until the lock is in an unlocked state, then set it to locked and return True. Note that the name of this first argument differs from that in *threading.Lock.acquire()*.

With the *block* argument set to False, the method call does not block. If the lock is currently in a locked state, return False; otherwise set the lock to a locked state and return True.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of None (the default) set the timeout period to infinite. Note that the treatment of negative or None values for *timeout* differs from the implemented behavior in *threading.Lock.acquire()*. The *timeout* argument has no practical implications if the *block* argument is set to False and is thus ignored. Returns True if the lock has been acquired or False if the timeout period has elapsed.

release()

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in *threading.Lock.release()* except that when invoked on an unlocked lock, a *ValueError* is raised.

locked()

Return a boolean indicating whether this object is locked right now.

在 3.14 版被加入.

class multiprocessing.**RLock**

A recursive lock object: a close analog of *threading.RLock*. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that *RLock* is actually a factory function which returns an instance of multiprocessing.synchronize.RLock initialized with a default context.

RLock supports the *context manager* protocol and thus may be used in with statements.

acquire(*block=True*, *timeout=None*)

Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to True, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of True. Note that there

are several differences in this first argument's behavior compared to the implementation of *threading.RLock.acquire()*, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in *Lock.acquire()*. Note that some of these behaviors of *timeout* differ from the implemented behaviors in *threading.RLock.acquire()*.

release()

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An *AssertionError* is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in *threading.RLock.release()*.

locked()

Return a boolean indicating whether this object is locked right now.

在 3.14 版被加入.

class multiprocessing.**Semaphore**([*value*])

A semaphore object: a close analog of *threading.Semaphore*.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with *Lock.acquire()*.

> **備🄵**
>
> On macOS, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

> **備🄵**
>
> Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an *ImportError*. See bpo-3770 for additional information.

共享的 ctypes 物件

It is possible to create shared objects using shared memory which can be inherited by child processes.

multiprocessing.**Value**(*typecode_or_type*, **args*, *lock=True*)

Return a *ctypes* object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the *value* attribute of a *Value*.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the *array* module. **args* is passed on to the constructor for the type.

If *lock* is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False`

then access to the returned object will not be automatically protected by a lock, so it will not necessarily be ”process-safe”.

Operations like += which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

`multiprocessing.`**`Array`**(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the *array* module. If *size_or_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be ”process-safe”.

Note that *lock* is a keyword only argument.

Note that an array of *ctypes.c_char* has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

`multiprocessing.sharedctypes` 模組

The *multiprocessing.sharedctypes* module provides functions for allocating *ctypes* objects from shared memory which can be inherited by child processes.

> **備🄵**
>
> Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.`**`RawArray`**(*typecode_or_type*, *size_or_initializer*)

Return a ctypes array allocated from shared memory.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the *array* module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic -- use *Array()* instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.`**`RawValue`**(*typecode_or_type*, **args*)

Return a ctypes object allocated from shared memory.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the *array* module. **args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic -- use *Value()* instead to make sure that access is automatically synchronized using a lock.

Note that an array of *ctypes.c_char* has `value` and `raw` attributes which allow one to use it to store and retrieve strings -- see documentation for *ctypes*.

`multiprocessing.sharedctypes.`**`Array`**(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

The same as *RawArray()* except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.`**`Value`**(*typecode_or_type*, **args*, *lock=True*)

The same as *RawValue()* except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

`multiprocessing.sharedctypes.`**`copy`**(*obj*)

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

`multiprocessing.sharedctypes.`**`synchronized`**(*obj*[, *lock*])

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a *multiprocessing.RLock* object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

在 3.5 版的變更: Synchronized objects support the *context manager* protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of *ctypes.Structure*.)

ctypes	sharedctypes using type	sharedctypes using typecode
c_double(2.4)	RawValue(c_double, 2.4)	RawValue('d', 2.4)
MyStruct(4, 6)	RawValue(MyStruct, 4, 6)	
(c_short * 7)()	RawArray(c_short, 7)	RawArray('h', 7)
(c_int * 3)(9, 2, 8)	RawArray(c_int, (9, 2, 8))	RawArray('i', (9, 2, 8))

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
```

(繼續下一頁)

(繼續上一頁)

```
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375,9.5)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print(n.value)
    print(x.value)
    print(s.value)
    print([(a.x, a.y) for a in A])
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.`**`Manager`**`()`

Returns a started *SyncManager* object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the *multiprocessing.managers* module:

class multiprocessing.managers.**BaseManager**(*address=None*, *authkey=None*, *serializer='pickle'*, *ctx=None*, ***, *shutdown_timeout=1.0*)

建立一個 BaseManager 物件。

Once created one should call *start()* or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If *address* is `None` then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is `None` then `current_process().authkey` is used. Otherwise *authkey* is used and it must be a byte string.

serializer must be `'pickle'` (use *pickle* serialization) or `'xmlrpclib'` (use *xmlrpc.client* serialization).

ctx is a context object, or `None` (use the current context). See the `get_context()` function.

shutdown_timeout is a timeout in seconds used to wait until the process used by the manager completes in the *shutdown()* method. If the shutdown times out, the process is terminated. If terminating the process also times out, the process is killed.

在 3.11 版的變更: 新增 *shutdown_timeout* 參數。

start(*[initializer[, initargs]]*)

Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

get_server()

Returns a `Server` object which represents the actual server under the control of the Manager. The `Server` object supports the `serve_forever()` method:

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=('', 50000), authkey=b'abc')
>>> server = manager.get_server()
>>> server.serve_forever()
```

`Server` additionally has an *address* attribute.

connect()

Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 50000), authkey=b'abc')
>>> m.connect()
```

shutdown()

Stop the process used by the manager. This is only available if *start()* has been used to start the server process.

This can be called multiple times.

register(*typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]]]*)

A classmethod which can be used for registering a type or callable with the manager class.

typeid is a "type identifier" which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the *connect()* method, or if the *create_method* argument is `False` then this can be left as `None`.

proxytype is a subclass of *BaseProxy* which is used to create proxies for shared objects with this *typeid*. If `None` then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this typeid should be allowed to access using *BaseProxy._callmethod()*. (If *exposed* is `None` then `proxytype._exposed_` is used instead if it exists.) In the case where no exposed list is specified, all "public methods" of the shared object will be accessible. (Here a "public method" means any attribute which has a `__call__()` method and whose name does not begin with `'_'`.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method_to_typeid* is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method's name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

BaseManager instances also have one read-only property:

address

The address used by the manager.

在 3.3 版的變更: Manager objects support the context management protocol -- see 情境管理器型🄵. *__enter__()* starts the server process (if it has not already started) and then returns the manager object. *__exit__()* calls *shutdown()*.

In previous versions *__enter__()* did not start the manager's server process if it was not already started.

class multiprocessing.managers.**SyncManager**

A subclass of *BaseManager* which can be used for the synchronization of processes. Objects of this type are returned by *multiprocessing.Manager()*.

Its methods create and return *Proxy Objects* for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

Barrier(*parties*[, *action*[, *timeout*]])

Create a shared *threading.Barrier* object and return a proxy for it.

在 3.3 版被加入.

BoundedSemaphore([*value*])

Create a shared *threading.BoundedSemaphore* object and return a proxy for it.

Condition([*lock*])

Create a shared *threading.Condition* object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a *threading.Lock* or *threading.RLock* object.

在 3.3 版的變更: The *wait_for()* method was added.

Event()

Create a shared *threading.Event* object and return a proxy for it.

Lock()

Create a shared *threading.Lock* object and return a proxy for it.

Namespace()

Create a shared *Namespace* object and return a proxy for it.

Queue([*maxsize*])

Create a shared *queue.Queue* object and return a proxy for it.

RLock()

Create a shared *threading.RLock* object and return a proxy for it.

Semaphore([*value*])

Create a shared *threading.Semaphore* object and return a proxy for it.

Array(*typecode*, *sequence*)

Create an array and return a proxy for it.

Value(*typecode*, *value*)

Create an object with a writable `value` attribute and return a proxy for it.

dict()

dict(*mapping*)

dict(*sequence*)

Create a shared *dict* object and return a proxy for it.

list()

list(*sequence*)

Create a shared *list* object and return a proxy for it.

set()

set(*sequence*)

set(*mapping*)

Create a shared *set* object and return a proxy for it.

在 3.14 版被加入: *set* support was added.

在 3.6 版的變更: Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the *SyncManager*.

class multiprocessing.managers.**Namespace**

A type that can register with *SyncManager*.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with `'_'` will be an attribute of the proxy and not an attribute of the referent:

```
>>> mp_context = multiprocessing.get_context('spawn')
>>> manager = mp_context.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3    # this is an attribute of the proxy
>>> print(Global)
Namespace(x=10, y='hello')
```

Customized managers

To create one's own manager, one creates a subclass of *BaseManager* and uses the *register()* classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))         # 印出 7
        print(maths.mul(7, 8))         # 印出 56
```

Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```
>>> from multiprocessing.managers import BaseManager
>>> from queue import Queue
>>> queue = Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda:queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super().__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```
>>> mp_context = multiprocessing.get_context('spawn')
>>> manager = mp_context.Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying *str()* to a proxy will return the representation of the referent, whereas applying *repr()* will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain *Proxy Objects*. This permits nesting of these managed lists, dicts, and other *Proxy Objects*:

```
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)         # referent of a now contains referent of b
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']
```

Similarly, dict and list proxies may be nested inside one another:

```
>>> l_outer = manager.list([ manager.dict() for i in range(2) ])
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) *list* or *dict* objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, but by
# updating the dictionary, the proxy is notified of the change
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested *Proxy Objects* for most use cases but also demonstrates a level of control over the synchronization.

備🄵

The proxy types in *multiprocessing* do nothing to support comparisons by value. So, for instance, we have:

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

class multiprocessing.managers.**BaseProxy**

Proxy objects are instances of subclasses of *BaseProxy*.

_callmethod(*methodname*[, *args*[, *kwds*]])

Call and return the result of a method of the proxy's referent.

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object -- see documentation for the *method_to_typeid* argument of *BaseManager.register()*.

If an exception is raised by the call, then is re-raised by *_callmethod()*. If some other exception is raised in the manager's process then this is converted into a `RemoteError` exception and is raised by *_callmethod()*.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of *_callmethod()*:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),)) # 等價於 l[2:7]
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))          # 等價於 l[20]
Traceback (most recent call last):
...
IndexError: list index out of range
```

_getvalue()

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

__repr__()

Return a representation of the proxy object.

__str__()

Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the *Pool* class.

class multiprocessing.pool.**Pool**([*processes*[, *initializer*[, *initargs*[, *maxtasksperchild*[, *context*]]]]])

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

processes is the number of worker processes to use. If *processes* is `None` then the number returned by *os.process_cpu_count()* is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

maxtasksperchild is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default *maxtasksperchild* is `None`, which means worker processes will live as long as the pool.

context can be used to specify the context used for starting the worker processes. Usually a pool is created using the function `multiprocessing.Pool()` or the *Pool()* method of a context object. In both cases *context* is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

警告

multiprocessing.pool objects have internal resources that need to be properly managed (like any other resource) by using the pool as a context manager or by calling *close()* and *terminate()* manually. Failure to do this can lead to the process hanging on finalization.

Note that it is **not correct** to rely on the garbage collector to destroy the pool as CPython does not assure that the finalizer of the pool will be called (see `object.__del__()` for more information).

在 3.2 版的變更: 新增 *maxtasksperchild* 參數。

在 3.4 版的變更: 新增 *context* 參數。

在 3.13 版的變更: *processes* uses *os.process_cpu_count()* by default, instead of *os.cpu_count()*.

備🄵

Worker processes within a *Pool* typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The *maxtasksperchild* argument to the *Pool* exposes this ability to the end user.

apply(*func*[, *args*[, *kwds*]])

Call *func* with arguments *args* and keyword arguments *kwds*. It blocks until the result is ready. Given this blocks, *apply_async()* is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

apply_async(*func*[, *args*[, *kwds*[, *callback*[, *error_callback*]]]])

A variant of the *apply()* method which returns a *AsyncResult* object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

map(*func*, *iterable*[, *chunksize*])

A parallel equivalent of the *map()* built-in function (it supports only one *iterable* argument though, for multiple iterables see *starmap()*). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

Note that it may cause high memory usage for very long iterables. Consider using *imap()* or *imap_unordered()* with explicit *chunksize* option for better efficiency.

map_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A variant of the *map()* method which returns a *AsyncResult* object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

imap(*func*, *iterable*[, *chunksize*])

A lazier version of `map()`.

The *chunksize* argument is the same as the one used by the `map()` method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of `1`.

Also if *chunksize* is `1` then the `next()` method of the iterator returned by the `imap()` method has an optional *timeout* parameter: `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within *timeout* seconds.

imap_unordered(*func*, *iterable*[, *chunksize*])

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be "correct".)

starmap(*func*, *iterable*[, *chunksize*])

Like `map()` except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1,2), (3, 4)]` results in `[func(1,2), func(3,4)]`.

在 3.3 版被加入.

starmap_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A combination of `starmap()` and `map_async()` that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

在 3.3 版被加入.

close()

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

terminate()

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

join()

Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

在 3.3 版的變更: Pool objects now support the context management protocol -- see 情境管理器型🄵. `__enter__()` returns the pool object, and `__exit__()` calls `terminate()`.

class multiprocessing.pool.**AsyncResult**

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

get([*timeout*])

Return the result when it arrives. If *timeout* is not `None` and the result does not arrive within *timeout* seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.

wait([*timeout*])

Wait until the result is available or until *timeout* seconds pass.

ready()

Return whether the call has completed.

successful()

Return whether the call completed without raising an exception. Will raise *ValueError* if the result is not ready.

在 3.7 版的變更: If the result is not ready, *ValueError* is raised instead of *AssertionError*.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(processes=4) as pool:          # start 4 worker processes
        result = pool.apply_async(f, (10,)) # evaluate "f(10)" asynchronously in a single␣
↪process
        print(result.get(timeout=1))         # prints "100" unless your computer is *very*␣
↪slow

        print(pool.map(f, range(10)))        # prints "[0, 1, 4,..., 81]"

        it = pool.imap(f, range(10))
        print(next(it))                      # prints "0"
        print(next(it))                      # prints "1"
        print(it.next(timeout=1))            # prints "4" unless your computer is *very* slow

        result = pool.apply_async(time.sleep, (10,))
        print(result.get(timeout=1))         # raises multiprocessing.TimeoutError
```

Listeners and Clients

Usually message passing between processes is done using queues or by using *Connection* objects returned by *Pipe()*.

However, the *multiprocessing.connection* module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the *hmac* module, and for polling multiple connections at the same time.

multiprocessing.connection.**deliver_challenge**(*connection*, *authkey*)

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise *AuthenticationError* is raised.

multiprocessing.connection.**answer_challenge**(*connection*, *authkey*)

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then *AuthenticationError* is raised.

multiprocessing.connection.**Client**(*address*[, *family*[, *authkey*]])

Attempt to set up a connection to the listener which is using address *address*, returning a *Connection*.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See *Address Formats*)

If *authkey* is given and not `None`, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is `None`. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

class multiprocessing.connection.**Listener**([*address*[, *family*[, *backlog*[, *authkey*]]]])

A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

address is the address to be used by the bound socket or named pipe of the listener object.

> **備🄵**
>
> If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

family is the type of socket (or named pipe) to use. This can be one of the strings `'AF_INET'` (for a TCP socket), `'AF_UNIX'` (for a Unix domain socket) or `'AF_PIPE'` (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is `None` then the family is inferred from the format of *address*. If *address* is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if *family* is `'AF_UNIX'` and address is `None` then the socket will be created in a private temporary directory created using *tempfile.mkstemp()*.

If the listener object uses a socket then *backlog* (1 by default) is passed to the *listen()* method of the socket once it has been bound.

If *authkey* is given and not `None`, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is `None`. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

accept()

Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

close()

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address

The address which is being used by the Listener object.

last_accepted

The address from which the last accepted connection came. If this is unavailable then it is `None`.

在 3.3 版的變更: Listener objects now support the context management protocol -- see 情境管理器型🄵. *__enter__()* returns the listener object, and *__exit__()* calls *close()*.

multiprocessing.connection.**wait**(*object_list*, *timeout=None*)

Wait till an object in *object_list* is ready. Returns the list of those objects in *object_list* which are ready. If *timeout* is a float then the call blocks for at most that many seconds. If *timeout* is `None` then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both POSIX and Windows, an object can appear in *object_list* if it is

- a readable *Connection* object;
- a connected and readable *socket.socket* object; or
- the *sentinel* attribute of a *Process* object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

POSIX: `wait(object_list, timeout)` almost equivalent `select.select(object_list, [], [], timeout)`. The difference is that, if *select.select()* is interrupted by a signal, it can raise *OSError* with an error number of `EINTR`, whereas *wait()* will not.

Windows: An item in *object_list* must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a *fileno()* method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are **not** waitable handles.)

在 3.3 版被加入.

Examples

The following server code creates a listener which uses `'secret password'` as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)     # family is deduced to be 'AF_INET'

with Listener(address, authkey=b'secret password') as listener:
    with listener.accept() as conn:
        print('connection accepted from', listener.last_accepted)

        conn.send([2.25, None, 'junk', float])

        conn.send_bytes(b'hello')

        conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())                  # => [2.25, None, 'junk', float]

    print(conn.recv_bytes())            # => 'hello'

    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr))    # => 8
    print(arr)                          # => array('i', [42, 1729, 0, 0, 0])
```

The following code uses *wait()* to wait for messages from multiple processes at once:

```
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now to be sure that
        # p is the only process which owns a handle for it.  This
        # ensures that when p closes its handle for the writable end,
        # wait() will promptly report the readable end as being ready.
        w.close()

    while readers:
        for r in wait(readers):
            try:
```

(繼續下一頁)

(繼續上一頁)

```
            msg = r.recv()
        except EOFError:
            readers.remove(r)
        else:
            print(msg)
```

Address Formats

- An `'AF_INET'` address is a tuple of the form `(hostname, port)` where *hostname* is a string and *port* is an integer.
- An `'AF_UNIX'` address is a string representing a filename on the filesystem.
- An `'AF_PIPE'` address is a string of the form `r'\\.\pipe\`*PipeName*`'`. To use *`Client()`* to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\\`*`ServerName`*`\pipe\`*`PipeName`*`'` instead.

Note that any string beginning with two backslashes is assumed by default to be an `'AF_PIPE'` address rather than an `'AF_UNIX'` address.

Authentication keys

When one uses *`Connection.recv`*, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore *`Listener`* and *`Client()`* use the *`hmac`* module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see *`Process`*). This value will be automatically inherited by any *`Process`* object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using *`os.urandom()`*.

Logging

Some support for logging is available. Note, however, that the *`logging`* package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.`**`get_logger`**`()`

Returns the logger used by *`multiprocessing`*. If necessary, a new one will be created.

When first created the logger has level *`logging.NOTSET`* and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger -- any other customization of the logger will not be inherited.

`multiprocessing.`**`log_to_stderr`**`(`*level=None*`)`

This function performs a call to *`get_logger()`* but in addition to returning the logger created by get_logger, it adds a handler which sends output to *`sys.stderr`* using format `'[%(levelname)s/%(processName)s] %(message)s'`. You can modify `levelname` of the logger by passing a `level` argument.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
```

(繼續下一頁)

(繼續上一頁)

```
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

For a full table of logging levels, see the *logging* module.

multiprocessing.dummy 模組

multiprocessing.dummy replicates the API of *multiprocessing* but is no more than a wrapper around the *threading* module.

In particular, the `Pool` function provided by *multiprocessing.dummy* returns an instance of *ThreadPool*, which is a subclass of *Pool* that supports all the same method calls but uses a pool of worker threads rather than worker processes.

class multiprocessing.pool.**ThreadPool**([*processes*[, *initializer*[, *initargs*]]])

A thread pool object which controls a pool of worker threads to which jobs can be submitted. *ThreadPool* instances are fully interface compatible with *Pool* instances, and their resources must also be properly managed, either by using the pool as a context manager or by calling *close()* and *terminate()* manually.

processes is the number of worker threads to use. If *processes* is `None` then the number returned by *os.process_cpu_count()* is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

Unlike *Pool*, *maxtasksperchild* and *context* cannot be provided.

> **備🄵**
>
> A *ThreadPool* shares the same interface as *Pool*, which is designed around a pool of processes and predates the introduction of the *concurrent.futures* module. As such, it inherits some operations that don't make sense for a pool backed by threads, and it has its own type for representing the status of asynchronous jobs, *AsyncResult*, that is not understood by any other libraries.
>
> Users should generally prefer to use *concurrent.futures.ThreadPoolExecutor*, which has a simpler interface that was designed around threads from the start, and which returns *concurrent.futures.Future* instances that are compatible with many other libraries, including *asyncio*.

18.2.3 Programming guidelines

There are certain guidelines and idioms which should be adhered to when using *multiprocessing*.

All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On POSIX when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or *active_children()* is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's *Process.is_alive* will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the *spawn* or *forkserver* start methods many types from *multiprocessing* need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the *Process.terminate* method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using *Process.terminate* on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the "feeder" thread to the underlying pipe. (The child process can call the *Queue.cancel_join_thread* method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                    # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On POSIX using the *fork* start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing *sys.stdin* with a ”file like object”

multiprocessing originally unconditionally called:

```
os.close(sys.stdin.fileno())
```

in the `multiprocessing.Process._bootstrap()` method --- this resulted in issues with processes-in-processes. This has been changed to:

```
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY), closefd=False)
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace *sys.stdin()* with a ”file-like object” with output buffering. This danger is that if multiple processes call *close()* on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see bpo-5155, bpo-5313 and bpo-5331

The *spawn* and *forkserver* start methods

There are a few extra restrictions which don’t apply to the *fork* start method.

More picklability

Ensure that all arguments to *Process* are picklable. Also, if you subclass `Process.__init__`, you must make sure that instances will be picklable when the *Process.start* method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that *Process.start* was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, using the *spawn* or *forkserver* start method running the following module would fail with a *RuntimeError*:

```
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```

Instead one should protect the "entry point" of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_support, set_start_method

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

18.2.4 范例

Demonstration of how to create and use customized managers and proxies:

```
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
```

(繼續下一頁)

(繼續上一頁)

```
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print('-' * 20)

    it = manager.baz()
    for i in it:
        print('<%d>' % i, end=' ')
    print()

    print('-' * 20)
```

(繼續下一頁)

18.3 multiprocessing.shared_memory --- 對於共享記憶體的跨行程直接存取

原始碼： Lib/multiprocessing/shared_memory.py

在 3.8 版被加入.

該模組提供了一個*SharedMemory* 類🄵，用於分配和管理被多核心或對稱多處理器 (symmetric multiprocessor, SMP) 機器上的一個或多個行程存取的共享記憶體。🄵了協助共享記憶體的生命🄵期管理，特🄵是跨不同行程的管理，*multiprocessing.managers* 模組中還提供了一個*BaseManager* 子類🄵*SharedMemoryManager*。

在此模組中，共享記憶體是指「POSIX 風格」的共享記憶體區塊（🄵管不一定如此明確實作），而不是指「分散式共享記憶體 (distributed shared memory)」。這種型🄵的共享記憶體允許不同的行程🄵在地讀取和寫入揮發性記憶體 (volatile memory) 的公開（或共享）區域。通常行程只能存取自己的行程記憶體空間，但共享記憶體允許在行程之間共享資料，從而避免需要跨行程傳遞資料的情境。與透過硬碟或 socket 或其他需要序列化/還原序列化 (serialization/deserialization) 和🄵🄵資料的通訊方式以共享資料相比，直接透過記憶體共享資料可以提供顯著的性能優勢。

class multiprocessing.shared_memory.**SharedMemory**(*name=None*, *create=False*, *size=0*, ***, *track=True*)

建立 SharedMemory 類🄵的實例，用於建立新的共享記憶體區塊或附加到現有的共享記憶體區塊。每個共享記憶體區塊都被分配了一個唯一的名稱。透過這種方式，一個行程可以建立具有特定名稱的共享記憶體區塊，而不同的行程可以使用該相同名稱附加到同一共享記憶體塊。

作🄵跨行程共享資料的資源，共享記憶體區塊的壽命可能比建立它們的原始行程還要長。當一個行程不再需要存取但其他行程可能仍需要的共享記憶體區塊時，應該呼叫*close()* 方法。當任何行程不再需要共享記憶體區塊時，應呼叫*unlink()* 方法以確保正確清理。

參數

- **name** (str | *None*) -- 所請求的共享記憶體的唯一名稱，指定🄵字串。建立新的共享記憶體區塊時，如果名稱提供🄵 None（預設值），則會生成一個新的名稱。
- **create** (bool) -- 控制是否建立新的共享記憶體區塊 (True) 或附加現有的共享記憶體區塊 (False)。
- **size** (int) -- 指定建立新共享記憶體區塊時請求的位元組數。由於某些平台會根據該平台的記憶體頁 (memory page) 大小來選擇分配記憶體區塊，因此共享記憶體區塊的確切大小可能大於或等於請求的大小。當附加到現有共享記憶體區塊時，size 參數將被忽略。
- **track** (bool) -- When True, register the shared memory block with a resource tracker process on platforms where the OS does not do this automatically. The resource tracker ensures proper cleanup of the shared memory even if all other processes with access to the memory exit without doing so. Python processes created from a common ancestor using *multiprocessing* facilities share a single resource tracker process, and the lifetime of shared memory segments is handled automatically among these processes. Python processes created in any other way will receive their own resource tracker when accessing shared memory with *track* enabled. This will cause the shared memory to be deleted by the resource tracker of the first process that terminates. To avoid this issue, users of *subprocess* or standalone Python processes should set *track* to False when there is already another process in place that does the bookkeeping. *track* is ignored on Windows, which has its own tracking and automatically deletes shared memory when all handles to it have been closed.

在 3.13 版的變更: 新增 *track* 參數。

close()

Close the file descriptor/handle to the shared memory from this instance. *close()* should be called once access to the shared memory block from this instance is no longer needed. Depending on operating system, the underlying memory may or may not be freed even if all handles to it have been closed. To ensure proper cleanup, use the *unlink()* method.

unlink()

Delete the underlying shared memory block. This should be called only once per shared memory block regardless of the number of handles to it, even in other processes. *unlink()* and *close()* can be called in any order, but trying to access data inside a shared memory block after *unlink()* may result in memory access errors, depending on platform.

This method has no effect on Windows, where the only way to delete a shared memory block is to close all handles.

buf

共享記憶體區塊🄴容的記憶體視圖 (memoryview)。

name

對共享記憶體區塊之唯一名稱的唯讀存取。

size

對共享記憶體區塊大小（以位元組🄴單位）的唯讀存取。

以下範例示範了*SharedMemory* 實例的低階使用方式：

```
>>> from multiprocessing import shared_memory
>>> shm_a = shared_memory.SharedMemory(create=True, size=10)
>>> type(shm_a.buf)
<class 'memoryview'>
>>> buffer = shm_a.buf
>>> len(buffer)
10
>>> buffer[:4] = bytearray([22, 33, 44, 55])  # Modify multiple at once
>>> buffer[4] = 100                           # Modify single byte at a time
>>> # Attach to an existing shared memory block
>>> shm_b = shared_memory.SharedMemory(shm_a.name)
>>> import array
>>> array.array('b', shm_b.buf[:5])  # Copy the data into a new array.array
array('b', [22, 33, 44, 55, 100])
>>> shm_b.buf[:5] = b'howdy'  # Modify via shm_b using bytes
>>> bytes(shm_a.buf[:5])      # Access via shm_a
b'howdy'
>>> shm_b.close()   # Close each SharedMemory instance
>>> shm_a.close()
>>> shm_a.unlink()  # Call unlink only once to release the shared memory
```

以下範例示範了*SharedMemory* 類🄴與 NumPy 陣列的實際用法：從兩個不同的 Python shell 存取相同的 `numpy.ndarray`：

```
>>> # In the first Python interactive shell
>>> import numpy as np
>>> a = np.array([1, 1, 2, 3, 5, 8])  # Start with an existing NumPy array
>>> from multiprocessing import shared_memory
>>> shm = shared_memory.SharedMemory(create=True, size=a.nbytes)
>>> # Now create a NumPy array backed by shared memory
>>> b = np.ndarray(a.shape, dtype=a.dtype, buffer=shm.buf)
>>> b[:] = a[:]  # Copy the original data into shared memory
>>> b
array([1, 1, 2, 3, 5, 8])
>>> type(b)
```

(繼續下一頁)

(繼續上一頁)

```
<class 'numpy.ndarray'>
>>> type(a)
<class 'numpy.ndarray'>
>>> shm.name  # We did not specify a name so one was chosen for us
'psm_21467_46075'

>>> # In either the same shell or a new Python shell on the same machine
>>> import numpy as np
>>> from multiprocessing import shared_memory
>>> # Attach to the existing shared memory block
>>> existing_shm = shared_memory.SharedMemory(name='psm_21467_46075')
>>> # Note that a.shape is (6,) and a.dtype is np.int64 in this example
>>> c = np.ndarray((6,), dtype=np.int64, buffer=existing_shm.buf)
>>> c
array([1, 1, 2, 3, 5, 8])
>>> c[-1] = 888
>>> c
array([  1,   1,   2,   3,   5, 888])

>>> # Back in the first Python interactive shell, b reflects this change
>>> b
array([  1,   1,   2,   3,   5, 888])

>>> # Clean up from within the second Python shell
>>> del c  # Unnecessary; merely emphasizing the array is no longer used
>>> existing_shm.close()

>>> # Clean up from within the first Python shell
>>> del b  # Unnecessary; merely emphasizing the array is no longer used
>>> shm.close()
>>> shm.unlink()  # Free and release the shared memory block at the very end
```

class multiprocessing.managers.**SharedMemoryManager**([*address*[, *authkey*]])

multiprocessing.managers.BaseManager 的子類🄵，可用於跨行程管理共享記憶體區塊。

在 SharedMemoryManager 實例上呼叫*start()* 會🄵動一個新行程。這個新行程的唯一目的是管理那些透過它建立出的所有共享記憶體區塊的生命🄵期。要觸發釋放該行程管理的所有共享記憶體區塊，請在實例上呼叫*shutdown()*，這會觸發對該行程管理的所有*SharedMemory* 物件的*unlink()* 呼叫，然後再停止這個行程。透過 SharedMemoryManager 建立 SharedMemory 實例，我們無需手動追🄵和觸發共享記憶體資源的釋放。

此類🄵提供了用於建立和回傳*SharedMemory* 實例以及建立由共享記憶體支援的類串列物件 (*ShareableList*) 的方法。

請參🄵*BaseManager* 了解繼承的 *address* 和 *authkey* 可選輸入引數的描述以及如何使用它們從其他行程連接到現有的 SharedMemoryManager 服務。

SharedMemory(*size*)

建立🄵回傳一個新的*SharedMemory* 物件，該物件具有指定的 *size*（以位元組🄵單位）。

ShareableList(*sequence*)

建立🄵回傳一個新的*ShareableList* 物件，該物件由輸入 *sequence* 中的值初始化。

以下範例示範了*SharedMemoryManager* 的基本作用機制：

```
>>> from multiprocessing.managers import SharedMemoryManager
>>> smm = SharedMemoryManager()
>>> smm.start()  # Start the process that manages the shared memory blocks
>>> sl = smm.ShareableList(range(4))
>>> sl
ShareableList([0, 1, 2, 3], name='psm_6572_7512')
>>> raw_shm = smm.SharedMemory(size=128)
```

(繼續下一頁)

(繼續上一頁)

```
>>> another_sl = smm.ShareableList('alpha')
>>> another_sl
ShareableList(['a', 'l', 'p', 'h', 'a'], name='psm_6572_12221')
>>> smm.shutdown()  # Calls unlink() on sl, raw_shm, and another_sl
```

以下範例描述了一種可能更方便的模式，即透過 `with` 陳述式使用*SharedMemoryManager* 物件，以確保所有共享記憶體區塊不再被需要後都被釋放：

```
>>> with SharedMemoryManager() as smm:
...     sl = smm.ShareableList(range(2000))
...     # Divide the work among two processes, storing partial results in sl
...     p1 = Process(target=do_work, args=(sl, 0, 1000))
...     p2 = Process(target=do_work, args=(sl, 1000, 2000))
...     p1.start()
...     p2.start()  # A multiprocessing.Pool might be more efficient
...     p1.join()
...     p2.join()   # Wait for all work to complete in both processes
...     total_result = sum(sl)  # Consolidate the partial results now in sl
```

在 `with` 陳述式中使用*SharedMemoryManager* 時，當 `with` 陳述式的程式碼區塊執行完畢時，使用該管理器建立的共享記憶體區塊都會被釋放。

class multiprocessing.shared_memory.**ShareableList**(*sequence=None*, *, *name=None*)

提供一個類似 list 的可變物件，其中儲存的所有值都儲存在共享記憶體區塊中。這將可儲存值限制🄵以下🄵建資料型🄵：

- *int*（有符號 64 位元）
- *float*
- *bool*
- *str*（編碼🄵 UTF-8 時每個小於 10M 位元組）
- *bytes*（每個小於 10M 位元組）
- `None`

它也與🄵建*list* 型🄵明顯不同，因🄵這些 list 不能更改其總長度（即🄵有 `append()`、`insert()` 等）🄵且不支援通過切片動態建立新的 `ShareableList` 實例。

sequence 用於填充 (populate) 一個充滿值的新 `ShareableList`。設定🄵 `None` 以透過其唯一的共享記憶體名稱來附加到已經存在的 `ShareableList`。

如*SharedMemory* 的定義中所述，*name* 是被請求之共享記憶體的唯一名稱。當附加到現有的 `ShareableList` 時，指定其共享記憶體區塊的唯一名稱，同時將 *sequence* 設定🄵 `None`。

> **備🄵**
>
> *bytes* 和*str* 值存在一個已知問題。如果它們以 `\x00` nul 位元組或字元結尾，那🄵當透過索引從 `ShareableList` 中取得它們時，這些位元組或字元可能會被默默地🄵離 *(silently stripped)*。這種 `.rstrip(b'\x00')` 行🄵被認🄵是一個錯誤，將來可能會消失。請參🄵 gh-106939。

對於去除尾隨空值 (rstripping of trailing nulls) 會出問題的應用程式，變通解法 (workaround) 是始終無條件地在儲存時於此類值的末尾追加一個額外非 0 位元組，🄵在取得時也無條件地🄵除它：

```
>>> from multiprocessing import shared_memory
>>> nul_bug_demo = shared_memory.ShareableList(['?\x00', b'\x03\x02\x01\x00\x00\x00'])
>>> nul_bug_demo[0]
'?'
>>> nul_bug_demo[1]
b'\x03\x02\x01'
```

(繼續下一頁)

(繼續上一頁)

```
>>> nul_bug_demo.shm.unlink()
>>> padded = shared_memory.ShareableList(['?\x00\x07', b'\x03\x02\x01\x00\x00\x00\x07'])
>>> padded[0][:-1]
'?\x00'
>>> padded[1][:-1]
b'\x03\x02\x01\x00\x00\x00'
>>> padded.shm.unlink()
```

count(*value*)

回傳 *value* 出現的次數。

index(*value*)

回傳 *value* 的第一個索引位置。如果 *value* 不存在，則引發*ValueError*。

format

唯讀屬性，包含所有目前有儲存的值所使用的*struct* 打包格式。

shm

儲存值的*SharedMemory* 實例。

以下範例示範了*ShareableList* 實例的基本用法：

```
>>> from multiprocessing import shared_memory
>>> a = shared_memory.ShareableList(['howdy', b'HoWdY', -273.154, 100, None, True, 42])
>>> [ type(entry) for entry in a ]
[<class 'str'>, <class 'bytes'>, <class 'float'>, <class 'int'>, <class 'NoneType'>, <class
↪'bool'>, <class 'int'>]
>>> a[2]
-273.154
>>> a[2] = -78.5
>>> a[2]
-78.5
>>> a[2] = 'dry ice'  # Changing data types is supported as well
>>> a[2]
'dry ice'
>>> a[2] = 'larger than previously allocated storage space'
Traceback (most recent call last):
  ...
ValueError: exceeds available storage for existing str
>>> a[2]
'dry ice'
>>> len(a)
7
>>> a.index(42)
6
>>> a.count(b'howdy')
0
>>> a.count(b'HoWdY')
1
>>> a.shm.close()
>>> a.shm.unlink()
>>> del a  # Use of a ShareableList after call to unlink() is unsupported
```

以下範例描述了一個、兩個或多個行程如何透過提供後面的共享記憶體區塊名稱來存取同一個*ShareableList*：

```
>>> b = shared_memory.ShareableList(range(5))          # In a first process
>>> c = shared_memory.ShareableList(name=b.shm.name)   # In a second process
>>> c
ShareableList([0, 1, 2, 3, 4], name='...')
>>> c[-1] = -999
```

(繼續下一頁)

(繼續上一頁)

```
>>> b[-1]
-999
>>> b.shm.close()
>>> c.shm.close()
>>> c.shm.unlink()
```

以下範例示範了如果需要，可以對*ShareableList*（和底層*SharedMemory*）物件進行 pickle 和 unpickle。請注意，它仍然是相同的共享物件。發生這種情🄴是因🄴反序列化的物件具有相同的唯一名稱，🄵且只是附加到具有相同名稱的現有物件（如果該物件仍然存在）：

```
>>> import pickle
>>> from multiprocessing import shared_memory
>>> sl = shared_memory.ShareableList(range(10))
>>> list(sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> deserialized_sl = pickle.loads(pickle.dumps(sl))
>>> list(deserialized_sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> sl[0] = -1
>>> deserialized_sl[1] = -2
>>> list(sl)
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(deserialized_sl)
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> sl.shm.close()
>>> sl.shm.unlink()
```

18.4 concurrent 套件

此套件包含下列模組：

- *concurrent.futures* -- 🄵動平行任務
- *concurrent.interpreters* -- 在同一行程中使用多個直譯器

18.5 concurrent.futures --- 🄵動平行任務

在 3.2 版被加入.

原　　始　　碼： Lib/concurrent/futures/thread.py、Lib/concurrent/futures/process.py 與 Lib/concurrent/futures/interpreter.py

---

concurrent.futures 模組提供了一個高階介面來非同步地 (asynchronously) 執行可呼叫物件 (callable) 。

非同步執行可以透過*ThreadPoolExecutor* 或*InterpreterPoolExecutor* 來使用執行緒 (thread) 執行，或透過*ProcessPoolExecutor* 來使用單獨行程 (process) 執行。兩者都實作了相同的介面，該介面由抽象的*Executor* 類🄴定義。

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄴*WebAssembly 平台*。

18.5.1 Executor 物件

class concurrent.futures.**Executor**

提供非同步執行呼叫方法的抽象類🄵。不應直接使用它，而應透過其具體子類🄵來使用。

submit(*fn*, */*, **args*, ***kwargs*)

🄵可呼叫物件 *fn* 排程來以 `fn(*args, **kwargs)` 的形式執行🄵回傳一個表示可呼叫的執行的*Future* 物件。

```
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 1235)
    print(future.result())
```

map(*fn*, **iterables*, *timeout=None*, *chunksize=1*, *buffersize=None*)

類似於*map(fn, *iterables)*，除了：

- The *iterables* are collected immediately rather than lazily, unless a *buffersize* is specified to limit the number of submitted tasks whose results have not yet been yielded. If the buffer is full, iteration over the *iterables* pauses until a result is yielded from the buffer.
- *fn* 是非同步執行的，🄵且對 *fn* 的多次呼叫可以🄵行處理。

如果*__next__()* 被呼叫，且在原先呼叫*Executor.map()* 的 *timeout* 秒後結果仍不可用，回傳的🄵代器就會引發*TimeoutError*。*timeout* 可以是整數或浮點數。如果未指定 *timeout* 或🄵 `None`，則等待時間就不會有限制。

如果 *fn* 呼叫引發例外，則當從🄵代器中檢索到它的值時將引發該例外。

使用*ProcessPoolExecutor* 時，此方法將 *iterables* 分成許多分塊 (chunks)，🄵將其作🄵獨立的任務來提交給池 (pool)。可以透過將 *chunksize* 設定🄵正整數來指定這些分塊的（約略）大小。對於非常長的可🄵代物件，*chunksize* 使用較大的值（與預設大小 1 相比）可以顯著提高性能。對於*ThreadPoolExecutor* 和*InterpreterPoolExecutor*，*chunksize* 無效。

在 3.5 版的變更: 新增 *chunksize* 參數。

在 3.14 版的變更: 新增 *buffersize* 參數。

shutdown(*wait=True*, ***, *cancel_futures=False*)

向 executor 發出訊號 (signal)，表明它應該在目前未定 (pending) 的 future 完成執行時釋放它正在使用的任何資源。在關閉後呼叫*Executor.submit()* 和*Executor.map()* 將引發*RuntimeError*。

如果 *wait* 🄵 `True` 則此方法將不會回傳，直到所有未定的 futures 完成執行🄵且與 executor 關聯的資源都被釋放。如果 *wait* 🄵 `False` 則此方法將立即回傳，🄵且當所有未定的 future 執行完畢時，與 executor 關聯的資源將被釋放。不管 *wait* 的值如何，整個 Python 程式都不會退出，直到所有未定的 futures 執行完畢。

如果 *cancel_futures* 🄵 `True`，此方法將取消 executor 尚未開始運行的所有未定 future。無論 *cancel_futures* 的值如何，任何已完成或正在運行的 future 都不會被取消。

如果 *cancel_futures* 和 *wait* 都🄵 `True`，則 executor 已開始運行的所有 future 將在此方法回傳之前完成。剩余的 future 被取消。

如果使用 `with` 陳述式來將 executor 用作*context manager*，那你就可以不用明確地呼叫此方法，這將會自己關閉*Executor*（如同呼叫*Executor.shutdown()* 時 *wait* 被設定🄵 `True` 般等待）：

```
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
```

在 3.9 版的變更: 新增 *cancel_futures*。

18.5.2 ThreadPoolExecutor

ThreadPoolExecutor 是一個*Executor* 子類🄴，它使用執行緒池來非同步地執行呼叫。

當與*Future* 關聯的可呼叫物件等待另一個*Future* 的結果時，可能會發生死鎖 (deadlock)。例如：

```
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b 永遠不會完成，因🄵它正在等待 a。
    return 5

def wait_on_a():
    time.sleep(5)
    print(a.result())  # a 永遠不會完成，因🄵它正在等待 b。
    return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

和：

```
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # 這將永遠不會完成，因🄵只有一個工作執行緒且
    # 它正在執行這個函式。
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```

class concurrent.futures.**ThreadPoolExecutor**(*max_workers=None*, *thread_name_prefix=''*, *initializer=None*, *initargs=()*)

一個*Executor* 子類🄴，它使用最多有 *max_workers* 個執行緒的池來非同步地執行呼叫。

所有排隊到 ThreadPoolExecutor 的執行緒都將在直譯器退出之前加入。請注意，執行此操作的退出處理程式會在任何使用 atexit 新增的退出處理程式之前執行。這意味著必須捕獲🄴處理主執行緒中的例外，以便向執行緒發出訊號來正常退出 (gracefully exit)。因此，建議不要將 ThreadPoolExecutor 用於長時間運行的任務。

initializer 是一個可選的可呼叫物件，在每個工作執行緒開始時呼叫；*initargs* 是傳遞給 initializer 的引數元組 (tuple)。如果 *initializer* 引發例外，所有目前未定的作業以及任何向池中提交 (submit) 更多作業的嘗試都將引發*BrokenThreadPool*。

在 3.5 版的變更: 如果 *max_workers* 🄵 None 或未給定，它將預設🄵機器上的處理器數量乘以 5，這假定了*ThreadPoolExecutor* 通常用於 I/O 重🄵而非 CPU 密集的作業，🄵且 worker 的數量應該高於*ProcessPoolExecutor* 的 worker 數量。

在 3.6 版的變更: 新增 *thread_name_prefix* 參數以允許使用者控制由池所建立的工作執行緒 (worker thread) 的*threading.Thread* 名稱，以便於除錯。

在 3.7 版的變更: 新增 *initializer* 與 *initargs* 引數。

在 3.8 版的變更: *max_workers* 的預設值改🄵 min(32, os.cpu_count() + 4)。此預設值🄵 I/O 密集任務至少保留了 5 個 worker。它最多使用 32 個 CPU 核心來執行 CPU 密集任務，以釋放 GIL。🄵且它避免了在多核機器上隱晦地使用非常大量的資源。

ThreadPoolExecutor 現在在🄵動 *max_workers* 工作執行緒之前會重用 (reuse) 空🄵的工作執行緒。

在 3.13 版的變更: *max_workers* 的預設值被改🄵 min(32, (os.process_cpu_count() or 1) + 4)。

ThreadPoolExecutor 范例

```
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://nonexistent-subdomain.python.org/']

# Retrieve a single page and report the URL and contents
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout) as conn:
        return conn.read()

# We can use a with statement to ensure threads are cleaned up promptly
with concurrent.futures.ThreadPoolExecutor(max_workers=5) as executor:
    # Start the load operations and mark each future with its URL
    future_to_url = {executor.submit(load_url, url, 60): url for url in URLS}
    for future in concurrent.futures.as_completed(future_to_url):
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:
            print('%r generated an exception: %s' % (url, exc))
        else:
            print('%r page is %d bytes' % (url, len(data)))
```

18.5.3 InterpreterPoolExecutor

The *InterpreterPoolExecutor* class uses a pool of interpreters to execute calls asynchronously. It is a *ThreadPoolExecutor* subclass, which means each worker is running in its own thread. The difference here is that each worker has its own interpreter, and runs each task using that interpreter.

The biggest benefit to using interpreters instead of only threads is true multi-core parallelism. Each interpreter has its own *Global Interpreter Lock*, so code running in one interpreter can run on one CPU core, while code in another interpreter runs unblocked on a different core.

The tradeoff is that writing concurrent code for use with multiple interpreters can take extra effort. However, this is because it forces you to be deliberate about how and when interpreters interact, and to be explicit about what data is shared between interpreters. This results in several benefits that help balance the extra effort, including true multi-core parallelism, For example, code written this way can make it easier to reason about concurrency. Another major benefit is that you don't have to deal with several of the big pain points of using threads, like race conditions.

Each worker's interpreter is isolated from all the other interpreters. "Isolated" means each interpreter has its own runtime state and operates completely independently. For example, if you redirect *sys.stdout* in one interpreter, it will not be automatically redirected to any other interpreter. If you import a module in one interpreter, it is not automatically imported in any other. You would need to import the module separately in interpreter where you need it. In fact, each module imported in an interpreter is a completely separate object from the same module in a different interpreter, including *sys*, *builtins*, and even `__main__`.

Isolation means a mutable object, or other data, cannot be used by more than one interpreter at the same time. That effectively means interpreters cannot actually share such objects or data. Instead, each interpreter must have its own copy, and you will have to synchronize any changes between the copies manually. Immutable objects and data, like the builtin singletons, strings, and tuples of immutable objects, don't have these limitations.

Communicating and synchronizing between interpreters is most effectively done using dedicated tools, like those proposed in **PEP 734**. One less efficient alternative is to serialize with *pickle* and then send the bytes over a shared *socket* or *pipe*.

class concurrent.futures.**InterpreterPoolExecutor**(*max_workers=None*, *thread_name_prefix=''*, *initializer=None*, *initargs=()*)

A *ThreadPoolExecutor* subclass that executes calls asynchronously using a pool of at most *max_workers* threads. Each thread runs tasks in its own interpreter. The worker interpreters are isolated from each other, which means each has its own runtime state and that they can't share any mutable objects or other data. Each interpreter has its own *Global Interpreter Lock*, which means code run with this executor has true multi-core parallelism.

The optional *initializer* and *initargs* arguments have the same meaning as for `ThreadPoolExecutor`: the initializer is run when each worker is created, though in this case it is run in the worker's interpreter. The executor serializes the *initializer* and *initargs* using *pickle* when sending them to the worker's interpreter.

> **備🄵**
>
> The executor may replace uncaught exceptions from *initializer* with *ExecutionFailed*.

Other caveats from parent *ThreadPoolExecutor* apply here.

submit() and *map()* work like normal, except the worker serializes the callable and arguments using *pickle* when sending them to its interpreter. The worker likewise serializes the return value when sending it back.

When a worker's current task raises an uncaught exception, the worker always tries to preserve the exception as-is. If that is successful then it also sets the `__cause__` to a corresponding *ExecutionFailed* instance, which contains a summary of the original exception. In the uncommon case that the worker is not able to preserve the original as-is then it directly preserves the corresponding *ExecutionFailed* instance instead.

18.5.4 ProcessPoolExecutor

ProcessPoolExecutor 類🄵是一個*Executor* 的子類🄵，它使用行程池來非同步地執行呼叫。*ProcessPoolExecutor* 使用了*multiprocessing* 模組，這允許它避開全域直譯器鎖 *(Global Interpreter Lock)*，但也意味著只能執行和回傳可被 pickle 的 (picklable) 物件。

`__main__` 模組必須可以被工作子行程 (worker subprocess) 引入。這意味著*ProcessPoolExecutor* 將無法在交互式直譯器 (interactive interpreter) 中工作。

從提交給*ProcessPoolExecutor* 的可呼叫物件中呼叫*Executor* 或*Future* 方法將導致死鎖。

Note that the restrictions on functions and arguments needing to picklable as per *multiprocessing.Process* apply when using *submit()* and *map()* on a *ProcessPoolExecutor*. A function defined in a REPL or a lambda should not be expected to work.

class concurrent.futures.**ProcessPoolExecutor**(*max_workers=None*, *mp_context=None*, *initializer=None*, *initargs=()*, *max_tasks_per_child=None*)

一個*Executor* 子類🄵，它使用了最多有 *max_workers* 個行程的池來非同步地執行呼叫。如果 *max_workers* 🄵 `None` 或未給定，它將被預設🄵*os.process_cpu_count()*。如果 *max_workers* 小於或等於 `0`，則會引發*ValueError*。在 Windows 上，*max_workers* 必須小於或等於 `61`。如果不是，則會引發*ValueError*。如果 *max_workers* 🄵 `None`，則預設選擇最多🄵 `61`，即便有更多處理器可用。*mp_context* 可以是*multiprocessing* 情境 (context) 或 `None`。它將用於🄵動 worker。如果 *mp_context* 🄵 `None` 或未給定，則使用預設的*multiprocessing* 情境。請見*Contexts and start methods*。

initializer 是一個可選的可呼叫物件，在每個工作行程 (worker process) 開始時呼叫；*initargs* 是傳遞給 initializer 的引數元組。如果 *initializer* 引發例外，所有目前未定的作業以及任何向池中提交更多作業的嘗試都將引發*BrokenProcessPool*。

max_tasks_per_child 是一個可選引數，它指定單個行程在退出🄵被新的工作行程替🄵之前可以執行的最大任務數。預設情🄵下 *max_tasks_per_child* 是 `None`，這意味著工作行程的生命🄵期將與池一樣長。當指定最大值時，在🄵有 *mp_context* 參數的情🄵下，將預設使用"spawn" 做🄵 multiprocessing 🄵動方法。此功能與"fork" 🄵動方法不相容。

在 3.3 版的變更: 當其中一個工作行程突然終止時，現在會引發*BrokenProcessPool* 錯誤。在過去，此行🄵是未定義的 (undefined)，但對 executor 或其 future 的操作經常會發生凍結或死鎖。

在 3.7 版的變更: 新增了 *mp_context* 引數以允許使用者控制由池所建立的工作行程的 start_method。

新增 *initializer* 與 *initargs* 引數。

在 3.11 版的變更: 新增了 *max_tasks_per_child* 引數以允許使用者控制池中 worker 的生命🄵期。

在 3.12 版的變更: 在 POSIX 系統上，如果你的應用程式有多個執行緒🄵且*multiprocessing* 情境使用了 "fork" 🄵動方法: 🄵部呼叫以🄵生 worker 的*os.fork()* 函式可能會引發*DeprecationWarning*。傳遞一個 *mp_context* 以配置🄵使用不同的🄵動方法。更多🄵明請參🄵*os.fork()* 文件。

在 3.13 版的變更: *max_workers* uses *os.process_cpu_count()* by default, instead of *os.cpu_count()*.

在 3.14 版的變更: The default process start method (see *Contexts and start methods*) changed away from *fork*. If you require the *fork* start method for *ProcessPoolExecutor* you must explicitly pass `mp_context=multiprocessing.get_context("fork")`.

terminate_workers()

Attempt to terminate all living worker processes immediately by calling *Process.terminate* on each of them. Internally, it will also call *Executor.shutdown()* to ensure that all other resources associated with the executor are freed.

After calling this method the caller should no longer submit tasks to the executor.

在 3.14 版被加入.

kill_workers()

Attempt to kill all living worker processes immediately by calling *Process.kill* on each of them. Internally, it will also call *Executor.shutdown()* to ensure that all other resources associated with the executor are freed.

After calling this method the caller should no longer submit tasks to the executor.

在 3.14 版被加入.

(繼續上一頁)

```
    with concurrent.futures.ProcessPoolExecutor() as executor:
        for number, prime in zip(PRIMES, executor.map(is_prime, PRIMES)):
            print('%d is prime: %s' % (number, prime))

if __name__ == '__main__':
    main()
```

18.5.5 Future 物件

Future 類🄵封裝了可呼叫物件的非同步執行。*Future* 實例由*Executor.submit()* 建立。

class concurrent.futures.**Future**

封裝可呼叫物件的非同步執行。*Future* 實例由*Executor.submit()* 建立，且除測試外不應直接建立。

cancel()

嘗試取消呼叫。如果呼叫目前正在執行或已完成運行且無法取消，則該方法將回傳 `False`，否則呼叫將被取消🄵且該方法將回傳 `True`。

cancelled()

如果該呼叫成功被取消，則回傳 `True`。

running()

如果呼叫正在執行且無法取消，則回傳 `True`。

done()

如果呼叫成功被取消或結束運行，則回傳 `True`。

result(*timeout=None*)

回傳該呼叫回傳的值。如果呼叫尚未完成，則此方法將等待至多 *timeout* 秒。如果呼叫在 *timeout* 秒🄵未完成，則會引發*TimeoutError*。*timeout* 可以是整數或浮點數。如果未指定 *timeout* 或🄵 `None`，則等待時間就不會有限制。

如果 future 在完成之前被取消，那🄵*CancelledError* 將被引發。

如果該呼叫引發了例外，此方法將引發相同的例外。

exception(*timeout=None*)

回傳該呼叫引發的例外。如果呼叫尚未完成，則此方法將等待至多 *timeout* 秒。如果呼叫在 *timeout* 秒🄵未完成，則會引發*TimeoutError*。*timeout* 可以是整數或浮點數。如果未指定 *timeout* 或🄵 `None`，則等待時間就不會有限制。

如果 future 在完成之前被取消，那🄵*CancelledError* 將被引發。

如果呼叫在🄵有引發的情🄵下完成，則回傳 `None`。

add_done_callback(*fn*)

將可呼叫的 *fn* 附加到 future 上。當 future 被取消或完成運行時，*fn* 將被以 future 作🄵其唯一引數來呼叫。

新增的可呼叫物件按新增順序呼叫，🄵且始終在屬於新增它們的行程的執行緒中呼叫。如果可呼叫物件引發*Exception* 子類🄵，它將被記🄵 (log) 🄵忽略。如果可呼叫物件引發*BaseException* 子類🄵，該行🄵未定義。

如果 future 已經完成或被取消，*fn* 將立即被呼叫。

以下*Future* 方法旨在用於單元測試和*Executor* 實作。

set_running_or_notify_cancel()

此方法只能在與*Future* 關聯的工作被執行之前於*Executor* 實作中呼叫，或者在單元測試中呼叫。

如果該方法回傳 False 則*Future* 已被取消，即*Future.cancel()* 被呼叫🄵回傳 True。任何等待*Future* 完成的執行緒（即透過*as_completed()* 或*wait()*）將被🄵醒。

如果該方法回傳 True 則代表*Future* 未被取消🄵已進入運行狀態，意即呼叫*Future.running()* 將回傳 True。

此方法只能呼叫一次，且不能在呼叫*Future.set_result()* 或*Future.set_exception()* 之後呼叫。

set_result(*result*)

將與*Future* 關聯的工作結果設定🄵 *result*。

此方法只能在*Executor* 實作中和單元測試中使用。

在 3.8 版的變更: 如果*Future* 已經完成，此方法會引發*concurrent.futures.InvalidStateError*。

set_exception(*exception*)

將與*Future* 關聯的工作結果設定🄵*Exception* *exception*。

此方法只能在*Executor* 實作中和單元測試中使用。

在 3.8 版的變更: 如果*Future* 已經完成，此方法會引發*concurrent.futures.InvalidStateError*。

18.5.6 模組函式

concurrent.futures.**wait**(*fs*, *timeout=None*, *return_when=ALL_COMPLETED*)

等待 *fs* 給定的*Future* 實例（可能由不同的*Executor* 實例建立）完成。提供給 *fs* 的重🄵 future 將被🄵除，🄵且只會回傳一次。回傳一個集合的附名二元組 (named 2-tuple of sets)。第一組名🄵 done，包含在等待完成之前完成的 future（已完成或被取消的 future）。第二組名🄵 not_done，包含未完成的 future（未定或運行中的 future）。

timeout 可用於控制回傳前等待的最大秒數。*timeout* 可以是整數或浮點數。如果未指定 *timeout* 或🄵 None，則等待時間就🄵有限制。

return_when 表示此函式應回傳的時間。它必須是以下常數之一：

常數	描述
concurrent.futures.**FIRST_COMPLETED**	當任何 future 完成或被取消時，該函式就會回傳。
concurrent.futures.**FIRST_EXCEPTION**	該函式會在任何 future 透過引發例外而完結時回傳。如果 future 🄵有引發例外，那🄵它等同於*ALL_COMPLETED*。
concurrent.futures.**ALL_COMPLETED**	當所有 future 都完成或被取消時，該函式才會回傳。

concurrent.futures.**as_completed**(*fs*, *timeout=None*)

回傳由 *fs* 給定的*Future* 實例（可能由不同的*Executor* 實例建立）的🄵代器，它在完成時🄵生 future（已完成或被取消的 future）。*fs* 給定的任何重🄵的 future 將只被回傳一次。呼叫*as_completed()* 之前完成的任何 future 將首先🄵生。如果*__next__()* 被呼叫，🄵且在原先呼叫*as_completed()* 的 *timeout* 秒後結果仍不可用，則回傳的🄵代器會引發*TimeoutError*。*timeout* 可以是整數或浮點數。如果未指定 *timeout* 或🄵 None，則等待時間就🄵有限制。

也參考

PEP 3148 -- futures - 非同步地執行運算
描述此功能🄵提出被包含於 Python 標準函式庫中的提案。

18.5.7 例外類🄵

exception concurrent.futures.**CancelledError**

當 future 被取消時引發。

exception concurrent.futures.**TimeoutError**

TimeoutError 的🄵用🄵名，在 future 操作超過給定超時 (timeout) 時引發。

在 3.11 版的變更: 這個類🄵是*TimeoutError* 的🄵名。

exception concurrent.futures.**BrokenExecutor**

衍生自*RuntimeError*，當執行器因某種原因損壞時會引發此例外類🄴，🄵且不能用於提交或執行新任務。

在 3.7 版被加入.

exception concurrent.futures.**InvalidStateError**

目前狀態下不允許的 future 操作被執行時而引發。

在 3.8 版被加入.

exception concurrent.futures.thread.**BrokenThreadPool**

衍生自*BrokenExecutor*，當*ThreadPoolExecutor* 的其中一個 worker 初始化失敗時會引發此例外類🄵。

在 3.7 版被加入.

exception concurrent.futures.interpreter.**BrokenInterpreterPool**

衍生自*BrokenThreadPool*，當*InterpreterPoolExecutor* 的其中一個 worker 初始化失敗時會引發此例外類🄵。

在 3.14 版被加入.

exception concurrent.futures.interpreter.**ExecutionFailed**

Raised from *InterpreterPoolExecutor* when the given initializer fails or from *submit()* when there's an uncaught exception from the submitted task.

在 3.14 版被加入.

exception concurrent.futures.process.**BrokenProcessPool**

衍生自*BrokenExecutor*（以前🄵*RuntimeError*），當*ProcessPoolExecutor* 的其中一個 worker 以不乾🄵的方式終止時將引發此例外類🄵（例如它是從外面被 kill 掉的）。

在 3.3 版被加入.

18.6 concurrent.interpreters --- 在同一個行程中使用多個直譯器

在 3.14 版被加入.

原始碼： Lib/concurrent/interpreters

The concurrent.interpreters module constructs higher-level interfaces on top of the lower level _interpreters module.

The module is primarily meant to provide a basic API for managing interpreters (AKA "subinterpreters") and running things in them. Running mostly involves switching to an interpreter (in the current thread) and calling a function in that execution context.

For concurrency, interpreters themselves (and this module) don't provide much more than isolation, which on its own isn't useful. Actual concurrency is available separately through *threads* See *below*

也參考

InterpreterPoolExecutor
combines threads with interpreters in a familiar interface.

isolating-extensions-howto
how to update an extension module to support multiple interpreters

PEP 554

PEP 734

PEP 684

可用性: not WASI.

This module does not work or is not available on WebAssembly. See *WebAssembly 平台* for more information.

18.6.1 Key details

Before we dive in further, there are a small number of details to keep in mind about using multiple interpreters:

- *isolated*, by default
- no implicit threads
- not all PyPI packages support use in multiple interpreters yet

18.6.2 Introduction

An ”interpreter” is effectively the execution context of the Python runtime. It contains all of the state the runtime needs to execute a program. This includes things like the import state and builtins. (Each thread, even if there's only the main thread, has some extra runtime state, in addition to the current interpreter, related to the current exception and the bytecode eval loop.)

The concept and functionality of the interpreter have been a part of Python since version 2.2, but the feature was only available through the C-API and not well known, and the *isolation* was relatively incomplete until version 3.12.

Multiple Interpreters and Isolation

A Python implementation may support using multiple interpreters in the same process. CPython has this support. Each interpreter is effectively isolated from the others (with a limited number of carefully managed process-global exceptions to the rule).

That isolation is primarily useful as a strong separation between distinct logical components of a program, where you want to have careful control of how those components interact.

備🄵

Interpreters in the same process can technically never be strictly isolated from one another since there are few restrictions on memory access within the same process. The Python runtime makes a best effort at isolation but extension modules may easily violate that. Therefore, do not use multiple interpreters in security-sensitive situations, where they shouldn't have access to each other's data.

Running in an Interpreter

Running in a different interpreter involves switching to it in the current thread and then calling some function. The runtime will execute the function using the current interpreter's state. The `concurrent.interpreters` module provides a basic API for creating and managing interpreters, as well as the switch-and-call operation.

No other threads are automatically started for the operation. There is *a helper* for that though. There is another dedicated helper for calling the builtin `exec()` in an interpreter.

When *exec()* (or *eval()*) are called in an interpreter, they run using the interpreter's `__main__` module as the "globals" namespace. The same is true for functions that aren't associated with any module. This is the same as how scripts invoked from the command-line run in the `__main__` module.

Concurrency and Parallelism

As noted earlier, interpreters do not provide any concurrency on their own. They strictly represent the isolated execution context the runtime will use *in the current thread*. That isolation makes them similar to processes, but they still enjoy in-process efficiency, like threads.

All that said, interpreters do naturally support certain flavors of concurrency. There's a powerful side effect of that isolation. It enables a different approach to concurrency than you can take with async or threads. It's a similar concurrency model to CSP or the actor model, a model which is relatively easy to reason about.

You can take advantage of that concurrency model in a single thread, switching back and forth between interpreters, Stackless-style. However, this model is more useful when you combine interpreters with multiple threads. This mostly involves starting a new thread, where you switch to another interpreter and run what you want there.

Each actual thread in Python, even if you're only running in the main thread, has its own *current* execution context. Multiple threads can use the same interpreter or different ones.

At a high level, you can think of the combination of threads and interpreters as threads with opt-in sharing.

As a significant bonus, interpreters are sufficiently isolated that they do not share the *GIL*, which means combining threads with multiple interpreters enables full multi-core parallelism. (This has been the case since Python 3.12.)

直譯器之間的溝通

In practice, multiple interpreters are useful only if we have a way to communicate between them. This usually involves some form of message passing, but can even mean sharing data in some carefully managed way.

With this in mind, the `concurrent.interpreters` module provides a *queue.Queue* implementation, available through *create_queue()*.

"Sharing" Objects

Any data actually shared between interpreters loses the thread-safety provided by the *GIL*. There are various options for dealing with this in extension modules. However, from Python code the lack of thread-safety means objects can't actually be shared, with a few exceptions. Instead, a copy must be created, which means mutable objects won't stay in sync.

By default, most objects are copied with *pickle* when they are passed to another interpreter. Nearly all of the immutable builtin objects are either directly shared or copied efficiently. For example:

- *None*
- *bool* (*True* 和*False*)
- *bytes*
- *str*
- *int*
- *float*
- *tuple* (of similarly supported objects)

There is a small number of Python types that actually share mutable data between interpreters:

- *memoryview*
- *Queue*

18.6.3 Reference

This module defines the following functions:

`concurrent.interpreters.`**`list_all`**`()`

Return a *`list`* of *`Interpreter`* objects, one for each existing interpreter.

`concurrent.interpreters.`**`get_current`**`()`

Return an *`Interpreter`* object for the currently running interpreter.

`concurrent.interpreters.`**`get_main`**`()`

Return an *`Interpreter`* object for the main interpreter. This is the interpreter the runtime created to run the *REPL* or the script given at the command-line. It is usually the only one.

`concurrent.interpreters.`**`create`**`()`

Initialize a new (idle) Python interpreter and return a *`Interpreter`* object for it.

`concurrent.interpreters.`**`create_queue`**`()`

Initialize a new cross-interpreter queue and return a *`Queue`* object for it.

Interpreter objects

`class` `concurrent.interpreters.`**`Interpreter`**`(`*id*`)`

A single interpreter in the current process.

Generally, *`Interpreter`* shouldn't be called directly. Instead, use *`create()`* or one of the other module functions.

`id`

(read-only)

The underlying interpreter's ID.

`whence`

(read-only)

A string describing where the interpreter came from.

`is_running``()`

Return `True` if the interpreter is currently executing code in its `__main__` module and `False` otherwise.

`close``()`

Finalize and destroy the interpreter.

`prepare_main``(`*ns=None*, ***kwargs*`)`

Bind objects in the interpreter's `__main__` module.

Some objects are actually shared and some are copied efficiently, but most are copied via *`pickle`*. See *"Sharing" Objects*.

`exec``(`*code*, */*, *dedent=True*`)`

Run the given source code in the interpreter (in the current thread).

`call``(`*callable*, */*, **args*, ***kwargs*`)`

Return the result of calling running the given function in the interpreter (in the current thread).

`call_in_thread``(`*callable*, */*, **args*, ***kwargs*`)`

Run the given function in the interpreter (in a new thread).

例外

`exception` `concurrent.interpreters.`**`InterpreterError`**

This exception, a subclass of *`Exception`*, is raised when an interpreter-related error happens.

exception concurrent.interpreters.**InterpreterNotFoundError**

This exception, a subclass of *InterpreterError*, is raised when the targeted interpreter no longer exists.

exception concurrent.interpreters.**ExecutionFailed**

This exception, a subclass of *InterpreterError*, is raised when the running code raised an uncaught exception.

excinfo

A basic snapshot of the exception raised in the other interpreter.

exception concurrent.interpreters.**NotShareableError**

This exception, a subclass of *TypeError*, is raised when an object cannot be sent to another interpreter.

在直譯器之間溝通

class concurrent.interpreters.**Queue**(*id*)

A wrapper around a low-level, cross-interpreter queue, which implements the *queue.Queue* interface. The underlying queue can only be created through *create_queue()*.

Some objects are actually shared and some are copied efficiently, but most are copied via *pickle*. See *"Sharing" Objects*.

id

(read-only)

The queue's ID.

exception concurrent.interpreters.**QueueEmptyError**

This exception, a subclass of *queue.Empty*, is raised from `Queue.get()` and `Queue.get_nowait()` when the queue is empty.

exception concurrent.interpreters.**QueueFullError**

This exception, a subclass of *queue.Full*, is raised from `Queue.put()` and `Queue.put_nowait()` when the queue is full.

18.6.4 基本用法

建立一個直譯器🄵在其中運行程式碼:

```
from concurrent import interpreters

interp = interpreters.create()

# Run in the current OS thread.

interp.exec('print("spam!")')

interp.exec("""if True:
    print('spam!')
    """)

from textwrap import dedent
interp.exec(dedent("""
    print('spam!')
    """))

def run(arg):
    return arg

res = interp.call(run, 'spam!')
print(res)
```

(繼續下一頁)

(繼續上一頁)

```
def run():
    print('spam!')

interp.call(run)

# Run in new OS thread.

t = interp.call_in_thread(run)
t.join()
```

18.7 subprocess --- 子行程管理

原始碼： Lib/subprocess.py

The *subprocess* module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```
os.system
os.spawn*
```

Information about how the *subprocess* module can be used to replace these modules and functions can be found in the following sections.

> **也參考**
>
> **PEP 324** -- 提議 subprocess 模組的 PEP

可用性: not Android, not iOS, not WASI.

此模組在行動平台或*WebAssembly* 平台上不支援。

18.7.1 Using the subprocess Module

The recommended approach to invoking subprocesses is to use the *run()* function for all use cases it can handle. For more advanced use cases, the underlying *Popen* interface can be used directly.

subprocess.**run**(*args*, *, *stdin=None*, *input=None*, *stdout=None*, *stderr=None*, *capture_output=False*, *shell=False*, *cwd=None*, *timeout=None*, *check=False*, *encoding=None*, *errors=None*, *text=None*, *env=None*, *universal_newlines=None*, **other_popen_kwargs*)

Run the command described by *args*. Wait for command to complete, then return a *CompletedProcess* instance.

The arguments shown above are merely the most common ones, described below in *Frequently Used Arguments* (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the *Popen* constructor - most of the arguments to this function are passed through to that interface. (*timeout*, *input*, *check*, and *capture_output* are not.)

If *capture_output* is true, stdout and stderr will be captured. When used, the internal *Popen* object is automatically created with *stdout* and *stderr* both set to *PIPE*. The *stdout* and *stderr* arguments may not be supplied at the same time as *capture_output*. If you wish to capture and combine both streams into one, set *stdout* to *PIPE* and *stderr* to *STDOUT*, instead of using *capture_output*.

A *timeout* may be specified in seconds, it is internally passed on to *Popen.communicate()*. If the timeout expires, the child process will be killed and waited for. The *TimeoutExpired* exception will be re-raised after the child process has terminated. The initial process creation itself cannot be interrupted on many platform APIs so you are not guaranteed to see a timeout exception until at least after however long process creation takes.

The *input* argument is passed to *Popen.communicate()* and thus to the subprocess's stdin. If used it must be a byte sequence, or a string if *encoding* or *errors* is specified or *text* is true. When used, the internal *Popen* object is automatically created with *stdin* set to *PIPE*, and the *stdin* argument may not be used as well.

If *check* is true, and the process exits with a non-zero exit code, a *CalledProcessError* exception will be raised. Attributes of that exception hold the arguments, the exit code, and stdout and stderr if they were captured.

If *encoding* or *errors* are specified, or *text* is true, file objects for stdin, stdout and stderr are opened in text mode using the specified *encoding* and *errors* or the *io.TextIOWrapper* default. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. It is passed directly to *Popen*. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like *os.environ* or *os.environb*.

範例：

```
>>> subprocess.run(["ls", "-l"])  # 不捕捉輸出
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run("exit 1", shell=True, check=True)
Traceback (most recent call last):
  ...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1

>>> subprocess.run(["ls", "-l", "/dev/null"], capture_output=True)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0,
stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null\n', stderr=b'')
```

在 3.5 版被加入.

在 3.6 版的變更: 新增 *encoding* 與 *errors* 參數。

在 3.7 版的變更: Added the *text* parameter, as a more understandable alias of *universal_newlines*. Added the *capture_output* parameter.

在 3.12 版的變更: Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

class subprocess.**CompletedProcess**

The return value from *run()*, representing a process that has finished.

args

The arguments used to launch the process. This may be a list or a string.

returncode

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

stdout

Captured stdout from the child process. A bytes sequence, or a string if *run()* was called with an encoding, errors, or text=True. `None` if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and *stderr* will be `None`.

stderr

Captured stderr from the child process. A bytes sequence, or a string if *run()* was called with an encoding, errors, or text=True. `None` if stderr was not captured.

check_returncode()

If *returncode* is non-zero, raise a *CalledProcessError*.

在 3.5 版被加入.

subprocess.**DEVNULL**

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *Popen* and indicates that the special file *os.devnull* will be used.

在 3.3 版被加入.

subprocess.**PIPE**

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *Popen* and indicates that a pipe to the standard stream should be opened. Most useful with *Popen.communicate()*.

subprocess.**STDOUT**

Special value that can be used as the *stderr* argument to *Popen* and indicates that standard error should go into the same handle as standard output.

exception subprocess.**SubprocessError**

Base class for all other exceptions from this module.

在 3.3 版被加入.

exception subprocess.**TimeoutExpired**

Subclass of *SubprocessError*, raised when a timeout expires while waiting for a child process.

cmd

Command that was used to spawn the child process.

timeout

Timeout in seconds.

output

Output of the child process if it was captured by *run()* or *check_output()*. Otherwise, `None`. This is always *bytes* when any output was captured regardless of the `text=True` setting. It may remain `None` instead of `b''` when no output was observed.

stdout

Alias for output, for symmetry with *stderr*.

stderr

Stderr output of the child process if it was captured by *run()*. Otherwise, `None`. This is always *bytes* when stderr output was captured regardless of the `text=True` setting. It may remain `None` instead of `b''` when no stderr output was observed.

在 3.3 版被加入.

在 3.5 版的變更: *stdout* and *stderr* attributes added

exception subprocess.**CalledProcessError**

Subclass of *SubprocessError*, raised when a process run by *check_call()*, *check_output()*, or *run()* (with `check=True`) returns a non-zero exit status.

returncode

Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

cmd

Command that was used to spawn the child process.

output

Output of the child process if it was captured by *run()* or *check_output()*. Otherwise, `None`.

stdout

Alias for output, for symmetry with *stderr*.

stderr

Stderr output of the child process if it was captured by *run()*. Otherwise, None.

在 3.5 版的變更: *stdout* and *stderr* attributes added

Frequently Used Arguments

To support a wide variety of use cases, the *Popen* constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

args is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either *shell* must be *True* (see below) or else the string must simply name the program to be executed without specifying any arguments.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are None, *PIPE*, *DEVNULL*, an existing file descriptor (a positive integer), and an existing *file object* with a valid file descriptor. With the default settings of None, no redirection will occur. *PIPE* indicates that a new pipe to the child should be created. *DEVNULL* indicates that the special file *os.devnull* will be used. Additionally, *stderr* can be *STDOUT*, which indicates that the stderr data from the child process should be captured into the same file handle as for *stdout*.

If *encoding* or *errors* are specified, or *text* (also known as *universal_newlines*) is true, the file objects *stdin*, *stdout* and *stderr* will be opened in text mode using the *encoding* and *errors* specified in the call or the defaults for *io.TextIOWrapper*.

For *stdin*, line ending characters '\n' in the input will be converted to the default line separator *os.linesep*. For *stdout* and *stderr*, all line endings in the output will be converted to '\n'. For more information see the documentation of the *io.TextIOWrapper* class when the *newline* argument to its constructor is None.

If text mode is not used, *stdin*, *stdout* and *stderr* will be opened as binary streams. No encoding or line ending conversion is performed.

在 3.6 版的變更: 新增 *encoding* 與 *errors* 參數。

在 3.7 版的變更: Added the *text* parameter as an alias for *universal_newlines*.

> **備🄵**
>
> The newlines attribute of the file objects *Popen.stdin*, *Popen.stdout* and *Popen.stderr* are not updated by the *Popen.communicate()* method.

If *shell* is True, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of ~ to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, *glob*, *fnmatch*, *os.walk()*, *os.path.expandvars()*, *os.path.expanduser()*, and *shutil*).

在 3.3 版的變更: When *universal_newlines* is True, the class uses the encoding *locale.getpreferredencoding(False)* instead of locale.getpreferredencoding(). See the *io.TextIOWrapper* class for more information on this change.

> **備F**
>
> Read the *Security Considerations* section before using `shell=True`.

These options, along with all of the other options, are described in more detail in the `Popen` constructor documentation.

Popen Constructor

The underlying process creation and management in this module is handled by the `Popen` class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

class subprocess.**Popen**(*args*, *bufsize=-1*, *executable=None*, *stdin=None*, *stdout=None*, *stderr=None*, *preexec_fn=None*, *close_fds=True*, *shell=False*, *cwd=None*, *env=None*, *universal_newlines=None*, *startupinfo=None*, *creationflags=0*, *restore_signals=True*, *start_new_session=False*, *pass_fds=()*, ***, *group=None*, *extra_groups=None*, *user=None*, *umask=-1*, *encoding=None*, *errors=None*, *text=None*, *pipesize=-1*, *process_group=None*)

Execute a child program in a new process. On POSIX, the class uses `os.execvpe()`-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to `Popen` are as follows.

args should be a sequence of program arguments or else a single string or *path-like object*. By default, the program to execute is the first item in *args* if *args* is a sequence. If *args* is a string, the interpretation is platform-dependent and described below. See the *shell* and *executable* arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass *args* as a sequence.

> **警告**
>
> For maximum reliability, use a fully qualified path for the executable. To search for an unqualified name on `PATH`, use `shutil.which()`. On all platforms, passing `sys.executable` is the recommended way to launch the current Python interpreter again, and use the `-m` command-line format to launch an installed module.
>
> Resolving the path of *executable* (or the first item of *args*) is platform dependent. For POSIX, see `os.execvpe()`, and note that when resolving or searching for the executable path, *cwd* overrides the current working directory and *env* can override the `PATH` environment variable. For Windows, see the documentation of the `lpApplicationName` and `lpCommandLine` parameters of WinAPI `CreateProcess`, and note that when resolving or searching for the executable path with `shell=False`, *cwd* does not override the current working directory and *env* cannot override the `PATH` environment variable. Using a full path avoids all of these variations.

An example of passing some arguments to an external program as a sequence is:

```
Popen(["/usr/bin/git", "commit", "-m", "Fixes a bug."])
```

On POSIX, if *args* is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

> **備F**
>
> It may not be obvious how to break a shell command into a sequence of arguments, especially in complex cases. `shlex.split()` can illustrate how to determine the correct tokenization for *args*:
>
> ```
> >>> import shlex, subprocess
> >>> command_line = input()
> /bin/vikings -input eggs.txt -output "spam spam.txt" -cmd "echo '$MONEY'"
> >>> args = shlex.split(command_line)
> ```

```
>>> print(args)
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', "echo '
↪$MONEY'"]
>>> p = subprocess.Popen(args) # 成功！
```

Note in particular that options (such as *-input*) and arguments (such as *eggs.txt*) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the *echo* command shown above) are single list elements.

On Windows, if *args* is a sequence, it will be converted to a string in a manner described in *Converting an argument sequence to a string on Windows*. This is because the underlying `CreateProcess()` operates on strings.

在 3.6 版的變更: *args* parameter accepts a *path-like object* if *shell* is `False` and a sequence containing path-like objects on POSIX.

在 3.8 版的變更: *args* parameter accepts a *path-like object* if *shell* is `False` and a sequence containing bytes and path-like objects on Windows.

The *shell* argument (which defaults to `False`) specifies whether to use the shell as the program to execute. If *shell* is `True`, it is recommended to pass *args* as a string rather than as a sequence.

On POSIX with `shell=True`, the shell defaults to `/bin/sh`. If *args* is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, *Popen* does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with `shell=True`, the `COMSPEC` environment variable specifies the default shell. The only time you need to specify `shell=True` on Windows is when the command you wish to execute is built into the shell (e.g. **`dir`** or **`copy`**). You do not need `shell=True` to run a batch file or console-based executable.

備🄵

Read the *Security Considerations* section before using `shell=True`.

bufsize will be supplied as the corresponding argument to the *open()* function when creating the stdin/stdout/stderr pipe file objects:

- `0` means unbuffered (read and write are one system call and can return short)
- `1` means line buffered (only usable if `text=True` or `universal_newlines=True`)
- any other positive value means use a buffer of approximately that size
- negative bufsize (the default) means the system default of io.DEFAULT_BUFFER_SIZE will be used.

在 3.3.1 版的變更: *bufsize* now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to `0` which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The *executable* argument specifies a replacement program to execute. It is very seldom needed. When `shell=False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On POSIX, the *args* name becomes the display name for the executable in utilities such as **`ps`**. If `shell=True`, on POSIX the *executable* argument specifies a replacement shell for the default `/bin/sh`.

在 3.6 版的變更: *executable* parameter accepts a *path-like object* on POSIX.

在 3.8 版的變更: *executable* parameter accepts a bytes and *path-like object* on Windows.

在 3.12 版的變更: Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are `None`, `PIPE`, `DEVNULL`, an existing file descriptor (a positive integer), and an existing *file object* with a valid file descriptor. With the default settings of `None`, no redirection will occur. `PIPE` indicates that a new pipe to the child should be created. `DEVNULL` indicates that the special file `os.devnull` will be used. Additionally, *stderr* can be `STDOUT`, which indicates that the stderr data from the applications should be captured into the same file handle as for *stdout*.

If *preexec_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

警告

The *preexec_fn* parameter is NOT SAFE to use in the presence of threads in your application. The child process could deadlock before exec is called.

備🄵

If you need to modify the environment for the child use the *env* parameter rather than doing it in a *preexec_fn*. The *start_new_session* and *process_group* parameters should take the place of code using *preexec_fn* to call `os.setsid()` or `os.setpgid()` in the child.

在 3.8 版的變更: The *preexec_fn* parameter is no longer supported in subinterpreters. The use of the parameter in a subinterpreter raises `RuntimeError`. The new restriction may affect applications that are deployed in mod_wsgi, uWSGI, and other embedded environments.

If *close_fds* is true, all file descriptors except `0`, `1` and `2` will be closed before the child process is executed. Otherwise when *close_fds* is false, file descriptors obey their inheritable flag as described in *Inheritance of File Descriptors*.

On Windows, if *close_fds* is true then no handles will be inherited by the child process unless explicitly passed in the `handle_list` element of `STARTUPINFO.lpAttributeList`, or by standard handle redirection.

在 3.2 版的變更: The default for *close_fds* was changed from `False` to what is described above.

在 3.7 版的變更: On Windows the default for *close_fds* was changed from `False` to `True` when redirecting the standard handles. It's now possible to set *close_fds* to `True` when redirecting the standard handles.

pass_fds is an optional sequence of file descriptors to keep open between the parent and child. Providing any *pass_fds* forces *close_fds* to be `True`. (POSIX only)

在 3.2 版的變更: 新增 *pass_fds* 參數。

If *cwd* is not `None`, the function changes the working directory to *cwd* before executing the child. *cwd* can be a string, bytes or *path-like* object. On POSIX, the function looks for *executable* (or for the first item in *args*) relative to *cwd* if the executable path is a relative path.

在 3.6 版的變更: *cwd* parameter accepts a *path-like object* on POSIX.

在 3.7 版的變更: *cwd* parameter accepts a *path-like object* on Windows.

在 3.8 版的變更: *cwd* parameter accepts a bytes object on Windows.

If *restore_signals* is true (the default) all signals that Python has set to SIG_IGN are restored to SIG_DFL in the child process before the exec. Currently this includes the SIGPIPE, SIGXFZ and SIGXFSZ signals. (POSIX only)

在 3.2 版的變更: 新增 *restore_signals*。

If *start_new_session* is true the `setsid()` system call will be made in the child process prior to the execution of the subprocess.

可用性: POSIX

在 3.2 版的變更: 新增 *start_new_session*。

If *process_group* is a non-negative integer, the `setpgid(0, value)` system call will be made in the child process prior to the execution of the subprocess.

可用性: POSIX

在 3.11 版的變更: 新增 *process_group*。

If *group* is not `None`, the setregid() system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via *grp.getgrnam()* and the value in `gr_gid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

可用性: POSIX

在 3.9 版被加入.

If *extra_groups* is not `None`, the setgroups() system call will be made in the child process prior to the execution of the subprocess. Strings provided in *extra_groups* will be looked up via *grp.getgrnam()* and the values in `gr_gid` will be used. Integer values will be passed verbatim. (POSIX only)

可用性: POSIX

在 3.9 版被加入.

If *user* is not `None`, the setreuid() system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via *pwd.getpwnam()* and the value in `pw_uid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

可用性: POSIX

在 3.9 版被加入.

If *umask* is not negative, the umask() system call will be made in the child process prior to the execution of the subprocess.

可用性: POSIX

在 3.9 版被加入.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like *os.environ* or *os.environb*.

備🄵

If specified, *env* must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly the specified *env* **must** include a valid `SystemRoot`.

If *encoding* or *errors* are specified, or *text* is true, the file objects *stdin*, *stdout* and *stderr* are opened in text mode with the specified *encoding* and *errors*, as described above in *Frequently Used Arguments*. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

在 3.6 版被加入: 新增 *encoding* 與 *errors*。

在 3.7 版被加入: *text* was added as a more readable alias for *universal_newlines*.

If given, *startupinfo* will be a *STARTUPINFO* object, which is passed to the underlying `CreateProcess` function.

If given, *creationflags*, can be one or more of the following flags:

- *CREATE_NEW_CONSOLE*
- *CREATE_NEW_PROCESS_GROUP*
- *ABOVE_NORMAL_PRIORITY_CLASS*
- *BELOW_NORMAL_PRIORITY_CLASS*
- *HIGH_PRIORITY_CLASS*
- *IDLE_PRIORITY_CLASS*
- *NORMAL_PRIORITY_CLASS*
- *REALTIME_PRIORITY_CLASS*
- *CREATE_NO_WINDOW*
- *DETACHED_PROCESS*
- *CREATE_DEFAULT_ERROR_MODE*
- *CREATE_BREAKAWAY_FROM_JOB*

pipesize can be used to change the size of the pipe when *PIPE* is used for *stdin*, *stdout* or *stderr*. The size of the pipe is only changed on platforms that support this (only Linux at this time of writing). Other platforms will ignore this parameter.

在 3.10 版的變更: 新增 `pipesize` 參數。

Popen objects are supported as context managers via the `with` statement: on exit, standard file descriptors are closed, and the process is waited for.

```
with Popen(["ifconfig"], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

Popen and the other functions in this module that use it raise an *auditing event* `subprocess.Popen` with arguments `executable`, `args`, `cwd`, and `env`. The value for `args` may be a single string or a list of strings, depending on platform.

在 3.2 版的變更: 新增情境管理器的支援。

在 3.6 版的變更: Popen destructor now emits a *ResourceWarning* warning if the child process is still running.

在 3.8 版的變更: Popen can use *os.posix_spawn()* in some cases for better performance. On Windows Subsystem for Linux and QEMU User Emulation, Popen constructor using *os.posix_spawn()* no longer raise an exception on errors like missing program, but the child process fails with a non-zero *returncode*.

例外

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent.

The most common exception raised is *OSError*. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for *OSError* exceptions. Note that, when `shell=True`, *OSError* will be raised by the child only if the selected shell itself was not found. To determine if the shell failed to find the requested application, it is necessary to check the return code or output from the subprocess.

A *ValueError* will be raised if *Popen* is called with invalid arguments.

check_call() and *check_output()* will raise *CalledProcessError* if the called process returns a non-zero return code.

All of the functions and methods that accept a *timeout* parameter, such as *run()* and *Popen.communicate()* will raise *TimeoutExpired* if the timeout expires before the process exits.

Exceptions defined in this module all inherit from *SubprocessError*.

在 3.3 版被加入: The *SubprocessError* base class was added.

18.7.2 安全性注意事項

Unlike some other popen functions, this library will not implicitly choose to call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. On *some platforms*, it is possible to use *`shlex.quote()`* for this escaping.

On Windows, batch files (`*.bat` or `*.cmd`) may be launched by the operating system in a system shell regardless of the arguments passed to this library. This could result in arguments being parsed according to shell rules, but without any escaping added by Python. If you are intentionally launching a batch file with arguments from untrusted sources, consider passing `shell=True` to allow Python to escape special characters. See gh-114539 for additional discussion.

18.7.3 Popen Objects

Instances of the *`Popen`* class have the following methods:

`Popen.`**`poll`**`()`

Check if child process has terminated. Set and return *`returncode`* attribute. Otherwise, returns `None`.

`Popen.`**`wait`**`(`*timeout=None*`)`

Wait for child process to terminate. Set and return *`returncode`* attribute.

If the process does not terminate after *timeout* seconds, raise a *`TimeoutExpired`* exception. It is safe to catch this exception and retry the wait.

> **備🄵**
>
> This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use *`Popen.communicate()`* when using pipes to avoid that.

> **備🄵**
>
> When the `timeout` parameter is not `None`, then (on POSIX) the function is implemented using a busy loop (non-blocking call and short sleeps). Use the *`asyncio`* module for an asynchronous wait: see *`asyncio.create_subprocess_exec`*.

在 3.3 版的變更: 新增 *timeout*。

`Popen.`**`communicate`**`(`*input=None*, *timeout=None*`)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate and set the *`returncode`* attribute. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. If streams were opened in text mode, *input* must be a string. Otherwise, it must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`. The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process's stdin, you need to create the Popen object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

If the process does not terminate after *timeout* seconds, a *`TimeoutExpired`* exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```
proc = subprocess.Popen(...)
try:
    outs, errs = proc.communicate(timeout=15)
except TimeoutExpired:
    proc.kill()
    outs, errs = proc.communicate()
```

> **備🄵**
>
> The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

在 3.3 版的變更: 新增 *timeout*。

`Popen.`**`send_signal`**`(`*signal*`)`

Sends the signal *signal* to the child.

Do nothing if the process completed.

> **備🄵**
>
> On Windows, SIGTERM is an alias for *`terminate()`*. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

`Popen.`**`terminate`**`()`

Stop the child. On POSIX OSs the method sends *`SIGTERM`* to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

`Popen.`**`kill`**`()`

Kills the child. On POSIX OSs the function sends SIGKILL to the child. On Windows *`kill()`* is an alias for *`terminate()`*.

The following attributes are also set by the class for you to access. Reassigning them to new values is unsupported:

`Popen.`**`args`**

The *args* argument as it was passed to *`Popen`* -- a sequence of program arguments or else a single string.

在 3.3 版被加入.

`Popen.`**`stdin`**

If the *stdin* argument was *`PIPE`*, this attribute is a writeable stream object as returned by *`open()`*. If the *encoding* or *errors* arguments were specified or the *text* or *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdin* argument was not *`PIPE`*, this attribute is `None`.

`Popen.`**`stdout`**

If the *stdout* argument was *`PIPE`*, this attribute is a readable stream object as returned by *`open()`*. Reading from the stream provides output from the child process. If the *encoding* or *errors* arguments were specified or the *text* or *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdout* argument was not *`PIPE`*, this attribute is `None`.

`Popen.`**`stderr`**

If the *stderr* argument was *`PIPE`*, this attribute is a readable stream object as returned by *`open()`*. Reading from the stream provides error output from the child process. If the *encoding* or *errors* arguments were specified or the *text* or *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stderr* argument was not *`PIPE`*, this attribute is `None`.

> **警告**
>
> Use *communicate()* rather than *.stdin.write*, *.stdout.read* or *.stderr.read* to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

`Popen.`**`pid`**

The process ID of the child process.

Note that if you set the *shell* argument to `True`, this is the process ID of the spawned shell.

`Popen.`**`returncode`**

The child return code. Initially `None`, *returncode* is set by a call to the *poll()*, *wait()*, or *communicate()* methods if they detect that the process has terminated.

A `None` value indicates that the process hadn't yet terminated at the time of the last method call.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

18.7.4 Windows Popen Helpers

The *STARTUPINFO* class and following constants are only available on Windows.

class subprocess.**STARTUPINFO**(**, dwFlags=0, hStdInput=None, hStdOutput=None, hStdError=None, wShowWindow=0, lpAttributeList=None*)

Partial support of the Windows STARTUPINFO structure is used for *Popen* creation. The following attributes can be set by passing them as keyword-only arguments.

在 3.7 版的變更: Keyword-only argument support was added.

dwFlags

A bit field that determines whether certain *STARTUPINFO* attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess.STARTF_USESHOWWINDOW
```

hStdInput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard input handle for the process. If *STARTF_USESTDHANDLES* is not specified, the default for standard input is the keyboard buffer.

hStdOutput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

hStdError

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

wShowWindow

If *dwFlags* specifies *STARTF_USESHOWWINDOW*, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the ShowWindow function, except for `SW_SHOWDEFAULT`. Otherwise, this attribute is ignored.

SW_HIDE is provided for this attribute. It is used when *Popen* is called with `shell=True`.

lpAttributeList

A dictionary of additional attributes for process creation as given in `STARTUPINFOEX`, see UpdateProcThreadAttribute.

Supported attributes:

handle_list
Sequence of handles that will be inherited. *close_fds* must be true if non-empty.

The handles must be temporarily made inheritable by `os.set_handle_inheritable()` when passed to the `Popen` constructor, else `OSError` will be raised with Windows error `ERROR_INVALID_PARAMETER` (87).

> **⚠ 警告**
>
> In a multithreaded process, use caution to avoid leaking handles that are marked inheritable when combining this feature with concurrent calls to other process creation functions that inherit all handles such as `os.system()`. This also applies to standard handle redirection, which temporarily creates inheritable handles.

在 3.7 版被加入.

Windows Constants

The `subprocess` module exposes the following constants.

`subprocess.`**`STD_INPUT_HANDLE`**
The standard input device. Initially, this is the console input buffer, `CONIN$`.

`subprocess.`**`STD_OUTPUT_HANDLE`**
The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.`**`STD_ERROR_HANDLE`**
The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

`subprocess.`**`SW_HIDE`**
Hides the window. Another window will be activated.

`subprocess.`**`STARTF_USESTDHANDLES`**
Specifies that the `STARTUPINFO.hStdInput`, `STARTUPINFO.hStdOutput`, and `STARTUPINFO.hStdError` attributes contain additional information.

`subprocess.`**`STARTF_USESHOWWINDOW`**
Specifies that the `STARTUPINFO.wShowWindow` attribute contains additional information.

`subprocess.`**`STARTF_FORCEONFEEDBACK`**
A `STARTUPINFO.dwFlags` parameter to specify that the *Working in Background* mouse cursor will be displayed while a process is launching. This is the default behavior for GUI processes.

在 3.13 版被加入.

`subprocess.`**`STARTF_FORCEOFFFEEDBACK`**
A `STARTUPINFO.dwFlags` parameter to specify that the mouse cursor will not be changed when launching a process.

在 3.13 版被加入.

`subprocess.`**`CREATE_NEW_CONSOLE`**
The new process has a new console, instead of inheriting its parent's console (the default).

`subprocess.`**`CREATE_NEW_PROCESS_GROUP`**
A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if `CREATE_NEW_CONSOLE` is specified.

subprocess.**ABOVE_NORMAL_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have an above average priority.

在 3.7 版被加入.

subprocess.**BELOW_NORMAL_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have a below average priority.

在 3.7 版被加入.

subprocess.**HIGH_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have a high priority.

在 3.7 版被加入.

subprocess.**IDLE_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have an idle (lowest) priority.

在 3.7 版被加入.

subprocess.**NORMAL_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have a normal priority. (default)

在 3.7 版被加入.

subprocess.**REALTIME_PRIORITY_CLASS**

A *Popen* `creationflags` parameter to specify that a new process will have realtime priority. You should almost never use REALTIME_PRIORITY_CLASS, because this interrupts system threads that manage mouse input, keyboard input, and background disk flushing. This class can be appropriate for applications that "talk" directly to hardware or that perform brief tasks that should have limited interruptions.

在 3.7 版被加入.

subprocess.**CREATE_NO_WINDOW**

A *Popen* `creationflags` parameter to specify that a new process will not create a window.

在 3.7 版被加入.

subprocess.**DETACHED_PROCESS**

A *Popen* `creationflags` parameter to specify that a new process will not inherit its parent's console. This value cannot be used with CREATE_NEW_CONSOLE.

在 3.7 版被加入.

subprocess.**CREATE_DEFAULT_ERROR_MODE**

A *Popen* `creationflags` parameter to specify that a new process does not inherit the error mode of the calling process. Instead, the new process gets the default error mode. This feature is particularly useful for multithreaded shell applications that run with hard errors disabled.

在 3.7 版被加入.

subprocess.**CREATE_BREAKAWAY_FROM_JOB**

A *Popen* `creationflags` parameter to specify that a new process is not associated with the job.

在 3.7 版被加入.

18.7.5 Older high-level API

Prior to Python 3.5, these three functions comprised the high level API to subprocess. You can now use *run()* in many cases, but lots of existing code calls these functions.

subprocess.**call**(*args*, *, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*, ***other_popen_kwargs*)

Run the command described by *args*. Wait for command to complete, then return the *returncode* attribute.

Code needing to capture stdout or stderr should use *run()* instead:

```
run(...).returncode
```

To suppress stdout or stderr, supply a value of *DEVNULL*.

The arguments shown above are merely some common ones. The full function signature is the same as that of the *Popen* constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

> **備F**
>
> Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

在 3.3 版的變更: 新增 *timeout*。

在 3.12 版的變更: Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

subprocess.**check_call**(*args*, *, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*, ***other_popen_kwargs*)

Run command with arguments. Wait for command to complete. If the return code was zero then return, otherwise raise *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute. If *check_call()* was unable to start the process it will propagate the exception that was raised.

Code needing to capture stdout or stderr should use *run()* instead:

```
run(..., check=True)
```

To suppress stdout or stderr, supply a value of *DEVNULL*.

The arguments shown above are merely some common ones. The full function signature is the same as that of the *Popen* constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

> **備F**
>
> Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

在 3.3 版的變更: 新增 *timeout*。

在 3.12 版的變更: Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

subprocess.**check_output**(*args*, *, *stdin=None*, *stderr=None*, *shell=False*, *cwd=None*, *encoding=None*, *errors=None*, *universal_newlines=None*, *timeout=None*, *text=None*, ***other_popen_kwargs*)

Run command with arguments and return its output.

If the return code was non-zero it raises a *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute and any output in the *output* attribute.

這等同於:

```
run(..., check=True, stdout=PIPE).stdout
```

The arguments shown above are merely some common ones. The full function signature is largely the same as that of *run()* - most arguments are passed directly through to that interface. One API deviation from *run()* behavior exists: passing `input=None` will behave the same as `input=b''` (or `input=''`, depending on other arguments) rather than using the parent's standard input file handle.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting *text*, *encoding*, *errors*, or *universal_newlines* to `True` as described in *Frequently Used Arguments* and *run()*.

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

在 3.1 版被加入.

在 3.3 版的變更: 新增 *timeout*。

在 3.4 版的變更: 新增 *input* 關鍵字引數的支援。

在 3.6 版的變更: 新增 *encoding* 與 *errors*。細節請見*run()*。

在 3.7 版被加入: *text* was added as a more readable alias for *universal_newlines*.

在 3.12 版的變更: Changed Windows shell search order for `shell=True`. The current directory and `%PATH%` are replaced with `%COMSPEC%` and `%SystemRoot%\System32\cmd.exe`. As a result, dropping a malicious program named `cmd.exe` into a current directory no longer works.

18.7.6 Replacing Older Functions with the `subprocess` Module

In this section, "a becomes b" means that b can be used as a replacement for a.

> **備🄵**
>
> All "a" functions in this section fail (more or less) silently if the executed program cannot be found; the "b" replacements raise *OSError* instead.
>
> In addition, the replacements using *check_output()* will fail with a *CalledProcessError* if the requested operation produces a non-zero return code. The output is still available as the *output* attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the *subprocess* module.

Replacing `/bin/sh` shell command substitution

```
output=$(mycmd myarg)
```

變成:

```
output = check_output(["mycmd", "myarg"])
```

Replacing shell pipeline

```
output=$(dmesg | grep hda)
```

變成：

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the p2 is important in order for p1 to receive a SIGPIPE if p2 exits before p1.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```
output=$(dmesg | grep hda)
```

變成：

```
output = check_output("dmesg | grep hda", shell=True)
```

取代 `os.system()`

```
sts = os.system("mycmd" + " myarg")
# 變成
retcode = call("mycmd" + " myarg", shell=True)
```

🄵解：

- Calling the program through the shell is usually not required.
- The *`call()`* return value is encoded differently to that of *`os.system()`*.
- The *`os.system()`* function ignores SIGINT and SIGQUIT signals while the command is running, but the caller must do this separately when using the *`subprocess`* module.

A more realistic example would look like this:

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print("Child was terminated by signal", -retcode, file=sys.stderr)
    else:
        print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)
```

Replacing the `os.spawn` family

P_NOWAIT 範例：

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

P_WAIT 範例：

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])
```

向量範例：

```
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

環境範例：

```
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```

取代 `os.popen()`

Return code handling translates as follows:

```
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
==>
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")
```

18.7.7 Legacy Shell Invocation Functions

This module also provides the following legacy functions from the 2.x `commands` module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

`subprocess.`**`getstatusoutput`**(*cmd*, *, *encoding=None*, *errors=None*)

Return `(exitcode, output)` of executing *cmd* in a shell.

Execute the string *cmd* in a shell with `Popen.check_output()` and return a 2-tuple `(exitcode, output)`. *encoding* and *errors* are used to decode output; see the notes on *Frequently Used Arguments* for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of subprocess. Example:

```
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

可用性: Unix, Windows.

在 3.3.4 版的變更: 新增對 Windows 的支援。

The function now returns (exitcode, output) instead of (status, output) as it did in Python 3.3.3 and earlier. exitcode has the same value as *`returncode`*.

在 3.11 版的變更: 新增 *encoding* 與 *errors* 參數。

`subprocess.`**`getoutput`**(*cmd*, *, *encoding=None*, *errors=None*)

Return output (stdout and stderr) of executing *cmd* in a shell.

Like *getstatusoutput()*, except the exit code is ignored and the return value is a string containing the command's output. Example:

```
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

可用性: Unix, Windows.

在 3.3.4 版的變更: 新增對 Windows 的支援

在 3.11 版的變更: 新增 *encoding* 與 *errors* 參數。

18.7.8 🄵解

Timeout Behavior

When using the `timeout` parameter in functions like *run()*, *Popen.wait()*, or *Popen.communicate()*, users should be aware of the following behaviors:

1. **Process Creation Delay**: The initial process creation itself cannot be interrupted on many platform APIs. This means that even when specifying a timeout, you are not guaranteed to see a timeout exception until at least after however long process creation takes.
2. **Extremely Small Timeout Values**: Setting very small timeout values (such as a few milliseconds) may result in almost immediate *TimeoutExpired* exceptions because process creation and system scheduling inherently require time.

Converting an argument sequence to a string on Windows

On Windows, an *args* sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

也參考

shlex
Module which provides function to parse and escape command lines.

停用 `posix_spawn()`

在 Linux 上，*subprocess* 在安全的情🄵下預設會在🄵部使用 `vfork()` 系統呼叫，而不是 `fork()`，這顯著地提高了性能。

```
subprocess._USE_POSIX_SPAWN = False  # 見 CPython 問題 gh-NNNNNN。
```

在任何 Python 版本上將這個設定🄵 false 都是安全的。當不受支援時，它對舊版本或🄵有支援的新版本🄵有影響。不要假設屬性可供讀取。🄵管它的名稱是這樣，真實值🄵不表示將使用相應的函式，而只是表示可能會使用。

每當你需要使用這些私有開關以重現你所看到的問題時，請隨時提出問題 (file issues)。從程式碼中的🄵解連結到該問題。

在 3.8 版被加入: _USE_POSIX_SPAWN

18.8 sched --- 事件排程器

原始碼： Lib/sched.py

---

sched 模組定義了一個有實作通用事件排程器的類🄵：

class sched.**scheduler**(*timefunc=time.monotonic*, *delayfunc=time.sleep*)

scheduler 類🄵定義了事件排程的泛用介面。它需要兩個函式來和「外部世界」作用——*timefunc* 應不帶引數地被呼叫，🄵回傳一個數字（🄵「時間」，可🄵任何單位）。*delayfunc* 函式應以一個引數呼叫，🄵與 *timefunc* 的輸出相容，且應延遲其指定的時間單位。每個事件運行後，也會以引數 0 呼叫 *delayfunc*，來使得其他執行緒有機會在多執行緒應用程式中運行。

在 3.3 版的變更: *timefunc* 和 *delayfunc* 參數是可選的。

在 3.3 版的變更: *scheduler* 類🄵可以安全地在多執行緒環境中使用。

範例：

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
...     print("From print_time", time.time(), a)
...
>>> def print_some_times():
...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional',))
...     # 🄵管優先順序較高，但由於 enter() 是相對的，'keyword' 在 'positional' 之後運行
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'})
...     s.enterabs(1_650_000_000, 10, print_time, argument=("first enterabs",))
...     s.enterabs(1_650_000_000, 5, print_time, argument=("second enterabs",))
...     s.run()
...     print(time.time())
...
>>> print_some_times()
1652342830.3640375
From print_time 1652342830.3642538 second enterabs
From print_time 1652342830.3643398 first enterabs
From print_time 1652342835.3694863 positional
From print_time 1652342835.3696074 keyword
From print_time 1652342840.369612 default
1652342840.3697174
```

18.8.1 排程器物件

scheduler 實例具有以下方法和屬性：

scheduler.**enterabs**(*time*, *priority*, *action*, *argument=()*, *kwargs={}*)

🄵一個新事件排程。*time* 引數應該是與傳遞給建構函式的 *timefunc* 函式回傳值相容的數字型🄵。安排在相同 *time* 的事件將按照其 *priority* 的順序執行。數字越小代表優先順序越高。

執行事件意味著執行 `action(*argument, **kwargs)`。*argument* 是一個包含 *action* 之位置引數的序列。*kwargs* 是一個字典，帶有 *action* 的關鍵字引數。

回傳值是一個事件，可用於後續取消該事件（請見*cancel()*）。

在 3.3 版的變更: *argument* 參數是可選的。

在 3.3 版的變更: 新增 *kwargs* 參數。

scheduler.**enter**(*delay*, *priority*, *action*, *argument=()*, *kwargs={}*)

🄵一個排程事件延期 *delay* 個時間單位。除了相對時間之外，其他引數、效果和回傳值皆與*enterabs()* 的相同。

在 3.3 版的變更: *argument* 參數是可選的。

在 3.3 版的變更: 新增 *kwargs* 參數。

scheduler.**cancel**(*event*)

從🄵列中🄵除該事件。如果 *event* 不是目前🄵列中的事件，此方法將引發*ValueError*。

scheduler.**empty**()

如果事件🄵列🄵空，則回傳 `True`。

scheduler.**run**(*blocking=True*)

運行所有已排程的事件。此方法將會等待（使用傳遞給建構函式的 *delayfunc* 函式）下一個事件，然後執行它，🄵依此類推，直到不再有排程好的事件。

如果 *blocking* 🄵 false，則執行最快到期的已排程事件（如存在），然後回傳排程器中下一個排程呼叫（如存在）的截止時間。

action 或 *delayfunc* 都可能引發例外。無論哪種情🄵，排程器都將保持一致的狀態🄵傳遞例外。如果是由 *action* 引發例外，則後續呼叫*run()* 時將不會嘗試運行該事件。

如果一系列事件的運行時長比執行下一個事件前的可用時長 (available time) 更長，那🄵排程器就單純會落後。不會有事件被🄵🄵；呼叫程式碼也要負責取消不再相關的事件。

在 3.3 版的變更: 新增 *blocking* 參數。

scheduler.**queue**

會按事件運行順序回傳即將發生的事件串列的唯讀屬性。每個事件都以附 名元組 *(named tuple)* 表示，🄵包含以下欄位：時間、優先順序、動作 (action)、引數、kwargs。

18.9 queue --- 同步🄵列 (synchronized queue) 類🄵

原始碼： Lib/queue.py

---

queue module（模組）實作多生🄵者、多消費者🄵列。在執行緒程式設計中，必須在多執行緒之間安全地交🄵資訊時，特🄵有用。此 module 中的*Queue* class 實作所有必需的鎖定語義 (locking semantics)。

此 module 實作三種型🄵的🄵列，它們僅在取出條目的順序上有所不同。在 FIFO 🄵列中，先加入的任務是第一個被取出的。在 LIFO 🄵列中，最近被加入的條目是第一個被取出的（像堆🄵 (stack) 一樣操作）。使用優先🄵列 (priority queue) 時，條目將保持排序狀態（使用*heapq* module），🄵先取出最低值條目。

在🄵部，這三種型🄵的🄵列使用鎖 (lock) 來暫時阻塞競🄵執行緒；但是，它們🄵不是被設計來處理執行緒🄵的 reentrancy（可重入）。

此外，此 module 實作一個「簡單」的 FIFO 🄵列型🄵*SimpleQueue*，其特定的實作是以較少的功能🄵代價，來提供額外的保證。

queue module 定義了以下的 class 和例外：

class queue.**Queue**(*maxsize=0*)

FIFO 🄵列的建構子 (constructor)。*maxsize* 是一個整數，用於設置🄵列中可放置的項目數的上限。一旦達到此大小，插入將會阻塞，直到🄵列中的項目被消耗。如果 *maxsize* 小於或等於零，則🄵列大小🄵無限。

class queue.**LifoQueue**(*maxsize=0*)

LIFO 🄵列的建構子。*maxsize* 是一個整數，用於設置🄵列中可放置的項目數的上限。一旦達到此大小，插入將被鎖定，到🄵列中的項目被消耗。如果 *maxsize* 小於或等於零，則🄵列大小🄵無限。

class queue.**PriorityQueue**(*maxsize=0*)

優先🄵列的建構子。*maxsize* 是一個整數，用於設置🄵列中可放置的項目數的上限。一旦達到此大小，插入將被阻塞，直到🄵列中的項目被消耗。如果 *maxsize* 小於或等於零，則🄵列大小🄵無限。

最低值的條目會最先被取出（最低值的條目是被會 `min(entries)` 回傳的那一個）。條目的典型模式是格式🄵 `(priority_number, data)` 的 tuple（元組）。

如果 *data* 元素🄵不可比較的，則可以將資料包裝在一個 class 中，該 class 忽略資料項目🄵僅比較優先數：

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

class queue.**SimpleQueue**

無界的 FIFO 🄵列的建構子。簡單🄵列缺少任務追🄵等進階功能。

在 3.7 版被加入.

exception queue.**Empty**

當對一個空的*Queue* 物件呼叫非阻塞的 (non-blocking) *get()*（或*get_nowait()*）將引發此例外。

exception queue.**Full**

當對一個已滿的*Queue* 物件呼叫非阻塞的*put()*（或*put_nowait()*）將引發此例外。

exception queue.**ShutDown**

當對一個已關閉的*Queue* 物件呼叫*put()* 或*get()* 時將引發此例外。

在 3.13 版被加入.

18.9.1 🄵列物件

🄵列物件（*Queue*、*LifoQueue*、*PriorityQueue*）提供下面描述的公用 method。

Queue.**qsize**()

回傳🄵列的近似大小。注意，qsize() > 0 🄵不能保證後續的 get() 不會阻塞，qsize() < maxsize 也不會保證 put() 不會阻塞。

Queue.**empty**()

如果🄵列🄵空，則回傳 `True`，否則回傳 `False`。如果 empty() 回傳 `True`，則不保證後續呼叫 put() 不會阻塞。同樣，如果 empty() 回傳 `False`，則不保證後續呼叫 get() 不會阻塞。

Queue.**full**()

如果🄵列已滿，則回傳 `True` ，否則回傳 `False`。如果 full() 回傳 `True`，則不保證後續呼叫 get() 不會阻塞。同樣，如果 full() 回傳 `False`，則不保證後續呼叫 put() 不會阻塞。

Queue.**put**(*item*, *block=True*, *timeout=None*)

將 *item* 放入🄵列中。如果可選的 args *block* 🄵 true、*timeout* 🄵 `None`（預設值），則在必要時阻塞，直到自由槽 (free slot) 可用。如果 *timeout* 🄵正數，則最多阻塞 *timeout* 秒，如果該時間🄵🄵有可用的自由槽，則會引發*Full* 例外。否則（*block* 🄵 false），如果自由槽立即可用，則將項目放在🄵列中，否則引發*Full* 例外（在這種情🄵下，*timeout* 將被忽略）。

如果🄵列已被關閉，則引發*ShutDown*。

Queue.**put_nowait**(*item*)

等效於 `put(item, block=False)`。

Queue.**get**(*block=True*, *timeout=None*)

從🄵列中移除🄵回傳一個項目。如果可選的 args *block* 🄵 true，且 *timeout* 🄵 None（預設值），則在必要時阻塞，直到有可用的項目。如果 *timeout* 是正數，則最多會阻塞 *timeout* 秒，如果該時間🄵🄵有可用的項目，則會引發*Empty* 例外。否則（*block* 🄵 false），如果立即可用，則回傳一個項目，否則引發*Empty* 例外（在這種情🄵下，*timeout* 將被忽略）。

在 POSIX 系統的 3.0 版之前，以及 Windows 的所有版本，如果 *block* 🄵 true 且 *timeout* 🄵 None，則此操作將在底層鎖上進入不間斷等待。這意味著不會發生例外，特🄵是 SIGINT（中斷訊號）不會觸發*KeyboardInterrupt*。

如果🄵列已被關閉且🄵空，或🄵列已立即關閉，則引發*ShutDown*。

Queue.**get_nowait**()

等效於 get(False)。

有兩個 method 可以支援追🄵放入🄵列的任務是否已由常駐消費者執行緒 (daemon consumer threads) 完全處理。

Queue.**task_done**()

表示先前放入🄵列的任務已完成。由🄵列消費者執行緒使用。對於用來提取任務的每個*get()*，隨後呼叫*task_done()* 告訴🄵列任務的處理已完成。

如果目前*join()* 阻塞，它將會在所有項目都已處理完畢後恢復（代表對於以*put()* 放進🄵列的每個項目，都要收到*task_done()* 的呼叫）。

shutdown(immediate=True) calls *task_done()* for each remaining item in the queue.

如果呼叫次數超過🄵列中放置的項目數量，則引發*ValueError*。

Queue.**join**()

持續阻塞直到🄵列中的所有項目都已被取得🄵處理完畢。

每當項目被加到🄵列中時，未完成任務的計數都會增加。每當消費者執行緒呼叫*task_done()* 以指示該項目已被取出🄵且對其的所有工作都已完成時，計數就會下降。當未完成任務的計數降至零時，*join()* 將停止阻塞。

如何等待放入🄵列的任務完成的範例：

```
import threading
import queue

q = queue.Queue()

def worker():
    while True:
        item = q.get()
        print(f'Working on {item}')
        print(f'Finished {item}')
        q.task_done()

# Turn-on the worker thread.
threading.Thread(target=worker, daemon=True).start()

# Send thirty task requests to the worker.
for item in range(30):
    q.put(item)

# Block until all tasks are done.
q.join()
print('All work completed')
```

Terminating queues

Queue objects can be made to prevent further interaction by shutting them down.

Queue.**shutdown**(*immediate=False*)

Shut down the queue, making *get()* and *put()* raise *ShutDown*.

By default, *get()* on a shut down queue will only raise once the queue is empty. Set *immediate* to true to make *get()* raise immediately instead.

All blocked callers of *put()* and *get()* will be unblocked. If *immediate* is true, a task will be marked as done for each remaining item in the queue, which may unblock callers of *join()*.

在 3.13 版被加入.

18.9.2 SimpleQueue 物件

SimpleQueue 物件提供下面描述的公用 method。

SimpleQueue.**qsize**()

傳回F列的近似大小。注意，qsize() > 0 F不能保證後續的 get() 不會阻塞。

SimpleQueue.**empty**()

如果F列F空，則回傳 `True`，否則回傳 `False`。如果 empty() 回傳 `False`，則不保證後續呼叫 get() 不會阻塞。

SimpleQueue.**put**(*item*, *block=True*, *timeout=None*)

將 *item* 放入F列中。此 method 從不阻塞，F且都會成功（除了F在的低階錯誤，像是分配記憶體失敗）。可選的 args *block* 和 *timeout* 會被忽略，它們僅是F了與*Queue.put()* 相容才存在。

此 method 有一個可重入 (reentrant) 的 C 實作。意思就是，一個 `put()` 或 `get()` 呼叫，可以被同一執行緒中的另一個 `put()` 呼叫中斷，而不會造成死鎖 (deadlock) 或損壞F列中的F部狀態。這使得它適合在解構子 (destructor) 中使用，像是 `__del__` method 或*weakref* 回呼函式 (callback)。

SimpleQueue.**put_nowait**(*item*)

等效於 `put(item, block=False)`，用於與*Queue.put_nowait()* 相容。

SimpleQueue.**get**(*block=True*, *timeout=None*)

從F列中移除F回傳一個項目。如果可選的 args *block* F true，且 *timeout* F `None`（預設值），則在必要時阻塞，直到有可用的項目。如果 *timeout* 是正數，則最多會阻塞 *timeout* 秒，如果該時間FF有可用的項目，則會引發*Empty* 例外。否則（*block* F false），如果立即可用，則回傳一個項目，否則引發*Empty* 例外（在這種情F下，*timeout* 將被忽略）。

SimpleQueue.**get_nowait**()

等效於 `get(False)`。

也參考

Class ***multiprocessing.Queue***
用於多行程處理 (multi-processing)（而非多執行緒）情境 (context) 的F列 class。

collections.deque 是無界F列的替代實作，有快速且具原子性 (atomic) 的*append()* 和*popleft()* 操作，這些操作不需要鎖定，F且還支持索引。

18.10 contextvars --- 情境變數

本模組供 API 來管理、儲存及存取單一情境各自的狀態（context-local state）。用*ContextVar* 類F宣告和處理情境變數。*copy_context()* 函式和*Context* 類F應在非同步框架中管理目前的情境。

帶有狀態的 Context Manager 應該使用情境變數，而不是*threading.local()*，才能防止它們的狀態在🄵行（concurrent）程式碼中使用時意外外溢🄵干擾到其他程式碼。

其他詳細資訊，請參🄵 **PEP 567**。

在 3.7 版被加入.

18.10.1 情境變數

class contextvars.**ContextVar**(*name*[, *, *default*])

此類🄵用在宣告新的情境變數，例如：

```
var: ContextVar[int] = ContextVar('var', default=42)
```

必要參數 *name* 用於自我檢查（introspection）和除錯。

當在目前的情境中找不到變數的值時，*ContextVar.get()* 會回傳可選的僅限關鍵字參數 *default*。

重要： 情境變數應該在最頂端的模組層級建立，🄵對不要在閉包（closure）中建立。*Context* 物件持有情境變數的🄵參照，這會阻止情境變數被正確地垃圾回收（garbage collected）。

name

這個變數的名稱。這是一個唯讀屬性。

在 3.7.1 版被加入.

get([*default*])

回傳當前情境的情境變數值。

如果在當前情境中🄵有變數的值，此方法將：

- 回傳方法的 *default* 引數值（如果有的話）；否則
- 回傳情境變數的預設值（如果建立情境變數時有指定預設值的話）；否則
- 會引發一個*LookupError*。

set(*value*)

在目前的情境中，呼叫以設定情境變數的新值。

value 屬必要引數，是情境變數的新值。

回傳一個*Token* 物件，該物件可透過*ContextVar.reset()* 方法，用來將變數還原到之前的值。

reset(*token*)

將情境變數重設🄵使用*ContextVar.set()* 建立 *token* 前的值。

舉例來🄵：

```
var = ContextVar('var')

token = var.set('new value')
# 使用 'var' 的程式碼；var.get() 回傳 'new value'。
var.reset(token)

# 在重設呼叫之後，var 又🄵有值了，所以
# var.get() 會引發 LookupError。
```

class contextvars.**Token**

Token 物件由*ContextVar.set()* 方法回傳，可以傳遞給*ContextVar.reset()* 方法，用以將變數的值還原🄵相對應的 *set* 之前的值。

The token supports context manager protocol to restore the corresponding context variable value at the exit from `with` block:

```
var = ContextVar('var', default='default value')

with var.set('new value'):
    assert var.get() == 'new value'

assert var.get() == 'default value'
```

在 3.14 版被加入: 新增對用作情境管理器的支援。

var

唯讀屬性。指向建立 token 的*ContextVar* 物件。

old_value

唯讀屬性。值🄵變數在呼叫*ContextVar.set()* 方法之前的值。如果變數在呼叫前🄵有設定，則指向*Token.MISSING*。

MISSING

由*Token.old_value* 使用的標記物件。

18.10.2 手動情境管理

contextvars.**copy_context**()

回傳目前*Context* 物件的🄵本（copy）。

以下程式碼片段會取得目前情境的🄵本，🄵顯示在其中設定的所有變數及其值：：

```
ctx: Context = copy_context()
print(list(ctx.items()))
```

這個函式具有 *O*(1) 的🄵雜度，也就是🄵，對於只有少許情境變數的情境和有大量情境變數的情境，速度都一樣快。

class contextvars.**Context**

ContextVars 到其值的映射。

`Context()` 會建立一個🄵有值的空情境。要取得目前情境的🄵本，請使用*copy_context()* 函式。

每個執行緒都有自己的 `Context` 物件中目前主控中的堆🄵（stack）。*current context* 是目前執行緒堆🄵頂端的 `Context` 物件。堆🄵中的所有 `Context` 物件都被視🄵已進入。

進入一個情境，可以藉由呼叫其*run()* 方法來完成，此進入的動作會將一情境推到目前執行緒的情境堆🄵的頂端，使該情境成🄵目前的情境。

如果你傳遞給*run()* 方法的回呼函式（callback functions），該函式回傳之後，就會自動退出目前的情境，這會將目前的情境還原到進入情境之前的狀態，方法是將情境從情境堆🄵的頂端彈出。

因🄵每個執行緒都有自己的情境堆🄵，當值在不同的執行緒中被指定時，*ContextVar* 物件的行🄵與*threading.local()* 相似。

嘗試進入已進入的情境，包括在其他執行緒中進入的情境，會引發*RuntimeError*。

退出情境後，之後可以重新進入（從任何執行緒）。

任何透過*ContextVar.set()* 方法對*ContextVar* 值的改變都會記🄵在目前的情境中。*ContextVar.get()* 方法回傳與當前情境相關的值。退出情境實際造成的效果會像是將其在進入情境時對情境變數所做的任何變一一彈出🄵還原（如果需要，可以透過重新進入情境來還原值）。

情境（Context）實作了*collections.abc.Mapping* 介面。

run(*callable*, **args*, ***kwargs*)

進入 Context，執行 `callable(*args, **kwargs)`，然後退出 Context。回傳 *callable* 的回傳值，如果發生例外（exception），則傳播例外。

例如：

```
import contextvars

var = contextvars.ContextVar('var')
var.set('spam')
print(var.get())  # 'spam'

ctx = contextvars.copy_context()

def main():
    # 'var' 之前被設成 'spam'
    # 呼叫 'copy_context()' 和 'ctx.run(main)', 所以:
    print(var.get())  # 'spam'
    print(ctx[var])  # 'spam'

    var.set('ham')

    # 現在, 在把 'var' 的值設成 'ham' 後:
    print(var.get())  # 'ham'
    print(ctx[var])  # 'ham'

# 'main' 函式對 'var' 所做的任何變更都會
# 包含在 'ctx' 🄵: .
ctx.run(main)

# 'main()' 函式是在 'ctx' 情境中執行,
# 所以對 'var' 的變更會保存在 'ctx' 中:
print(ctx[var])  # 'ham'

# 但是, 在 'ctx' 外, 'var' 的值仍然是 'spam':
print(var.get())  # 'spam'
```

copy()

回傳情境物件的淺層🄵本（shallow copy）。

var in context

如果情境🄵面有 *var* 的值，則回傳 `True`，否則回傳 `False`。

context[var]

回傳 *var* *ContextVar* 變數的值。如果該變數🄵🄵有在情境物件中設定，則會引發*KeyError* 錯誤。

get(*var*[, *default*])

如果 *var* 的值在情境物件中，則回傳 *var* 的值。否則回傳 *default*。如果🄵有 *default* 值，則回傳 `None`。

iter(context)

回傳儲存於情境物件中變數的🄵代器。

len(proxy)

回傳情境物件中的變數個數。

keys()

回傳情境物件中所有變數的串列。

values()

回傳情境物件中所有變數的值的串列。

items()

回傳情境物件中所有變數與其值的 2-元組（2-tuples）的串列。

18.10.3 對 asyncio 的支援

asyncio 原生支援情境變數，不需任何額外設定。舉例來🄵，以下是一個簡單的 echo 伺服器，使用情境變數讓遠端用🄵端的位址在處理該用🄵端的任務中可用：

```
import asyncio
import contextvars

client_addr_var = contextvars.ContextVar('client_addr')

def render_goodbye():
    # 即使不把目前處理中的用🄵端 (client) 傳入此函式
    # 仍可取得其位址

    client_addr = client_addr_var.get()
    return f'Good bye, client @ {client_addr}\r\n'.encode()

async def handle_request(reader, writer):
    addr = writer.transport.get_extra_info('socket').getpeername()
    client_addr_var.set(addr)

    # 在任何我們呼叫的程式碼中，都可以
    # 呼叫 'client_addr_var.get()' 來取得用🄵端的位址

    while True:
        line = await reader.readline()
        print(line)
        if not line.strip():
            break

    writer.write(b'HTTP/1.1 200 OK\r\n')  # status line
    writer.write(b'\r\n')  # headers
    writer.write(render_goodbye())  # body
    writer.close()

async def main():
    srv = await asyncio.start_server(
        handle_request, '127.0.0.1', 8081)

    async with srv:
        await srv.serve_forever()

asyncio.run(main())

# 你可以使用 telnet 或 curl 測試:
#     telnet 127.0.0.1 8081
#     curl 127.0.0.1:8081
```

以下是支援部份上述服務的模組：

18.11 _thread --- 低階執行緒 API

這個模組提供了與多個執行緒（也稱🄵:dfn: *輕量級行程*或:dfn: *任務*）一起工作的低階原始物件 --- 多個控制執行緒分享其全域資料空間。🄵了處理同步問題，也提供了簡單的鎖 (lock) 機制（也稱🄵:dfn: *互斥鎖*或 *二進位號*🄵）。*threading* 模組提供了一個建立在這個模組之上的更易於使用和高階的執行緒 API。

在 3.7 版的變更: 這個模組之前是可選擇性的，但現在已經是可用的。

這個模組定義了以下的常數和函式：

exception _thread.**error**

在執行緒相關的錯誤發生時引發。

在 3.3 版的變更: 現在是🄵建例外*RuntimeError* 的🄵名。

_thread.**LockType**

這是鎖物件的型🄵。

_thread.**start_new_thread**(*function*, *args*[, *kwargs*])

開始一個新的執行緒🄵回傳其識🄵字 (identifier) 。該執行緒執行帶有引數列表 *args**（必須是一個 *tuple*（元組））的函式 **function*。可選的 *kwargs* 引數指定一個關鍵字引數的字典。

當函式回傳時，執行緒會🄵默退出。

當函式因未處理的例外終止時，將呼叫*sys.unraisablehook()* 來處理該例外。🄵子引數的 *object* 屬性是 *function*。預設情🄵下，會列印堆🄵跟🄵，然後執行緒退出（但其他執行緒會繼續運行）。

當函式引發*SystemExit* 例外時，它會被🄵默忽略。

引發一個稽核事件 _thread.start_new_thread，帶有引數 function、args 和 kwargs。

在 3.8 版的變更: 現在使用*sys.unraisablehook()* 來處理未處理的例外。

_thread.**interrupt_main**(*signum=signal.SIGINT*, */*)

模擬一個訊號到達主執行緒的效果。執行緒可以使用此函式來中斷主執行緒，但無法保證中斷會立即發生。

如果提供了 *signum*，則模擬指定的訊號編號。如果未提供 *signum*，則模擬*signal.SIGINT* 訊號。

如果給定的訊號在 Python 中未被處理（即設置🄵*signal.SIG_DFL* 或*signal.SIG_IGN*），此函式不做任何操作。

在 3.10 版的變更: 新增了 *signum* 引數以自定義訊號編號。

> **備🄵**
>
> 這🄵不會發出對應的訊號，而是安排呼叫相應的處理器（如果存在的話）。如果你想真正發出訊號，請使用*signal.raise_signal()*。

_thread.**exit**()

引發*SystemExit* 例外。當未捕獲時，將導致執行緒🄵默退出。

_thread.**allocate_lock**()

回傳一個新的鎖物件。鎖物件的方法如下所述。初始狀🄵下鎖是解鎖狀態。

_thread.**get_ident**()

回傳目前執行緒的「執行緒識🄵字」。這是一個非零的整數。它的值🄵有直接的含義；它被用作一個 magic cookie，例如用於索引特定於執行緒的資料的字典。當執行緒退出🄵建立另一個執行緒時，執行緒識🄵字可能會被重🄵使用。

_thread.**get_native_id**()

回傳由核心 (kernel) 分配的目前執行緒的原生整數執行緒 ID。這是一個非負整數。它的值可用於在整個系統中唯一標識此特定執行緒（直到執行緒終止後，該值可能被操作系統重新使用）。

可用性: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD, GNU/kFreeBSD.

在 3.8 版被加入.

在 3.13 版的變更: 新增了對 GNU/kFreeBSD 的支援。

_thread.**stack_size**([*size*])

回傳在建立新執行緒時使用的執行緒堆🄵大小。可選的 *size* 引數指定了隨後建立的執行緒要使用的堆🄵大小，必須是 0（使用平台或配置的預設值）或至少 32,768（32 KiB）的正整數值。如果未指定 *size*，則使用 0。如果不支持更改執行緒堆🄵大小，則會引發*RuntimeError* 錯誤。如果指定的堆

🄵大小無效，則會引發*ValueError* 錯誤，🄵且堆🄵大小不會被修改。目前，32 KiB 是保證直譯器本身具有足🄵堆🄵空間所支持的最小堆🄵大小值。請注意，某些平台對於堆🄵大小的值可能有特定的限制，例如要求最小堆🄵大小 > 32 KiB，或要求按系統記憶體頁面大小的倍數進行分配。應參考平台文件以取得更多訊息（4 KiB 頁面是比較普遍的；在缺乏更具體訊息的情🄵下，建議使用 4096 的倍數作🄵堆🄵大小）。

可用性: Windows, pthreads.

Unix 平台上支援 POSIX 執行緒。

_thread.**TIMEOUT_MAX**

Lock.acquire 的 *timeout* 參數所允許的最大值。指定超過此值的 timeout 將引發*OverflowError* 錯誤。

在 3.2 版被加入.

鎖物件具有以下方法：

lock.**acquire**(*blocking=True*, *timeout=-1*)

🄵有任何可選引數時，此方法無條件地取得鎖，必要時會等待直到被另一個執行緒釋放（一次只能有一個執行緒取得鎖 --- 這正是鎖存在的原因）。

如果存在 *blocking* 引數，則根據其值執行操作：如果🄵 False，只有在可以立即獲取鎖而無需等待的情🄵下才取得鎖，而如果🄵 True，則像上面一樣無條件地取得鎖。

如果存在浮點數的 *timeout* 引數且🄵正值，則它指定了在回傳之前的最大等待時間（以秒🄵單位）。如果 *timeout* 引數🄵負值，則表示等待時間會無限期地等待。如果 *blocking* 🄵 False，則你無法指定 *timeout*。

如果成功取得鎖，回傳值🄵 `True`，否則🄵 `False`。

在 3.2 版的變更: 新增的 *timeout* 參數。

在 3.2 版的變更: 現在取得鎖的操作可以被 POSIX 訊號中斷。

在 3.14 版的變更: Lock acquires can now be interrupted by signals on Windows.

lock.**release**()

釋放鎖。鎖必須先前被取得，但不一定是由同一個執行緒取得的。

lock.**locked**()

回傳鎖的狀態：如果鎖已被某個執行緒取得，則回傳 `True`，否則回傳 `False`。

除了這些方法之外，鎖物件還可以透過 `with` 語句來使用，例如：

```
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock 在執行這🄵時被鎖定")
```

注意事項：

- 中斷總會跳到主執行緒（該執行緒將接收*KeyboardInterrupt* 例外。）
- 呼叫*sys.exit()* 函式或引發*SystemExit* 例外等同於呼叫*_thread.exit()* 函式。
- 當主執行緒退出時，其他執行緒是否保留是由系統🄵定的。在大多數系統上，它們將被終止，而不會執行 `try` ... `finally` 子句或執行物件的解構函式。

CHAPTER 19

網路與行程間通訊

本章所描述的模組提供了網路和行程間通訊的機制。

某些模組僅適用於同一台機器上的兩個行程，例如*signal* 和*mmap*。其他模組則支援網路通訊協定，可供兩個或多個行程跨機器進行通訊。

本章所述的模組列表如下：

19.1 asyncio --- 非同步 I/O

Hello World!

```
import asyncio

async def main():
    print('Hello ...')
    await asyncio.sleep(1)
    print('... World!')

asyncio.run(main())
```

asyncio 是讓使用者以 **async/await** 語法來編寫🄵行 *(concurrent)* 程式碼的函式庫 (library)。

asyncio 作🄵多個 Python 非同步框架的基礎，在高效能網路與網頁伺服器、資料庫連🄵函式庫、分散式任務🄵列等服務都可以看得到它。

asyncio 往往是個建構 IO 密集型與高階層**結構化**網路程式碼的完美選擇。

也參考

a-conceptual-overview-of-asyncio
asyncio 的基本原理🄵明。

asyncio 提供了一系列**高階** API：

- 🄵行地運行 *Python* 協程 *(coroutine)* 🄵擁有完整控制權；

- 執行網路 *IO* 與 *IPC*；
- 控制子行程 *(subprocess)*；
- 透過🄵列 *(queue)* 分配任務；
- 同步🄵行程式碼；

此外，還有一些給函式庫與框架 *(framework)* 開發者的**低階** API：

- 建立與管理*event loops*（事件🄵圈），它提供了能被用於網路、執行子行程、處理作業系統訊號等任務的非同步 API；
- 使用*transports*（*asyncio* 底層傳輸相關類🄵）來實作高效能協定；
- 透過 async/await 語法來橋接基於回呼 (callback-based) 的函式庫與程式碼。

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

asyncio REPL

你能在*REPL* 中對一個 `asyncio` 的🄵行情境 (context) 進行實驗：

```
$ python -m asyncio
asyncio REPL ...
Use "await" directly instead of "asyncio.run()".
Type "help", "copyright", "credits" or "license" for more information.
>>> import asyncio
>>> await asyncio.sleep(10, result='hello')
'hello'
```

🄵生一個稽核事件 `cpython.run_stdin` 且🄵有引數。

在 3.12.5 版的變更: (也包括 3.11.10、3.10.15、3.9.20 及 3.8.20）發出稽核事件。

在 3.13 版的變更: 可能的話使用 PyREPL，在這種情🄵下 `PYTHONSTARTUP` 也會被執行。發出稽核事件。

參🄵

19.1.1 Runners (執行器)

原始碼： Lib/asyncio/runners.py

這個章節概述用於執行 asyncio 程式碼的高階 asyncio 原始物件。

他們是基於一個事件🄵圈，目的是🄵了簡化常見且廣泛運用場景的非同步程式碼。

- *運行一個 asyncio 程式*
- *Runner context manager*
- *Handling Keyboard Interruption*

運行一個 asyncio 程式

`asyncio.`**`run`**(*coro*, *, *debug=None*, *loop_factory=None*)

在 asyncio 事件🄵圈中執行 *coro* 🄵回傳結果。

該引數可以是任何可等待物件 (awaitable object)。

這個函式負責運行被傳入的可等待物件、管理 asyncio 的事件🄵圈、終結非同步🄵生器以及關閉執行器。

當另一個非同步事件🄵圈在同一執行緒中執行時，無法呼叫此函式。

如果 *debug* 🄵 `True`，事件🄵圈會以除錯模式執行。`False` 則會關閉除錯模式。`None` 則會優先使用除錯模式的全域設定。

如果 *loop_factory* 不🄵 `None`，它會被用於建立一個新的事件🄵圈；否則會改用 *asyncio.new_event_loop()*。🄵圈會在最後關閉。這個函式應該要作🄵 asyncio 程式的主要進入點，且理想上僅會被呼叫一次。推薦使用 *loop_factory* 來設定事件🄵圈時而不是使用 policies（政策）。傳遞 *asyncio.EventLoop* 可以讓 asyncio 在🄵有政策系統的情🄵下運行。

The executor is given a timeout duration of 5 minutes to shutdown. If the executor hasn't finished within that duration, a warning is emitted and the executor is closed.

範例：

```
async def main():
    await asyncio.sleep(1)
    print('hello')

asyncio.run(main())
```

在 3.7 版被加入.

在 3.9 版的變更: Updated to use *loop.shutdown_default_executor()*.

在 3.10 版的變更: *debug* is `None` by default to respect the global debug mode settings.

在 3.12 版的變更: 新增 *loop_factory* 參數。

在 3.14 版的變更: *coro* can be any awaitable object.

備🄵

The `asyncio` policy system is deprecated and will be removed in Python 3.16; from there on, an explicit *loop_factory* is needed to configure the event loop.

Runner context manager

class asyncio.**Runner**(*, *debug=None*, *loop_factory=None*)

A context manager that simplifies *multiple* async function calls in the same context.

Sometimes several top-level async functions should be called in the same *event loop* and *contextvars.Context*.

如果 *debug* 🄵 `True`，事件🄵圈會以除錯模式執行。`False` 則會關閉除錯模式。`None` 則會優先使用除錯模式的全域設定。

loop_factory could be used for overriding the loop creation. It is the responsibility of the *loop_factory* to set the created loop as the current one. By default *asyncio.new_event_loop()* is used and set as current event loop with *asyncio.set_event_loop()* if *loop_factory* is `None`.

Basically, *asyncio.run()* example can be rewritten with the runner usage:

```
async def main():
    await asyncio.sleep(1)
    print('hello')

with asyncio.Runner() as runner:
    runner.run(main())
```

在 3.11 版被加入.

run(*coro*, *, *context=None*)

Execute *coro* in the embedded event loop.

該引數可以是任何可等待物件 (awaitable object)。

If the argument is a coroutine, it is wrapped in a Task.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the code to run in. The runner's default context is used if context is `None`.

Returns the awaitable's result or raises an exception.

當另一個非同步事件🄵圈在同一執行緒中執行時，無法呼叫此函式。

在 3.14 版的變更: *coro* can be any awaitable object.

close()

Close the runner.

Finalize asynchronous generators, shutdown default executor, close the event loop and release embedded *contextvars.Context*.

get_loop()

Return the event loop associated with the runner instance.

備🄵

Runner uses the lazy initialization strategy, its constructor doesn't initialize underlying low-level structures.

Embedded *loop* and *context* are created at the `with` body entering or the first call of *run()* or *get_loop()*.

Handling Keyboard Interruption

在 3.11 版被加入.

When *signal.SIGINT* is raised by `Ctrl-C`, *KeyboardInterrupt* exception is raised in the main thread by default. However this doesn't work with *asyncio* because it can interrupt asyncio internals and can hang the program from exiting.

To mitigate this issue, *asyncio* handles *signal.SIGINT* as follows:

1. *asyncio.Runner.run()* installs a custom *signal.SIGINT* handler before any user code is executed and removes it when exiting from the function.
2. The *Runner* creates the main task for the passed coroutine for its execution.
3. When *signal.SIGINT* is raised by `Ctrl-C`, the custom signal handler cancels the main task by calling *asyncio.Task.cancel()* which raises *asyncio.CancelledError* inside the main task. This causes the Python stack to unwind, `try/except` and `try/finally` blocks can be used for resource cleanup. After the main task is cancelled, *asyncio.Runner.run()* raises *KeyboardInterrupt*.
4. A user could write a tight loop which cannot be interrupted by *asyncio.Task.cancel()*, in which case the second following `Ctrl-C` immediately raises the *KeyboardInterrupt* without cancelling the main task.

19.1.2 協程與任務

This section outlines high-level asyncio APIs to work with coroutines and Tasks.

- 協程

- *Scheduling From Other Threads*
- *Introspection*
- *Task 物件*

協程

原始碼： Lib/asyncio/coroutines.py

Coroutines declared with the async/await syntax is the preferred way of writing asyncio applications. For example, the following snippet of code prints ”hello”, waits 1 second, and then prints ”world”:

```
>>> import asyncio

>>> async def main():
...     print('hello')
...     await asyncio.sleep(1)
...     print('world')

>>> asyncio.run(main())
hello
world
```

Note that simply calling a coroutine will not schedule it to be executed:

```
>>> main()
<coroutine object main at 0x1053bb7c8>
```

To actually run a coroutine, asyncio provides the following mechanisms:

- The `asyncio.run()` function to run the top-level entry point ”main()” function (see the above example.)
- Awaiting on a coroutine. The following snippet of code will print ”hello” after waiting for 1 second, and then print ”world” after waiting for *another* 2 seconds:

```
import asyncio
import time

async def say_after(delay, what):
    await asyncio.sleep(delay)
    print(what)

async def main():
    print(f"started at {time.strftime('%X')}")

    await say_after(1, 'hello')
    await say_after(2, 'world')
```

(繼續下一頁)

(繼續上一頁)

```
    print(f"finished at {time.strftime('%X')}")

asyncio.run(main())
```

預期的輸出:

```
started at 17:13:52
hello
world
finished at 17:13:55
```

- The *asyncio.create_task()* function to run coroutines concurrently as asyncio *Tasks*.

  Let's modify the above example and run two `say_after` coroutines *concurrently*:

```
async def main():
    task1 = asyncio.create_task(
        say_after(1, 'hello'))

    task2 = asyncio.create_task(
        say_after(2, 'world'))

    print(f"started at {time.strftime('%X')}")

    # Wait until both tasks are completed (should take
    # around 2 seconds.)
    await task1
    await task2

    print(f"finished at {time.strftime('%X')}")
```

  Note that expected output now shows that the snippet runs 1 second faster than before:

```
started at 17:14:32
hello
world
finished at 17:14:34
```

- The *asyncio.TaskGroup* class provides a more modern alternative to *create_task()*. Using this API, the last example becomes:

```
async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(
            say_after(1, 'hello'))

        task2 = tg.create_task(
            say_after(2, 'world'))

        print(f"started at {time.strftime('%X')}")

    # The await is implicit when the context manager exits.

    print(f"finished at {time.strftime('%X')}")
```

  The timing and output should be the same as for the previous version.

  在 3.11 版被加入: *asyncio.TaskGroup*。

Awaitables

We say that an object is an **awaitable** object if it can be used in an `await` expression. Many asyncio APIs are designed to accept awaitables.

There are three main types of *awaitable* objects: **coroutines**, **Tasks**, and **Futures**.

協程

Python coroutines are *awaitables* and therefore can be awaited from other coroutines:

```
import asyncio

async def nested():
    return 42

async def main():
    # Nothing happens if we just call "nested()".
    # A coroutine object is created but not awaited,
    # so it *won't run at all*.
    nested()  # will raise a "RuntimeWarning".

    # Let's do it differently now and await it:
    print(await nested())  # will print "42".

asyncio.run(main())
```

重要

In this documentation the term ”coroutine” can be used for two closely related concepts:

- a *coroutine function*: an `async def` function;
- a *coroutine object*: an object returned by calling a *coroutine function*.

Tasks

Tasks are used to schedule coroutines *concurrently*.

When a coroutine is wrapped into a *Task* with functions like *`asyncio.create_task()`* the coroutine is automatically scheduled to run soon:

```
import asyncio

async def nested():
    return 42

async def main():
    # Schedule nested() to run soon concurrently
    # with "main()".
    task = asyncio.create_task(nested())

    # "task" can now be used to cancel "nested()", or
    # can simply be awaited to wait until it is complete:
    await task

asyncio.run(main())
```

Futures

A *Future* is a special **low-level** awaitable object that represents an **eventual result** of an asynchronous operation.

When a Future object is *awaited* it means that the coroutine will wait until the Future is resolved in some other place.

Future objects in asyncio are needed to allow callback-based code to be used with async/await.

Normally **there is no need** to create Future objects at the application level code.

Future objects, sometimes exposed by libraries and some asyncio APIs, can be awaited:

```
async def main():
    await function_that_returns_a_future_object()

    # this is also valid:
    await asyncio.gather(
        function_that_returns_a_future_object(),
        some_python_coroutine()
    )
```

A good example of a low-level function that returns a Future object is *loop.run_in_executor()*.

Creating Tasks

原始碼： Lib/asyncio/tasks.py

---

asyncio.**create_task**(*coro*, *, *name=None*, *context=None*, *eager_start=None*, ***kwargs*)

Wrap the *coro* *coroutine* into a *Task* and schedule its execution. Return the Task object.

The full function signature is largely the same as that of the *Task* constructor (or factory) - all of the keyword arguments to this function are passed through to that interface.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the *coro* to run in. The current context copy is created when no *context* is provided.

An optional keyword-only *eager_start* argument allows specifying if the task should execute eagerly during the call to create_task, or be scheduled later. If *eager_start* is not passed the mode set by *loop.set_task_factory()* will be used.

The task is executed in the loop returned by *get_running_loop()*, *RuntimeError* is raised if there is no running loop in current thread.

> **備🄵**
>
> *asyncio.TaskGroup.create_task()* is a new alternative leveraging structural concurrency; it allows for waiting for a group of related tasks with strong safety guarantees.

> **重要**
>
> Save a reference to the result of this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn't referenced elsewhere may get garbage collected at any time, even before it's done. For reliable "fire-and-forget" background tasks, gather them in a collection:
>
> ```
> background_tasks = set()
>
> for i in range(10):
>     task = asyncio.create_task(some_coro(param=i))
>
>     # Add task to the set. This creates a strong reference.
>     background_tasks.add(task)
> ```

```
    # To prevent keeping references to finished tasks forever,
    # make each task remove its own reference from the set after
    # completion:
    task.add_done_callback(background_tasks.discard)
```

在 3.7 版被加入.

在 3.8 版的變更: 新增 *name* 參數。

在 3.11 版的變更: 新增 *context* 參數。

在 3.14 版的變更: Added the *eager_start* parameter by passing on all *kwargs*.

Task Cancellation

Tasks can easily and safely be cancelled. When a task is cancelled, *asyncio.CancelledError* will be raised in the task at the next opportunity.

It is recommended that coroutines use `try/finally` blocks to robustly perform clean-up logic. In case *asyncio.CancelledError* is explicitly caught, it should generally be propagated when clean-up is complete. *asyncio.CancelledError* directly subclasses *BaseException* so most code will not need to be aware of it.

The asyncio components that enable structured concurrency, like *asyncio.TaskGroup* and *asyncio.timeout()*, are implemented using cancellation internally and might misbehave if a coroutine swallows *asyncio.CancelledError*. Similarly, user code should not generally call *uncancel*. However, in cases when suppressing *asyncio.CancelledError* is truly desired, it is necessary to also call `uncancel()` to completely remove the cancellation state.

Task Groups

Task groups combine a task creation API with a convenient and reliable way to wait for all tasks in the group to finish.

class asyncio.**TaskGroup**

An asynchronous context manager holding a group of tasks. Tasks can be added to the group using *create_task()*. All tasks are awaited when the context manager exits.

在 3.11 版被加入.

create_task(*coro*, *, *name=None*, *context=None*, *eager_start=None*, ***kwargs*)

Create a task in this task group. The signature matches that of *asyncio.create_task()*. If the task group is inactive (e.g. not yet entered, already finished, or in the process of shutting down), we will close the given `coro`.

在 3.13 版的變更: Close the given coroutine if the task group is not active.

在 3.14 版的變更: Passes on all *kwargs* to *loop.create_task()*

範例:

```
async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(some_coro(...))
        task2 = tg.create_task(another_coro(...))
    print(f"Both tasks have completed now: {task1.result()}, {task2.result()}")
```

The `async with` statement will wait for all tasks in the group to finish. While waiting, new tasks may still be added to the group (for example, by passing `tg` into one of the coroutines and calling `tg.create_task()` in that coroutine). Once the last task has finished and the `async with` block is exited, no new tasks may be added to the group.

The first time any of the tasks belonging to the group fails with an exception other than *asyncio.CancelledError*, the remaining tasks in the group are cancelled. No further tasks can then be added to the group. At this point, if

the body of the `async with` statement is still active (i.e., `__aexit__()` hasn't been called yet), the task directly containing the `async with` statement is also cancelled. The resulting *asyncio.CancelledError* will interrupt an `await`, but it will not bubble out of the containing `async with` statement.

Once all tasks have finished, if any tasks have failed with an exception other than *asyncio.CancelledError*, those exceptions are combined in an *ExceptionGroup* or *BaseExceptionGroup* (as appropriate; see their documentation) which is then raised.

Two base exceptions are treated specially: If any task fails with *KeyboardInterrupt* or *SystemExit*, the task group still cancels the remaining tasks and waits for them, but then the initial *KeyboardInterrupt* or *SystemExit* is re-raised instead of *ExceptionGroup* or *BaseExceptionGroup*.

If the body of the `async with` statement exits with an exception (so `__aexit__()` is called with an exception set), this is treated the same as if one of the tasks failed: the remaining tasks are cancelled and then waited for, and non-cancellation exceptions are grouped into an exception group and raised. The exception passed into `__aexit__()`, unless it is *asyncio.CancelledError*, is also included in the exception group. The same special case is made for *KeyboardInterrupt* and *SystemExit* as in the previous paragraph.

Task groups are careful not to mix up the internal cancellation used to "wake up" their `__aexit__()` with cancellation requests for the task in which they are running made by other parties. In particular, when one task group is syntactically nested in another, and both experience an exception in one of their child tasks simultaneously, the inner task group will process its exceptions, and then the outer task group will receive another cancellation and process its own exceptions.

In the case where a task group is cancelled externally and also must raise an *ExceptionGroup*, it will call the parent task's *cancel()* method. This ensures that a *asyncio.CancelledError* will be raised at the next `await`, so the cancellation is not lost.

Task groups preserve the cancellation count reported by *asyncio.Task.cancelling()*.

在 3.13 版的變更: Improved handling of simultaneous internal and external cancellations and correct preservation of cancellation counts.

Terminating a Task Group

While terminating a task group is not natively supported by the standard library, termination can be achieved by adding an exception-raising task to the task group and ignoring the raised exception:

```
import asyncio
from asyncio import TaskGroup

class TerminateTaskGroup(Exception):
    """Exception raised to terminate a task group."""

async def force_terminate_task_group():
    """Used to force termination of a task group."""
    raise TerminateTaskGroup()

async def job(task_id, sleep_time):
    print(f'Task {task_id}: start')
    await asyncio.sleep(sleep_time)
    print(f'Task {task_id}: done')

async def main():
    try:
        async with TaskGroup() as group:
            # spawn some tasks
            group.create_task(job(1, 0.5))
            group.create_task(job(2, 1.5))
            # sleep for 1 second
            await asyncio.sleep(1)
            # add an exception-raising task to force the group to terminate
            group.create_task(force_terminate_task_group())
```

(繼續下一頁)

(繼續上一頁)

```
    except* TerminateTaskGroup:
        pass

asyncio.run(main())
```

預期的輸出：

```
Task 1: start
Task 2: start
Task 1: done
```

Sleeping

async asyncio.**sleep**(*delay*, *result=None*)

Block for *delay* seconds.

If *result* is provided, it is returned to the caller when the coroutine completes.

`sleep()` always suspends the current task, allowing other tasks to run.

Setting the delay to 0 provides an optimized path to allow other tasks to run. This can be used by long-running functions to avoid blocking the event loop for the full duration of the function call.

Example of coroutine displaying the current date every second for 5 seconds:

```
import asyncio
import datetime

async def display_date():
    loop = asyncio.get_running_loop()
    end_time = loop.time() + 5.0
    while True:
        print(datetime.datetime.now())
        if (loop.time() + 1.0) >= end_time:
            break
        await asyncio.sleep(1)

asyncio.run(display_date())
```

在 3.10 版的變更: 移除 *loop* 參數。

在 3.13 版的變更: 如果 *delay* 是*nan*，則引發*ValueError*。

Running Tasks Concurrently

awaitable asyncio.**gather**(**aws*, *return_exceptions=False*)

Run *awaitable objects* in the *aws* sequence *concurrently*.

If any awaitable in *aws* is a coroutine, it is automatically scheduled as a Task.

If all awaitables are completed successfully, the result is an aggregate list of returned values. The order of result values corresponds to the order of awaitables in *aws*.

If *return_exceptions* is `False` (default), the first raised exception is immediately propagated to the task that awaits on `gather()`. Other awaitables in the *aws* sequence **won't be cancelled** and will continue to run.

If *return_exceptions* is `True`, exceptions are treated the same as successful results, and aggregated in the result list.

If `gather()` is *cancelled*, all submitted awaitables (that have not completed yet) are also *cancelled*.

If any Task or Future from the *aws* sequence is *cancelled*, it is treated as if it raised *CancelledError* -- the `gather()` call is **not** cancelled in this case. This is to prevent the cancellation of one submitted Task/Future to cause other Tasks/Futures to be cancelled.

> **備🄵**
>
> A new alternative to create and run tasks concurrently and wait for their completion is `asyncio.TaskGroup`. *TaskGroup* provides stronger safety guarantees than *gather* for scheduling a nesting of subtasks: if a task (or a subtask, a task scheduled by a task) raises an exception, *TaskGroup* will, while *gather* will not, cancel the remaining scheduled tasks).

範例：

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number + 1):
        print(f"Task {name}: Compute factorial({number}), currently i={i}...")
        await asyncio.sleep(1)
        f *= i
    print(f"Task {name}: factorial({number}) = {f}")
    return f

async def main():
    # Schedule three calls *concurrently*:
    L = await asyncio.gather(
        factorial("A", 2),
        factorial("B", 3),
        factorial("C", 4),
    )
    print(L)

asyncio.run(main())

# Expected output:
#
#     Task A: Compute factorial(2), currently i=2...
#     Task B: Compute factorial(3), currently i=2...
#     Task C: Compute factorial(4), currently i=2...
#     Task A: factorial(2) = 2
#     Task B: Compute factorial(3), currently i=3...
#     Task C: Compute factorial(4), currently i=3...
#     Task B: factorial(3) = 6
#     Task C: Compute factorial(4), currently i=4...
#     Task C: factorial(4) = 24
#     [2, 6, 24]
```

> **備🄵**
>
> If *return_exceptions* is false, cancelling gather() after it has been marked done won't cancel any submitted awaitables. For instance, gather can be marked done after propagating an exception to the caller, therefore, calling `gather.cancel()` after catching an exception (raised by one of the awaitables) from gather won't cancel any other awaitables.

在 3.7 版的變更: If the *gather* itself is cancelled, the cancellation is propagated regardless of *return_exceptions*.

在 3.10 版的變更: 移除 *loop* 參數。

在 3.10 版之後被🄴用: Deprecation warning is emitted if no positional arguments are provided or not all positional arguments are Future-like objects and there is no running event loop.

Eager Task Factory

asyncio.**eager_task_factory**(*loop*, *coro*, *, *name=None*, *context=None*)

A task factory for eager task execution.

When using this factory (via *loop.set_task_factory(asyncio.eager_task_factory)*), coroutines begin execution synchronously during *Task* construction. Tasks are only scheduled on the event loop if they block. This can be a performance improvement as the overhead of loop scheduling is avoided for coroutines that complete synchronously.

A common example where this is beneficial is coroutines which employ caching or memoization to avoid actual I/O when possible.

> **備🄵**
>
> Immediate execution of the coroutine is a semantic change. If the coroutine returns or raises, the task is never scheduled to the event loop. If the coroutine execution blocks, the task is scheduled to the event loop. This change may introduce behavior changes to existing applications. For example, the application's task execution order is likely to change.

在 3.12 版被加入.

asyncio.**create_eager_task_factory**(*custom_task_constructor*)

Create an eager task factory, similar to *eager_task_factory()*, using the provided *custom_task_constructor* when creating a new task instead of the default *Task*.

custom_task_constructor must be a *callable* with the signature matching the signature of *Task.__init__*. The callable must return a *asyncio.Task*-compatible object.

This function returns a *callable* intended to be used as a task factory of an event loop via *loop.set_task_factory(factory)*).

在 3.12 版被加入.

Shielding From Cancellation

awaitable asyncio.**shield**(*aw*)

Protect an *awaitable object* from being *cancelled*.

If *aw* is a coroutine it is automatically scheduled as a Task.

The statement:

```
task = asyncio.create_task(something())
res = await shield(task)
```

is equivalent to:

```
res = await something()
```

except that if the coroutine containing it is cancelled, the Task running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. Although its caller is still cancelled, so the "await" expression still raises a *CancelledError*.

If `something()` is cancelled by other means (i.e. from within itself) that would also cancel `shield()`.

If it is desired to completely ignore cancellation (not recommended) the `shield()` function should be combined with a try/except clause, as follows:

```
task = asyncio.create_task(something())
try:
    res = await shield(task)
```

(繼續下一頁)

(繼續上一頁)

```
except CancelledError:
    res = None
```

重要

Save a reference to tasks passed to this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn't referenced elsewhere may get garbage collected at any time, even before it's done.

在 3.10 版的變更: 移除 *loop* 參數。

在 3.10 版之後被🄵用: Deprecation warning is emitted if *aw* is not Future-like object and there is no running event loop.

Timeouts

`asyncio.timeout`(*delay*)

Return an asynchronous context manager that can be used to limit the amount of time spent waiting on something.

delay can either be `None`, or a float/int number of seconds to wait. If *delay* is `None`, no time limit will be applied; this can be useful if the delay is unknown when the context manager is created.

In either case, the context manager can be rescheduled after creation using *Timeout.reschedule()*.

範例:

```
async def main():
    async with asyncio.timeout(10):
        await long_running_task()
```

If `long_running_task` takes more than 10 seconds to complete, the context manager will cancel the current task and handle the resulting *asyncio.CancelledError* internally, transforming it into a *TimeoutError* which can be caught and handled.

備🄵

The *asyncio.timeout()* context manager is what transforms the *asyncio.CancelledError* into a *TimeoutError*, which means the *TimeoutError* can only be caught *outside* of the context manager.

Example of catching *TimeoutError*:

```
async def main():
    try:
        async with asyncio.timeout(10):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we've handled it.")

    print("This statement will run regardless.")
```

The context manager produced by *asyncio.timeout()* can be rescheduled to a different deadline and inspected.

class `asyncio.Timeout`(*when*)

An asynchronous context manager for cancelling overdue coroutines.

`when` should be an absolute time at which the context should time out, as measured by the event loop's clock:

- If `when` is `None`, the timeout will never trigger.
- If `when < loop.time()`, the timeout will trigger on the next iteration of the event loop.

when() → *float* | *None*
Return the current deadline, or `None` if the current deadline is not set.

reschedule(*when:* float | None)
Reschedule the timeout.

expired() → *bool*
Return whether the context manager has exceeded its deadline (expired).

範例：

```
async def main():
    try:
        # We do not know the timeout when starting, so we pass ``None``.
        async with asyncio.timeout(None) as cm:
            # We know the timeout now, so we reschedule it.
            new_deadline = get_running_loop().time() + 10
            cm.reschedule(new_deadline)

            await long_running_task()
    except TimeoutError:
        pass

    if cm.expired():
        print("Looks like we haven't finished on time.")
```

Timeout context managers can be safely nested.

在 3.11 版被加入.

asyncio.**timeout_at**(*when*)
Similar to *asyncio.timeout()*, except *when* is the absolute time to stop waiting, or `None`.

範例：

```
async def main():
    loop = get_running_loop()
    deadline = loop.time() + 20
    try:
        async with asyncio.timeout_at(deadline):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we've handled it.")

    print("This statement will run regardless.")
```

在 3.11 版被加入.

async asyncio.**wait_for**(*aw*, *timeout*)
Wait for the *aw* *awaitable* to complete with a timeout.

If *aw* is a coroutine it is automatically scheduled as a Task.

timeout can either be `None` or a float or int number of seconds to wait for. If *timeout* is `None`, block until the future completes.

If a timeout occurs, it cancels the task and raises *TimeoutError*.

To avoid the task *cancellation*, wrap it in *shield()*.

The function will wait until the future is actually cancelled, so the total wait time may exceed the *timeout*. If an exception happens during cancellation, it is propagated.

If the wait is cancelled, the future *aw* is also cancelled.

範例：

```
async def eternity():
    # Sleep for one hour
    await asyncio.sleep(3600)
    print('yay!')

async def main():
    # Wait for at most 1 second
    try:
        await asyncio.wait_for(eternity(), timeout=1.0)
    except TimeoutError:
        print('timeout!')

asyncio.run(main())

# Expected output:
#
#     timeout!
```

在 3.7 版的變更: When *aw* is cancelled due to a timeout, `wait_for` waits for *aw* to be cancelled. Previously, it raised *TimeoutError* immediately.

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: 引發*TimeoutError* 而不是*asyncio.TimeoutError*。

Waiting Primitives

async asyncio.**wait**(*aws*, *, *timeout=None*, *return_when=ALL_COMPLETED*)

Run *Future* and *Task* instances in the *aws* iterable concurrently and block until the condition specified by *return_when*.

The *aws* iterable must not be empty.

Returns two sets of Tasks/Futures: `(done, pending)`.

用法：

```
done, pending = await asyncio.wait(aws)
```

timeout (a float or int), if specified, can be used to control the maximum number of seconds to wait before returning.

Note that this function does not raise *TimeoutError*. Futures or Tasks that aren't done when the timeout occurs are simply returned in the second set.

return_when indicates when this function should return. It must be one of the following constants:

常數	描述
asyncio.**FIRST_COMPLETED**	The function will return when any future finishes or is cancelled.
asyncio.**FIRST_EXCEPTION**	The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to *ALL_COMPLETED*.
asyncio.**ALL_COMPLETED**	The function will return when all futures finish or are cancelled.

Unlike *wait_for()*, `wait()` does not cancel the futures when a timeout occurs.

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: Passing coroutine objects to `wait()` directly is forbidden.

在 3.12 版的變更: Added support for generators yielding tasks.

`asyncio.`**`as_completed`**(*aws*, *, *timeout=None*)

Run *awaitable objects* in the *aws* iterable concurrently. The returned object can be iterated to obtain the results of the awaitables as they finish.

The object returned by `as_completed()` can be iterated as an *asynchronous iterator* or a plain *iterator*. When asynchronous iteration is used, the originally-supplied awaitables are yielded if they are tasks or futures. This makes it easy to correlate previously-scheduled tasks with their results. Example:

```
ipv4_connect = create_task(open_connection("127.0.0.1", 80))
ipv6_connect = create_task(open_connection("::1", 80))
tasks = [ipv4_connect, ipv6_connect]

async for earliest_connect in as_completed(tasks):
    # earliest_connect is done. The result can be obtained by
    # awaiting it or calling earliest_connect.result()
    reader, writer = await earliest_connect

    if earliest_connect is ipv6_connect:
        print("IPv6 connection established.")
    else:
        print("IPv4 connection established.")
```

During asynchronous iteration, implicitly-created tasks will be yielded for supplied awaitables that aren't tasks or futures.

When used as a plain iterator, each iteration yields a new coroutine that returns the result or raises the exception of the next completed awaitable. This pattern is compatible with Python versions older than 3.13:

```
ipv4_connect = create_task(open_connection("127.0.0.1", 80))
ipv6_connect = create_task(open_connection("::1", 80))
tasks = [ipv4_connect, ipv6_connect]

for next_connect in as_completed(tasks):
    # next_connect is not one of the original task objects. It must be
    # awaited to obtain the result value or raise the exception of the
    # awaitable that finishes next.
    reader, writer = await next_connect
```

A *TimeoutError* is raised if the timeout occurs before all awaitables are done. This is raised by the `async for` loop during asynchronous iteration or by the coroutines yielded during plain iteration.

在 3.10 版的變更: 移除 *loop* 參數。

在 3.10 版之後被🄴用: Deprecation warning is emitted if not all awaitable objects in the *aws* iterable are Future-like objects and there is no running event loop.

在 3.12 版的變更: Added support for generators yielding tasks.

在 3.13 版的變更: The result can now be used as either an *asynchronous iterator* or as a plain *iterator* (previously it was only a plain iterator).

Running in Threads

`async` `asyncio.`**`to_thread`**(*func*, */*, **args*, ***kwargs*)

Asynchronously run function *func* in a separate thread.

Any *args and **kwargs supplied for this function are directly passed to *func*. Also, the current *contextvars.Context* is propagated, allowing context variables from the event loop thread to be accessed in the separate thread.

Return a coroutine that can be awaited to get the eventual result of *func*.

This coroutine function is primarily intended to be used for executing IO-bound functions/methods that would otherwise block the event loop if they were run in the main thread. For example:

```
def blocking_io():
    print(f"start blocking_io at {time.strftime('%X')}")
    # Note that time.sleep() can be replaced with any blocking
    # IO-bound operation, such as file operations.
    time.sleep(1)
    print(f"blocking_io complete at {time.strftime('%X')}")

async def main():
    print(f"started main at {time.strftime('%X')}")

    await asyncio.gather(
        asyncio.to_thread(blocking_io),
        asyncio.sleep(1))

    print(f"finished main at {time.strftime('%X')}")

asyncio.run(main())

# Expected output:
#
# started main at 19:50:53
# start blocking_io at 19:50:53
# blocking_io complete at 19:50:54
# finished main at 19:50:54
```

Directly calling `blocking_io()` in any coroutine would block the event loop for its duration, resulting in an additional 1 second of run time. Instead, by using `asyncio.to_thread()`, we can run it in a separate thread without blocking the event loop.

備F

Due to the *GIL*, `asyncio.to_thread()` can typically only be used to make IO-bound functions non-blocking. However, for extension modules that release the GIL or alternative Python implementations that don't have one, `asyncio.to_thread()` can also be used for CPU-bound functions.

在 3.9 版被加入.

Scheduling From Other Threads

`asyncio.`**`run_coroutine_threadsafe`**(*coro*, *loop*)

Submit a coroutine to the given event loop. Thread-safe.

Return a *`concurrent.futures.Future`* to wait for the result from another OS thread.

This function is meant to be called from a different OS thread than the one where the event loop is running. Example:

```
def in_thread(loop: asyncio.AbstractEventLoop) -> None:
    # Run some blocking IO
    pathlib.Path("example.txt").write_text("hello world", encoding="utf8")

    # Create a coroutine
    coro = asyncio.sleep(1, result=3)

    # Submit the coroutine to a given loop
```

(繼續下一頁)

(繼續上一頁)

```
    future = asyncio.run_coroutine_threadsafe(coro, loop)

    # Wait for the result with an optional timeout argument
    assert future.result(timeout=2) == 3

async def amain() -> None:
    # Get the running loop
    loop = asyncio.get_running_loop()

    # Run something in a thread
    await asyncio.to_thread(in_thread, loop)
```

It's also possible to run the other way around. Example:

```
@contextlib.contextmanager
def loop_in_thread() -> Generator[asyncio.AbstractEventLoop]:
    loop_fut = concurrent.futures.Future[asyncio.AbstractEventLoop]()
    stop_event = asyncio.Event()

    async def main() -> None:
        loop_fut.set_result(asyncio.get_running_loop())
        await stop_event.wait()

    with concurrent.futures.ThreadPoolExecutor(1) as tpe:
        complete_fut = tpe.submit(asyncio.run, main())
        for fut in concurrent.futures.as_completed((loop_fut, complete_fut)):
            if fut is loop_fut:
                loop = loop_fut.result()
                try:
                    yield loop
                finally:
                    loop.call_soon_threadsafe(stop_event.set)
            else:
                fut.result()

# Create a loop in another thread
with loop_in_thread() as loop:
    # Create a coroutine
    coro = asyncio.sleep(1, result=3)

    # Submit the coroutine to a given loop
    future = asyncio.run_coroutine_threadsafe(coro, loop)

    # Wait for the result with an optional timeout argument
    assert future.result(timeout=2) == 3
```

If an exception is raised in the coroutine, the returned Future will be notified. It can also be used to cancel the task in the event loop:

```
try:
    result = future.result(timeout)
except TimeoutError:
    print('The coroutine took too long, cancelling the task...')
    future.cancel()
except Exception as exc:
    print(f'The coroutine raised an exception: {exc!r}')
else:
    print(f'The coroutine returned: {result!r}')
```

See the *concurrency and multithreading* section of the documentation.

Unlike other asyncio functions this function requires the *loop* argument to be passed explicitly.

在 3.5.1 版被加入.

Introspection

asyncio.**current_task**(*loop=None*)

Return the currently running *Task* instance, or `None` if no task is running.

If *loop* is `None` *get_running_loop()* is used to get the current loop.

在 3.7 版被加入.

asyncio.**all_tasks**(*loop=None*)

Return a set of not yet finished *Task* objects run by the loop.

If *loop* is `None`, *get_running_loop()* is used for getting current loop.

在 3.7 版被加入.

asyncio.**iscoroutine**(*obj*)

Return `True` if *obj* is a coroutine object.

在 3.4 版被加入.

Task 物件

class asyncio.**Task**(*coro*, *, *loop=None*, *name=None*, *context=None*, *eager_start=False*)

A *Future-like* object that runs a Python *coroutine*. Not thread-safe.

Tasks are used to run coroutines in event loops. If a coroutine awaits on a Future, the Task suspends the execution of the coroutine and waits for the completion of the Future. When the Future is *done*, the execution of the wrapped coroutine resumes.

Event loops use cooperative scheduling: an event loop runs one Task at a time. While a Task awaits for the completion of a Future, the event loop runs other Tasks, callbacks, or performs IO operations.

Use the high-level *asyncio.create_task()* function to create Tasks, or the low-level *loop.create_task()* or *ensure_future()* functions. Manual instantiation of Tasks is discouraged.

To cancel a running Task use the *cancel()* method. Calling it will cause the Task to throw a *CancelledError* exception into the wrapped coroutine. If a coroutine is awaiting on a Future object during cancellation, the Future object will be cancelled.

cancelled() can be used to check if the Task was cancelled. The method returns `True` if the wrapped coroutine did not suppress the *CancelledError* exception and was actually cancelled.

asyncio.Task inherits from *Future* all of its APIs except *Future.set_result()* and *Future.set_exception()*.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the *coro* to run in. If no *context* is provided, the Task copies the current context and later runs its coroutine in the copied context.

An optional keyword-only *eager_start* argument allows eagerly starting the execution of the *asyncio.Task* at task creation time. If set to `True` and the event loop is running, the task will start executing the coroutine immediately, until the first time the coroutine blocks. If the coroutine returns or raises without blocking, the task will be finished eagerly and will skip scheduling to the event loop.

在 3.7 版的變更: 新增對*contextvars* 模組的支援。

在 3.8 版的變更: 新增 *name* 參數。

在 3.10 版之後被🄵用: Deprecation warning is emitted if *loop* is not specified and there is no running event loop.

在 3.11 版的變更: 新增 *context* 參數。

在 3.12 版的變更: 新增 *eager_start* 參數。

done()

Return `True` if the Task is *done*.

A Task is *done* when the wrapped coroutine either returned a value, raised an exception, or the Task was cancelled.

result()

Return the result of the Task.

If the Task is *done*, the result of the wrapped coroutine is returned (or if the coroutine raised an exception, that exception is re-raised.)

If the Task has been *cancelled*, this method raises a *CancelledError* exception.

If the Task's result isn't yet available, this method raises an *InvalidStateError* exception.

exception()

Return the exception of the Task.

If the wrapped coroutine raised an exception that exception is returned. If the wrapped coroutine returned normally this method returns `None`.

If the Task has been *cancelled*, this method raises a *CancelledError* exception.

If the Task isn't *done* yet, this method raises an *InvalidStateError* exception.

add_done_callback(*callback*, *, *context=None*)

Add a callback to be run when the Task is *done*.

This method should only be used in low-level callback-based code.

See the documentation of *Future.add_done_callback()* for more details.

remove_done_callback(*callback*)

Remove *callback* from the callbacks list.

This method should only be used in low-level callback-based code.

See the documentation of *Future.remove_done_callback()* for more details.

get_stack(*, *limit=None*)

Return the list of stack frames for this Task.

If the wrapped coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

Only one stack frame is returned for a suspended coroutine.

The optional *limit* argument sets the maximum number of frames to return; by default all available frames are returned. The ordering of the returned list differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

print_stack(*, *limit=None*, *file=None*)

Print the stack or traceback for this Task.

This produces output similar to that of the traceback module for the frames retrieved by *get_stack()*.

The *limit* argument is passed to *get_stack()* directly.

The *file* argument is an I/O stream to which the output is written; by default output is written to *sys.stdout*.

get_coro()

Return the coroutine object wrapped by the *Task*.

> **備🄵**
>
> This will return None for Tasks which have already completed eagerly. See the *Eager Task Factory*.

在 3.8 版被加入.

在 3.12 版的變更: Newly added eager task execution means result may be None.

get_context()

Return the *contextvars.Context* object associated with the task.

在 3.12 版被加入.

get_name()

Return the name of the Task.

If no name has been explicitly assigned to the Task, the default asyncio Task implementation generates a default name during instantiation.

在 3.8 版被加入.

set_name(*value*)

Set the name of the Task.

The *value* argument can be any object, which is then converted to a string.

In the default Task implementation, the name will be visible in the *repr()* output of a task object.

在 3.8 版被加入.

cancel(*msg=None*)

Request the Task to be cancelled.

If the Task is already *done* or *cancelled*, return False, otherwise, return True.

The method arranges for a *CancelledError* exception to be thrown into the wrapped coroutine on the next cycle of the event loop.

The coroutine then has a chance to clean up or even deny the request by suppressing the exception with a try ... ... except CancelledError ... finally block. Therefore, unlike *Future.cancel()*, *Task.cancel()* does not guarantee that the Task will be cancelled, although suppressing cancellation completely is not common and is actively discouraged. Should the coroutine nevertheless decide to suppress the cancellation, it needs to call *Task.uncancel()* in addition to catching the exception.

在 3.9 版的變更: 新增 *msg* 參數。

在 3.11 版的變更: The msg parameter is propagated from cancelled task to its awaiter. The following example illustrates how coroutines can intercept the cancellation request:

```
async def cancel_me():
    print('cancel_me(): before sleep')

    try:
        # Wait for 1 hour
        await asyncio.sleep(3600)
    except asyncio.CancelledError:
        print('cancel_me(): cancel sleep')
        raise
    finally:
        print('cancel_me(): after sleep')
```

(繼續下一頁)

(繼續上一頁)

```
async def main():
    # Create a "cancel_me" Task
    task = asyncio.create_task(cancel_me())

    # Wait for 1 second
    await asyncio.sleep(1)

    task.cancel()
    try:
        await task
    except asyncio.CancelledError:
        print("main(): cancel_me is cancelled now")

asyncio.run(main())

# Expected output:
#
#     cancel_me(): before sleep
#     cancel_me(): cancel sleep
#     cancel_me(): after sleep
#     main(): cancel_me is cancelled now
```

cancelled()

Return `True` if the Task is *cancelled*.

The Task is *cancelled* when the cancellation was requested with *cancel()* and the wrapped coroutine propagated the *CancelledError* exception thrown into it.

uncancel()

Decrement the count of cancellation requests to this Task.

Returns the remaining number of cancellation requests.

Note that once execution of a cancelled task completed, further calls to *uncancel()* are ineffective.

在 3.11 版被加入.

This method is used by asyncio's internals and isn't expected to be used by end-user code. In particular, if a Task gets successfully uncancelled, this allows for elements of structured concurrency like *Task Groups* and *asyncio.timeout()* to continue running, isolating cancellation to the respective structured block. For example:

```
async def make_request_with_timeout():
    try:
        async with asyncio.timeout(1):
            # Structured block affected by the timeout:
            await make_request()
            await make_another_request()
    except TimeoutError:
        log("There was a timeout")
    # Outer code not affected by the timeout:
    await unrelated_code()
```

While the block with `make_request()` and `make_another_request()` might get cancelled due to the timeout, `unrelated_code()` should continue running even in case of the timeout. This is implemented with *uncancel()*. *TaskGroup* context managers use *uncancel()* in a similar fashion.

If end-user code is, for some reason, suppressing cancellation by catching *CancelledError*, it needs to call this method to remove the cancellation state.

When this method decrements the cancellation count to zero, the method checks if a previous *cancel()* call had arranged for *CancelledError* to be thrown into the task. If it hasn't been thrown yet, that arrangement will be rescinded (by resetting the internal `_must_cancel` flag).

在 3.13 版的變更: Changed to rescind pending cancellation requests upon reaching zero.

cancelling()

Return the number of pending cancellation requests to this Task, i.e., the number of calls to *cancel()* less the number of *uncancel()* calls.

Note that if this number is greater than zero but the Task is still executing, *cancelled()* will still return `False`. This is because this number can be lowered by calling *uncancel()*, which can lead to the task not being cancelled after all if the cancellation requests go down to zero.

This method is used by asyncio's internals and isn't expected to be used by end-user code. See *uncancel()* for more details.

在 3.11 版被加入.

19.1.3 串流

原始碼： Lib/asyncio/streams.py

串流是支援 async/await (async/await-ready) 的高階原始物件 (high-level primitive)，用於處理網路連🄵。串流不需要使用回呼 (callback) 或低階協定和傳輸 (transport) 就能🄵傳送和接收資料。

這是一個使用 asyncio 串流編寫的 TCP echo 用🄵端範例：

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()
    await writer.wait_closed()

asyncio.run(tcp_echo_client('Hello World!'))
```

另請參🄵下方*Examples* 段落。

串流函式

下面的高階 asyncio 函式可以用來建立和處理串流：

async asyncio.**open_connection**(*host=None*, *port=None*, ***, *limit=None*, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *happy_eyeballs_delay=None*, *interleave=None*)

建立網路連🄵🄵回傳一對 `(reader, writer)` 物件。

回傳的 *reader* 和 *writer* 物件是*StreamReader* 和*StreamWriter* 類🄵的實例。

limit 指定了回傳的*StreamReader* 實例所使用的緩衝區 (buffer) 大小限制。*limit* 預設🄵 64 KiB。

其余的引數會直接傳遞到*loop.create_connection()*。

> **備🄵**
>
> The *sock* argument transfers ownership of the socket to the `StreamWriter` created. To close the socket, call its `close()` method.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 參數。

在 3.8 版的變更: 新增 *happy_eyeballs_delay* 和 *interleave* 參數。

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: 新增 *ssl_shutdown_timeout* 參數。

async asyncio.**start_server**(*client_connected_cb*, *host=None*, *port=None*, *, *limit=None*, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *keep_alive=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*)

🄵動 socket 伺服器。

當一個新的用🄵端連🄵被建立時，回呼函式 *client_connected_cb* 就會被呼叫。該函式會接收到一對引數 `(reader, writer)`，分🄵🄵`StreamReader` 和`StreamWriter` 的實例。

client_connected_cb 既可以是普通的可呼叫物件 (callable)，也可以是一個協程函式；如果它是一個協程函式，它將自動作🄵`Task` 來被排程。

limit 指定了回傳的`StreamReader` 實例所使用的緩衝區 (buffer) 大小限制。*limit* 預設🄵 64 KiB。

剩下的引數將會直接傳遞給`loop.create_server()`。

> **備🄵**
>
> The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's `close()` method.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 與 *start_serving* 參數。

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: 新增 *ssl_shutdown_timeout* 參數。

在 3.13 版的變更: 新增 *keep_alive* 參數。

Unix Sockets

async asyncio.**open_unix_connection**(*path=None*, *, *limit=None*, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

建立一個 Unix socket 連🄵🄵回傳一對 `(reader, writer)`。

與`open_connection()` 相似，但是是操作 Unix sockets。

另請參🄵`loop.create_unix_connection()` 文件。

> **備🄵**
>
> The *sock* argument transfers ownership of the socket to the `StreamWriter` created. To close the socket, call its `close()` method.

可用性: Unix.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 參數。*path* 參數現在可以是個*path-like object*

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: 新增 *ssl_shutdown_timeout* 參數。

async asyncio.**start_unix_server**(*client_connected_cb*, *path=None*, ***, *limit=None*, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*, *cleanup_socket=True*)

🄵動一個 Unix socket 伺服器。

與*start_server()* 相似，但會是操作 Unix sockets。

If *cleanup_socket* is true then the Unix socket will automatically be removed from the filesystem when the server is closed, unless the socket has been replaced after the server has been created.

另請參🄵*loop.create_unix_server()* 文件。

備🄵

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's *close()* method.

可用性: Unix.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 與 *start_serving* 參數。*path* 參數現在可以是個*path-like object*。

在 3.10 版的變更: 移除 *loop* 參數。

在 3.11 版的變更: 新增 *ssl_shutdown_timeout* 參數。

在 3.13 版的變更: 新增 *cleanup_socket* 參數。

StreamReader

class asyncio.**StreamReader**

表示一個有提供 API 來從 IO 串流中讀取資料的 reader 物件。作🄵一個*asynchronous iterable*，此物件支援 `async for` 陳述式。

不建議直接實例化 *StreamReader* 物件；使用*open_connection()* 和*start_server()* 會是較好的做法。

feed_eof()

Acknowledge the EOF.

async read(*n=-1*)

從串流中讀取至多 *n* 個位元組的資料。

如果🄵有設定 *n* 或是被設🄵 `-1`，則會持續讀取直到 EOF，然後回傳所有讀取到的*bytes*。讀取到 EOF 且🄵部緩衝區是空的，則回傳一個空的 `bytes` 物件。

如果 *n* 🄵 `0`，則立即回傳一個空的 `bytes` 物件。

If *n* is positive, return at most *n* available `bytes` as soon as at least 1 byte is available in the internal buffer. If EOF is received before any byte is read, return an empty `bytes` object.

async readline()

讀取一行，其中" 行" 指的是以 `\n` 結尾的位元組序列。

如果讀取到 EOF 而🄵有找到 `\n`，該方法會回傳部分的已讀取資料。

如果讀取到 EOF 且🄵部緩衝區是空的，則回傳一個空的 `bytes` 物件。

async readexactly(*n*)

讀取剛好 *n* 個位元組。

如果在讀取完 *n* 個位元組之前讀取到 EOF，則會引發*IncompleteReadError*。使用*IncompleteReadError.partial* 屬性來取得串流結束前已讀取的部分資料。

async readuntil(*separator=b'\n'*)

從串流中持續讀取資料直到出現 *separator*。

成功後，資料和 separator（分隔符號）會從🄵部緩衝區中🄵除（或者🄵是被消費掉 (consumed)）。回傳的資料在末尾會有一個 separator。

如果讀取的資料量超過了設定的串流限制，將會引發*LimitOverrunError* 例外，資料將被留在🄵部緩衝區中，🄵可以再次被讀取。

如果在完整的 separator 被找到之前就讀取到 EOF，則會引發*IncompleteReadError* 例外，且🄵部緩衝區會被重置。*IncompleteReadError.partial* 屬性可能包含一部分的 separator。

The *separator* may also be a tuple of separators. In this case the return value will be the shortest possible that has any separator as the suffix. For the purposes of *LimitOverrunError*, the shortest possible separator is considered to be the one that matched.

在 3.5.2 版被加入.

在 3.13 版的變更: 現在 *separator* 參數可以是一個分隔符號的*tuple*。

at_eof()

如果緩衝區是空的且*feed_eof()* 曾被呼叫則回傳 `True`。

StreamWriter

class asyncio.**StreamWriter**

表示一個有提供 API 來將資料寫入 IO 串流的 writer 物件。

不建議直接實例化 *StreamWriter* 物件；使用*open_connection()* 和*start_server()* 會是較好的做法。

write(*data*)

此方法會嘗試立即將 *data* 寫入到底層的 socket。如果失敗，資料會被放到🄵部寫入緩衝中排隊等待 (queue)，直到它可被發送。

此方法應當與 `drain()` 方法一起使用：

```
stream.write(data)
await stream.drain()
```

> **備🄵**
>
> The *data* buffer should be a C contiguous one-dimensional *bytes-like object*.

writelines(*data*)

此方法會立即嘗試將一個位元組 list（或任何可🄵代物件 (iterable)）寫入到底層的 socket。如果失敗，資料會被放到🄵部寫入緩衝中排隊等待，直到它可被發送。

此方法應當與 `drain()` 方法一起使用：

```
stream.writelines(lines)
await stream.drain()
```

close()

此方法會關閉串流以及底層的 socket。

此方法應與 `wait_closed()` 方法一起使用，但🄵非🄵制：

```
stream.close()
await stream.wait_closed()
```

can_write_eof()

如果底層的傳輸支援*write_eof()* 方法就回傳 `True`，否則回傳 `False`。

write_eof()

在已緩衝的寫入資料被清理 (flush) 後關閉串流的寫入端。

transport

回傳底層的 asyncio 傳輸。

get_extra_info(*name*, *default=None*)

存取可選的傳輸資訊；詳情請見*BaseTransport.get_extra_info()*。

async drain()

等待直到可以繼續寫入到串流。範例：

```
writer.write(data)
await writer.drain()
```

這是一個與底層 IO 寫入緩衝區互動的流程控制方法。當緩衝區大小達到最高標記位 (high watermark) 時，*drain()* 會阻塞直到緩衝區大小🄵少至最低標記位 (low watermark) 以便繼續寫入。當🄵有要等待的資料時，*drain()* 會立即回傳。

async start_tls(*sslcontext*, *, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

將現有的基於串流的連🄵升級到 TLS。

參數：

- *sslcontext*：一個*SSLContext* 的已配置實例。
- *server_hostname*：設定或覆寫將會被目標伺服器憑證比對的主機名稱。
- *ssl_handshake_timeout* is the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- *ssl_shutdown_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

在 3.11 版被加入.

在 3.12 版的變更: 新增 *ssl_shutdown_timeout* 參數。

is_closing()

如果串流已被關閉或正在被關閉則回傳 `True`。

在 3.7 版被加入.

async wait_closed()

等待直到串流被關閉。

應當在*close()* 之後才被呼叫，這會持續等待直到底層的連🄵被關閉，以確保在這之前（例如在程式退出前）所有資料都已經被清空

在 3.7 版被加入.

范例

使用串流的 TCP echo 用🄵端

使用*asyncio.open_connection()* 函式的 TCP echo 用🄵端：

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()
    await writer.wait_closed()

asyncio.run(tcp_echo_client('Hello World!'))
```

也參考

使用低階*loop.create_connection()* 方法的*TCP echo* 用🄵端協定範例。

使用串流的 TCP echo 伺服器

TCP echo 伺服器使用*asyncio.start_server()* 函式：

```
import asyncio

async def handle_echo(reader, writer):
    data = await reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')

    print(f"Received {message!r} from {addr!r}")

    print(f"Send: {message!r}")
    writer.write(data)
    await writer.drain()

    print("Close the connection")
    writer.close()
    await writer.wait_closed()

async def main():
    server = await asyncio.start_server(
        handle_echo, '127.0.0.1', 8888)

    addrs = ', '.join(str(sock.getsockname()) for sock in server.sockets)
    print(f'Serving on {addrs}')

    async with server:
        await server.serve_forever()

asyncio.run(main())
```

也參考

使用*loop.create_server()* 方法的*TCP echo 伺服器協定* 範例。

取得 HTTP 標頭

查詢自命令列傳入之 URL 所帶有 HTTP 標頭的簡單範例：

```
import asyncio
import urllib.parse
import sys

async def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        reader, writer = await asyncio.open_connection(
            url.hostname, 443, ssl=True)
    else:
        reader, writer = await asyncio.open_connection(
            url.hostname, 80)

    query = (
        f"HEAD {url.path or '/'} HTTP/1.0\r\n"
        f"Host: {url.hostname}\r\n"
        f"\r\n"
    )

    writer.write(query.encode('latin-1'))
    while True:
        line = await reader.readline()
        if not line:
            break

        line = line.decode('latin1').rstrip()
        if line:
            print(f'HTTP header> {line}')

    # Ignore the body, close the socket
    writer.close()
    await writer.wait_closed()

url = sys.argv[1]
asyncio.run(print_http_headers(url))
```

用法：

```
python example.py http://example.com/path/page.html
```

或使用 HTTPS：

```
python example.py https://example.com/path/page.html
```

🄵🄵一個使用串流來等待資料的開放 socket

等待直到 socket 透過使用*open_connection()* 函式接收到資料的協程：

```
import asyncio
import socket

async def wait_for_data():
    # Get a reference to the current event loop because
    # we want to access low-level APIs.
```

(繼續下一頁)

(繼續上一頁)

```
    loop = asyncio.get_running_loop()

    # Create a pair of connected sockets.
    rsock, wsock = socket.socketpair()

    # Register the open socket to wait for data.
    reader, writer = await asyncio.open_connection(sock=rsock)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = await reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()
    await writer.wait_closed()

    # Close the second socket
    wsock.close()

asyncio.run(wait_for_data())
```

也參考

在🄵🄵一個開🄵的 *socket* 以等待有使用協定的資料範例中，有使用了低階協定以及*loop.create_connection()* 方法。

在監視檔案描述器以讀取事件範例中，有使用低階的*loop.add_reader()* 方法來監視檔案描述器。

19.1.4 同步化原始物件 (Synchronization Primitives)

原始碼： Lib/asyncio/locks.py

---

asyncio 的同步化原始物件被設計成和那些*threading* 模組 (module) 中的同名物件相似，但有兩個重要的限制條件：

- asyncio 原始物件🄵不支援執行緒安全 (thread-safe)，因此他們不可被用於 OS 執行緒同步化（請改用*threading*）；
- 這些同步化原始物件的方法 (method) 🄵不接受 *timeout* 引數；要達成有超時 (timeout) 設定的操作請改用*asyncio.wait_for()* 函式。

asyncio 有以下基礎同步化原始物件：

- *Lock*
- *Event*
- *Condition*
- *Semaphore*
- *BoundedSemaphore*
- *Barrier*

Lock

class asyncio.**Lock**

實作了一個給 asyncio 任務 (task) 用的互斥鎖 (mutex lock)。不支援執行緒安全。

一個 asyncio 的鎖可以用來確保一個共享資源的存取權被獨🄴。

使用 Lock 的推薦方式是透過 `async with` 陳述式：

```
lock = asyncio.Lock()

# ... later
async with lock:
    # access shared state
```

這等價於：

```
lock = asyncio.Lock()

# ... later
await lock.acquire()
try:
    # access shared state
finally:
    lock.release()
```

在 3.10 版的變更: 移除 `loop` 參數。

async acquire()

獲得鎖。

此方法會持續等待直到鎖的狀態成🄵 *unlocked*，🄴將其設置🄵 *locked* 和回傳 `True`。

當多於一個的協程 (coroutine) 在*acquire()* 中等待解鎖而被阻塞，最終只會有其中的一個被處理。

鎖的取得方式是公平的：被處理的協程會是最早開始等待解鎖的那一個。

release()

釋放鎖。

如果鎖的狀態🄵 *locked* 則將其重置🄵 *unlocked* 🄴回傳。

如果鎖的狀態🄵 *unlocked* 則*RuntimeError* 會被引發。

locked()

如果鎖的狀態🄵 *locked* 則回傳 `True`。

Event

class asyncio.**Event**

一個事件 (event) 物件。不支援執行緒安全。

一個 asyncio 事件可以被用於通知多個有發生某些事件於其中的 asyncio 任務。

一個 Event 物件會管理一個🄴部旗標 (flag)，它可以透過*set()* 方法來被設🄵 *true* 🄴透過*clear()* 方法來重置🄵 *false*。*wait()* 方法會被阻塞 (block) 直到該旗標被設🄵 *true*。該旗標初始設置🄵 *false*。

在 3.10 版的變更: 移除 `loop` 參數。 範例：

```
async def waiter(event):
    print('waiting for it ...')
    await event.wait()
    print('... got it!')
```

(繼續下一頁)

(繼續上一頁)

```
async def main():
    # Create an Event object.
    event = asyncio.Event()

    # Spawn a Task to wait until 'event' is set.
    waiter_task = asyncio.create_task(waiter(event))

    # Sleep for 1 second and set the event.
    await asyncio.sleep(1)
    event.set()

    # Wait until the waiter task is finished.
    await waiter_task

asyncio.run(main())
```

async wait()

持續等待直到事件被設置。

如果事件有被設置則立刻回傳 `True`。否則持續阻塞直到另一個任務呼叫*set()*。

set()

設置事件。

所有正在等待事件被設置的任務會立即被🄵醒。

clear()

清除（還原）事件。

正透過*wait()* 等待的後續 Tasks 現在會持續阻塞直到*set()* 方法再次被呼叫。

is_set()

如果事件有被設置則回傳 `True`。

Condition

class asyncio.**Condition**(*lock=None*)

一個條件 (codition) 物件。不支援執行緒安全。

一個 asyncio 條件原始物件可以被任務用來等待某事件發生，🄵獲得一個共享資源的獨🄵存取權。

本質上，一個 Condition 物件會結合*Event* 和*Lock* 的功能。多個 Condition 物件共享一個 Lock 是有可能發生的，這能🄵協調關注同一共享資源的不同狀態以取得其獨🄵存取權的多個任務。

可選的 *lock* 引數必須是一個*Lock* 物件或者🄵 `None`。如🄵後者則一個新的 Lock 物件會被自動建立。

在 3.10 版的變更: 移除 `loop` 參數。

使用 Condition 的推薦方式是透過 `async with` 陳述式:

```
cond = asyncio.Condition()

# ... later
async with cond:
    await cond.wait()
```

這等價於:

```
cond = asyncio.Condition()

# ... later
await cond.acquire()
try:
```

(繼續下一頁)

(繼續上一頁)

```
    await cond.wait()
finally:
    cond.release()
```

async acquire()

取得底層的鎖。

此方法會持續等待直到底層的鎖🄵 *unlocked*，🄵將其設🄵 *locked* 🄵回傳 `True`。

notify(*n=1*)

🄵醒至多 *n* 個正在等待此條件的任務（預設🄵 1），如果少於 *n* 個任務則全部被🄵醒。

在此方法被呼叫前必須先獲得鎖，🄵在之後立刻將其釋放。如果呼叫於一個 *unlocked* 的鎖則*RuntimeError* 錯誤會被引發。

locked()

如果已取得底層的鎖則回傳 `True`。

notify_all()

🄵醒所有正在等待此條件的任務。

這個方法的行🄵就像*notify()*，但會🄵醒所有正在等待的任務。

在此方法被呼叫前必須先獲得鎖，🄵在之後立刻將其釋放。如果呼叫於一個 *unlocked* 的鎖則*RuntimeError* 錯誤會被引發。

release()

釋放底層的鎖。

當叫用於一個未被解開的鎖之上時，會引發一個*RuntimeError*。

async wait()

持續等待直到被通知 (notify)。

當此方法被呼叫時，如果呼叫它的任務還🄵有取得鎖的話，*RuntimeError* 會被引發。

此方法會釋放底層的鎖，然後持續阻塞直到被*notify()* 或*notify_all()* 的呼叫所🄵醒。一但被🄵醒，Condition 會重新取得該鎖且此方法會回傳 `True`。

Note that a task *may* return from this call spuriously, which is why the caller should always re-check the state and be prepared to *wait()* again. For this reason, you may prefer to use *wait_for()* instead.

async wait_for(*predicate*)

持續等待直到謂語 (predicate) 成🄵 *true*。

謂語必須是一個結果可被直譯🄵一個 boolean 值的可呼叫物件 (callable)。此方法會重🄵地*wait()* 直到謂語求值結果🄵 *true*。最終的值即🄵回傳值。

Semaphore

class asyncio.**Semaphore**(*value=1*)

一個旗號 (semaphore) 物件。不支援執行緒安全。

一個旗號物件會管理一個🄵部計數器，會在每次呼叫*acquire()* 時🄵少一、每次呼叫*release()* 時增加一。此計數器永遠不會少於零；當*acquire()* 發現它是零時，它會持續阻塞🄵等待某任務呼叫*release()*。

可選的 *value* 引數給定了🄵部計數器的初始值（預設🄵 `1`）。如給定的值少於 `0` 則*ValueError* 會被引發。

在 3.10 版的變更: 移除 `loop` 參數。

使用 Semaphore 的推薦方式是透過 `async with` 陳述式：

```
sem = asyncio.Semaphore(10)

# ... later
async with sem:
    # work with shared resource
```

這等價於：

```
sem = asyncio.Semaphore(10)

# ... later
await sem.acquire()
try:
    # work with shared resource
finally:
    sem.release()
```

async acquire()

取得一個旗號。

如果🄵部計數器大於零，將其🄵一🄵立刻回傳 `True`。如果🄵零，則持續等待直到*release()* 被呼叫，🄵回傳 `True`。

locked()

如果旗號無法立即被取得則回傳 `True`。

release()

釋放一個旗號，🄵🄵其🄵部的計數器數值增加一。可以把一個正在等待取得旗號的任務叫醒。

和*BoundedSemaphore* 不同，*Semaphore* 允許 `release()` 的呼叫次數多於 `acquire()`。

BoundedSemaphore

class asyncio.**BoundedSemaphore**(*value=1*)

一個有界的旗號物件。不支援執行緒安全。

Bounded Semaphore 是*Semaphore* 的另一版本，如果其🄵部的計數器數值增加至大於初始 *value* 值的話，*ValueError* 會在*release()* 時被引發。

在 3.10 版的變更: 移除 `loop` 參數。

Barrier

class asyncio.**Barrier**(*parties*)

一個屏障 (barrier) 物件。不支援執行緒安全。

A barrier is a simple synchronization primitive that allows to block until *parties* number of tasks are waiting on it. Tasks can wait on the *wait()* method and would be blocked until the specified number of tasks end up waiting on *wait()*. At that point all of the waiting tasks would unblock simultaneously.

`async with` can be used as an alternative to awaiting on *wait()*.

The barrier can be reused any number of times.

範例：

```
async def example_barrier():
   # barrier with 3 parties
   b = asyncio.Barrier(3)

   # create 2 new waiting tasks
   asyncio.create_task(b.wait())
   asyncio.create_task(b.wait())
```

(繼續下一頁)

(繼續上一頁)

```
    await asyncio.sleep(0)
    print(b)

    # The third .wait() call passes the barrier
    await b.wait()
    print(b)
    print("barrier passed")

    await asyncio.sleep(0)
    print(b)

asyncio.run(example_barrier())
```

Result of this example is:

```
<asyncio.locks.Barrier object at 0x... [filling, waiters:2/3]>
<asyncio.locks.Barrier object at 0x... [draining, waiters:0/3]>
barrier passed
<asyncio.locks.Barrier object at 0x... [filling, waiters:0/3]>
```

在 3.11 版被加入.

async wait()

Pass the barrier. When all the tasks party to the barrier have called this function, they are all unblocked simultaneously.

When a waiting or blocked task in the barrier is cancelled, this task exits the barrier which stays in the same state. If the state of the barrier is "filling", the number of waiting task decreases by 1.

The return value is an integer in the range of 0 to `parties-1`, different for each task. This can be used to select a task to do some special housekeeping, e.g.:

```
...
async with barrier as position:
    if position == 0:
        # Only one task prints this
        print('End of *draining phase*')
```

This method may raise a *BrokenBarrierError* exception if the barrier is broken or reset while a task is waiting. It could raise a *CancelledError* if a task is cancelled.

async reset()

Return the barrier to the default, empty state. Any tasks waiting on it will receive the *BrokenBarrierError* exception.

If a barrier is broken it may be better to just leave it and create a new one.

async abort()

Put the barrier into a broken state. This causes any active or future calls to *wait()* to fail with the *BrokenBarrierError*. Use this for example if one of the tasks needs to abort, to avoid infinite waiting tasks.

parties

The number of tasks required to pass the barrier.

n_waiting

The number of tasks currently waiting in the barrier while filling.

broken

A boolean that is `True` if the barrier is in the broken state.

exception asyncio.**BrokenBarrierError**

This exception, a subclass of *RuntimeError*, is raised when the *Barrier* object is reset or broken.

在 3.9 版的變更: 透過 `await lock` 或 `yield from lock` 和/或 `with` 陳述式 (`with await lock`, `with (yield from lock)`) 來取得鎖的方式已被移除。請改用 `async with lock`。

19.1.5 子行程

原始碼： Lib/asyncio/subprocess.py、Lib/asyncio/base_subprocess.py

---

This section describes high-level async/await asyncio APIs to create and manage subprocesses.

Here's an example of how asyncio can run a shell command and obtain its result:

```
import asyncio

async def run(cmd):
    proc = await asyncio.create_subprocess_shell(
        cmd,
        stdout=asyncio.subprocess.PIPE,
        stderr=asyncio.subprocess.PIPE)

    stdout, stderr = await proc.communicate()

    print(f'[{cmd!r} exited with {proc.returncode}]')
    if stdout:
        print(f'[stdout]\n{stdout.decode()}')
    if stderr:
        print(f'[stderr]\n{stderr.decode()}')

asyncio.run(run('ls /zzz'))
```

會印出:

```
['ls /zzz' exited with 1]
[stderr]
ls: /zzz: No such file or directory
```

Because all asyncio subprocess functions are asynchronous and asyncio provides many tools to work with such functions, it is easy to execute and monitor multiple subprocesses in parallel. It is indeed trivial to modify the above example to run several commands simultaneously:

```
async def main():
    await asyncio.gather(
        run('ls /zzz'),
        run('sleep 1; echo "hello"'))

asyncio.run(main())
```

另請參🄵*Examples*。

建立子行程

async asyncio.**create_subprocess_exec**(*program*, **args*, *stdin=None*, *stdout=None*, *stderr=None*, *limit=None*, ***kwds*)

建立一個子行程。

The *limit* argument sets the buffer limit for *StreamReader* wrappers for *stdout* and *stderr* (if *subprocess.PIPE* is passed to *stdout* and *stderr* arguments).

回傳一個`Process`實例。

See the documentation of `loop.subprocess_exec()` for other parameters.

在 3.10 版的變更: 移除了 *loop* 參數。

async asyncio.**create_subprocess_shell**(*cmd*, *stdin=None*, *stdout=None*, *stderr=None*, *limit=None*, ***kwds*)

執行 *cmd* shell 命令。

The *limit* argument sets the buffer limit for `StreamReader` wrappers for `stdout` and `stderr` (if `subprocess.PIPE` is passed to *stdout* and *stderr* arguments).

回傳一個`Process`實例。

See the documentation of `loop.subprocess_shell()` for other parameters.

重要

It is the application's responsibility to ensure that all whitespace and special characters are quoted appropriately to avoid shell injection vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and special shell characters in strings that are going to be used to construct shell commands.

在 3.10 版的變更: 移除了 *loop* 參數。

備🄵

Subprocesses are available for Windows if a `ProactorEventLoop` is used. See *Subprocess Support on Windows* for details.

也參考

asyncio also has the following *low-level* APIs to work with subprocesses: `loop.subprocess_exec()`, `loop.subprocess_shell()`, `loop.connect_read_pipe()`, `loop.connect_write_pipe()`, as well as the *Subprocess Transports* and *Subprocess Protocols*.

常數

asyncio.subprocess.**PIPE**

Can be passed to the *stdin*, *stdout* or *stderr* parameters.

If *PIPE* is passed to *stdin* argument, the `Process.stdin` attribute will point to a `StreamWriter` instance.

If *PIPE* is passed to *stdout* or *stderr* arguments, the `Process.stdout` and `Process.stderr` attributes will point to `StreamReader` instances.

asyncio.subprocess.**STDOUT**

Special value that can be used as the *stderr* argument and indicates that standard error should be redirected into standard output.

asyncio.subprocess.**DEVNULL**

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to process creation functions. It indicates that the special file `os.devnull` will be used for the corresponding subprocess stream.

與子行程互動

Both `create_subprocess_exec()` and `create_subprocess_shell()` functions return instances of the *Process* class. *Process* is a high-level wrapper that allows communicating with subprocesses and watching for their completion.

class asyncio.subprocess.**Process**

An object that wraps OS processes created by the `create_subprocess_exec()` and `create_subprocess_shell()` functions.

This class is designed to have a similar API to the `subprocess.Popen` class, but there are some notable differences:

- unlike Popen, Process instances do not have an equivalent to the `poll()` method;
- the `communicate()` and `wait()` methods don't have a *timeout* parameter: use the `wait_for()` function;
- the `Process.wait()` method is asynchronous, whereas `subprocess.Popen.wait()` method is implemented as a blocking busy loop;
- the *universal_newlines* parameter is not supported.

This class is *not thread safe*.

See also the *Subprocess and Threads* section.

async wait()

Wait for the child process to terminate.

Set and return the `returncode` attribute.

> **備🄵**
>
> This method can deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates so much output that it blocks waiting for the OS pipe buffer to accept more data. Use the `communicate()` method when using pipes to avoid this condition.

async communicate(*input=None*)

Interact with process:

1. send data to *stdin* (if *input* is not `None`);
2. 關閉 *stdin*;
3. 從 *stdout* 和 *stderr* 讀取資料，直到 EOF;
4. 等待行程終止。

The optional *input* argument is the data (`bytes` object) that will be sent to the child process.

回傳一個 `(stdout_data, stderr_data)` 元組。

If either `BrokenPipeError` or `ConnectionResetError` exception is raised when writing *input* into *stdin*, the exception is ignored. This condition occurs when the process exits before all data are written into *stdin*.

If it is desired to send data to the process' *stdin*, the process needs to be created with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, the process has to be created with `stdout=PIPE` and/or `stderr=PIPE` arguments.

Note, that the data read is buffered in memory, so do not use this method if the data size is large or unlimited.

在 3.12 版的變更: *stdin* gets closed when `input=None` too.

send_signal(*signal*)

Sends the signal *signal* to the child process.

> **備🄵**
>
> On Windows, *SIGTERM* is an alias for *terminate()*. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a *creationflags* parameter which includes CREATE_NEW_PROCESS_GROUP.

terminate()

Stop the child process.

On POSIX systems this method sends *SIGTERM* to the child process.

On Windows the Win32 API function TerminateProcess() is called to stop the child process.

kill()

Kill the child process.

On POSIX systems this method sends *SIGKILL* to the child process.

On Windows this method is an alias for *terminate()*.

stdin

Standard input stream (*StreamWriter*) or None if the process was created with stdin=None.

stdout

Standard output stream (*StreamReader*) or None if the process was created with stdout=None.

stderr

Standard error stream (*StreamReader*) or None if the process was created with stderr=None.

> **警告**
>
> Use the *communicate()* method rather than *process.stdin.write()*, *await process.stdout.read()* or *await process.stderr.read()*. This avoids deadlocks due to streams pausing reading or writing and blocking the child process.

pid

Process identification number (PID).

Note that for processes created by the *create_subprocess_shell()* function, this attribute is the PID of the spawned shell.

returncode

Return code of the process when it exits.

A None value indicates that the process has not terminated yet.

A negative value -N indicates that the child was terminated by signal N (POSIX only).

子行程與執行緒

Standard asyncio event loop supports running subprocesses from different threads by default.

On Windows subprocesses are provided by *ProactorEventLoop* only (default), *SelectorEventLoop* has no subprocess support.

Note that alternative event loop implementations might have own limitations; please refer to their documentation.

也參考

The *Concurrency and multithreading in asyncio* section.

范例

An example using the `Process` class to control a subprocess and the `StreamReader` class to read from its standard output.

The subprocess is created by the `create_subprocess_exec()` function:

```
import asyncio
import sys

async def get_date():
    code = 'import datetime; print(datetime.datetime.now())'

    # Create the subprocess; redirect the standard output
    # into a pipe.
    proc = await asyncio.create_subprocess_exec(
        sys.executable, '-c', code,
        stdout=asyncio.subprocess.PIPE)

    # Read one line of output.
    data = await proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit.
    await proc.wait()
    return line

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the *same example* written using low-level APIs.

19.1.6 🄵列 (Queues)

原始碼： Lib/asyncio/queues.py

---

asyncio 🄵列被設計成與`queue` 模組類似。🄵管 asyncio 🄵列不支援執行緒安全 (thread-safe)，但他們是被設計來專用於 async/await 程式。

注意 asyncio 的🄵列🄵有 *timeout* 參數；請使用`asyncio.wait_for()` 函式來🄵🄵列新增具有超時 (timeout) 設定的操作。

另請參🄵下方*Examples*。

Queue

class asyncio.**Queue**(*maxsize=0*)

先進先出 (FIFO) 🄵列。

如果 *maxsize* 小於或等於零，則🄵列大小是無限制的。如果是大於 `0` 的整數，則當🄵列達到 *maxsize* 時，`await put()` 將會阻塞 (block)，直到某個元素被`get()` 取出。

不像標准函式庫中執行緒類型的`queue`，🄵列的大小一直是已知的，可以透過呼叫`qsize()` 方法回傳。

在 3.10 版的變更: 移除 *loop* 參數。

這個類🄵是不支援執行緒安全的。

maxsize

🄵列中可存放的元素數量。

empty()

如果🄵列🄴空則回傳 `True`，否則回傳 `False`。

full()

如果有*maxsize* 個條目在🄵列中，則回傳 `True`。

如果🄵列用 `maxsize=0` （預設）初始化，則*full()* 永遠不會回傳 `True`。

async get()

從🄵列中🄴除🄵回傳一個元素。如果🄵列🄴空，則持續等待直到🄵列中有元素。

Raises *QueueShutDown* if the queue has been shut down and is empty, or if the queue has been shut down immediately.

get_nowait()

如果🄵列🄴有值則立即回傳🄵列中的元素，否則引發*QueueEmpty*。

async join()

持續阻塞直到🄵列中所有的元素都被接收和處理完畢。

當條目新增到🄵列的時候，未完成任務的計數就會增加。每當一個消耗者 (consumer) 協程呼叫*task_done()*，表示這個條目已經被取回且被它包含的所有工作都已完成，未完成任務計數就會🄵少。當未完成計數降到零的時候，*join()* 阻塞會被解除 (unblock)。

async put(*item*)

將一個元素放進🄵列。如果🄵列滿了，在新增元素之前，會持續等待直到有空🄵插槽 (free slot) 能被使用。

如果🄵列已經被關閉，則引發*QueueShutDown*。

put_nowait(*item*)

不阻塞地將一個元素放入🄵列。

如果🄵有立即可用的空🄵插槽，引發*QueueFull*。

qsize()

回傳🄵列中的元素數量。

shutdown(*immediate=False*)

Shut down the queue, making *get()* and *put()* raise *QueueShutDown*.

By default, *get()* on a shut down queue will only raise once the queue is empty. Set *immediate* to true to make *get()* raise immediately instead.

All blocked callers of *put()* and *get()* will be unblocked. If *immediate* is true, a task will be marked as done for each remaining item in the queue, which may unblock callers of *join()*.

在 3.13 版被加入.

task_done()

表示前面一個排隊的工作項目已經完成。

由🄵列消耗者使用。對於每個用於取得一個工作項目的*get()*，接續的*task_done()* 呼叫會告訴🄵列這個工作項目的處理已經完成。

如果*join()* 目前正在阻塞，在所有項目都被處理後會解除阻塞（意味著每個以*put()* 放進🄵列的條目都會收到一個*task_done()*）。

`shutdown(immediate=True)` calls *task_done()* for each remaining item in the queue.

如果被呼叫的次數多於放入🄵列中的項目數量，將引發*ValueError*。

Priority Queue（優先🄵列）

class asyncio.**PriorityQueue**

Queue 的變形；按優先順序取出條目 (最小的先取出)。

條目通常是 `(priority_number, data)` 形式的 tuple（元組）。

LIFO Queue

class asyncio.**LifoQueue**

Queue 的變形，先取出最近新增的條目（後進先出）。

例外

exception asyncio.**QueueEmpty**

當🄵列🄵空的時候，呼叫*get_nowait()* 方法會引發這個例外。

exception asyncio.**QueueFull**

當🄵列中條目數量已經達到它的 *maxsize* 時，呼叫*put_nowait()* 方法會引發這個例外。

exception asyncio.**QueueShutDown**

Exception raised when *put()* or *get()* is called on a queue which has been shut down.

在 3.13 版被加入.

范例

🄵列能被用於多個🄵行任務的工作分配：

```
import asyncio
import random
import time

async def worker(name, queue):
    while True:
        # Get a "work item" out of the queue.
        sleep_for = await queue.get()

        # Sleep for the "sleep_for" seconds.
        await asyncio.sleep(sleep_for)

        # Notify the queue that the "work item" has been processed.
        queue.task_done()

        print(f'{name} has slept for {sleep_for:.2f} seconds')

async def main():
    # Create a queue that we will use to store our "workload".
    queue = asyncio.Queue()

    # Generate random timings and put them into the queue.
    total_sleep_time = 0
    for _ in range(20):
        sleep_for = random.uniform(0.05, 1.0)
        total_sleep_time += sleep_for
        queue.put_nowait(sleep_for)

    # Create three worker tasks to process the queue concurrently.
    tasks = []
    for i in range(3):
```

(繼續下一頁)

(繼續上一頁)

```
        task = asyncio.create_task(worker(f'worker-{i}', queue))
        tasks.append(task)

    # Wait until the queue is fully processed.
    started_at = time.monotonic()
    await queue.join()
    total_slept_for = time.monotonic() - started_at

    # Cancel our worker tasks.
    for task in tasks:
        task.cancel()
    # Wait until all worker tasks are cancelled.
    await asyncio.gather(*tasks, return_exceptions=True)

    print('====')
    print(f'3 workers slept in parallel for {total_slept_for:.2f} seconds')
    print(f'total expected sleep time: {total_sleep_time:.2f} seconds')

asyncio.run(main())
```

19.1.7 例外

原始碼： Lib/asyncio/exceptions.py

---

exception asyncio.**TimeoutError**

TimeoutError 的一個已被🄵用的🄵名，當操作已超過規定的截止時間時被引發。

在 3.11 版的變更: 此 class 是*TimeoutError* 的一個🄵名。

exception asyncio.**CancelledError**

該操作已被取消。

當 asyncio Task 被取消時，可以捕獲此例外以執行客🄵化操作。在幾乎所有情🄵下，該例外必須重新被引發。

在 3.8 版的變更: *CancelledError* 現在是*BaseException* 而非*Exception* 的子類🄵。

exception asyncio.**InvalidStateError**

Task 或*Future* 的無效🄵部狀態。

可以在像是🄵已設定結果值的 *Future* 物件設定結果值的情🄵下引發。

exception asyncio.**SendfileNotAvailableError**

”sendfile” 系統呼叫不適用於給定的 socket 或檔案型🄵。

一個*RuntimeError* 的子類🄵。

exception asyncio.**IncompleteReadError**

請求的讀取操作未全部完成。

由*asyncio 串流 APIs* 引發。

此例外是*EOFError* 的子類🄵。

expected

預期的位元組總數 (*int*)。

partial

串流結束之前讀取的*bytes* 字串。

exception asyncio.**LimitOverrunError**

在查詢分隔符號 (separator) 時達到緩衝區 (buffer) 大小限制。

由*asyncio 串流 APIs* 引發。

consumed

要消耗的位元組總數。

19.1.8 Call Graph Introspection

原始碼： Lib/asyncio/graph.py

---

asyncio has powerful runtime call graph introspection utilities to trace the entire call graph of a running *coroutine* or *task*, or a suspended *future*. These utilities and the underlying machinery can be used from within a Python program or by external profilers and debuggers.

在 3.14 版被加入.

asyncio.**print_call_graph**(*future=None*, */*, ***, *file=None*, *depth=1*, *limit=None*)

Print the async call graph for the current task or the provided *Task* or *Future*.

This function prints entries starting from the top frame and going down towards the invocation point.

The function receives an optional *future* argument. If not passed, the current running task will be used.

If the function is called on *the current task*, the optional keyword-only *depth* argument can be used to skip the specified number of frames from top of the stack.

If the optional keyword-only *limit* argument is provided, each call stack in the resulting graph is truncated to include at most `abs(limit)` entries. If *limit* is positive, the entries left are the closest to the invocation point. If *limit* is negative, the topmost entries are left. If *limit* is omitted or `None`, all entries are present. If *limit* is `0`, the call stack is not printed at all, only "awaited by" information is printed.

If *file* is omitted or `None`, the function will print to *sys.stdout*.

範例：

以下 Python 程式碼：

```
import asyncio

async def test():
    asyncio.print_call_graph()

async def main():
    async with asyncio.TaskGroup() as g:
        g.create_task(test(), name='test')

asyncio.run(main())
```

會印出：

```
* Task(name='test', id=0x1039f0fe0)
+ Call stack:
|   File 't2.py', line 4, in async test()
+ Awaited by:
   * Task(name='Task-1', id=0x103a5e060)
      + Call stack:
      |   File 'taskgroups.py', line 107, in async TaskGroup.__aexit__()
      |   File 't2.py', line 7, in async main()
```

asyncio.**format_call_graph**(*future=None*, */*, *, *depth=1*, *limit=None*)

Like *print_call_graph()*, but returns a string. If *future* is None and there's no current task, the function returns an empty string.

asyncio.**capture_call_graph**(*future=None*, */*, *, *depth=1*, *limit=None*)

Capture the async call graph for the current task or the provided *Task* or *Future*.

The function receives an optional *future* argument. If not passed, the current running task will be used. If there's no current task, the function returns None.

If the function is called on *the current task*, the optional keyword-only *depth* argument can be used to skip the specified number of frames from top of the stack.

會回傳一個 FutureCallGraph 資料類🄴物件：

- FutureCallGraph(future, call_stack, awaited_by)

  Where *future* is a reference to a *Future* or a *Task* (or their subclasses.)

  call_stack 是一個由 FrameCallGraphEntry 物件組成的元組。

  awaited_by 是一個由 FutureCallGraph 物件組成的元組。

- FrameCallGraphEntry(frame)

  Where *frame* is a frame object of a regular Python function in the call stack.

低階工具函式

To introspect an async call graph asyncio requires cooperation from control flow structures, such as *shield()* or *TaskGroup*. Any time an intermediate *Future* object with low-level APIs like *Future.add_done_callback()* is involved, the following two functions should be used to inform asyncio about how exactly such intermediate future objects are connected with the tasks they wrap or control.

asyncio.**future_add_to_awaited_by**(*future*, *waiter*, */*)

Record that *future* is awaited on by *waiter*.

Both *future* and *waiter* must be instances of *Future* or *Task* or their subclasses, otherwise the call would have no effect.

A call to future_add_to_awaited_by() must be followed by an eventual call to the *future_discard_from_awaited_by()* function with the same arguments.

asyncio.**future_discard_from_awaited_by**(*future*, *waiter*, */*)

Record that *future* is no longer awaited on by *waiter*.

Both *future* and *waiter* must be instances of *Future* or *Task* or their subclasses, otherwise the call would have no effect.

19.1.9 事件🄵圈

原始碼： Lib/asyncio/events.py、Lib/asyncio/base_events.py

前言

事件🄵圈是每個 asyncio 應用程式的核心。事件🄵圈執行非同步任務和回呼、執行網路 IO 操作🄵🄵動子行程。

應用程式開發人員通常應使用高階的 asyncio 函式，例如*asyncio.run()*，🄵且很少需要參照事件🄵圈物件或呼叫其方法。本節主要針對那些需要更細粒度控制事件🄵圈行🄵的低階程式碼、函式庫和框架的作者。

取得事件🄵圈

以下的低階函式可用於取得、設置或建立事件🄵圈：

asyncio.**get_running_loop**()

在目前作業系統執行緒中回傳正在運行的事件🄵圈。

如果🄵有運行的事件🄵圈，則引發*RuntimeError*。

此函式只能從協程或回呼函式中呼叫。

在 3.7 版被加入.

asyncio.**get_event_loop**()

取得目前的事件🄵圈。

當從協程或回呼函式呼叫此函式（例如，使用 call_soon 或類似的 API 於排程呼叫），此函式將永遠回傳正在運行的事件🄵圈。

如果🄵有設定正在運行的事件🄵圈，該函式將回傳 `get_event_loop_policy().get_event_loop()` 呼叫的結果。

由於此函式具有相當🄵雜的行🄵（尤其是在使用自訂事件🄵圈策略時），在協程和回呼函式中，建議使用*get_running_loop()* 函式，而不是*get_event_loop()*。

如上所述，可以考慮使用高階的*asyncio.run()* 函式，而不是使用這些較低階的函式手動建立和關閉事件🄵圈。

在 3.14 版的變更: 如果🄵有目前的事件🄵圈，則引發*RuntimeError*。

> **備🄵**
>
> The `asyncio` policy system is deprecated and will be removed in Python 3.16; from there on, this function will return the current running event loop if present else it will return the loop set by *set_event_loop()*.

asyncio.**set_event_loop**(*loop*)

將 *loop* 設置🄵目前 OS 執行緒的目前事件🄵圈。

asyncio.**new_event_loop**()

建立🄵回傳新的事件🄵圈物件。

請注意*get_event_loop()*、*set_event_loop()* 和*new_event_loop()* 函式的行🄵可以透過*設定自訂事件🄵圈策略*進行調整。

目🄵

本頁文件包含以下章節：

- *事件🄵圈方法*章節是事件🄵圈 API 們的參照文件；
- *回呼處理*章節記🄵了從排程方法（如*loop.call_soon()* 和*loop.call_later()*）回傳的*Handle* 和*TimerHandle* 實例；
- *Server 物件*章節記🄵了從事件🄵圈方法（如*loop.create_server()*）回傳的資料型🄵；
- *事件🄵圈實作*章節記🄵了*SelectorEventLoop* 和*ProactorEventLoop* 類🄵；
- *範例*章節展示了如何使用一些事件🄵圈 API。

事件🄵圈方法

事件🄵圈提供以下**低階** API：

- 🄵動和停止🄵圈
- 排程回呼函式
- 排程延遲的回呼函式
- 建立 *Futures* 和 *Tasks*
- 打開網路連🄵
- 建立網路伺服器
- 傳輸檔案
- *TLS* 升級
- 監視檔案描述器
- 直接使用 *socket* 物件
- *DNS*
- 使用管道
- *Unix* 訊號
- 在執行緒池或行程池中執行程式碼
- 錯誤處理 *API*
- 🄵用除錯模式
- 運行子行程

🄵動和停止🄵圈

loop.**run_until_complete**(*future*)

運行直到 *future* （一個*Future* 實例）完成。

如果引數是*協程物件*，則它將被隱式排程🄵*asyncio.Task* 運行。

回傳 Future 的結果或引發其例外。

loop.**run_forever**()

運行事件🄵圈直到*stop()* 被呼叫。

如果在呼叫*run_forever()* 之前呼叫*stop()*，則🄵圈將使用超時🄵零的方式輪詢 I/O 選擇器，運行所有回應 I/O 事件（以及已經排程的事件）的回呼，然後退出。

如果在*run_forever()* 運行時呼叫*stop()*，則🄵圈將運行目前批次的回呼函式，然後退出。請注意，由回呼函式排程的新回呼在此情🄵下不會運行；而是在下次呼叫*run_forever()* 或*run_until_complete()* 時運行。

loop.**stop**()

停止事件🄵圈。

loop.**is_running**()

如果事件🄵圈目前正在運行，則回傳 `True`。

loop.**is_closed**()

如果事件🄵圈已關閉，則回傳 `True`。

loop.**close**()

關閉事件🄵圈。

不得於🄵圈運行中呼叫此函式。將🄵🄵任何待處理的回呼。

此方法清除所有🄵列🄵關閉執行器，但不等待執行器完成。

此方法是🄵等且不可逆的。在事件🄵圈關閉後不應呼叫其他方法。

async loop.**shutdown_asyncgens**()

排程所有目前打開的非同步🄵生器物件使用 aclose() 呼叫來關閉。呼叫此方法後，如果🄵代新的非同步🄵生器，事件🄵圈將發出警告。應該使用此方法可靠地完成所有已排程的非同步🄵生器。

請注意，使用*asyncio.run()* 時不需要呼叫此函式。

範例：

```
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens())
    loop.close()
```

在 3.6 版被加入.

async loop.**shutdown_default_executor**(*timeout=None*)

排程預設執行器的關閉，🄵等待它加入*ThreadPoolExecutor* 中的所有執行緒。一旦呼叫了此方法，使用預設執行器與*loop.run_in_executor()* 將引發*RuntimeError*。

timeout 參數指定執行器完成加入所需的時間（以*float* 秒🄵單位）。預設情🄵下🄵 None，不會限制執行器所花費的時間。

如果達到 *timeout*，將發出*RuntimeWarning* 警告，預設執行器將立即終止，不等待其執行緒完成加入。

備🄵

使用*asyncio.run()* 時請勿呼叫此方法，因🄵後者會自動處理預設執行器的關閉。

在 3.9 版被加入.

在 3.12 版的變更: 加入 *timeout* 參數。

排程回呼函式

loop.**call_soon**(*callback*, **args*, *context=None*)

在事件🄵圈的下一次🄵代中排程以 *args* 引數呼叫 *callback* *callback*。

回傳*asyncio.Handle* 的實例，稍後可以用於取消回呼函式。

回呼函式按照其🄵🄵的順序呼叫。每個回呼函式將被呼叫恰好一次。

選用的僅限關鍵字引數 *context* 指定了要給 *callback* 執行的自定義*contextvars.Context*。當未提供 *context* 時，回呼函式使用目前情境。

與*call_soon_threadsafe()* 不同，此方法不是執行緒安全的。

loop.**call_soon_threadsafe**(*callback*, **args*, *context=None*)

這是*call_soon()* 的執行緒安全變體。當從另一個執行緒排程回呼函式時，必須使用此函式，因🄵*call_soon()* 不是執行緒安全的。

This function is safe to be called from a reentrant context or signal handler, however, it is not safe or fruitful to use the returned handle in such contexts.

如果在已關閉的🄵圈上呼叫，則引發*RuntimeError*。在主應用程式關閉時，這可能發生在次要執行緒上。

請參🄵文件的🄵行和多執行緒部分。

在 3.7 版的變更: 新增了 *context* 僅限關鍵字參數。詳細資訊請參🄵 **PEP 567**。

備🄵

大多數*asyncio*排程函式不允許傳遞關鍵字引數。要傳遞關鍵字引數，請使用*functools.partial()*：

```
# 將會排程 "print("Hello", flush=True)"
loop.call_soon(
    functools.partial(print, "Hello", flush=True))
```

通常使用 partial 物件比使用 lambda 更方便，因🄵 asyncio 可以在除錯和錯誤訊息中更好地呈現 partial 物件。

排程延遲的回呼函式

事件🄵圈提供🄵回呼函式排程在將來某個時間點才呼叫的機制。事件🄵圈使用了單調時鐘來追🄵時間。

`loop.`**`call_later`**(*delay*, *callback*, **args*, *context=None*)

排程 *callback* 在給定的 *delay* 秒數後呼叫（可以是整數或浮點數）。

回傳*asyncio.TimerHandle* 的實例，可用於取消回呼函式。

callback 將只被呼叫恰好一次。如果有兩個回呼函式被排程在完全相同的時間，則其呼叫順序是不定的。

可選的位置引數 *args* 將在呼叫回呼函式時傳遞。如果要使用關鍵字引數呼叫回呼函數，請使用*functools.partial()*。

可選的僅限關鍵字 *context* 引數允許🄵 *callback* 指定自定義的*contextvars.Context* 以提供運行。當未提供 *context* 時，將使用目前情境。

備🄵

For performance, callbacks scheduled with *loop.call_later()* may run up to one clock-resolution early (see `time.get_clock_info('monotonic').resolution`).

在 3.7 版的變更: 新增了 *context* 僅限關鍵字參數。詳細資訊請參🄵 **PEP 567**。

在 3.8 版的變更: 在 Python 3.7 及更早版本中，使用預設事件🄵圈實作時，*delay* 不能超過一天。這在 Python 3.8 中已經修復。

`loop.`**`call_at`**(*when*, *callback*, **args*, *context=None*)

排程 *callback* 在給定的🄵對時間戳 *when*（整數或浮點數）處呼叫，使用與*loop.time()* 相同的時間參照。

此方法的行🄵與*call_later()* 相同。

回傳*asyncio.TimerHandle* 的實例，可用於取消回呼函式。

備🄵

For performance, callbacks scheduled with *loop.call_at()* may run up to one clock-resolution early (see `time.get_clock_info('monotonic').resolution`).

在 3.7 版的變更: 新增了 *context* 僅限關鍵字參數。詳細資訊請參🄵 **PEP 567**。

在 3.8 版的變更: 在 Python 3.7 及更早版本中，使用預設事件🄵圈實作時，*when* 和目前時間之間的差值不能超過一天。這在 Python 3.8 中已經修復。

`loop.`**`time`**()

根據事件🄵圈的🄵部單調時鐘，回傳目前時間，以*float* 值表示。

備🄵

在 3.8 版的變更: 在 Python 3.7 及更早版本中，超時（相對 *delay* 或🄵對 *when*）不應超過一天。這在 Python 3.8 中已經修復。

也參考

函式 *asyncio.sleep()*。

建立 Futures 和 Tasks

loop.**create_future**()

建立附加到事件🄵圈的 *asyncio.Future* 物件。

這是在 asyncio 中建立 Futures 的首選方式。這允許第三方事件🄵圈提供 Future 物件的替代實作（具有更好的性能或儀器計測表現）。

在 3.5.2 版被加入.

loop.**create_task**(*coro*, *, *name=None*, *context=None*, *eager_start=None*, ***kwargs*)

排程執行協程 *coro*。回傳 *Task* 物件。

第三方事件🄵圈可以使用其自己的 *Task* 子類🄵以實現互操作性（interoperability）。在這種情🄵下，結果類型是 *Task* 的子類🄵。

The full function signature is largely the same as that of the *Task* constructor (or factory) - all of the keyword arguments to this function are passed through to that interface.

如果提供了 *name* 引數且不🄵 `None`，則將其設置🄵任務的名稱，使用 *Task.set_name()*。

可選的僅限關鍵字 *context* 引數允許🄵 *coro* 指定自定義的 *contextvars.Context* 以提供運行。當未提供 *context* 時，將建立目前情境的副本。

An optional keyword-only *eager_start* argument allows specifying if the task should execute eagerly during the call to create_task, or be scheduled later. If *eager_start* is not passed the mode set by *loop.set_task_factory()* will be used.

在 3.8 版的變更: 加入 *name* 參數。

在 3.11 版的變更: 加入 *context* 參數。

在 3.13.3 版的變更: Added `kwargs` which passes on arbitrary extra parameters, including `name` and `context`.

在 3.13.4 版的變更: Rolled back the change that passes on *name* and *context* (if it is None), while still passing on other arbitrary keyword arguments (to avoid breaking backwards compatibility with 3.13.3).

在 3.14 版的變更: All *kwargs* are now passed on. The *eager_start* parameter works with eager task factories.

loop.**set_task_factory**(*factory*)

設置將由 *loop.create_task()* 使用的任務工廠。

如果 *factory* 🄵 `None`，將設置預設的任務工廠。否則，*factory* 必須是一個具有匹配簽名 `(loop, coro, **kwargs)` 的 *callable*，其中 *loop* 是有效事件🄵圈的參照、*coro* 是一個協程物件。該可呼叫物件必須傳遞所有 *kwargs* 🄵回傳一個與 *asyncio.Task* 相容的物件。

在 3.13.3 版的變更: Required that all *kwargs* are passed on to *asyncio.Task*.

在 3.13.4 版的變更: *name* is no longer passed to task factories. *context* is no longer passed to task factories if it is `None`.

在 3.14 版的變更: *name* and *context* are now unconditionally passed on to task factories again.

loop.**get_task_factory**()

回傳任務工廠，如果使用預設任務工廠則回傳 None。

打開網路連🄵

async loop.**create_connection**(*protocol_factory*, *host=None*, *port=None*, *, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *happy_eyeballs_delay=None*, *interleave=None*, *all_errors=False*)

打開以 *host* 和 *port* 指定之給定地址的串流傳輸連🄵。

根據 *host**（或提供的 **family* 引數）的情🄵，socket 家族可以是*AF_INET* 或*AF_INET6*。

Socket 類型將🄵*SOCK_STREAM*。

protocol_factory 必須是一個回傳*asyncio protocol* 實作的可呼叫函式。

此方法將嘗試在背景建立連🄵。成功時，它將回傳一對 (transport, protocol)。

底層操作的時間軸簡介如下：

1. 建立連🄵🄵🄵其建立傳輸。
2. *protocol_factory* 在無引數的情🄵下被呼叫，🄵且預計回傳一個協定 實例。
3. 通過呼叫其*connection_made()* 方法，將協定實例與傳輸連🄵在一起。
4. 成功時回傳一個 (transport, protocol) 元組。

建立的傳輸是一個依賴實作的雙向串流。

其他引數：

- 若有給定 *ssl* 且非 false，將建立 SSL/TLS 傳輸（預設建立普通 TCP 傳輸）。如果 *ssl* 🄵*ssl.SSLContext* 物件，則使用該情境來建立傳輸；如果 *ssl* 🄵*True*，則使用*ssl.create_default_context()* 回傳的預設情境。

  > **也參考**
  >
  > *SSL/TLS 安全考量*

- *server_hostname* 設置或覆蓋目標伺服器憑證將匹配的主機名稱。僅在 *ssl* 不🄵 None 時傳遞。預設情🄵下，將使用 *host* 引數的值。如果 *host* 🄵空，則🄵有預設值，必須傳遞 *server_hostname* 的值。若 *server_hostname* 🄵空字串，將停用主機名稱匹配（這是一個嚴重的安全風險，可能導致中間人攻擊）。
- *family*、*proto*、*flags* 是可選的位址家族、協定和旗標，用於傳遞至 getaddrinfo() 進行 *host* 解析。若有給定這些應該都是相應*socket* 模組常數的整數。
- 若有給定，*happy_eyeballs_delay* 會🄵用此連🄵的 Happy Eyeballs。它應該是一個浮點數，表示等待連🄵嘗試完成的秒數，然後在🄵行🄵動下一次嘗試。這是 **RFC 8305** 中定義的「連🄵嘗試延遲」。RFC 建議的合理預設值🄵 0.25 秒（250 毫秒）。
- *interleave* 控制主機名稱解析🄵多個 IP 位址時的地址重新排序。若🄵 0 或未指定，將不執行重排序，🄵按*getaddrinfo()* 回傳的順序嘗試位址。如果指定正整數，則按地址家族交錯排列，給定的整數直譯🄵 **RFC 8305** 中定義的「首個地址家族計數」。如果未指定 *happy_eyeballs_delay*，則預設值🄵 0，如果指定則🄵 1。
- 若有給定 *sock* 則其應🄵已存在且已連🄵的*socket.socket* 物件，可供傳輸使用。如果提供了 *sock*，則不應指定 *host*、*port*、*family*、*proto*、*flags*、*happy_eyeballs_delay*、*interleave* 和 *local_addr* 中的任何一項。

> **備🄵**
>
> 引數 *sock* 將 socket 所有權轉移給所建立的傳輸 socket，請呼叫傳輸的`close()` 方法。

- 若有給定 *local_addr* 則其🄵一個 `(local_host, local_port)` 元組，用於在本地綁定 socket。將使用 `getaddrinfo()` 查找 *local_host* 和 *local_port*，方式類似於 *host* 和 *port*。
- *ssl_handshake_timeout*（對於 TLS 連🄵）是等待 TLS 交握的時間，以秒🄵單位，在那之前若未完成則會中斷連🄵。如果🄵 `None`（預設值），則會等待 `60.0` 秒。
- *ssl_shutdown_timeout* 是等待 SSL 關閉完成以前中斷連🄵的時間，以秒🄵單位。如果🄵 `None`（預設值），則會等待 `30.0` 秒。
- *all_errors* 🄵定在無法建立連🄵時會引發哪些例外。預設情🄵下，只會引發單一 `Exception`：如果只有一個例外或所有錯誤訊息相同，則引發第一個例外，否則引發包含所有錯誤訊息的單一 `OSError`。當 `all_errors` 🄵 `True` 時，將引發包含所有例外的 `ExceptionGroup`（即使只有一個例外）。

在 3.5 版的變更: 新增`ProactorEventLoop` 中的 SSL/TLS 支援。

在 3.6 版的變更: 所有 TCP 連🄵都預設有*socket.TCP_NODELAY* socket 選項。

在 3.7 版的變更: 增加 *ssl_handshake_timeout* 參數。

在 3.8 版的變更: 加入 *happy_eyeballs_delay* 和 *interleave* 參數。

Happy Eyeballs 演算法：雙協定堆🄵主機 (Dual-Stack Hosts) 的成功。當伺服器的 IPv4 路徑和協定運作正常，但伺服器的 IPv6 路徑和協定不運作時，雙棧用🄴端應用程式會比僅具 IPv4 的用🄵端體驗到顯著的連🄵延遲。這是不希望的，因🄵這會導致雙棧用🄵端的使用者體驗變差。本文件具體🄵明了🄵少此用🄵可見延遲的演算法要求🄵提供了一種演算法。

更多資訊請見：https://datatracker.ietf.org/doc/html/rfc6555

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

在 3.12 版的變更: 已新增 *all_errors*。

> **也參考**
>
> 函式`open_connection()` 是高階的替代 API。它回傳一對 (`StreamReader`, `StreamWriter`) 可直接在 async/await 程式碼中使用。

async `loop.`**create_datagram_endpoint**(*protocol_factory*, *local_addr=None*, *remote_addr=None*, ***, *family=0*, *proto=0*, *flags=0*, *reuse_port=None*, *allow_broadcast=None*, *sock=None*)

建立一個資料報連🄵。

Socket 家族可以是`AF_INET`、`AF_INET6` 或`AF_UNIX`，視乎 *host*（或提供的 *family* 引數）而定。

Socket 類型將🄵`SOCK_DGRAM`。

protocol_factory 必須是可呼叫的函式，回傳*protocol* 實作。

成功時回傳 `(transport, protocol)` 元組。

其他引數：

- *local_addr*，如果提供，是一個 `(local_host, local_port)` 元組，用於在本地綁定 socket。*local_host* 和 *local_port* 使用`getaddrinfo()` 來查找。

> **備🄵**

On Windows, when using the proactor event loop with `local_addr=None`, an *OSError* with `errno.WSAEINVAL` will be raised when running it.

- *remote_addr*，如果提供，是一個 `(remote_host, remote_port)` 元組，用於將 socket 連🄵到遠端位址。*remote_host* 和 *remote_port* 使用*getaddrinfo()* 來查找。
- *family*、*proto* 和 *flags* 是用於傳遞給*getaddrinfo()* 以解析 *host* 的可選地址家族、協定和旗標。如果提供，這些應該都是來自相應的*socket* 模組常數的整數。
- *reuse_port* 告訴核心允許將此端點綁定到與其他現有端點相同的埠，只要它們在建立時都設定了此旗標。此選項不受 Windows 和某些 Unix 系統支援。如果未定義 `SO_REUSEPORT` 常數，則不支援此功能。
- *allow_broadcast* 告訴核心允許此端點向廣播位址發送訊息。
- *sock* 可以選擇性地指定，以使用預先存在且已連🄵的*socket.socket* 物件供傳輸使用。如果指定，*local_addr* 和 *remote_addr* 應省略（必須是*None*）。

備🄵

引數 *sock* 將 socket 所有權轉移給所建立的傳輸 socket，請呼叫傳輸的*close()* 方法。

請參🄵*UDP 回應用🄵端協定* 和*UDP 回應伺服器協定* 範例。

在 3.4.4 版的變更: 新增 *family*、*proto*、*flags*、*reuse_address*、*reuse_port*、*allow_broadcast* 和 *sock* 參數。

在 3.8 版的變更: 新增對於 Windows 的支援。

在 3.8.1 版的變更: 不再支援 *reuse_address* 參數，因🄵使用 `SO_REUSEADDR` 對於 UDP 存有重大的安全疑慮。明確傳遞 `reuse_address=True` 將引發例外。

當具有不同 UID 的多個行程使用 `SO_REUSEADDR` 將 socket 分配給相同的 UDP socket 地址時，傳入的封包可能會在 socket 之間隨機分🄵。

對於有支援的平台，*reuse_port* 可以用作類似功能的替代方案。使用 *reuse_port*，將改🄵使用 `SO_REUSEPORT`，該選項明確禁止具有不同 UID 的行程將 socket 分配給相同的 socket 地址。

在 3.11 版的變更: 自 Python 3.9.0、3.8.1、3.7.6 和 3.6.10 起，已完全移除 *reuse_address* 參數。

async loop.**create_unix_connection**(*protocol_factory*, *path=None*, ***, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

建立一個 Unix 連🄵。

Socket 家族將🄵*AF_UNIX*；socket 類型將🄵*SOCK_STREAM*。

成功時回傳 `(transport, protocol)` 元組。

path 是 Unix 域 socket 的名稱，除非指定 *sock* 參數，否則🄵必填。支援抽象 Unix sockets、*str*、*bytes* 和*Path* 路徑。

有關此方法的引數資訊，請參🄵*loop.create_connection()* 方法的文件。

可用性: Unix.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 參數。*path* 參數現在可以是*path-like object*。

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

建立網路伺服器

async loop.**create_server**(*protocol_factory*, *host=None*, *port=None*, ***, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *keep_alive=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*)

建立一個 TCP 伺服器（socket 類型*SOCK_STREAM*），監聽 *host* 位址的 *port*。

回傳一個*Server* 物件。

引數：

- *protocol_factory* 必須是可呼叫的函式，回傳*protocol* 實作。
- 可以將 *host* 參數設🄵幾種類型，以確定伺服器將監聽的位置：
  - 如果 *host* 是字串，則 TCP 伺服器綁定到由 *host* 指定的單個網路介面。
  - 如果 *host* 是字串序列，則 TCP 伺服器綁定到序列指定的所有網路介面。
  - 若 *host* 是空字串或 `None`，則所有介面都被假定🄵回傳多個 socket 的清單（可能一個用於 IPv4，另一個用於 IPv6）。
- 可以設定 *port* 參數以指定伺服器應該監聽的埠。如果是 `0` 或 `None`（預設值），將隨機選擇一個未使用的埠（請注意，如果 *host* 解析🄵多個網路介面，將🄵每個介面隨機選擇不同的隨機埠）。
- *family* 可以設定🄵*socket.AF_INET* 或*AF_INET6* 以🄵制使用 IPv4 或 IPv6。如果未設定，*family* 將從主機名稱🄵定（預設🄵*AF_UNSPEC*）。
- *flags* 是*getaddrinfo()* 的位元遮罩。
- 可以可選地指定 *sock* 以使用現有的 socket 物件。如果指定了，*host* 和 *port* 不能指定。

> **備🄵**
>
> *sock* 引數將 socket 的所有權轉移給建立的伺服器。要關閉 socket，請呼叫伺服器的*close()* 方法。

- *backlog* 是傳遞給*listen()* 的最大🄵列連🄵數（預設🄵 100）。
- *ssl* 可以設定🄵*SSLContext* 實例以在接受的連🄵上🄵用 TLS。
- *reuse_address* 告訴🄵核重用 `TIME_WAIT` 狀態下的本地 socket，而不等待其自然超時過期。如果未指定，在 Unix 上將自動設置🄵 `True`。
- *reuse_port* 告訴🄵核允許此端點🄵結到與其他現有端點🄵結的相同埠，只要它們在建立時都設置了此旗標。此選項在旗標 Windows 上不受支援。
- 將 *keep_alive* 設🄵 `True` 透過🄵用定期的訊息傳輸來保持連🄵活躍。

在 3.13 版的變更: 加入 *keep_alive* 參數。

- （對於 TLS 伺服器）*ssl_handshake_timeout* 是在中斷連🄵之前等待 TLS 握手完成的時間（以秒🄵單位）。如果🄵 `None`（預設），則🄵 `60.0` 秒。
- *ssl_shutdown_timeout* 是等待 SSL 關閉完成以前中斷連🄵的時間，以秒🄵單位。如果🄵 `None`（預設值），則會等待 `30.0` 秒。
- 將 *start_serving* 設置🄵 `True`（預設）將使建立的伺服器立即開始接受連接。當設置🄵 `False` 時，用🄵應該等待*Server.start_serving()* 或*Server.serve_forever()* 來使伺服器開始接受連🄵。

在 3.5 版的變更: 新增*ProactorEventLoop* 中的 SSL/TLS 支援。

在 3.5.1 版的變更: *host* 參數可以是字串序列。

在 3.6 版的變更: 新增 *ssl_handshake_timeout* 與 *start_serving* 參數。所有 TCP 連🄵都預設有*socket.TCP_NODELAY* socket 選項。

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

> **也參考**
>
> *start_server()* 函式是一個更高階的替代 API，它回傳一對*StreamReader* 和*StreamWriter*，可以在 async/await 程式碼中使用。

async loop.**create_unix_server**(*protocol_factory*, *path=None*, *, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*, *cleanup_socket=True*)

類似*loop.create_server()*，但適用於*AF_UNIX* socket 家族。

path 是 Unix 域 socket 的名稱，除非提供了 *sock* 引數，否則必須給定。支援抽象 Unix sockets、*str*、*bytes* 和*Path* 路徑。

如果 *cleanup_socket* 🄵真，則 Unix socket 將在伺服器關閉時自動從檔案系統中🄵除，除非在建立伺服器後替🄵了 socket。

有關此方法的引數資訊，請參🄵*loop.create_server()* 方法的文件。

可用性: Unix.

在 3.7 版的變更: 新增 *ssl_handshake_timeout* 與 *start_serving* 參數。*path* 參數現在可🄵一個*Path* 物件。

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

在 3.13 版的變更: 加入 *cleanup_socket* 參數。

async loop.**connect_accepted_socket**(*protocol_factory*, *sock*, *, *ssl=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

將已接受的連🄵包裝成傳輸層/協定對。

此方法可以由在 asyncio 外接受連🄵但使用 asyncio 處理連🄵的伺服器使用。

參數:

- *protocol_factory* 必須是可呼叫的函式，回傳*protocol* 實作。
- *sock* 是從*socket.accept* 回傳的預先存在的 socket 物件。

  > **備🄵**
  >
  > 引數 *sock* 將 socket 所有權轉移給所建立的傳輸 socket，請呼叫傳輸的*close()* 方法。

- *ssl* 可以設置🄵*SSLContext* 以在已接受的連🄵上🄵用 SSL。
- （對於 SSL 連🄵）*ssl_handshake_timeout* 是在中斷連🄵之前等待 SSL 握手完成的時間（以秒🄵單位）。如果🄵 `None`（預設），則🄵 `60.0` 秒。
- *ssl_shutdown_timeout* 是等待 SSL 關閉完成以前中斷連🄵的時間，以秒🄵單位。如果🄵 `None`（預設值），則會等待 `30.0` 秒。

回傳 `(transport, protocol)` 對。

在 3.5.3 版被加入.

在 3.7 版的變更: 增加 *ssl_handshake_timeout* 參數。

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

傳輸檔案

async loop.**sendfile**(*transport*, *file*, *offset=0*, *count=None*, *, *fallback=True*)

通過 *transport* 發送 *file*。回傳發送的總位元組數。

如果可用，該方法使用高性能*os.sendfile()*。

file 必須是以二進位模式打開的常規檔案物件。

offset 告訴從哪🄵開始讀取檔案。如果指定了，*count* 是要傳輸的總位元組數，而不是發送檔案直到達到 EOF。即使此方法引發錯誤時，檔案位置也始終更新，可以使用*file.tell()* 取得實際發送的位元組數。

將 *fallback* 設置🄵 `True` 會使 asyncio 在平台不支援 sendfile 系統呼叫時（例如 Windows 或 Unix 上的 SSL socket）手動讀取和發送檔案。

如果系統不支援 *sendfile* 系統呼叫且 *fallback* 🄵 `False`，則引發*SendfileNotAvailableError*。

在 3.7 版被加入.

TLS 升級

async loop.**start_tls**(*transport*, *protocol*, *sslcontext*, *, *server_side=False*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

將基於傳輸的現有連🄵升級到 TLS。

建立 TLS 編解碼器實例🄵在 *transport* 和 *protocol* 之間插入它。編解碼器既實作了對於 *transport* 的協定，也實作了對於 *protocol* 的傳輸。

回傳建立的雙介面實例。在 *await* 後，*protocol* 必須停止使用原始的 *transport*，僅與回傳的物件通信，因🄵編碼器快取了 *protocol* 端的資料，🄵且與 *transport* 間歇性地交🄵額外的 TLS session 封包。

在某些情🄵下（例如傳入的傳輸已經關閉），此函式可能回傳 `None`。

參數:

- *transport* 和 *protocol* 實例，由像*create_server()* 和*create_connection()* 等方法回傳。
- *sslcontext*：配置好的*SSLContext* 實例。
- 當升級伺服器端連🄵時（像由*create_server()* 建立的那樣）傳遞 `True`。
- *server_hostname*：設置或覆蓋將用於匹配目標伺服器憑證的主機名。
- *ssl_handshake_timeout*（對於 TLS 連🄵）是等待 TLS 交握的時間，以秒🄵單位，在那之前若未完成則會中斷連🄵。如果🄵 `None`（預設值），則會等待 `60.0` 秒。
- *ssl_shutdown_timeout* 是等待 SSL 關閉完成以前中斷連🄵的時間，以秒🄵單位。如果🄵 `None`（預設值），則會等待 `30.0` 秒。

在 3.7 版被加入.

在 3.11 版的變更: 增加 *ssl_shutdown_timeout* 參數。

監視檔案描述器

loop.**add_reader**(*fd*, *callback*, **args*)

開始監視 *fd* 檔案描述器的讀取可用性，一但 *fd* 可讀取，使用指定引數叫用 *callback*。

任何預先存在、🄵 *fd* 🄵🄵的回呼函式將被取消🄵替🄵🄵 *callback*。

loop.**remove_reader**(*fd*)

停止監視 *fd* 檔案描述器的讀取可用性。如果 *fd* 之前正在監視讀取，則回傳 `True`。

loop.**add_writer**(*fd*, *callback*, **args*)

開始監視 *fd* 檔案描述器的寫入可用性，一旦 *fd* 可寫入，使用指定引數叫用 *callback*。

任何預先存在、🄵 *fd* 🄵🄵的回呼函式將被取消🄵替🄵🄵 *callback*。

使用*functools.partial()* 向 *callback* 傳送關鍵字引數。

loop.**remove_writer**(*fd*)

停止監視 *fd* 檔案描述器的寫入可用性。如果 *fd* 之前正在監視寫入，則回傳 `True`。

另請參🄵平台支援部分以了解這些方法的一些限制。

直接使用 socket 物件

一般情🄵下，使用基於傳輸的 API（如*loop.create_connection()* 和*loop.create_server()*）的協定實作比直接使用 socket 的實作更快。然而在某些情🄵下性能不是關鍵，直接使用*socket* 物件更方便。

async loop.**sock_recv**(*sock*, *nbytes*)

從 *sock* 接收最多 *nbytes*。*socket.recv()* 的非同步版本。

將接收到的資料作🄵 bytes 物件回傳。

sock 必須是非阻塞 socket。

在 3.7 版的變更: 🄵管此方法一直記🄵🄵協程方法，但 Python 3.7 之前的版本回傳*Future*。自 Python 3.7 起，這是 `async def` 方法。

async loop.**sock_recv_into**(*sock*, *buf*)

從 *sock* 接收資料到 *buf* 緩衝區。仿照阻塞*socket.recv_into()* 方法。

回傳寫入緩衝區位元組的數目。

sock 必須是非阻塞 socket。

在 3.7 版被加入.

async loop.**sock_recvfrom**(*sock*, *bufsize*)

從 *sock* 接收最多 *bufsize* 大小的資料單元。*socket.recvfrom()* 的非同步版本。

回傳一個元組 (received data, remote address)。

sock 必須是非阻塞 socket。

在 3.11 版被加入.

async loop.**sock_recvfrom_into**(*sock*, *buf*, *nbytes=0*)

從 *sock* 接收最多 *nbytes* 大小的資料單元到 *buf*。*socket.recvfrom_into()* 的非同步版本。

回傳一個元組 (number of bytes received, remote address)。

sock 必須是非阻塞 socket。

在 3.11 版被加入.

async loop.**sock_sendall**(*sock*, *data*)

將 *data* 發送到 *sock* socket。*socket.sendall()* 的非同步版本。

此方法將繼續發送到 socket，直到 *data* 中的所有資料都已發送或發生錯誤。成功時回傳 `None`。錯誤時引發例外。此外，🄵有辦法確定接收端成功處理了多少資料（如果有的話）。

sock 必須是非阻塞 socket。

在 3.7 版的變更: 🄵管該方法一直被記🄵🄵協程方法，但在 Python 3.7 之前它回傳*Future*。從 Python 3.7 開始，這是一個 `async def` 方法。

async loop.**sock_sendto**(*sock*, *data*, *address*)

從 *sock* 向 *address* 發送一個資料單元。*socket.sendto()* 的非同步版本。

回傳發送的位元組數。

sock 必須是非阻塞 socket。

在 3.11 版被加入.

async loop.**sock_connect**(*sock*, *address*)

將 *sock* 連🄵到位於 *address* 的遠端 socket。

socket.connect() 的非同步版本。

sock 必須是非阻塞 socket。

在 3.5.2 版的變更: 不再需要解析 `address`。`sock_connect` 將嘗試透過呼叫*socket.inet_pton()* 檢查 *address* 是否已解析。如果🄵有，將使用*loop.getaddrinfo()* 解析 *address*。

> **也參考**
>
> *loop.create_connection()* 和*asyncio.open_connection()*。

async loop.**sock_accept**(*sock*)

接受一個連🄵。模擬阻塞的*socket.accept()* 方法。

Socket 必須🄵結到一個地址🄵偵聽連🄵。回傳值是一個 (conn, address) 對，其中 *conn* 是一個 新 socket 物件，可在連🄵上發送和接收資料，*address* 是連接另一端對應的 socket 地址。

sock 必須是非阻塞 socket。

在 3.7 版的變更: 🄵管該方法一直被記🄵🄵協程方法，但在 Python 3.7 之前它回傳*Future*。從 Python 3.7 開始，這是一個 async def 方法。

> **也參考**
>
> *loop.create_server()* 和*start_server()*。

async loop.**sock_sendfile**(*sock*, *file*, *offset=0*, *count=None*, *, *fallback=True*)

如果可行，使用高性能*os.sendfile* 發送檔案。回傳發送的總位元組數。

socket.sendfile() 的非同步版本。

sock 必須是非阻塞的*socket.SOCK_STREAM socket*。

file 必須是以二進位模式打開的常規檔案物件。

offset 告訴從哪🄵開始讀取檔案。如果指定了，*count* 是要傳輸的總位元組數，而不是發送檔案直到達到 EOF。即使此方法引發錯誤時，檔案位置也始終更新，可以使用*file.tell()* 取得實際發送的位元組數。

當設置🄵 True 時，*fallback* 使 asyncio 在平台不支援 sendfile 系統呼叫時（例如 Windows 或 Unix 上的 SSL socket）手動讀取和發送檔案。

如果系統不支援 *sendfile* 系統呼叫且 *fallback* 🄵 False，引發*SendfileNotAvailableError*。

sock 必須是非阻塞 socket。

在 3.7 版被加入.

DNS

async loop.**getaddrinfo**(*host*, *port*, *, *family=0*, *type=0*, *proto=0*, *flags=0*)

socket.getaddrinfo() 的非同步版本。

async loop.**getnameinfo**(*sockaddr*, *flags=0*)

socket.getnameinfo() 的非同步版本。

> **備🄵**
>
> Both *getaddrinfo* and *getnameinfo* internally utilize their synchronous versions through the loop's default thread pool executor. When this executor is saturated, these methods may experience delays, which higher-level networking libraries may report as increased timeouts. To mitigate this, consider using a custom executor for other user tasks, or setting a default executor with a larger number of workers.

在 3.7 版的變更: *getaddrinfo* 和 *getnameinfo* 方法一直被記🄵🄵回傳協程，但在 Python 3.7 之前它們實際上回傳*asyncio.Future* 物件。從 Python 3.7 開始，兩個方法都是協程。

使用管道

async loop.**connect_read_pipe**(*protocol_factory*, *pipe*)

在事件🄴圈中🄵🄴 *pipe* 的讀取端。

protocol_factory 必須是一個回傳*asyncio protocol* 實作的可呼叫函式。

pipe 是*類檔案物件*。

回傳 `(transport, protocol)` 對，其中 *transport* 支援*ReadTransport* 介面，*protocol* 是由 *protocol_factory* 實例化的物件。

使用*SelectorEventLoop* 事件🄴圈時，*pipe* 設置🄵非阻塞模式。

async loop.**connect_write_pipe**(*protocol_factory*, *pipe*)

在事件🄴圈中🄵🄴 *pipe* 的寫入端。

protocol_factory 必須是一個回傳*asyncio protocol* 實作的可呼叫函式。

pipe 是*file-like object*。

回傳 `(transport, protocol)` 對，其中 *transport* 支援*WriteTransport* 介面，*protocol* 是由 *protocol_factory* 實例化的物件。

使用*SelectorEventLoop* 事件🄴圈時，*pipe* 設置🄵非阻塞模式。

備🄵

SelectorEventLoop 在 Windows 上不支援上述方法。對於 Windows 請使用*ProactorEventLoop*。

也參考

loop.subprocess_exec() 和*loop.subprocess_shell()* 方法。

Unix 訊號

loop.**add_signal_handler**(*signum*, *callback*, **args*)

將 *callback* 設置🄵 *signum* 訊號的處理程式。

該回呼將由 *loop* 叫用，與該事件🄴圈的其他排隊回呼和可運行的協程一起。與使用*signal.signal()* 🄵🄵的訊號處理程式不同，使用此函式🄵🄵的回呼允許與事件🄴圈進行互動。

如果訊號號無效或不可捕獲，引發*ValueError*。如果設定處理程序有問題，🄵出*RuntimeError*。

使用*functools.partial()* 向 *callback* *傳送關鍵字引數*。

像*signal.signal()* 一樣，此函式必須在主執行緒中叫用。

loop.**remove_signal_handler**(*sig*)

移除 *sig* 訊號的處理程式。

如果訊號處理程式被移除，回傳 `True`；如果給定訊號🄵有設置處理程式，回傳 `False`。

可用性: Unix.

也參考

signal 模組。

在執行緒池或行程池中執行程式碼

awaitable loop.**run_in_executor**(*executor*, *func*, **args*)

安排在指定的執行器中呼叫 *func*。

The *executor* argument should be an *concurrent.futures.Executor* instance. The default executor is used if *executor* is None. The default executor can be set by *loop.set_default_executor()*, otherwise, a *concurrent.futures.ThreadPoolExecutor* will be lazy-initialized and used by *run_in_executor()* if needed.

範例：

```
import asyncio
import concurrent.futures

def blocking_io():
    # File operations (such as logging) can block the
    # event loop: run them in a thread pool.
    with open('/dev/urandom', 'rb') as f:
        return f.read(100)

def cpu_bound():
    # CPU-bound operations will block the event loop:
    # in general it is preferable to run them in a
    # process pool.
    return sum(i * i for i in range(10 ** 7))

async def main():
    loop = asyncio.get_running_loop()

    ## Options:

    # 1. Run in the default loop's executor:
    result = await loop.run_in_executor(
        None, blocking_io)
    print('default thread pool', result)

    # 2. Run in a custom thread pool:
    with concurrent.futures.ThreadPoolExecutor() as pool:
        result = await loop.run_in_executor(
            pool, blocking_io)
        print('custom thread pool', result)

    # 3. Run in a custom process pool:
    with concurrent.futures.ProcessPoolExecutor() as pool:
        result = await loop.run_in_executor(
            pool, cpu_bound)
        print('custom process pool', result)

    # 4. Run in a custom interpreter pool:
    with concurrent.futures.InterpreterPoolExecutor() as pool:
        result = await loop.run_in_executor(
            pool, cpu_bound)
        print('custom interpreter pool', result)

if __name__ == '__main__':
    asyncio.run(main())
```

請注意，由於*multiprocessing*（由*ProcessPoolExecutor* 使用）的特殊性，選項 3 需要進入點保護（if __name__ == '__main__'）。請參🄵主模組的安全引入。

此方法回傳*asyncio.Future* 物件。

使用*functools.partial()* 將來關鍵字引數傳遞給 *func*。

在 3.5.3 版的變更: *loop.run_in_executor()* 不再配置它建立的執行緒池執行器的 `max_workers`，而是讓執行緒池執行器（*ThreadPoolExecutor*）設定預設值。

`loop.`**`set_default_executor`**(*executor*)

將 *executor* 設置🄵*run_in_executor()* 使用的預設執行器。*executor* 必須是*ThreadPoolExecutor*（也包含*InterpreterPoolExecutor*）的實例。

在 3.11 版的變更: *executor* 必須是*ThreadPoolExecutor* 的實例。

錯誤處理 API

允許自定義事件🄵圈中的例外處理方式。

`loop.`**`set_exception_handler`**(*handler*)

將 *handler* 設定🄵新的事件🄵圈例外處理程式。

如果 *handler* 是 `None`，則將設置預設例外處理程式。否則，*handler* 必須是一個可呼叫物件，簽名匹配 `(loop, context)`，其中 `loop` 是參照活躍事件🄵圈的，`context` 是包含例外詳細資訊的 `dict` 物件（有關情境的詳細資訊，請參🄵*call_exception_handler()* 文件）。

如果代表*Task* 或*Handle* 呼叫處理程式，它將在該任務或回呼處理程式的*contextvars.Context* 中運行。

在 3.12 版的變更: 處理程式可能在引發例外的任務或處理程式的*Context* 中被呼叫。

`loop.`**`get_exception_handler`**()

回傳目前的例外處理程式，如果未設置自定義例外處理程式，則回傳 `None`。

在 3.5.2 版被加入.

`loop.`**`default_exception_handler`**(*context*)

預設例外處理程式。

當發生例外且未設置例外處理程式時呼叫此函式。自定義例外處理程式可以呼叫此函式以轉由預設處理程式處理。

context 參數與*call_exception_handler()* 中的意思相同。

`loop.`**`call_exception_handler`**(*context*)

呼叫目前事件🄵圈例外處理程式。

context 是一個包含以下鍵的 `dict` 物件（未來的 Python 版本中可能會引入新的鍵）：

- 'message'：錯誤訊息；
- 'exception'（可選）：例外物件；
- 'future'（可選）：*asyncio.Future* 實例；
- 'task'（可選）：*asyncio.Task* 實例；
- 'handle'（可選）：*asyncio.Handle* 實例；
- 'protocol'（可選）：*Protocol* 實例；
- 'transport'（可選）：*Transport* 實例；
- 'socket'（可選）：*socket.socket* 實例；
- 'source_traceback' (optional): Traceback of the source;
- 'handle_traceback' (optional): Traceback of the handle;
- **'asyncgen'(可選)：非同步🄵生器引發**
  例外。

> **備🄵**
>
> 此方法不應在子類🄵事件🄵圈中被覆寫。🄵了自定義例外處理，請使用*set_exception_handler()* 方法。

🄵用除錯模式

`loop.get_debug`()

取得事件🄵圈的除錯模式（*bool*）。

如果環境變數 `PYTHONASYNCIODEBUG` 被設定🄵非空字串，則預設值🄵 `True`，否則🄵 `False`。

`loop.set_debug`(*enabled:* bool)

設定事件🄵圈的除錯模式。

在 3.7 版的變更: 現在也可以使用新的*Python 開發模式* 🄵用除錯模式。

`loop.slow_callback_duration`

此屬性可用於設定被視🄵" 慢" 的最短執行時間（以秒🄵單位）。🄵用偵錯模式後，" 慢" 回呼將被記🄵。

預設值🄵 100 毫秒

> **也參考**
>
> *asyncio 的除錯模式*。

運行子行程

本小節描述的方法是低階的。在常規的 async/await 程式碼中，請考慮使用高階*asyncio.create_subprocess_shell()* 和*asyncio.create_subprocess_exec()* 輔助功能而不是。

> **備🄵**
>
> 在 Windows 上，預設事件🄵圈*ProactorEventLoop* 支援子行程，而*SelectorEventLoop* 不支援。詳細資訊請參見*Windows 上對於子行程的支援*。

async `loop.subprocess_exec`(*protocol_factory*, **args*, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

從 *args* 指定的一個或多個字串引數建立子行程。

args 必須是由以下項表示的字串串列:

- *str*;
- 或*bytes*，編碼🄵*檔案系統編碼*。

第一個字串指定程序可執行檔案，其余字串指定引數。字串引數一起組成程序的 `argv`。

這與標准函式庫*subprocess.Popen* 類似，使用 `shell=False` 呼叫🄵將字串串列作🄵第一個引數傳遞；然而，*Popen* 接受單個字串串列引數，*subprocess_exec* 接受多個字串引數。

protocol_factory 必須是回傳*asyncio.SubprocessProtocol* 子類🄵的可呼叫物件。

其他參數:

- *stdin* 可以是以下任意一個:
  - 類檔案物件
  - 現有的檔案描述器（正整數），例如用*os.pipe()* 建立的

  - *subprocess.PIPE* 常數（預設），它將建立一個新的管道🄵連🄵，
  - 值 None 將使子行程從此行程繼承檔案描述器
  - *subprocess.DEVNULL* 常數，表示將使用特殊的*os.devnull* 檔案
- *stdout* 可以是以下任意一個：
  - 類檔案物件
  - *subprocess.PIPE* 常數（預設），它將建立一個新的管道🄵連🄵，
  - 值 None 將使子行程從此行程繼承檔案描述器
  - *subprocess.DEVNULL* 常數，表示將使用特殊的*os.devnull* 檔案
- *stderr* 可以是以下任意一個：
  - 類檔案物件
  - *subprocess.PIPE* 常數（預設），它將建立一個新的管道🄵連🄵，
  - 值 None 將使子行程從此行程繼承檔案描述器
  - *subprocess.DEVNULL* 常數，表示將使用特殊的*os.devnull* 檔案
  - *subprocess.STDOUT* 常數，它將標準錯誤串流連🄵到行程的標準輸出串流
- 所有其他關鍵字引數都會傳遞給*subprocess.Popen* 而不進行直譯，但 *bufsize*、*universal_newlines*、*shell*、*text*、*encoding* 和 *errors* 除外，這些不應該指定。

  asyncio 子行程 API 不支援將串流解碼🄵文本。可以使用*bytes.decode()* 將從串流回傳的位元組轉🄵🄵文本。

如果傳遞給 *stdin*、*stdout* 或 *stderr* 的類檔案物件表示管道，則該管道的另一端應該使用*connect_write_pipe()* 或*connect_read_pipe()* 🄵🄵到事件🄵圈中。

有關其他引數的文件，請參🄵*subprocess.Popen* 類🄵的建構函式。

回傳 (transport, protocol) 對，其中 *transport* 符合*asyncio.SubprocessTransport* 基底類🄵，*protocol* 是由 *protocol_factory* 實例化的物件。

async loop.**subprocess_shell**(*protocol_factory*, *cmd*, *, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

使用平台的"shell" 語法從 *cmd* 建立子行程，*cmd* 可以是*str* 或編碼🄵*檔案系統編碼* 的*bytes* 字串。

這類似於標準函式庫中的*subprocess.Popen* 類🄵，使用 shell=True 呼叫。

protocol_factory 必須是回傳*SubprocessProtocol* 子類🄵的可呼叫物件。

有關其余引數的更多詳細資訊，請參🄵*subprocess_exec()*。

回傳一對 (transport, protocol)，其中 *transport* 符合*SubprocessTransport* 基底類🄵，而 *protocol* 是由 *protocol_factory* 實例化的物件。

備🄵

由應用程式負責確保適當引用所有空白和特殊字元，以避免 shell 注入風險。可以使用*shlex.quote()* 函式來正確跳🄵用於構建 shell 命令的字串中的空白和特殊字元。

回呼處理

class asyncio.**Handle**

由*loop.call_soon()* 和*loop.call_soon_threadsafe()* 回傳的回呼包裝器。

get_context()

回傳與處理相關聯的*contextvars.Context* 物件。

在 3.12 版被加入.

cancel()

取消回呼。如果回呼已被取消或執行，此方法將不起作用。

cancelled()

如果回呼已被取消，回傳 `True`。

在 3.7 版被加入.

class asyncio.**TimerHandle**

由*loop.call_later()* 和*loop.call_at()* 回傳的回呼包裝器。

這個類🄵是*Handle* 的子類🄵。

when()

回傳預定的回呼時間，以*float* 秒🄵單位。

時間是一個🄵對的時間戳，使用與*loop.time()* 相同的時間參照。

在 3.7 版被加入.

Server 物件

Server 物件是由*loop.create_server()*、*loop.create_unix_server()*、*start_server()* 和*start_unix_server()* 函式所建立。

請勿直接實例化*Server* 類🄵。

class asyncio.**Server**

Server 物件是非同步情境管理器。當在 `async with` 陳述中使用時，可以保證在完成 `async with` 陳述時，Server 物件將會關閉🄵停止接受新的連🄵：

```
srv = await loop.create_server(...)

async with srv:
    # 一些程式碼

# 此時 srv 已關閉，不再接受新的連🄵。
```

在 3.7 版的變更: 自 Python 3.7 起，Server 物件是非同步情境管理器。

在 3.11 版的變更: 此類🄵在 Python 3.9.11、3.10.3 和 3.11 中以 `asyncio.Server` 的形式被公開。

close()

停止服務：關閉監聽的 sockets 🄵將*sockets* 屬性設🄵 `None`。

代表現有傳入用🄵端連🄵的 sockets 仍然保持開🄵。

伺服器以非同步方式關閉；使用 `wait_close()` 協程等待伺服器關閉（不再有活躍連🄵）。

close_clients()

關閉所有現有的傳入用🄵端連🄵。

在所有關聯的傳輸上呼叫*close()*。

close() should be called before *close_clients()* when closing the server to avoid races with new clients connecting.

在 3.13 版被加入.

abort_clients()

立即關閉所有現有的傳入用🄵端連🄵，而不等待待定操作完成。

在所有關聯的傳輸上呼叫*close()*。

close() should be called before *abort_clients()* when closing the server to avoid races with new clients connecting.

在 3.13 版被加入.

get_loop()

回傳與伺服器物件關聯的事件🄵圈。

在 3.7 版被加入.

async start_serving()

開始接受連🄵。

此方法是冪等的，因此可以在伺服器已經運行時呼叫。

start_serving 僅限關鍵字參數只能在*loop.create_server()* 和*asyncio.start_server()* 中使用，允許建立一個最初不接受連🄵的 Server 物件。在這種情🄵下，可以使用 `Server.start_serving()` 或*Server.serve_forever()* 來使 Server 開始接受連🄵。

在 3.7 版被加入.

async serve_forever()

開始接受連🄵，直到協程被取消。取消 `serve_forever` 任務會導致伺服器關閉。

如果伺服器已經接受連🄵，則可以呼叫此方法。每個 *Server* 物件只能存在一個 `serve_forever` 任務。

範例：

```
async def client_connected(reader, writer):
    # 透過讀取器/寫入器串流
    # 與用🄴端溝通。例如：
    await reader.readline()

async def main(host, port):
    srv = await asyncio.start_server(
        client_connected, host, port)
    await srv.serve_forever()

asyncio.run(main('127.0.0.1', 0))
```

在 3.7 版被加入.

is_serving()

如果伺服器正在接受新連🄵，則回傳 `True`。

在 3.7 版被加入.

async wait_closed()

等待*close()* 方法完成且所有活動連🄵都已結束。

sockets

伺服器正在監聽的類似 socket 的物件串列，`asyncio.trsock.TransportSocket`。

在 3.7 版的變更: 在 Python 3.7 之前，`Server.sockets` 曾經直接回傳🄵部伺服器 sockets 的串列。在 3.7 中回傳了該串列的副本。

事件🄵圈實作

asyncio 🄵附兩個不同的事件🄵圈實作：*SelectorEventLoop* 和*ProactorEventLoop*。

預設情🄵下，asyncio 被配置🄵要使用*EventLoop*。

class asyncio.**SelectorEventLoop**

基於*selectors* 模組的一個*AbstractEventLoop* 子類🄵。

使用特定平台上最有效的 *selector*。也可以手動配置要使用的確切 selector 實作：

```
import asyncio
import selectors

async def main():
    ...

loop_factory = lambda: asyncio.SelectorEventLoop(selectors.SelectSelector())
asyncio.run(main(), loop_factory=loop_factory)
```

可用性: Unix, Windows.

class asyncio.**ProactorEventLoop**

用於 Windows 的*AbstractEventLoop* 子類🄵，使用「I/O 完成埠 (IOCP, I/O Completion Ports)」。

可用性: Windows.

> **也參考**
>
> I/O 完成埠的 MSDN 文件。

class asyncio.**EventLoop**

An alias to the most efficient available subclass of *AbstractEventLoop* for the given platform.

在 Unix 上是*SelectorEventLoop* 的🄵名，在 Windows 上是*ProactorEventLoop* 的🄵名。

在 3.13 版被加入.

class asyncio.**AbstractEventLoop**

🄵符合 asyncio 標准的事件🄵圈的抽象基礎類🄵。

事件🄵圈方法 部分列出了替代 AbstractEventLoop 實作應該定義的所有方法。

范例

請注意，本節中的所有範例都 **故意**展示如何使用低階事件🄵圈 API，如*loop.run_forever()* 和*loop.call_soon()*。現代 asyncio 應用程式很少需要這種方式撰寫；請考慮使用高階的函式，如*asyncio.run()*。

使用 call_soon() 的 Hello World 范例

使用*loop.call_soon()* 方法排程回呼的範例。回呼會顯示 "Hello World"，然後停止事件🄵圈：

```
import asyncio

def hello_world(loop):
    """列印 'Hello World' 🄵停止事件🄵圈的回呼"""
    print('Hello World')
    loop.stop()

loop = asyncio.new_event_loop()

# 排程對 hello_world() 的呼叫
loop.call_soon(hello_world, loop)

# 阻塞呼叫被 loop.stop() 中斷
try:
    loop.run_forever()
finally:
    loop.close()
```

也參考

使用協程和*run()* 函式建立的類似*Hello World* 範例。

使用 call_later() 顯示目前日期

一個回呼的範例，每秒顯示目前日期。回呼使用*loop.call_later()* 方法在 5 秒後重新排程自己，然後停止事件🄴圈：

```
import asyncio
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.new_event_loop()

# 排程 display_date() 的第一次呼叫
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# 阻塞呼叫被 loop.stop() 中斷
try:
    loop.run_forever()
finally:
    loop.close()
```

也參考

使用協程和*run()* 函式建立的類似*current date* 範例。

監聽檔案描述器以進行讀取事件

使用*loop.add_reader()* 方法等待檔案描述器接收到某些資料，然後關閉事件🄴圈：

```
import asyncio
from socket import socketpair

# 建立一對連接的檔案描述器
rsock, wsock = socketpair()

loop = asyncio.new_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())

    # 我們完成了：🄵銷檔案描述器
    loop.remove_reader(rsock)

    # 停止事件🄴圈
    loop.stop()

# 🄵讀取事件🄵🄵檔案描述器
```

(繼續下一頁)

(繼續上一頁)

```
loop.add_reader(rsock, reader)

# 模擬從網路接收資料
loop.call_soon(wsock.send, 'abc'.encode())

try:
    # 運行事件🄵圈
    loop.run_forever()
finally:
    # 我們完成了。關閉 socket 和事件🄵圈。
    rsock.close()
    wsock.close()
    loop.close()
```

也參考

- 使用傳輸、協定和*loop.create_connection()* 方法的類似範例。
- 另一個使用高階*asyncio.open_connection()* 函式和串流的類似範例。

設定 SIGINT 和 SIGTERM 的訊號處理程式

（此 `signals` 範例僅在 Unix 上運作。）

使用*loop.add_signal_handler()* 方法🄵🄵訊號 `SIGINT` 和 `SIGTERM` 的處理程式：

```
import asyncio
import functools
import os
import signal

def ask_exit(signame, loop):
    print("got signal %s: exit" % signame)
    loop.stop()

async def main():
    loop = asyncio.get_running_loop()

    for signame in {'SIGINT', 'SIGTERM'}:
        loop.add_signal_handler(
            getattr(signal, signame),
            functools.partial(ask_exit, signame, loop))

    await asyncio.sleep(3600)

print("Event loop running for 1 hour, press Ctrl+C to interrupt.")
print(f"pid {os.getpid()}: send SIGINT or SIGTERM to exit.")

asyncio.run(main())
```

19.1.10 Futures

原始碼： Lib/asyncio/futures.py、source:‘Lib/asyncio/base_futures.py

---

Future 物件被用來連結**低階回呼式程式**和高階 async/await 程式。

Future 函式

asyncio.**isfuture**(*obj*)

如果 *obj* 🄵下面任意物件，回傳 `True`：

- 一個*asyncio.Future* 的實例、
- 一個*asyncio.Task* 的實例、
- 帶有 `_asyncio_future_blocking` 屬性的類 Future 物件 (Future-like object)。

在 3.5 版被加入.

asyncio.**ensure_future**(*obj*, *, *loop=None*)

回傳：

- *obj* 引數會保持原樣，*obj* 須🄵*Future*、*Task* 或類 Future 物件（可以用*isfuture()* 來進行檢查。）
- 包裝 (wrap) 了 *obj* 的*Task* 物件，如果 *obj* 是一個協程 (coroutine) (可以用*iscoroutine()* 來進行檢查)；在此情🄵下該協程將透過 `ensure_future()` 來排程。
- 一個會等待 *obj* 的*Task* 物件，*obj* 須🄵一個可等待物件（*inspect.isawaitable()* 用於測試。）

如果 *obj* 不是上述物件的話會引發一個*TypeError* 例外。

> **重要**
>
> 將參照 (reference) 儲存至此函式的結果，用以防止任務在執行中消失。
>
> 請見*create_task()* 函式，它是建立新 Task 的推薦方法。或者使用*asyncio.TaskGroup*，它會在🄵部保留對 Task 的參照。

在 3.5.1 版的變更: 這個函式接受任意*awaitable* 物件。

在 3.10 版之後被🄵用: 如果 *obj* 不是類 Future 物件且 *loop* 🄵未被指定，同時🄵有正在執行的事件🄵圈 (event loop)，則會發出🄵用警告。

asyncio.**wrap_future**(*future*, *, *loop=None*)

將一個*concurrent.futures.Future* 物件包裝到*asyncio.Future* 物件中。

在 3.10 版之後被🄵用: 如果 *future* 不是類 Future 物件且 *loop* 未被指定，同時🄵有正在執行的事件🄵圈，則會發出🄵用警告。

Future 物件

class asyncio.**Future**(*, *loop=None*)

一個 Future 代表一個非同步運算的最終結果。🄵不支援執行緒安全 (thread-safe)。

Future 是一個*awaitable* 物件。協程可以等待 Future 物件直到它們有結果或例外被設置、或者被取消。一個 Future 可被多次等待而結果都會是相同的。

Future 通常用於讓低階基於回呼的程式（例如在協定實作中使用 asyncio *transports*）能🄵與高階 async/await 程式互動。

經驗法則🄵永遠不要在提供給使用者的 API 中公開 Future 物件，同時建議使用*loop.create_future()* 來建立 Future 物件。如此一來，不同實作的事件🄵圈可以注入自己最佳化實作的 Future 物件。

在 3.7 版的變更: 加入對*contextvars* 模組的支援。

在 3.10 版之後被🄵用: 如果未指定 *loop* 🄵且🄵有正在執行的事件🄵圈則會發出🄵用警告。

result()

回傳 Future 的結果。

如果 Future 狀態🄵 *done*（完成），🄵擁有*set_result()* 方法設定的一個結果，則回傳該結果之值。

如果 Future 狀態🄵 *done*，🄵擁有*set_exception()* 方法設定的一個例外，那🄵這個方法會引發該例外。

如果 Future 已被 *cancelled*（取消），此方法會引發一個*CancelledError* 例外。

如果 Future 的結果還不可用，此方法會引發一個*InvalidStateError* 例外。

set_result(*result*)

將 Future 標記🄵 *done* 🄵設定其結果。

如果 Future 已經 *done* 則引發一個*InvalidStateError* 錯誤。

set_exception(*exception*)

將 Future 標記🄵 *done* 🄵設定一個例外。

如果 Future 已經 *done* 則引發一個*InvalidStateError* 錯誤。

done()

如果 Future 已🄵 *done* 則回傳 `True`。

如果 Future 有被 *cancelled*、*set_result()* 有被呼叫來🄵其設定結果、或*set_exception()* 有被呼叫🄵其設定例外，那🄵它就是 *done*。

cancelled()

如果 Future 已經被 *cancelled* 則回傳 `True`。

這個方法通常在🄵 Future 設定結果或例外前用來確認它還🄵被 *cancelled*：

```
if not fut.cancelled():
    fut.set_result(42)
```

add_done_callback(*callback*, *, *context=None*)

新增一個在 Future 🄵 *done* 時執行的回呼函式。

呼叫 *callback* 🄵附帶做🄵唯一引數的 Future 物件。

如果呼叫這個方法時 Future 已經🄵 *done*，回呼函式會被*loop.call_soon()* 排程。

可選僅限關鍵字引數 *context* 用來指定一個讓 *callback* 執行於其中的客🄵化*contextvars.Context* 物件。如果🄵有提供 *context*，則使用目前情境。

可以用*functools.partial()* 傳遞引數給回呼函式，例如：

```
# Call 'print("Future:", fut)' when "fut" is done.
fut.add_done_callback(
    functools.partial(print, "Future:"))
```

在 3.7 版的變更: 加入僅限關鍵字參數 *context*。更多細節請參🄵 **PEP 567**。

remove_done_callback(*callback*)

從回呼列表中移除 *callback*。

回傳被移除的回呼函式數量，通常🄵 1，除非一個回呼函式被多次加入。

cancel(*msg=None*)

取消 Future 🄵🄵回呼函式排程。

如果 Future 已經是 *done* 或 *cancelled*，回傳 `False`。否則將 Future 狀態改🄵 *cancelled* 🄵在🄵回呼函式排程後回傳 `True`。

在 3.9 版的變更: 新增 *msg* 參數。

exception()

回傳被設定於此 Future 的例外。

只有 Future 在 *done* 時才回傳例外（如果🄵有設定例外則回傳 None）。

如果 Future 已被 *cancelled*（取消），此方法會引發一個*CancelledError* 例外。

如果 Future 還不🄵 *done*，此方法會引發一個*InvalidStateError* 例外。

get_loop()

回傳已被 Future 物件🄵結 (bind) 的事件🄵圈。

在 3.7 版被加入.

這個例子建立一個 Future 物件，建立一個非同步 Task 🄵🄵其排程以設定 Future 結果，然後等待 Future 結果出現：

```
async def set_after(fut, delay, value):
    # Sleep for *delay* seconds.
    await asyncio.sleep(delay)

    # Set *value* as a result of *fut* Future.
    fut.set_result(value)

async def main():
    # Get the current event loop.
    loop = asyncio.get_running_loop()

    # Create a new Future object.
    fut = loop.create_future()

    # Run "set_after()" coroutine in a parallel Task.
    # We are using the low-level "loop.create_task()" API here because
    # we already have a reference to the event loop at hand.
    # Otherwise we could have just used "asyncio.create_task()".
    loop.create_task(
        set_after(fut, 1, '... world'))

    print('hello ...')

    # Wait until *fut* has a result (1 second) and print it.
    print(await fut)

asyncio.run(main())
```

重要

該 Future 物件是🄵了模仿*concurrent.futures.Future* 而設計。主要差🄵包含：

- 與 asyncio 的 Future 不同，*concurrent.futures.Future* 實例不可被等待。
- *asyncio.Future.result()* 和*asyncio.Future.exception()* 不接受 *timeout* 引數。
- Future 不🄵 *done* 時*asyncio.Future.result()* 和*asyncio.Future.exception()* 會引發一個*InvalidStateError* 例外。
- 使用*asyncio.Future.add_done_callback()* 🄵🄵的回呼函式不會立即呼叫，而是被*loop.call_soon()* 排程。
- asyncio Future 不能與*concurrent.futures.wait()* 和*concurrent.futures.as_completed()* 函式相容。
- *asyncio.Future.cancel()* 接受一個可選的 msg 引數，但*concurrent.futures.Future.cancel()* 無此引數。

19.1.11 傳輸與協定

前言

Transports and Protocols are used by the **low-level** event loop APIs such as `loop.create_connection()`. They use callback-based programming style and enable high-performance implementations of network or IPC protocols (e.g. HTTP).

Essentially, transports and protocols should only be used in libraries and frameworks and never in high-level asyncio applications.

This documentation page covers both *Transports* and *Protocols*.

Introduction

At the highest level, the transport is concerned with *how* bytes are transmitted, while the protocol determines *which* bytes to transmit (and to some extent when).

A different way of saying the same thing: a transport is an abstraction for a socket (or similar I/O endpoint) while a protocol is an abstraction for an application, from the transport's point of view.

Yet another view is the transport and protocol interfaces together define an abstract interface for using network I/O and interprocess I/O.

There is always a 1:1 relationship between transport and protocol objects: the protocol calls transport methods to send data, while the transport calls protocol methods to pass it data that has been received.

Most of connection oriented event loop methods (such as `loop.create_connection()`) usually accept a *protocol_factory* argument used to create a *Protocol* object for an accepted connection, represented by a *Transport* object. Such methods usually return a tuple of `(transport, protocol)`.

目🄵

This documentation page contains the following sections:

- The *Transports* section documents asyncio `BaseTransport`, `ReadTransport`, `WriteTransport`, `Transport`, `DatagramTransport`, and `SubprocessTransport` classes.
- The *Protocols* section documents asyncio `BaseProtocol`, `Protocol`, `BufferedProtocol`, `DatagramProtocol`, and `SubprocessProtocol` classes.
- The *Examples* section showcases how to work with transports, protocols, and low-level event loop APIs.

Transports

原始碼： Lib/asyncio/transports.py

Transports are classes provided by `asyncio` in order to abstract various kinds of communication channels.

Transport objects are always instantiated by an *asyncio event loop*.

asyncio implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport's kind.

The transport classes are *not thread safe*.

Transports Hierarchy

class asyncio.**BaseTransport**

Base class for all transports. Contains methods that all asyncio transports share.

class asyncio.**WriteTransport**(*BaseTransport*)

A base transport for write-only connections.

Instances of the *WriteTransport* class are returned from the *loop.connect_write_pipe()* event loop method and are also used by subprocess-related methods like *loop.subprocess_exec()*.

class asyncio.**ReadTransport**(*BaseTransport*)

A base transport for read-only connections.

Instances of the *ReadTransport* class are returned from the *loop.connect_read_pipe()* event loop method and are also used by subprocess-related methods like *loop.subprocess_exec()*.

class asyncio.**Transport**(*WriteTransport*, *ReadTransport*)

Interface representing a bidirectional transport, such as a TCP connection.

The user does not instantiate a transport directly; they call a utility function, passing it a protocol factory and other information necessary to create the transport and protocol.

Instances of the *Transport* class are returned from or used by event loop methods like *loop.create_connection()*, *loop.create_unix_connection()*, *loop.create_server()*, *loop.sendfile()*, etc.

class asyncio.**DatagramTransport**(*BaseTransport*)

A transport for datagram (UDP) connections.

Instances of the *DatagramTransport* class are returned from the *loop.create_datagram_endpoint()* event loop method.

class asyncio.**SubprocessTransport**(*BaseTransport*)

An abstraction to represent a connection between a parent and its child OS process.

Instances of the *SubprocessTransport* class are returned from event loop methods *loop.subprocess_shell()* and *loop.subprocess_exec()*.

Base Transport

BaseTransport.**close**()

Close the transport.

If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the protocol's *protocol.connection_lost()* method will be called with *None* as its argument. The transport should not be used once it is closed.

BaseTransport.**is_closing**()

Return `True` if the transport is closing or is closed.

BaseTransport.**get_extra_info**(*name*, *default=None*)

Return information about the transport or underlying resources it uses.

name is a string representing the piece of transport-specific information to get.

default is the value to return if the information is not available, or if the transport does not support querying it with the given third-party event loop implementation or on the current platform.

For example, the following code attempts to get the underlying socket object of the transport:

```
sock = transport.get_extra_info('socket')
if sock is not None:
    print(sock.getsockopt(...))
```

Categories of information that can be queried on some transports:

- socket:
  - `'peername'`: the remote address to which the socket is connected, result of *socket.socket.getpeername()* (`None` on error)

  - `'socket'`: *socket.socket* instance
  - `'sockname'`: the socket's own address, result of *socket.socket.getsockname()*
- SSL socket:
  - `'compression'`: the compression algorithm being used as a string, or `None` if the connection isn't compressed; result of *ssl.SSLSocket.compression()*
  - `'cipher'`: a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of *ssl.SSLSocket.cipher()*
  - `'peercert'`: peer certificate; result of *ssl.SSLSocket.getpeercert()*
  - `'sslcontext'`: *ssl.SSLContext* instance
  - `'ssl_object'`: *ssl.SSLObject* or *ssl.SSLSocket* instance
- pipe:
  - `'pipe'`: pipe object
- subprocess:
  - `'subprocess'`: *subprocess.Popen* instance

`BaseTransport.`**`set_protocol`**(*protocol*)

Set a new protocol.

Switching protocol should only be done when both protocols are documented to support the switch.

`BaseTransport.`**`get_protocol`**()

Return the current protocol.

Read-only Transports

`ReadTransport.`**`is_reading`**()

Return `True` if the transport is receiving new data.

在 3.7 版被加入.

`ReadTransport.`**`pause_reading`**()

Pause the receiving end of the transport. No data will be passed to the protocol's *protocol.data_received()* method until *resume_reading()* is called.

在 3.7 版的變更: The method is idempotent, i.e. it can be called when the transport is already paused or closed.

`ReadTransport.`**`resume_reading`**()

Resume the receiving end. The protocol's *protocol.data_received()* method will be called once again if some data is available for reading.

在 3.7 版的變更: The method is idempotent, i.e. it can be called when the transport is already reading.

Write-only Transports

`WriteTransport.`**`abort`**()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's *protocol.connection_lost()* method will eventually be called with *None* as its argument.

`WriteTransport.`**`can_write_eof`**()

Return *True* if the transport supports *write_eof()*, *False* if not.

WriteTransport.**get_write_buffer_size**()

Return the current size of the output buffer used by the transport.

WriteTransport.**get_write_buffer_limits**()

Get the *high* and *low* watermarks for write flow control. Return a tuple `(low, high)` where *low* and *high* are positive number of bytes.

Use *set_write_buffer_limits()* to set the limits.

在 3.4.2 版被加入.

WriteTransport.**set_write_buffer_limits**(*high=None*, *low=None*)

Set the *high* and *low* watermarks for write flow control.

These two values (measured in number of bytes) control when the protocol's *protocol.pause_writing()* and *protocol.resume_writing()* methods are called. If specified, the low watermark must be less than or equal to the high watermark. Neither *high* nor *low* can be negative.

pause_writing() is called when the buffer size becomes greater than or equal to the *high* value. If writing has been paused, *resume_writing()* is called when the buffer size becomes less than or equal to the *low* value.

The defaults are implementation-specific. If only the high watermark is given, the low watermark defaults to an implementation-specific value less than or equal to the high watermark. Setting *high* to zero forces *low* to zero as well, and causes *pause_writing()* to be called whenever the buffer becomes non-empty. Setting *low* to zero causes *resume_writing()* to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use *get_write_buffer_limits()* to get the limits.

WriteTransport.**write**(*data*)

Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

WriteTransport.**writelines**(*list_of_data*)

Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling *write()* on each element yielded by the iterable, but may be implemented more efficiently.

WriteTransport.**write_eof**()

Close the write end of the transport after flushing all buffered data. Data may still be received.

This method can raise *NotImplementedError* if the transport (e.g. SSL) doesn't support half-closed connections.

Datagram Transports

DatagramTransport.**sendto**(*data*, *addr=None*)

Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is *None*, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

在 3.13 版的變更: This method can be called with an empty bytes object to send a zero-length datagram. The buffer size calculation used for flow control is also updated to account for the datagram header.

DatagramTransport.**abort**()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's *protocol.connection_lost()* method will eventually be called with *None* as its argument.

Subprocess Transports

SubprocessTransport.**get_pid**()

Return the subprocess process id as an integer.

SubprocessTransport.**get_pipe_transport**(*fd*)

Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- `0`: writable streaming transport of the standard input (*stdin*), or *None* if the subprocess was not created with `stdin=PIPE`
- `1`: readable streaming transport of the standard output (*stdout*), or *None* if the subprocess was not created with `stdout=PIPE`
- `2`: readable streaming transport of the standard error (*stderr*), or *None* if the subprocess was not created with `stderr=PIPE`
- other *fd*: *None*

SubprocessTransport.**get_returncode**()

Return the subprocess return code as an integer or *None* if it hasn't returned, which is similar to the *subprocess.Popen.returncode* attribute.

SubprocessTransport.**kill**()

Kill the subprocess.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for *terminate()*.

另請參🄵*subprocess.Popen.kill()*。

SubprocessTransport.**send_signal**(*signal*)

Send the *signal* number to the subprocess, as in *subprocess.Popen.send_signal()*.

SubprocessTransport.**terminate**()

Stop the subprocess.

On POSIX systems, this method sends *SIGTERM* to the subprocess. On Windows, the Windows API function `TerminateProcess()` is called to stop the subprocess.

另請參🄵*subprocess.Popen.terminate()*。

SubprocessTransport.**close**()

Kill the subprocess by calling the *kill()* method.

If the subprocess hasn't returned yet, and close transports of *stdin*, *stdout*, and *stderr* pipes.

Protocols

原始碼： Lib/asyncio/protocols.py

---

asyncio provides a set of abstract base classes that should be used to implement network protocols. Those classes are meant to be used together with *transports*.

Subclasses of abstract base protocol classes may implement some or all methods. All these methods are callbacks: they are called by transports on certain events, for example when some data is received. A base protocol method should be called by the corresponding transport.

Base Protocols

class asyncio.**BaseProtocol**

Base protocol with methods that all protocols share.

class asyncio.**Protocol**(*BaseProtocol*)

The base class for implementing streaming protocols (TCP, Unix sockets, etc).

class asyncio.**BufferedProtocol**(*BaseProtocol*)

A base class for implementing streaming protocols with manual control of the receive buffer.

class asyncio.**DatagramProtocol**(*BaseProtocol*)

The base class for implementing datagram (UDP) protocols.

class asyncio.**SubprocessProtocol**(*BaseProtocol*)

The base class for implementing protocols communicating with child processes (unidirectional pipes).

Base Protocol

All asyncio protocols can implement Base Protocol callbacks.

Connection Callbacks

Connection callbacks are called on all protocols, exactly once per a successful connection. All other protocol callbacks can only be called between those two methods.

BaseProtocol.**connection_made**(*transport*)

Called when a connection is made.

The *transport* argument is the transport representing the connection. The protocol is responsible for storing the reference to its transport.

BaseProtocol.**connection_lost**(*exc*)

Called when the connection is lost or closed.

The argument is either an exception object or *None*. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

Flow Control Callbacks

Flow control callbacks can be called by transports to pause or resume writing performed by the protocol.

See the documentation of the *set_write_buffer_limits()* method for more details.

BaseProtocol.**pause_writing**()

Called when the transport's buffer goes over the high watermark.

BaseProtocol.**resume_writing**()

Called when the transport's buffer drains below the low watermark.

If the buffer size equals the high watermark, *pause_writing()* is not called: the buffer size must go strictly over.

Conversely, *resume_writing()* is called when the buffer size is equal or lower than the low watermark. These end conditions are important to ensure that things go as expected when either mark is zero.

Streaming Protocols

Event methods, such as *loop.create_server()*, *loop.create_unix_server()*, *loop.create_connection()*, *loop.create_unix_connection()*, *loop.connect_accepted_socket()*, *loop.connect_read_pipe()*, and *loop.connect_write_pipe()* accept factories that return streaming protocols.

Protocol.**data_received**(*data*)

Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn't rely on specific semantics and instead make your parsing generic and flexible. However, data is always received in the correct order.

The method can be called an arbitrary number of times while a connection is open.

However, *protocol.eof_received()* is called at most once. Once `eof_received()` is called, `data_received()` is not called anymore.

`Protocol.`**`eof_received`**`()`

Called when the other end signals it won't send any more data (for example by calling *transport.write_eof()*, if the other end also uses asyncio).

This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, the protocol used determines whether to close the transport. Since the default implementation returns `None`, it implicitly closes the connection.

Some transports, including SSL, don't support half-closed connections, in which case returning true from this method will result in the connection being closed.

State machine:

```
start -> connection_made
    [-> data_received]*
    [-> eof_received]?
-> connection_lost -> end
```

Buffered Streaming Protocols

在 3.7 版被加入.

Buffered Protocols can be used with any event loop method that supports *Streaming Protocols*.

`BufferedProtocol` implementations allow explicit manual allocation and control of the receive buffer. Event loops can then use the buffer provided by the protocol to avoid unnecessary data copies. This can result in noticeable performance improvement for protocols that receive big amounts of data. Sophisticated protocol implementations can significantly reduce the number of buffer allocations.

The following callbacks are called on *BufferedProtocol* instances:

`BufferedProtocol.`**`get_buffer`**`(`*sizehint*`)`

Called to allocate a new receive buffer.

sizehint is the recommended minimum size for the returned buffer. It is acceptable to return smaller or larger buffers than what *sizehint* suggests. When set to -1, the buffer size can be arbitrary. It is an error to return a buffer with a zero size.

`get_buffer()` must return an object implementing the buffer protocol.

`BufferedProtocol.`**`buffer_updated`**`(`*nbytes*`)`

Called when the buffer was updated with the received data.

nbytes is the total number of bytes that were written to the buffer.

`BufferedProtocol.`**`eof_received`**`()`

See the documentation of the *protocol.eof_received()* method.

get_buffer() can be called an arbitrary number of times during a connection. However, *protocol.eof_received()* is called at most once and, if called, *get_buffer()* and *buffer_updated()* won't be called after it.

State machine:

```
start -> connection_made
    [-> get_buffer
        [-> buffer_updated]?
    ]*
    [-> eof_received]?
-> connection_lost -> end
```

Datagram Protocols

Datagram Protocol instances should be constructed by protocol factories passed to the *loop.create_datagram_endpoint()* method.

`DatagramProtocol.`**`datagram_received`**(*data*, *addr*)

Called when a datagram is received. *data* is a bytes object containing the incoming data. *addr* is the address of the peer sending the data; the exact format depends on the transport.

`DatagramProtocol.`**`error_received`**(*exc*)

Called when a previous send or receive operation raises an *OSError*. *exc* is the *OSError* instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram could not be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

備🄵

On BSD systems (macOS, FreeBSD, etc.) flow control is not supported for datagram protocols, because there is no reliable way to detect send failures caused by writing too many packets.

The socket always appears 'ready' and excess packets are dropped. An *OSError* with `errno` set to *errno.ENOBUFS* may or may not be raised; if it is raised, it will be reported to *DatagramProtocol.error_received()* but otherwise ignored.

Subprocess Protocols

Subprocess Protocol instances should be constructed by protocol factories passed to the *loop.subprocess_exec()* and *loop.subprocess_shell()* methods.

`SubprocessProtocol.`**`pipe_data_received`**(*fd*, *data*)

Called when the child process writes data into its stdout or stderr pipe.

fd is the integer file descriptor of the pipe.

data is a non-empty bytes object containing the received data.

`SubprocessProtocol.`**`pipe_connection_lost`**(*fd*, *exc*)

Called when one of the pipes communicating with the child process is closed.

fd is the integer file descriptor that was closed.

`SubprocessProtocol.`**`process_exited`**()

Called when the child process has exited.

It can be called before *pipe_data_received()* and *pipe_connection_lost()* methods.

范例

TCP Echo Server

Create a TCP echo server using the *loop.create_server()* method, send back received data, and close the connection:

```
import asyncio

class EchoServerProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
        print('Connection from {}'.format(peername))
        self.transport = transport
```

(繼續下一頁)

(繼續上一頁)

```
    def data_received(self, data):
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    server = await loop.create_server(
        EchoServerProtocol,
        '127.0.0.1', 8888)

    async with server:
        await server.serve_forever()

asyncio.run(main())
```

也參考

The *TCP echo server using streams* example uses the high-level `asyncio.start_server()` function.

TCP Echo Client

A TCP echo client using the `loop.create_connection()` method, sends data, and waits until the connection is closed:

```
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()
```

(繼續下一頁)

(繼續上一頁)

```
    on_con_lost = loop.create_future()
    message = 'Hello World!'

    transport, protocol = await loop.create_connection(
        lambda: EchoClientProtocol(message, on_con_lost),
        '127.0.0.1', 8888)

    # Wait until the protocol signals that the connection
    # is lost and close the transport.
    try:
        await on_con_lost
    finally:
        transport.close()

asyncio.run(main())
```

也參考

The *TCP echo client using streams* example uses the high-level `asyncio.open_connection()` function.

UDP Echo Server

A UDP echo server, using the `loop.create_datagram_endpoint()` method, sends back received data:

```
import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

async def main():
    print("Starting UDP server")

    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    # One protocol instance will be created to serve all
    # client requests.
    transport, protocol = await loop.create_datagram_endpoint(
        EchoServerProtocol,
        local_addr=('127.0.0.1', 9999))

    try:
        await asyncio.sleep(3600)  # Serve for 1 hour.
    finally:
        transport.close()
```

(繼續下一頁)

(繼續上一頁)

```
asyncio.run(main())
```

UDP Echo Client

A UDP echo client, using the *loop.create_datagram_endpoint()* method, sends data and closes the transport when it receives the answer:

```
import asyncio

class EchoClientProtocol:
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())

        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):
        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Connection closed")
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    on_con_lost = loop.create_future()
    message = "Hello World!"

    transport, protocol = await loop.create_datagram_endpoint(
        lambda: EchoClientProtocol(message, on_con_lost),
        remote_addr=('127.0.0.1', 9999))

    try:
        await on_con_lost
    finally:
        transport.close()

asyncio.run(main())
```

Connecting Existing Sockets

Wait until a socket receives data using the `loop.create_connection()` method with a protocol:

```
import asyncio
import socket

class MyProtocol(asyncio.Protocol):

    def __init__(self, on_con_lost):
        self.transport = None
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport;
        # connection_lost() will be called automatically.
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()
    on_con_lost = loop.create_future()

    # Create a pair of connected sockets
    rsock, wsock = socket.socketpair()

    # Register the socket to wait for data.
    transport, protocol = await loop.create_connection(
        lambda: MyProtocol(on_con_lost), sock=rsock)

    # Simulate the reception of data from the network.
    loop.call_soon(wsock.send, 'abc'.encode())

    try:
        await protocol.on_con_lost
    finally:
        transport.close()
        wsock.close()

asyncio.run(main())
```

也參考

The *watch a file descriptor for read events* example uses the low-level `loop.add_reader()` method to register an FD.

The *register an open socket to wait for data using streams* example uses high-level streams created by the `open_connection()` function in a coroutine.

loop.subprocess_exec() and SubprocessProtocol

An example of a subprocess protocol used to get the output of a subprocess and to wait for the subprocess exit.

The subprocess is created by the *loop.subprocess_exec()* method:

```
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()
        self.pipe_closed = False
        self.exited = False

    def pipe_connection_lost(self, fd, exc):
        self.pipe_closed = True
        self.check_for_exit()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exited = True
        # process_exited() method can be called before
        # pipe_connection_lost() method: wait until both methods are
        # called.
        self.check_for_exit()

    def check_for_exit(self):
        if self.pipe_closed and self.exited:
            self.exit_future.set_result(True)

async def get_date():
    # Get a reference to the event loop as we plan to use
    # low-level APIs.
    loop = asyncio.get_running_loop()

    code = 'import datetime; print(datetime.datetime.now())'
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by DateProtocol;
    # redirect the standard output into a pipe.
    transport, protocol = await loop.subprocess_exec(
        lambda: DateProtocol(exit_future),
        sys.executable, '-c', code,
        stdin=None, stderr=None)

    # Wait for the subprocess exit using the process_exited()
    # method of the protocol.
    await exit_future

    # Close the stdout pipe.
    transport.close()

    # Read the output which was collected by the
    # pipe_data_received() method of the protocol.
    data = bytes(protocol.output)
    return data.decode('ascii').rstrip()

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the *same example* written using high-level APIs.

19.1.12 Policies

> **警告**
>
> Policies are deprecated and will be removed in Python 3.16. Users are encouraged to use the `asyncio.run()` function or the `asyncio.Runner` with *loop_factory* to use the desired loop implementation.

An event loop policy is a global object used to get and set the current *event loop*, as well as create new event loops. The default policy can be *replaced* with *built-in alternatives* to use different event loop implementations, or substituted by a *custom policy* that can override these behaviors.

The *policy object* gets and sets a separate event loop per *context*. This is per-thread by default, though custom policies could define *context* differently.

Custom event loop policies can control the behavior of `get_event_loop()`, `set_event_loop()`, and `new_event_loop()`.

Policy objects should implement the APIs defined in the `AbstractEventLoopPolicy` abstract base class.

Getting and Setting the Policy

The following functions can be used to get and set the policy for the current process:

`asyncio.`**`get_event_loop_policy`**`()`

Return the current process-wide policy.

在 3.14 版之後被🄵用: The `get_event_loop_policy()` function is deprecated and will be removed in Python 3.16.

`asyncio.`**`set_event_loop_policy`**`(`*policy*`)`

Set the current process-wide policy to *policy*.

If *policy* is set to `None`, the default policy is restored.

在 3.14 版之後被🄵用: The `set_event_loop_policy()` function is deprecated and will be removed in Python 3.16.

Policy Objects

The abstract event loop policy base class is defined as follows:

`class` `asyncio.`**`AbstractEventLoopPolicy`**

An abstract base class for asyncio policies.

`get_event_loop``()`

Get the event loop for the current context.

Return an event loop object implementing the `AbstractEventLoop` interface.

This method should never return `None`.

在 3.6 版的變更.

`set_event_loop``(`*loop*`)`

Set the event loop for the current context to *loop*.

`new_event_loop``()`

Create and return a new event loop object.

This method should never return `None`.

在 3.14 版之後被🄵用: The *AbstractEventLoopPolicy* class is deprecated and will be removed in Python 3.16.

asyncio ships with the following built-in policies:

class asyncio.**DefaultEventLoopPolicy**

The default asyncio policy. Uses *SelectorEventLoop* on Unix and *ProactorEventLoop* on Windows.

There is no need to install the default policy manually. asyncio is configured to use the default policy automatically.

在 3.8 版的變更: On Windows, *ProactorEventLoop* is now used by default.

在 3.14 版的變更: The *get_event_loop()* method of the default asyncio policy now raises a *RuntimeError* if there is no set event loop.

在 3.14 版之後被🄵用: The *DefaultEventLoopPolicy* class is deprecated and will be removed in Python 3.16.

class asyncio.**WindowsSelectorEventLoopPolicy**

An alternative event loop policy that uses the *SelectorEventLoop* event loop implementation.

可用性: Windows.

在 3.14 版之後被🄵用: The *WindowsSelectorEventLoopPolicy* class is deprecated and will be removed in Python 3.16.

class asyncio.**WindowsProactorEventLoopPolicy**

An alternative event loop policy that uses the *ProactorEventLoop* event loop implementation.

可用性: Windows.

在 3.14 版之後被🄵用: The *WindowsProactorEventLoopPolicy* class is deprecated and will be removed in Python 3.16.

Custom Policies

To implement a new event loop policy, it is recommended to subclass *DefaultEventLoopPolicy* and override the methods for which custom behavior is wanted, e.g.:

```
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):

    def get_event_loop(self):
        """Get the event loop.

        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```

19.1.13 平台支援

asyncio module（模組）被設計🄵可🄵的 (portable)，但由於平臺的底層架構和功能不同，在一些平臺上存在細微的差🄵和限制。

所有平台

- *loop.add_reader()* 和*loop.add_writer()* 不能用來監視檔案 I/O。

Windows

原 始 碼： Lib/asyncio/proactor_events.py、source:'Lib/asyncio/windows_events.py、source:'Lib/asyncio/windows_utils.py

---

在 3.8 版的變更: 在 Windows 上，現在*ProactorEventLoop* 是預設的事件🄴圈。

Windows 上的所有事件🄴圈都不支援以下 method（方法）：

- 不支援*loop.create_unix_connection()* 和*loop.create_unix_server()*。*socket.AF_UNIX* socket 系列常數僅限於 Unix 上使用。
- 不支援*loop.add_signal_handler()* 和*loop.remove_signal_handler()*。

SelectorEventLoop 有以下限制：

- *SelectSelector* 只被用於等待 socket 事件：它支援 socket 且最多支援 512 個 socket。
- *loop.add_reader()* 和*loop.add_writer()* 只接受 socket 處理函式（例如不支援 pipe 檔案描述器 (pipe file descriptor)）。
- 因🄵不支援 pipe，所以*loop.connect_read_pipe()* 和*loop.connect_write_pipe()* method 🄵有被實作出來。
- 不支援*子行程 (subprocess)*，也就是🄵*loop.subprocess_exec()* 和*loop.subprocess_shell()* method 🄵有被實作出來。

ProactorEventLoop 有以下限制：

- 不支援*loop.add_reader()* 和*loop.add_writer()* method。

Windows 上單調時鐘 (monotonic clock) 的解析度大約🄵 15.6 毫秒。最佳的解析度是 0.5 毫秒。解析度和硬體（HPET 是否可用）與 Windows 的設定有關。

Windows 的子行程支援

在 Windows 上，預設的事件🄴圈*ProactorEventLoop* 支援子行程，而*SelectorEventLoop* 則不支援。

macOS

完整支援現在普遍流行的 macOS 版本。

macOS <= 10.8

在 macOS 10.6、10.7 和 10.8 上，預設的事件🄴圈是使用*selectors.KqueueSelector*，在這些版本上它🄵不支援字元裝置 (character device)。可以手工設置*SelectorEventLoop* 來使用*SelectSelector* 或*PollSelector* 以在這些舊版 macOS 上支援字元裝置。例如：

```
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```

19.1.14 擴充

The main direction for *asyncio* extending is writing custom *event loop* classes. Asyncio has helpers that could be used to simplify this task.

備🄵

Third-parties should reuse existing asyncio code with caution, a new Python version is free to break backward compatibility in *internal* part of API.

Writing a Custom Event Loop

asyncio.AbstractEventLoop declares very many methods. Implementing all them from scratch is a tedious job.

A loop can get many common methods implementation for free by inheriting from `asyncio.BaseEventLoop`.

In turn, the successor should implement a bunch of *private* methods declared but not implemented in `asyncio.BaseEventLoop`.

For example, `loop.create_connection()` checks arguments, resolves DNS addresses, and calls `loop._make_socket_transport()` that should be implemented by inherited class. The `_make_socket_transport()` method is not documented and is considered as an *internal* API.

Future and Task private constructors

asyncio.Future and *asyncio.Task* should be never created directly, please use corresponding *loop.create_future()* and *loop.create_task()*, or *asyncio.create_task()* factories instead.

However, third-party *event loops* may *reuse* built-in future and task implementations for the sake of getting a complex and highly optimized code for free.

For this purpose the following, *private* constructors are listed:

`Future.__init__`(*, *loop=None*)

Create a built-in future instance.

loop is an optional event loop instance.

`Task.__init__`(*coro*, *, *loop=None*, *name=None*, *context=None*)

Create a built-in task instance.

loop is an optional event loop instance. The rest of arguments are described in *loop.create_task()* description.

在 3.11 版的變更: *context* argument is added.

Task lifetime support

A third party task implementation should call the following functions to keep a task visible by *asyncio.all_tasks()* and *asyncio.current_task()*:

`asyncio._register_task`(*task*)

Register a new *task* as managed by *asyncio*.

Call the function from a task constructor.

`asyncio._unregister_task`(*task*)

Unregister a *task* from *asyncio* internal structures.

The function should be called when a task is about to finish.

`asyncio._enter_task`(*loop*, *task*)

Switch the current task to the *task* argument.

Call the function just before executing a portion of embedded *coroutine* (`coroutine.send()` or `coroutine.throw()`).

asyncio.**_leave_task**(*loop*, *task*)

Switch the current task back from *task* to `None`.

Call the function just after `coroutine.send()` or `coroutine.throw()` execution.

19.1.15 高階 API 索引

這個頁面列出了所有能使用 async/wait 的高階 asyncio API。

任務 (Tasks)

用於執行非同步程式、建立 Task 物件、帶有超時 (timeout) 設定地等待多個事件的工具程式。

run()	建立事件🄵圈 (event loop)、執行一個協程 (coroutine)、關閉事件🄵圈。
Runner	A context manager that simplifies multiple async function calls.
Task	Task 物件。
TaskGroup	A context manager that holds a group of tasks. Provides a convenient and reliable way to wait for all tasks in the group to finish.
create_task()	🄵動一個 asyncio 的 Task 物件，然後回傳它。
current_task()	回傳目前 Task 物件。
all_tasks()	回傳事件🄵圈中所有未完成的 task 物件。
await *sleep()*	休眠數秒鐘。
await *gather()*	🄵行 (concurrent) 地執行事件的排程與等待。
await *wait_for()*	有超時設置的執行。
await *shield()*	屏蔽取消操作。
await *wait()*	監控完成情🄵。
timeout()	Run with a timeout. Useful in cases when `wait_for` is not suitable.
to_thread()	在不同的 OS 執行緒 (thread) 中非同步地執行一個函式。
run_coroutine_threadsafe()	從其他 OS 執行緒中🄵一個協程排程。
for in *as_completed()*	用 `for` 🄵圈來監控完成情🄵。

范例

- 使用 *asyncio.gather()* 平行 *(parallel)* 執行。
- 使用 *asyncio.wait_for()* 🄵制設置超時。
- 取消任務。
- 使用 *asyncio.sleep()*。
- 請參🄵*Tasks* 文件頁面。

🄵列 (Queues)

🄵列應被用於🄵多個 asyncio Task 物件分配工作、實作 connection pools（連🄵池）以及 pub/sub（發行/訂🄵）模式。

Queue	一個先進先出 (FIFO) 🄵列。
PriorityQueue	一個優先🄵列 (priority queue)。
LifoQueue	一個後進先出 (LIFO) 🄵列。

范例

- 使用 *asyncio.Queue* 🄵多個 *Task* 分配工作。
- 請參🄵🄵列文件頁面。

子行程 (Subprocesses)

用於衍生（spawn）子行程和執行 shell 指令的工具程式。

`await create_subprocess_exec()`	建立一個子行程。
`await create_subprocess_shell()`	執行一個 shell 命令。

范例

- 執行一個 *shell* 指令。
- 請參🄵子行程 *APIs* 相關文件。

串流 (Streams)

用於網路 IO 處理的高階 API。

`await open_connection()`	建立一個 TCP 連🄵。
`await open_unix_connection()`	建立一個 Unix socket 連🄵。
`await start_server()`	🄵動一個 TCP 伺服器。
`await start_unix_server()`	🄵動一個 Unix socket 伺服器。
`StreamReader`	接收網路資料的高階 async/await 物件。
`StreamWriter`	傳送網路資料的高階 async/await 物件。

范例

- *TCP* 用🄵端範例。
- 請參🄵串流 *APIs* 文件。

同步化 (Synchronization)

類似執行緒且能被用於 Task 中的同步化原始物件 (primitive)。

`Lock`	一個互斥鎖 (mutex lock)。
`Event`	一個事件物件。
`Condition`	一個條件物件。
`Semaphore`	一個旗號 (semaphore) 物件。
`BoundedSemaphore`	一個有界的旗號物件。
`Barrier`	一個屏障物件。

范例

- 使用 *asyncio.Event*。
- 使用 *asyncio.Barrier*。
- 請參🄵 asyncio 關於同步化原始物件的文件。

例外

asyncio.CancelledError	當一 Task 物件被取消時被引發。請參🄵*Task.cancel()*。
asyncio.BrokenBarrierError	當一 Barrier 物件損壞時被引發。請參🄵*Barrier.wait()*。

范例

- *在取消請求發生的程式中處理 CancelledError 例外*。
- 請參🄵*asyncio 專用例外*完整列表。

19.1.16 低階 API 索引

本頁列出所有低階 asyncio APIs。

取得事件🄵圈

asyncio.get_running_loop()	**推薦使用**於取得目前運行事件🄴圈 (event loop) 的函式。
asyncio.get_event_loop()	獲得一個（正在運行的或透過目前 policy 建立的）事件🄵圈實例。
asyncio.set_event_loop()	透過目前 policy 來設定目前事件🄵圈。
asyncio.new_event_loop()	建立一個新的事件🄵圈。

范例

- *使用 asyncio.get_running_loop()*。

事件🄵圈方法

也請查🄵文件中關於*事件🄵圈方法*的主要段落。

生命🄵期

loop.run_until_complete()	執行一個 Future/Task/awaitable（可等待物件）直到完成。
loop.run_forever()	持續運行事件🄵圈。
loop.stop()	停止事件🄵圈。
loop.close()	關閉事件🄵圈。
loop.is_running()	如果事件🄵圈正在執行則回傳 `True`。
loop.is_closed()	如果事件🄵圈已經被關閉則回傳 `True`。
`await` *loop.shutdown_asyncgens()*	關閉非同步🄵生器 (asynchronous generators)。

除錯

loop.set_debug()	開🄴或禁用除錯模式。
loop.get_debug()	取得目前除錯模式。

🄵回呼函式排程

loop.call_soon()	🄵快呼叫回呼函式 (callback)。
loop.call_soon_threadsafe()	*loop.call_soon()* 方法之有支援執行緒安全 (thread-safe) 變體。
loop.call_later()	在給定時間之後呼叫回呼函式。
loop.call_at()	在給定時間當下呼叫回呼函式。

執行緒 (Thread)/直譯器 (Interpreter)/行程池 (Process Pool)

await *loop.run_in_executor()*	在*concurrent.futures* 執行器 (excutor) 中執行一個 CPU 密集型 (CPU-bound) 或其它阻塞型式的函式。
loop.set_default_executor()	🄵*loop.run_in_executor()* 設定預設執行器。

Tasks 與 Futures

loop.create_future()	建立一個*Future* 物件。
loop.create_task()	像是*Task* 一樣，🄵協程 (coroutine) 排程。
loop.set_task_factory()	設定被*loop.create_task()* 用來建立*Tasks* 的工廠函式 (factory)。
loop.get_task_factory()	取得被*loop.create_task()* 用來建立*Tasks* 的工廠函式。

DNS

await *loop.getaddrinfo()*	非同步版本的*socket.getaddrinfo()*。
await *loop.getnameinfo()*	非同步版本的*socket.getnameinfo()*。

網路和 IPC

await *loop.create_connection()*	開🄵一個 TCP 連🄵。
await *loop.create_server()*	建立一個 TCP 伺服器。
await *loop.create_unix_connection()*	開🄵一個 Unix socket 連🄵。
await *loop.create_unix_server()*	建立一個 Unix socket 伺服器。
await *loop.connect_accepted_socket()*	將*socket* 包裝成 `(transport, protocol)`。
await *loop.create_datagram_endpoint()*	開🄵一個資料單元 (datagram) (UDP) 連🄵。
await *loop.sendfile()*	透過傳輸通道傳送一個檔案。
await *loop.start_tls()*	將一個已存在的連🄵升級到 TLS。
await *loop.connect_read_pipe()*	將 pipe（管道）讀取端包裝成 `(transport, protocol)`。
await *loop.connect_write_pipe()*	將 pipe 寫入端包裝成 `(transport, protocol)`。

Sockets

await *loop.sock_recv()*	從*socket* 接收資料。
await *loop.sock_recv_into()*	將從*socket* 接收到的資料存放於一個緩衝區 (buffer) 中。
await *loop.sock_recvfrom()*	從*socket* 接收一個資料單元。
await *loop.sock_recvfrom_into()*	將從*socket* 接收到的資料單元存放於一個緩衝區中。
await *loop.sock_sendall()*	傳送資料到*socket*。
await *loop.sock_sendto()*	透過*socket* 將資料單元傳送至給定的地址。
await *loop.sock_connect()*	連接*socket*。
await *loop.sock_accept()*	接受一個*socket* 連🄵。
await *loop.sock_sendfile()*	透過*socket* 傳送一個檔案。
loop.add_reader()	開始監控一個檔案描述器 (file descriptor) 的可讀取性。
loop.remove_reader()	停止監控一個檔案描述器的可讀取性。
loop.add_writer()	開始監控一個檔案描述器的可寫入性。
loop.remove_writer()	停止監控一個檔案描述器的可寫入性。

Unix 信號

loop.add_signal_handler()	🄵*signal* 新增一個處理函式 (handler)。
loop.remove_signal_handler()	🄵除*signal* 的處理函式。

子行程

loop.subprocess_exec()	衍生 (spawn) 一個子行程 (subprocess)。
loop.subprocess_shell()	從 shell 指令衍生一個子行程。

錯誤處理

loop.call_exception_handler()	呼叫例外處理函式。
loop.set_exception_handler()	設定一個新的例外處理函式。
loop.get_exception_handler()	取得目前例外處理函式。
loop.default_exception_handler()	預設例外處理函式實作。

范例

- 使用 *asyncio.new_event_loop()* 和 *loop.run_forever()*。
- 使用 *loop.call_later()*。
- 使用 `loop.create_connection()` 以實作一個 *echo* 用🄵端。
- 使用 `loop.create_connection()` 來連接 *socket*。
- 使用 *add_reader()* 監控 *FD* 的讀取事件。
- 使用 *loop.add_signal_handler()*。
- 使用 *loop.add_signal_handler()*。

傳輸

所有傳輸方式都有實作以下方法：

transport.close()	關閉傳輸。
transport.is_closing()	如果傳輸正在關閉或已經關閉則回傳 `True`。
transport.get_extra_info()	請求傳輸的相關資訊。
transport.set_protocol()	設定一個新協定。
transport.get_protocol()	回傳目前協定。

可以接收資料（TCP 和 Unix 連🄵、pipe 等）的傳輸。它由*loop.create_connection()*、*loop.create_unix_connection()*、*loop.connect_read_pipe()* 等方法回傳：

讀取傳輸

transport.is_reading()	如果傳輸正在接收則回傳 `True`。
transport.pause_reading()	暫停接收。
transport.resume_reading()	繼續接收。

可以傳送資料（TCP 和 Unix 連🄵、pipe 等）的傳輸。它由*loop.create_connection()*、*loop.create_unix_connection()*、*loop.connect_write_pipe()* 等方法回傳：

寫入傳輸

transport.write()	將資料寫入傳輸。
transport.writelines()	將緩衝區資料寫入傳輸。
transport.can_write_eof()	如果傳輸支援傳送 EOF 則回傳*True*。
transport.write_eof()	在清除 (flush) 已緩衝的資料後關閉傳輸🄵傳送 EOF。
transport.abort()	立即關閉傳輸。
transport.get_write_buffer_size()	回傳目前輸出緩衝區的大小。
transport.get_write_buffer_limits()	回傳用於寫入流量控制 (write flow control) 的高低標記位 (high and low water marks)。
transport.set_write_buffer_limits()	🄵寫入流量控制設定高低標記位。

由*loop.create_datagram_endpoint()* 回傳的傳輸：

資料單元傳輸

transport.sendto()	傳送資料到連🄵遠端。
transport.abort()	立即關閉傳輸。

基於子行程的低階傳輸抽象，它會由*loop.subprocess_exec()* 和*loop.subprocess_shell()* 所回傳：

子行程傳輸

transport.get_pid()	回傳子行程的行程 id。
transport.get_pipe_transport()	回傳被請求用於通訊 pipe （*stdin*、*stdout* 或 *stderr*）的傳輸。
transport.get_returncode()	回傳子行程的回傳代號 (return code)。
transport.kill()	殺死子行程。
transport.send_signal()	傳送一個訊號到子行程。
transport.terminate()	停止子行程。
transport.close()	殺死子行程🄵關閉所有 pipes。

協定

協定類🄵可以實作以下**回呼方法**:

callback *connection_made()*	在連🄵建立時被呼叫。
callback *connection_lost()*	在失去連🄵或連🄵關閉時被呼叫。
callback *pause_writing()*	在傳輸緩衝區超過高標記位時被呼叫。
callback *resume_writing()*	在傳輸緩衝區低於低標記位時被呼叫。

串流協定 (TCP, Unix socket, Pipes)

callback *data_received()*	在接收到資料時被呼叫。
callback *eof_received()*	在接收到 EOF 時被呼叫。

緩沖串流協定

callback *get_buffer()*	呼叫後會分配新的接收緩衝區。
callback *buffer_updated()*	在以接收到的資料更新緩衝區時被呼叫。
callback *eof_received()*	在接收到 EOF 時被呼叫。

資料單元協定

callback *datagram_received()*	在接收到資料單元時被呼叫。
callback *error_received()*	在前一個傳送或接收操作引發*OSError* 時被呼叫。

子行程協定

callback *pipe_data_received()*	在子行程向 *stdout* 或 *stderr* pipe 寫入資料時被呼叫。
callback *pipe_connection_lost()*	在與子行程通訊的其中一個 pipes 關閉時被呼叫。
callback *process_exited()*	在子行程退出時呼叫。它可以在*pipe_data_received()* 和*pipe_connection_lost()* 方法之前呼叫。

事件🄵圈 Policies

Policy 是改變*asyncio.get_event_loop()* 這類函式行🄵的一個低階機制。更多細節請見*Policy 相關段落*。

存取 Policy

asyncio.get_event_loop_policy()	回傳目前整個行程中的 Policy。
asyncio.set_event_loop_policy()	設定整個行程中的一個新 Policy。
AbstractEventLoopPolicy	Policy 物件的基礎類🄵。

19.1.17 使用 asyncio 開發

非同步程式設計 (asynchronous programming) 與傳統的" 順序" 程式設計 (sequential programming) 不同。

本頁列出常見的錯誤和陷阱，🄵解釋如何避免它們。

除錯模式

在預設情🄵下 asyncio 以正式生🄵模式 (production mode) 執行。🄵了讓開發更輕松，asyncio 還有一種除錯模式 *(debug mode)*。

有幾種方法可以🄵用 asyncio 除錯模式：

- 將 `PYTHONASYNCIODEBUG` 環境變數設定🄵 `1`。
- 使用*Python 開發模式 (Development Mode)*。
- 將 `debug=True` 傳遞給*`asyncio.run()`*。
- 呼叫*`loop.set_debug()`*。

除了🄵用除錯模式外，還要考慮：

- 將*asyncio logger*（日🄵記🄵器）的日🄵級別設置🄵*`logging.DEBUG`*，例如下面的程式片段可以在應用程式🄵動時運行：

```
logging.basicConfig(level=logging.DEBUG)
```

- 配置*`warnings`* 模組以顯示*`ResourceWarning`* 警告。一種方法是使用 `-W default` 命令列選項。

🄵用除錯模式時：

- 許多非執行緒安全 (non-threadsafe) 的 asyncio APIs（例如*`loop.call_soon()`* 和*`loop.call_at()`* 方法），如果從錯誤的執行緒呼叫就會引發例外。
- 如果執行一個 I/O 操作花費的時間太長，則將 I/O 選擇器 (selector) 的執行時間記🄵到日🄵中。
- 執行時間超過 100 毫秒的回呼 (callback) 將會被記🄵於日🄵。屬性*`loop.slow_callback_duration`* 可用於設定以秒🄵單位的最小執行持續時間，超過這個值執行時間就會被視🄵" 緩慢"。

🄵行性和多執行緒 (Concurrency and Multithreading)

事件🄵圈在執行緒中運行（通常是主執行緒），🄵在其執行緒中執行所有回呼和 Tasks（任務）。當一個 Task 在事件🄵圈中運行時，🄵有其他 Task 可以在同一個執行緒中運行。當一個 Task 執行一個 `await` 運算式時，正在執行的 Task 會被暫停，而事件🄵圈會執行下一個 Task。

要從不同的 OS 執行緒🄵一個*callback* 排程，應該使用*`loop.call_soon_threadsafe()`* 方法。例如：

```
loop.call_soon_threadsafe(callback, *args)
```

幾乎所有 asyncio 物件都不支援執行緒安全 (thread safe)，這通常不是問題，除非在 Task 或回呼函式之外有程式需要和它們一起運作。如果需要這樣的程式來呼叫低階 asyncio API，應該使用*`loop.call_soon_threadsafe()`* 方法，例如：

```
loop.call_soon_threadsafe(fut.cancel)
```

要從不同的 OS 執行緒🄵一個協程物件排程，應該使用*`run_coroutine_threadsafe()`* 函式。它會回傳一個*`concurrent.futures.Future`* 以存取結果：

```
async def coro_func():
    return await asyncio.sleep(1, 42)

# Later in another OS thread:

future = asyncio.run_coroutine_threadsafe(coro_func(), loop)
# Wait for the result:
result = future.result()
```

🄵了能🄵處理訊號，事件🄵圈必須於主執行緒中運行。

`loop.run_in_executor()` 方法可以和*`concurrent.futures.ThreadPoolExecutor`* 或*`InterpreterPoolExecutor`* 一起使用，這能🄵在作業系統上另一個不同的執行緒中執行阻塞程式，且避免阻塞執行事件🄵圈的執行緒。

目前🄵有什🄵辦法能直接從另一個行程（例如透過*multiprocessing* 🄵動的程序）來🄵協程或回呼排程。事件🄵圈方法小節列出了可以從 pipes（管道）讀取🄵監視 file descriptor（檔案描述器）而不會阻塞事件🄵圈的 API。此外，asyncio 的子行程 API 提供了一種🄵動行程🄵從事件🄵圈與其通訊的辦法。最後，之前提到的*loop.run_in_executor()* 方法也可和*concurrent.futures.ProcessPoolExecutor* 搭配使用，以在另一個行程中執行程式。

執行阻塞的程式

不應該直接呼叫阻塞（CPU 密集型）程式。例如一個執行 1 秒 CPU 密集型計算的函式，那🄵所有🄵行非同步 Tasks 和 IO 操作都會被延遲 1 秒。

一個 executor（執行器）可以被用來在不同的執行緒（包含不同直譯器）、或甚至不同的行程中執行任務，以避免事件🄵圈阻塞了 OS 執行緒。詳情請見*loop.run_in_executor()* 方法。

日🄵記🄵

asyncio 使用*logging* 模組，所有日🄵記🄵都是透過 `"asyncio"` logger 執行的。

日🄵級🄵被預設🄵*logging.INFO*，它可以很容易地被調整：

```
logging.getLogger("asyncio").setLevel(logging.WARNING)
```

網路日🄵記🄵可能會阻塞事件🄵圈。建議使用獨立的執行緒來處理日🄵或使用非阻塞 IO，範例請參見 blocking-handlers。

偵測從未被等待的 (never-awaited) 協程

當協程函式被呼叫而不是被等待時（即執行 `coro()` 而不是 `await coro()`）或者協程🄵有透過*asyncio.create_task()* 被排程，asyncio 將會發出*RuntimeWarning*：

```
import asyncio

async def test():
    print("never scheduled")

async def main():
    test()

asyncio.run(main())
```

輸出：

```
test.py:7: RuntimeWarning: coroutine 'test' was never awaited
  test()
```

除錯模式中的輸出：

```
test.py:7: RuntimeWarning: coroutine 'test' was never awaited
Coroutine created at (most recent call last)
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)

  < .. >

  File "../t.py", line 7, in main
    test()
  test()
```

常用的修復方法是去等待協程或者呼叫*asyncio.create_task()* 函式：

```
async def main():
    await test()
```

偵測從未被取得的 (never-retrieved) 例外

如果呼叫*Future.set_exception()*，但 Future 物件從未被等待，例外將無法被傳播 (propagate) 到使用者程式。在這種情🄵下，當 Future 物件被垃圾回收 (garbage collected) 時，asyncio 將發出一則日🄵訊息。

未處理例外的例子：

```
import asyncio

async def bug():
    raise Exception("not consumed")

async def main():
    asyncio.create_task(bug())

asyncio.run(main())
```

輸出：

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test.py:3>
  exception=Exception('not consumed')>

Traceback (most recent call last):
  File "test.py", line 4, in bug
    raise Exception("not consumed")
Exception: not consumed
```

🄵用除錯模式以取得任務建立處的追🄵資訊 (traceback)：

```
asyncio.run(main(), debug=True)
```

除錯模式中的輸出：

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test.py:3>
    exception=Exception('not consumed') created at asyncio/tasks.py:321>

source_traceback: Object created at (most recent call last):
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)

< .. >

Traceback (most recent call last):
  File "../t.py", line 4, in bug
    raise Exception("not consumed")
Exception: not consumed
```

備🄵

asyncio 的原始碼可以在 Lib/asyncio/ 中找到。

19.2 socket —低階網路介面

原始碼： Lib/socket.py

這個模組提供了操作 BSD *socket* 的介面。這在所有現代 Unix 系統、Windows、MacOS，以及一些其他平台上都可用。

備🄵

由於是呼叫作業系統的 socket API，某些行🄵可能會因平台而有所差🄵。

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵 *WebAssembly 平台*。

Python 的介面是將 Unix 的系統呼叫和 socket 函式庫介面直接轉🄵成 Python 的物件導向風格：`socket()` 函式會回傳一個 *socket* 物件，這個物件的方法實作了各種 socket 系統呼叫。與 C 語言介面相比，參數型🄵較🄵高階：就像 Python 文件操作中的 `read()` 和 `write()` 一樣，接收操作時會自動分配緩衝區，而發送操作時的緩衝區長度則是隱含的。

也參考

***socketserver* 模組**
簡化編寫網路伺服器的類🄴。

***ssl* 模組**
對 socket 物件的 TLS/SSL 的包裝器 (wrapper)。

19.2.1 Socket 系列家族

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an *AF_UNIX* socket bound to a file system node is represented as a string, using the file system encoding and the `'surrogateescape'` error handler (see **PEP 383**). An address in Linux's abstract namespace is returned as a *bytes-like object* with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

  在 3.3 版的變更: Previously, *AF_UNIX* socket paths were assumed to use UTF-8 encoding.

  在 3.5 版的變更: Writable *bytes-like object* is now accepted.

- A pair `(host, port)` is used for the *AF_INET* address family, where *host* is a string representing either a hostname in internet domain notation like `'daring.cwi.nl'` or an IPv4 address like `'100.50.200.5'`, and *port* is an integer.

  - For IPv4 addresses, two special forms are accepted instead of a host address: `''` represents `INADDR_ANY`, which is used to bind to all interfaces, and the string `'<broadcast>'` represents `INADDR_BROADCAST`. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

- For *AF_INET6* address family, a four-tuple `(host, port, flowinfo, scope_id)` is used, where *flowinfo* and *scope_id* represent the `sin6_flowinfo` and `sin6_scope_id` members in `struct sockaddr_in6` in C. For *socket* module methods, *flowinfo* and *scope_id* can be omitted just for backward compatibility. Note, however, omission of *scope_id* can cause problems in manipulating scoped IPv6 addresses.

  在 3.7 版的變更: For multicast addresses (with *scope_id* meaningful) *address* may not contain `%scope_id` (or `zone id`) part. This information is superfluous and may be safely omitted (recommended).

- `AF_NETLINK` sockets are represented as pairs `(pid, groups)`.

- Linux-only support for TIPC is available using the `AF_TIPC` address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a

tuple, and the fields depend on the address type. The general tuple form is `(addr_type, v1, v2, v3 [, scope])`, where:

  - *addr_type* is one of `TIPC_ADDR_NAMESEQ`, `TIPC_ADDR_NAME`, or `TIPC_ADDR_ID`.
  - *scope* is one of `TIPC_ZONE_SCOPE`, `TIPC_CLUSTER_SCOPE`, and `TIPC_NODE_SCOPE`.
  - If *addr_type* is `TIPC_ADDR_NAME`, then *v1* is the server type, *v2* is the port identifier, and *v3* should be 0.

    If *addr_type* is `TIPC_ADDR_NAMESEQ`, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.

    If *addr_type* is `TIPC_ADDR_ID`, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.

- A tuple `(interface, )` is used for the *AF_CAN* address family, where *interface* is a string representing a network interface name like `'can0'`. The network interface name `''` can be used to receive packets from all network interfaces of this family.
  - *CAN_ISOTP* protocol require a tuple `(interface, rx_addr, tx_addr)` where both additional parameters are unsigned long integer that represent a CAN identifier (standard or extended).
  - *CAN_J1939* protocol require a tuple `(interface, name, pgn, addr)` where additional parameters are 64-bit unsigned integer representing the ECU name, a 32-bit unsigned integer representing the Parameter Group Number (PGN), and an 8-bit integer representing the address.
- A string or a tuple `(id, unit)` is used for the `SYSPROTO_CONTROL` protocol of the `PF_SYSTEM` family. The string is the name of a kernel control using a dynamically assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

  在 3.3 版被加入.
- *AF_BLUETOOTH* supports the following protocols and address formats:
  - *BTPROTO_L2CAP* accepts a tuple `(bdaddr, psm[, cid[, bdaddr_type]])` where:
    - `bdaddr` is a string specifying the Bluetooth address.
    - `psm` is an integer specifying the Protocol/Service Multiplexer.
    - `cid` is an optional integer specifying the Channel Identifier. If not given, defaults to zero.
    - `bdaddr_type` is an optional integer specifying the address type; one of *BDADDR_BREDR* (default), *BDADDR_LE_PUBLIC*, *BDADDR_LE_RANDOM*.

    在 3.14 版的變更: Added `cid` and `bdaddr_type` fields.
  - *BTPROTO_RFCOMM* accepts `(bdaddr, channel)` where `bdaddr` is the Bluetooth address as a string and `channel` is an integer.
  - *BTPROTO_HCI* accepts a format that depends on your OS.
    - On Linux it accepts an integer `device_id` or a tuple `(device_id, [channel])` where `device_id` specifies the number of the Bluetooth device, and `channel` is an optional integer specifying the HCI channel (*HCI_CHANNEL_RAW* by default).
    - On FreeBSD, NetBSD and DragonFly BSD it accepts `bdaddr` where `bdaddr` is the Bluetooth address as a string.

    在 3.2 版的變更: 加入對 NetBSD 和 DragonFlyBSD 的支援。

    在 3.13.3 版的變更: 新增對 FreeBSD 的支援。

    在 3.14 版的變更: Added `channel` field. `device_id` not packed in a tuple is now accepted.
  - *BTPROTO_SCO* accepts `bdaddr` where `bdaddr` is the Bluetooth address as a string or a *bytes* object. (ex. `'12:23:34:45:56:67'` or `b'12:23:34:45:56:67'`)

    在 3.14 版的變更: 新增對 FreeBSD 的支援。
- *AF_ALG* is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements `(type, name [, feat [, mask]])`, where:

- *type* is the algorithm type as string, e.g. `aead`, `hash`, `skcipher` or `rng`.
- *name* is the algorithm name and operation mode as string, e.g. `sha256`, `hmac(sha256)`, `cbc(aes)` or `drbg_nopr_ctr_aes256`.
- *feat* and *mask* are unsigned 32bit integers.

可用性: Linux >= 2.6.38.

Some algorithm types require more recent Kernels.

在 3.6 版被加入.

- *AF_VSOCK* allows communication between virtual machines and their hosts. The sockets are represented as a `(CID, port)` tuple where the context ID or CID and port are integers.

  可用性: Linux >= 3.9

  請見 *vsock(7)*

  在 3.7 版被加入.

- *AF_PACKET* is a low-level interface directly to network devices. The addresses are represented by the tuple `(ifname, proto[, pkttype[, hatype[, addr]]])` where:
  - *ifname* - String specifying the device name.
  - *proto* - The Ethernet protocol number. May be *ETH_P_ALL* to capture all protocols, one of the *ETHERTYPE_* constants* or any other Ethernet protocol number.
  - *pkttype* - Optional integer specifying the packet type:
    * `PACKET_HOST` (the default) - Packet addressed to the local host.
    * `PACKET_BROADCAST` - Physical-layer broadcast packet.
    * `PACKET_MULTICAST` - Packet sent to a physical-layer multicast address.
    * `PACKET_OTHERHOST` - Packet to some other host that has been caught by a device driver in promiscuous mode.
    * `PACKET_OUTGOING` - Packet originating from the local host that is looped back to a packet socket.
  - *hatype* - Optional integer specifying the ARP hardware address type.
  - *addr* - Optional bytes-like object specifying the hardware physical address, whose interpretation depends on the device.

  可用性: Linux >= 2.2.

- *AF_QIPCRTR* is a Linux-only socket based interface for communicating with services running on co-processors in Qualcomm platforms. The address family is represented as a `(node, port)` tuple where the *node* and *port* are non-negative integers.

  可用性: Linux >= 4.7.

  在 3.8 版被加入.

- `IPPROTO_UDPLITE` is a variant of UDP which allows you to specify what portion of a packet is covered with the checksum. It adds two socket options that you can change. `self.setsockopt(IPPROTO_UDPLITE, UDPLITE_SEND_CSCOV, length)` will change what portion of outgoing packets are covered by the checksum and `self.setsockopt(IPPROTO_UDPLITE, UDPLITE_RECV_CSCOV, length)` will filter out packets which cover too little of their data. In both cases `length` should be in `range(8, 2**16, 8)`.

  Such a socket should be constructed with `socket(AF_INET, SOCK_DGRAM, IPPROTO_UDPLITE)` for IPv4 or `socket(AF_INET6, SOCK_DGRAM, IPPROTO_UDPLITE)` for IPv6.

  可用性: Linux >= 2.6.20, FreeBSD >= 10.1

  在 3.9 版被加入.

- *AF_HYPERV* is a Windows-only socket based interface for communicating with Hyper-V hosts and guests. The address family is represented as a `(vm_id, service_id)` tuple where the `vm_id` and `service_id` are UUID strings.

  The `vm_id` is the virtual machine identifier or a set of known VMID values if the target is not a specific virtual machine. Known VMID constants defined on `socket` are:

  - `HV_GUID_ZERO`
  - `HV_GUID_BROADCAST`
  - `HV_GUID_WILDCARD` - Used to bind on itself and accept connections from all partitions.
  - `HV_GUID_CHILDREN` - Used to bind on itself and accept connection from child partitions.
  - `HV_GUID_LOOPBACK` - Used as a target to itself.
  - `HV_GUID_PARENT` - When used as a bind accepts connection from the parent partition. When used as an address target it will connect to the parent partition.

  The `service_id` is the service identifier of the registered service.

  在 3.12 版被加入.

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised. Errors related to socket or address semantics raise *OSError* or one of its subclasses.

Non-blocking mode is supported through *setblocking()*. A generalization of this based on timeouts is supported through *settimeout()*.

19.2.2 模組🄵容

The module *socket* exports the following elements.

例外

exception `socket.`**error**

一個已🄵用的*OSError* 的🄵名。

在 3.3 版的變更: Following **PEP 3151**, this class was made an alias of *OSError*.

exception `socket.`**herror**

A subclass of *OSError*, this exception is raised for address-related errors, i.e. for functions that use *h_errno* in the POSIX C API, including *gethostbyname_ex()* and *gethostbyaddr()*. The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. *h_errno* is a numeric value, while *string* represents the description of *h_errno*, as returned by the `hstrerror()` C function.

在 3.3 版的變更: This class was made a subclass of *OSError*.

exception `socket.`**gaierror**

A subclass of *OSError*, this exception is raised for address-related errors by *getaddrinfo()* and *getnameinfo()*. The accompanying value is a pair `(error, string)` representing an error returned by a library call. *string* represents the description of *error*, as returned by the `gai_strerror()` C function. The numeric *error* value will match one of the `EAI_*` constants defined in this module.

在 3.3 版的變更: This class was made a subclass of *OSError*.

exception `socket.`**timeout**

A deprecated alias of *TimeoutError*.

A subclass of *OSError*, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to *settimeout()* (or implicitly through *setdefaulttimeout()*). The accompanying value is a string whose value is currently always "timed out".

在 3.3 版的變更: This class was made a subclass of *OSError*.

在 3.10 版的變更: This class was made an alias of *TimeoutError*.

常數

The AF_* and SOCK_* constants are now `AddressFamily` and `SocketKind` *IntEnum* collections.

在 3.4 版被加入.

socket.**AF_UNIX**

socket.**AF_INET**

socket.**AF_INET6**

These constants represent the address (and protocol) families, used for the first argument to *socket()*. If the *AF_UNIX* constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

socket.**AF_UNSPEC**

AF_UNSPEC means that *getaddrinfo()* should return socket addresses for any address family (either IPv4, IPv6, or any other) that can be used.

socket.**SOCK_STREAM**

socket.**SOCK_DGRAM**

socket.**SOCK_RAW**

socket.**SOCK_RDM**

socket.**SOCK_SEQPACKET**

These constants represent the socket types, used for the second argument to *socket()*. More constants may be available depending on the system. (Only *SOCK_STREAM* and *SOCK_DGRAM* appear to be generally useful.)

socket.**SOCK_CLOEXEC**

socket.**SOCK_NONBLOCK**

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

> **也參考**
>
> Secure File Descriptor Handling for a more thorough explanation.

可用性: Linux >= 2.6.27.

在 3.2 版被加入.

SO_*

socket.**SOMAXCONN**

MSG_*

SOL_*

SCM_*

IPPROTO_*

IPPORT_*

INADDR_*

IP_*

IPV6_*

EAI_*

AI_*

NI_*

TCP_*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the *setsockopt()* and *getsockopt()* methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

在 3.6 版的變更: SO_DOMAIN, SO_PROTOCOL, SO_PEERSEC, SO_PASSSEC, TCP_USER_TIMEOUT, TCP_CONGESTION were added.

在 3.6.5 版的變更: Added support for TCP_FASTOPEN, TCP_KEEPCNT on Windows platforms when available.

在 3.7 版的變更: 新增 TCP_NOTSENT_LOWAT。

Added support for TCP_KEEPIDLE, TCP_KEEPINTVL on Windows platforms when available.

在 3.10 版的變更: IP_RECVTOS was added. Added TCP_KEEPALIVE. On MacOS this constant can be used in the same way that TCP_KEEPIDLE is used on Linux.

在 3.11 版的變更: Added TCP_CONNECTION_INFO. On MacOS this constant can be used in the same way that TCP_INFO is used on Linux and BSD.

在 3.12 版的變更: Added SO_RTABLE and SO_USER_COOKIE. On OpenBSD and FreeBSD respectively those constants can be used in the same way that SO_MARK is used on Linux. Also added missing TCP socket options from Linux: TCP_MD5SIG, TCP_THIN_LINEAR_TIMEOUTS, TCP_THIN_DUPACK, TCP_REPAIR, TCP_REPAIR_QUEUE, TCP_QUEUE_SEQ, TCP_REPAIR_OPTIONS, TCP_TIMESTAMP, TCP_CC_INFO, TCP_SAVE_SYN, TCP_SAVED_SYN, TCP_REPAIR_WINDOW, TCP_FASTOPEN_CONNECT, TCP_ULP, TCP_MD5SIG_EXT, TCP_FASTOPEN_KEY, TCP_FASTOPEN_NO_COOKIE, TCP_ZEROCOPY_RECEIVE, TCP_INQ, TCP_TX_DELAY. Added IP_PKTINFO, IP_UNBLOCK_SOURCE, IP_BLOCK_SOURCE, IP_ADD_SOURCE_MEMBERSHIP, IP_DROP_SOURCE_MEMBERSHIP.

在 3.13 版的變更: Added SO_BINDTOIFINDEX. On Linux this constant can be used in the same way that SO_BINDTODEVICE is used, but with the index of a network interface instead of its name.

在 3.14 版的變更: Added missing IP_FREEBIND, IP_RECVERR, IPV6_RECVERR, IP_RECVTTL, and IP_RECVORIGDSTADDR on Linux.

在 3.14 版的變更: Added support for TCP_QUICKACK on Windows platforms when available.

socket.**AF_CAN**

socket.**PF_CAN**

SOL_CAN_*

CAN_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

可用性: Linux >= 2.6.25, NetBSD >= 8.

在 3.3 版被加入.

在 3.11 版的變更: NetBSD support was added.

在 3.14 版的變更: Restored missing CAN_RAW_ERR_FILTER on Linux.

socket.**CAN_BCM**

CAN_BCM_*

CAN_BCM, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

可用性: Linux >= 2.6.25.

> **備🄵**
>
> The `CAN_BCM_CAN_FD_FRAME` flag is only available on Linux >= 4.8.

在 3.4 版被加入.

`socket.`**`CAN_RAW_FD_FRAMES`**

Enables CAN FD support in a CAN_RAW socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

可用性: Linux >= 3.6.

在 3.5 版被加入.

`socket.`**`CAN_RAW_JOIN_FILTERS`**

Joins the applied CAN filters such that only CAN frames that match all given CAN filters are passed to user space.

This constant is documented in the Linux documentation.

可用性: Linux >= 4.1.

在 3.9 版被加入.

`socket.`**`CAN_ISOTP`**

CAN_ISOTP, in the CAN protocol family, is the ISO-TP (ISO 15765-2) protocol. ISO-TP constants, documented in the Linux documentation.

可用性: Linux >= 2.6.25.

在 3.7 版被加入.

`socket.`**`CAN_J1939`**

CAN_J1939, in the CAN protocol family, is the SAE J1939 protocol. J1939 constants, documented in the Linux documentation.

可用性: Linux >= 5.4.

在 3.9 版被加入.

`socket.`**`AF_DIVERT`**

`socket.`**`PF_DIVERT`**

These two constants, documented in the FreeBSD divert(4) manual page, are also defined in the socket module.

可用性: FreeBSD >= 14.0.

在 3.12 版被加入.

`socket.`**`AF_PACKET`**

`socket.`**`PF_PACKET`**

`PACKET_*`

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

可用性: Linux >= 2.2.

`socket.`**`ETH_P_ALL`**

`ETH_P_ALL` can be used in the *socket* constructor as *proto* for the *AF_PACKET* family in order to capture every packet, regardless of protocol.

For more information, see the *packet(7)* manpage.

可用性: Linux.

在 3.12 版被加入.

socket.**AF_RDS**

socket.**PF_RDS**

socket.**SOL_RDS**

RDS_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

可用性: Linux >= 2.6.30.

在 3.3 版被加入.

socket.**SIO_RCVALL**

socket.**SIO_KEEPALIVE_VALS**

socket.**SIO_LOOPBACK_FAST_PATH**

RCVALL_*

Constants for Windows' WSAIoctl(). The constants are used as arguments to the *ioctl()* method of socket objects.

在 3.6 版的變更: 加入 SIO_LOOPBACK_FAST_PATH。

TIPC_*

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

socket.**AF_ALG**

socket.**SOL_ALG**

ALG_*

Constants for Linux Kernel cryptography.

可用性: Linux >= 2.6.38.

在 3.6 版被加入.

socket.**AF_VSOCK**

socket.**IOCTL_VM_SOCKETS_GET_LOCAL_CID**

VMADDR*

SO_VM*

Constants for Linux host/guest communication.

可用性: Linux >= 4.8.

在 3.7 版被加入.

socket.**AF_LINK**

可用性: BSD, macOS.

在 3.4 版被加入.

socket.**has_ipv6**

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.**AF_BLUETOOTH**

socket.**BTPROTO_L2CAP**

socket.**BTPROTO_RFCOMM**

socket.**BTPROTO_HCI**

socket.**BTPROTO_SCO**

Integer constants for use with Bluetooth addresses.

socket.**BDADDR_ANY**

socket.**BDADDR_LOCAL**

These are string constants containing Bluetooth addresses with special meanings. For example, *BDADDR_ANY* can be used to indicate any address when specifying the binding socket with *BTPROTO_RFCOMM*.

socket.**BDADDR_BREDR**

socket.**BDADDR_LE_PUBLIC**

socket.**BDADDR_LE_RANDOM**

These constants describe the Bluetooth address type when binding or connecting a *BTPROTO_L2CAP* socket.

可用性: Linux, FreeBSD

在 3.14 版被加入.

socket.**SOL_RFCOMM**

socket.**SOL_L2CAP**

socket.**SOL_HCI**

socket.**SOL_SCO**

socket.**SOL_BLUETOOTH**

Used in the level argument to the *setsockopt()* and *getsockopt()* methods of Bluetooth socket objects.

SOL_BLUETOOTH is only available on Linux. Other constants are available if the corresponding protocol is supported.

SO_L2CAP_*

socket.**L2CAP_LM**

L2CAP_LM_*

SO_RFCOMM_*

RFCOMM_LM_*

SO_SCO_*

SO_BTH_*

BT_*

Used in the option name and value argument to the *setsockopt()* and *getsockopt()* methods of Bluetooth socket objects.

`BT_*` and *L2CAP_LM* are only available on Linux. `SO_BTH_*` are only available on Windows. Other constants may be available on Linux and various BSD platforms.

在 3.14 版被加入.

socket.**HCI_FILTER**

socket.**HCI_TIME_STAMP**

socket.**HCI_DATA_DIR**

socket.**SO_HCI_EVT_FILTER**

socket.**SO_HCI_PKT_FILTER**

Option names for use with *BTPROTO_HCI*. Availability and format of the option values depend on platform.

在 3.14 版的變更: Added `SO_HCI_EVT_FILTER` and `SO_HCI_PKT_FILTER` on NetBSD and DragonFly BSD. Added `HCI_DATA_DIR` on FreeBSD, NetBSD and DragonFly BSD.

socket.**HCI_DEV_NONE**

The `device_id` value used to create an HCI socket that isn't specific to a single Bluetooth adapter.

可用性: Linux

在 3.14 版被加入.

socket.**HCI_CHANNEL_RAW**

socket.**HCI_CHANNEL_USER**

socket.**HCI_CHANNEL_MONITOR**

socket.**HCI_CHANNEL_CONTROL**

socket.**HCI_CHANNEL_LOGGING**

Possible values for `channel` field in the *BTPROTO_HCI* address.

可用性: Linux

在 3.14 版被加入.

socket.**AF_QIPCRTR**

Constant for Qualcomm's IPC router protocol, used to communicate with service providing remote processors.

可用性: Linux >= 4.7.

socket.**SCM_CREDS2**

socket.**LOCAL_CREDS**

socket.**LOCAL_CREDS_PERSISTENT**

LOCAL_CREDS and LOCAL_CREDS_PERSISTENT can be used with SOCK_DGRAM, SOCK_STREAM sockets, equivalent to Linux/DragonFlyBSD SO_PASSCRED, while LOCAL_CREDS sends the credentials at first read, LOCAL_CREDS_PERSISTENT sends for each read, SCM_CREDS2 must be then used for the latter for the message type.

在 3.11 版被加入.

可用性: FreeBSD.

socket.**SO_INCOMING_CPU**

Constant to optimize CPU locality, to be used in conjunction with `SO_REUSEPORT`.

在 3.11 版被加入.

可用性: Linux >= 3.9

socket.**SO_REUSEPORT_LB**

Constant to enable duplicate address and port bindings with load balancing.

在 3.14 版被加入.

可用性: FreeBSD >= 12.0

socket.**AF_HYPERV**

socket.**HV_PROTOCOL_RAW**

socket.**HVSOCKET_CONNECT_TIMEOUT**

socket.**HVSOCKET_CONNECT_TIMEOUT_MAX**

socket.**HVSOCKET_CONNECTED_SUSPEND**

socket.**HV_GUID_WILDCARD**

socket.**HV_GUID_BROADCAST**

socket.**HV_GUID_CHILDREN**

socket.**HV_GUID_LOOPBACK**

socket.**HV_GUID_PARENT**

Constants for Windows Hyper-V sockets for host/guest communications.

可用性: Windows.

在 3.12 版被加入.

socket.**ETHERTYPE_ARP**

socket.**ETHERTYPE_IP**

socket.**ETHERTYPE_IPV6**

socket.**ETHERTYPE_VLAN**

IEEE 802.3 protocol number. constants.

可用性: Linux, FreeBSD, macOS.

在 3.12 版被加入.

socket.**SHUT_RD**

socket.**SHUT_WR**

socket.**SHUT_RDWR**

These constants are used by the *shutdown()* method of socket objects.

可用性: not WASI.

函式

建立 sockets

The following functions all create *socket objects*.

class socket.**socket**(*family=AF_INET*, *type=SOCK_STREAM*, *proto=0*, *fileno=None*)

Create a new socket using the given address family, socket type and protocol number. The address family should be *AF_INET* (the default), *AF_INET6*, *AF_UNIX*, *AF_CAN*, *AF_PACKET*, or *AF_RDS*. The socket type should be *SOCK_STREAM* (the default), *SOCK_DGRAM*, *SOCK_RAW* or perhaps one of the other SOCK_ constants. The protocol number is usually zero and may be omitted or in the case where the address family is *AF_CAN* the protocol should be one of CAN_RAW, *CAN_BCM*, *CAN_ISOTP* or *CAN_J1939*.

If *fileno* is specified, the values for *family*, *type*, and *proto* are auto-detected from the specified file descriptor. Auto-detection can be overruled by calling the function with explicit *family*, *type*, or *proto* arguments. This only affects how Python represents e.g. the return value of *socket.getpeername()* but not the actual OS resource. Unlike *socket.fromfd()*, *fileno* will return the same socket and not a duplicate. This may help close a detached socket using *socket.close()*.

The newly created socket is *non-inheritable*.

引發一個附帶引數 `self`、`family`、`type`、`protocol` 的稽核事件 `socket.__new__`。

在 3.3 版的變更: The AF_CAN family was added. The AF_RDS family was added.

在 3.4 版的變更: 新增 CAN_BCM 協定。

在 3.4 版的變更: The returned socket is now non-inheritable.

在 3.7 版的變更: 新增 CAN_ISOTP 協定。

在 3.7 版的變更: When *SOCK_NONBLOCK* or *SOCK_CLOEXEC* bit flags are applied to *type* they are cleared, and *socket.type* will not reflect them. They are still passed to the underlying system `socket()` call. Therefore,

```
sock = socket.socket(
    socket.AF_INET,
    socket.SOCK_STREAM | socket.SOCK_NONBLOCK)
```

will still create a non-blocking socket on OSes that support SOCK_NONBLOCK, but `sock.type` will be set to `socket.SOCK_STREAM`.

在 3.9 版的變更: 新增 CAN_J1939 協定。

在 3.10 版的變更: 新增 IPPROTO_MPTCP 協定。

socket.**socketpair**([*family*[, *type*[, *proto*]]])

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the *socket()* function above. The default family is *AF_UNIX* if defined on the platform; otherwise, the default is *AF_INET*.

The newly created sockets are *non-inheritable*.

在 3.2 版的變更: The returned socket objects now support the whole socket API, rather than a subset.

在 3.4 版的變更: The returned sockets are now non-inheritable.

在 3.5 版的變更: 新增對 Windows 的支援。

socket.**create_connection**(*address*, *timeout=GLOBAL_DEFAULT*, *source_address=None*, *, *all_errors=False*)

Connect to a TCP service listening on the internet *address* (a 2-tuple `(host, port)`), and return the socket object. This is a higher-level function than *socket.connect()*: if *host* is a non-numeric hostname, it will try to resolve it for both *AF_INET* and *AF_INET6*, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by *getdefaulttimeout()* is used.

If supplied, *source_address* must be a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. If host or port are ” or 0 respectively the OS default behavior will be used.

When a connection cannot be created, an exception is raised. By default, it is the exception from the last address in the list. If *all_errors* is `True`, it is an *ExceptionGroup* containing the errors of all attempts.

在 3.2 版的變更: 新增 *source_address*。

在 3.11 版的變更: 新增 *all_errors*。

socket.**create_server**(*address*, *, *family=AF_INET*, *backlog=None*, *reuse_port=False*, *dualstack_ipv6=False*)

Convenience function which creates a TCP socket bound to *address* (a 2-tuple `(host, port)`) and returns the socket object.

family should be either *AF_INET* or *AF_INET6*. *backlog* is the queue size passed to *socket.listen()*; if not specified , a default reasonable value is chosen. *reuse_port* dictates whether to set the `SO_REUSEPORT` socket option.

If *dualstack_ipv6* is true, *family* is *AF_INET6* and the platform supports it the socket will be able to accept both IPv4 and IPv6 connections, else it will raise *ValueError*. Most POSIX platforms and Windows are supposed to support this functionality. When this functionality is enabled the address returned by *socket.getpeername()* when an IPv4 connection occurs will be an IPv6 address represented as an IPv4-mapped IPv6 address. If *dualstack_ipv6* is false it will explicitly disable this functionality on platforms that enable it by default (e.g. Linux). This parameter can be used in conjunction with *has_dualstack_ipv6()*:

```
import socket

addr = ("", 8080)  # all interfaces, port 8080
if socket.has_dualstack_ipv6():
    s = socket.create_server(addr, family=socket.AF_INET6, dualstack_ipv6=True)
else:
    s = socket.create_server(addr)
```

備🄵

On POSIX platforms the `SO_REUSEADDR` socket option is set in order to immediately reuse previous sockets which were bound on the same *address* and remained in TIME_WAIT state.

在 3.8 版被加入.

socket.**has_dualstack_ipv6**()

Return `True` if the platform supports creating a TCP socket which can handle both IPv4 and IPv6 connections.

在 3.8 版被加入.

socket.**fromfd**(*fd*, *family*, *type*, *proto=0*)

Duplicate the file descriptor *fd* (an integer as returned by a file object's *fileno()* method) and build a socket object from the result. Address family, socket type and protocol number are as for the *socket()* function above. The file descriptor should refer to a socket, but this is not checked --- subsequent operations on the

object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is *non-inheritable*.

在 3.4 版的變更: The returned socket is now non-inheritable.

`socket.`**`fromshare`**(*data*)

Instantiate a socket from data obtained from the `socket.share()` method. The socket is assumed to be in blocking mode.

可用性: Windows.

在 3.3 版被加入.

`socket.`**`SocketType`**

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

其他函式

The `socket` module also offers various network-related services:

`socket.`**`close`**(*fd*)

Close a socket file descriptor. This is like `os.close()`, but for sockets. On some platforms (most noticeable Windows) `os.close()` does not work for socket file descriptors.

在 3.7 版被加入.

`socket.`**`getaddrinfo`**(*host*, *port*, *family=AF_UNSPEC*, *type=0*, *proto=0*, *flags=0*)

This function wraps the C function `getaddrinfo` of the underlying system.

Translate the *host*/*port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *type* and *proto* arguments can be optionally specified in order to provide options and limit the list of addresses returned. Pass their default values (`AF_UNSPEC`, 0, and 0, respectively) to not limit the results. See the note below for details.

The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, type, proto, canonname, sockaddr)
```

In these tuples, *family*, *type*, *proto* are all integers and are meant to be passed to the `socket()` function. *canonname* will be a string representing the canonical name of the *host* if `AI_CANONNAME` is part of the *flags* argument; else *canonname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a `(address, port)` 2-tuple for `AF_INET`, a `(address, port, flowinfo, scope_id)` 4-tuple for `AF_INET6`), and is meant to be passed to the `socket.connect()` method.

> **備🄵**
>
> If you intend to use results from `getaddrinfo()` to create a socket (rather than, for example, retrieve *canonname*), consider limiting the results by *type* (e.g. `SOCK_STREAM` or `SOCK_DGRAM`) and/or *proto* (e.g. `IPPROTO_TCP` or `IPPROTO_UDP`) that your application can handle.
>
> The behavior with default values of *family*, *type*, *proto* and *flags* is system-specific.

Many systems (for example, most Linux configurations) will return a sorted list of all matching addresses. These addresses should generally be tried in order until a connection succeeds (possibly tried in parallel, for example, using a Happy Eyeballs algorithm). In these cases, limiting the *type* and/or *proto* can help eliminate unsuccessful or unusable connection attempts.

Some systems will, however, only return a single address. (For example, this was reported on Solaris and AIX configurations.) On these systems, limiting the *type* and/or *proto* helps ensure that this address is usable.

引發一個附帶引數 `host`、`port`、`family`、`type`、`protocol` 的稽核事件 `socket.getaddrinfo`。

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, proto=socket.IPPROTO_TCP)
[(socket.AF_INET6, socket.SOCK_STREAM,
 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80, 0, 0)),
 (socket.AF_INET, socket.SOCK_STREAM,
 6, '', ('93.184.216.34', 80))]
```

在 3.2 版的變更: parameters can now be passed using keyword arguments.

在 3.7 版的變更: for IPv6 multicast addresses, string representing an address will not contain `%scope_id` part.

`socket.`**`getfqdn`**`(`[*name*]`)`

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by *gethostbyaddr()* is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available and *name* was provided, it is returned unchanged. If *name* was empty or equal to `'0.0.0.0'`, the hostname from *gethostname()* is returned.

`socket.`**`gethostbyname`**`(`*hostname*`)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See *gethostbyname_ex()* for a more complete interface. *gethostbyname()* does not support IPv6 name resolution, and *getaddrinfo()* should be used instead for IPv4/v6 dual stack support.

引發一個附帶引數 `hostname` 的稽核事件 `socket.gethostbyname`。

可用性: not WASI.

`socket.`**`gethostbyname_ex`**`(`*hostname*`)`

Translate a host name to IPv4 address format, extended interface. Return a 3-tuple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the host's primary host name, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). *gethostbyname_ex()* does not support IPv6 name resolution, and *getaddrinfo()* should be used instead for IPv4/v6 dual stack support.

引發一個附帶引數 `hostname` 的稽核事件 `socket.gethostbyname`。

可用性: not WASI.

`socket.`**`gethostname`**`()`

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

引發一個不附帶引數的稽核事件 `socket.gethostname`。

Note: *gethostname()* doesn't always return the fully qualified domain name; use *getfqdn()* for that.

可用性: not WASI.

socket.**gethostbyaddr**(*ip_address*)

Return a 3-tuple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function *getfqdn()*. *gethostbyaddr()* supports both IPv4 and IPv6.

引發一個附帶引數 `ip_address` 的稽核事件 `socket.gethostbyaddr`。

可用性: not WASI.

socket.**getnameinfo**(*sockaddr*, *flags*)

Translate a socket address *sockaddr* into a 2-tuple `(host, port)`. Depending on the settings of *flags*, the result can contain a fully qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

For IPv6 addresses, `%scope_id` is appended to the host part if *sockaddr* contains meaningful *scope_id*. Usually this happens for multicast addresses.

For more information about *flags* you can consult *getnameinfo(3)*.

引發一個附帶引數 `sockaddr` 的稽核事件 `socket.getnameinfo`。

可用性: not WASI.

socket.**getprotobyname**(*protocolname*)

Translate an internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the *socket()* function. This is usually only needed for sockets opened in "raw" mode (*SOCK_RAW*); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

可用性: not WASI.

socket.**getservbyname**(*servicename*[, *protocolname*])

Translate an internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

引發一個附帶引數 `sockaddr`、`protocolname` 的稽核事件 `socket.getservbyname`。

可用性: not WASI.

socket.**getservbyport**(*port*[, *protocolname*])

Translate an internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

引發一個附帶引數 `port`、`protocolname` 的稽核事件 `socket.getservbyport`。

可用性: not WASI.

socket.**ntohl**(*x*)

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.**ntohs**(*x*)

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

在 3.10 版的變更: Raises *OverflowError* if *x* does not fit in a 16-bit unsigned integer.

socket.**htonl**(*x*)

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.**htons**(*x*)

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

在 3.10 版的變更: Raises *OverflowError* if *x* does not fit in a 16-bit unsigned integer.

socket.**inet_aton**(*ip_string*)

Convert an IPv4 address from dotted-quad string format (for example, '123.45.67.89') to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `in_addr`, which is the C type for the 32-bit packed binary this function returns.

inet_aton() also accepts strings with less than three dots; see the Unix manual page *inet(3)* for details.

If the IPv4 address string passed to this function is invalid, *OSError* will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

inet_aton() does not support IPv6, and *inet_pton()* should be used instead for IPv4/v6 dual stack support.

socket.**inet_ntoa**(*packed_ip*)

Convert a 32-bit packed IPv4 address (a *bytes-like object* four bytes in length) to its standard dotted-quad string representation (for example, '123.45.67.89'). This is useful when conversing with a program that uses the standard C library and needs objects of type `in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, *OSError* will be raised. *inet_ntoa()* does not support IPv6, and *inet_ntop()* should be used instead for IPv4/v6 dual stack support.

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

socket.**inet_pton**(*address_family*, *ip_string*)

Convert an IP address from its family-specific string format to a packed, binary format. *inet_pton()* is useful when a library or network protocol calls for an object of type `in_addr` (similar to *inet_aton()*) or `in6_addr`.

Supported values for *address_family* are currently *AF_INET* and *AF_INET6*. If the IP address string *ip_string* is invalid, *OSError* will be raised. Note that exactly what is valid depends on both the value of *address_family* and the underlying implementation of `inet_pton()`.

可用性: Unix, Windows.

在 3.4 版的變更: Windows support added

socket.**inet_ntop**(*address_family*, *packed_ip*)

Convert a packed IP address (a *bytes-like object* of some number of bytes) to its standard, family-specific string representation (for example, `'7.10.0.5'` or `'5aef:2b::8'`). *inet_ntop()* is useful when a library or network protocol returns an object of type `in_addr` (similar to *inet_ntoa()*) or `in6_addr`.

Supported values for *address_family* are currently *AF_INET* and *AF_INET6*. If the bytes object *packed_ip* is not the correct length for the specified address family, *ValueError* will be raised. *OSError* is raised for errors from the call to *inet_ntop()*.

可用性: Unix, Windows.

在 3.4 版的變更: Windows support added

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

socket.**CMSG_LEN**(*length*)

Return the total length, without trailing padding, of an ancillary data item with associated data of the given *length*. This value can often be used as the buffer size for *recvmsg()* to receive a single item of ancillary data, but **RFC 3542** requires portable applications to use *CMSG_SPACE()* and thus include space for padding, even when the item will be the last in the buffer. Raises *OverflowError* if *length* is outside the permissible range of values.

可用性: Unix, not WASI.

Most Unix platforms.

在 3.3 版被加入.

socket.**CMSG_SPACE**(*length*)

Return the buffer size needed for *recvmsg()* to receive an ancillary data item with associated data of the given *length*, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the *CMSG_SPACE()* values for their associated data lengths. Raises *OverflowError* if *length* is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

可用性: Unix, not WASI.

most Unix platforms.

在 3.3 版被加入.

socket.**getdefaulttimeout**()

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

socket.**setdefaulttimeout**(*timeout*)

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is `None`. See *settimeout()* for possible values and their respective meanings.

socket.**sethostname**(*name*)

Set the machine's hostname to *name*. This will raise an *OSError* if you don't have enough rights.

引發一個附帶引數 `name` 的稽核事件 `socket.sethostname`。

可用性: Unix, not Android.

在 3.3 版被加入.

socket.**if_nameindex**()

Return a list of network interface information (index int, name string) tuples. *OSError* if the system call fails.

可用性: Unix, Windows, not WASI.

在 3.3 版被加入.

在 3.8 版的變更: 增加對 Windows 的支援。

備🄵

On Windows network interfaces have different names in different contexts (all names are examples):

- UUID: `{FB605B73-AAC2-49A6-9A2F-25416AEA0573}`
- name: `ethernet_32770`
- friendly name: `vEthernet (nat)`
- description: `Hyper-V Virtual Ethernet Adapter`

This function returns names of the second form from the list, `ethernet_32770` in this example case.

socket.**if_nametoindex**(*if_name*)

Return a network interface index number corresponding to an interface name. *OSError* if no interface with the given name exists.

可用性: Unix, Windows, not WASI.

在 3.3 版被加入.

在 3.8 版的變更: 增加對 Windows 的支援。

也參考

”Interface name” is a name as documented in `if_nameindex()`.

`socket.`**`if_indextoname`**(*if_index*)

Return a network interface name corresponding to an interface index number. `OSError` if no interface with the given index exists.

可用性: Unix, Windows, not WASI.

在 3.3 版被加入.

在 3.8 版的變更: 增加對 Windows 的支援。

也參考

”Interface name” is a name as documented in `if_nameindex()`.

`socket.`**`send_fds`**(*sock*, *buffers*, *fds*[, *flags*[, *address*]])

Send the list of file descriptors *fds* over an `AF_UNIX` socket *sock*. The *fds* parameter is a sequence of file descriptors. Consult `sendmsg()` for the documentation of these parameters.

可用性: Unix, not WASI.

Unix platforms supporting `sendmsg()` and `SCM_RIGHTS` mechanism.

在 3.9 版被加入.

`socket.`**`recv_fds`**(*sock*, *bufsize*, *maxfds*[, *flags*])

Receive up to *maxfds* file descriptors from an `AF_UNIX` socket *sock*. Return `(msg, list(fds), flags, addr)`. Consult `recvmsg()` for the documentation of these parameters.

可用性: Unix, not WASI.

Unix platforms supporting `recvmsg()` and `SCM_RIGHTS` mechanism.

在 3.9 版被加入.

備🄵

Any truncated integers at the end of the list of file descriptors.

19.2.3 Socket 物件

Socket objects have the following methods. Except for `makefile()`, these correspond to Unix system calls applicable to sockets.

在 3.2 版的變更: Support for the *context manager* protocol was added. Exiting the context manager is equivalent to calling `close()`.

`socket.`**`accept`**()

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The newly created socket is *non-inheritable*.

在 3.4 版的變更: The socket is now non-inheritable.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**bind**(*address*)

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family --- see above.)

引發一個附帶引數 `self`、`address` 的稽核事件 `socket.bind`。

可用性: not WASI.

socket.**close**()

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from *makefile()* are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to *close()* them explicitly, or to use a `with` statement around them.

在 3.6 版的變更: *OSError* is now raised if an error occurs when the underlying `close()` call is made.

> **備🄵**
>
> *close()* releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call *shutdown()* before *close()*.

socket.**connect**(*address*)

Connect to a remote socket at *address*. (The format of *address* depends on the address family --- see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a *TimeoutError* on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an *InterruptedError* exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

引發一個附帶引數 `self`、`address` 的稽核事件 `socket.connect`。

在 3.5 版的變更: The method now waits until the connection completes instead of raising an *InterruptedError* exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see the **PEP 475** for the rationale).

可用性: not WASI.

socket.**connect_ex**(*address*)

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as "host not found," can still raise exceptions). The error indicator is `0` if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

引發一個附帶引數 `self`、`address` 的稽核事件 `socket.connect`。

可用性: not WASI.

socket.**detach**()

Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

在 3.2 版被加入.

socket.**dup**()

Duplicate the socket.

The newly created socket is *non-inheritable*.

在 3.4 版的變更: The socket is now non-inheritable.

可用性: not WASI.

socket.**fileno**()

Return the socket's file descriptor (a small integer), or -1 on failure. This is useful with *select.select()*.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as *os.fdopen()*). Unix does not have this limitation.

socket.**get_inheritable**()

Get the *inheritable flag* of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

在 3.4 版被加入.

socket.**getpeername**()

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family --- see above.) On some systems this function is not supported.

socket.**getsockname**()

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family --- see above.)

socket.**getsockopt**(*level*, *optname*[, *buflen*])

Return the value of the given socket option (see the Unix man page *getsockopt(2)*). The needed symbolic constants (*SO_** *etc.*) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module *struct* for a way to decode C structures encoded as byte strings).

可用性: not WASI.

socket.**getblocking**()

Return `True` if socket is in blocking mode, `False` if in non-blocking.

這等同於檢查 `socket.gettimeout() != 0`。

在 3.7 版被加入.

socket.**gettimeout**()

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to *setblocking()* or *settimeout()*.

socket.**ioctl**(*control*, *option*)

The *ioctl()* method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation for more information.

On other platforms, the generic *fcntl.fcntl()* and *fcntl.ioctl()* functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: `SIO_RCVALL`, `SIO_KEEPALIVE_VALS`, and `SIO_LOOPBACK_FAST_PATH`.

可用性: Windows

在 3.6 版的變更: 加入 `SIO_LOOPBACK_FAST_PATH`。

socket.**listen**([*backlog*])

Enable a server to accept connections. If *backlog* is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

可用性: not WASI.

在 3.5 版的變更: The *backlog* parameter is now optional.

socket.**makefile**(*mode='r'*, *buffering=None*, ***, *encoding=None*, *errors=None*, *newline=None*)

Return a *file object* associated with the socket. The exact returned type depends on the arguments given to `makefile()`. These arguments are interpreted the same way as by the built-in `open()` function, except the only supported *mode* values are `'r'` (default), `'w'`, `'b'`, or a combination of those.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by `makefile()` won't close the original socket unless all other file objects have been closed and `socket.close()` has been called on the socket object.

> **備🄵**
>
> On Windows, the file-like object created by `makefile()` cannot be used where a file object with a file descriptor is expected, such as the stream arguments of `subprocess.Popen()`.

socket.**recv**(*bufsize*[, *flags*])

Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. A returned empty bytes object indicates that the client has disconnected. See the Unix manual page `recv(2)` for the meaning of the optional argument *flags*; it defaults to zero.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see **PEP 475** for the rationale).

socket.**recvfrom**(*bufsize*[, *flags*])

Receive data from the socket. The return value is a pair `(bytes, address)` where *bytes* is a bytes object representing the data received and *address* is the address of the socket sending the data. See the Unix manual page `recv(2)` for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family --- see above.)

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see **PEP 475** for the rationale).

在 3.7 版的變更: For multicast IPv6 address, first item of *address* does not contain `%scope_id` part anymore. In order to get full IPv6 address use `getnameinfo()`.

socket.**recvmsg**(*bufsize*[, *ancbufsize*[, *flags*]])

Receive normal data (up to *bufsize* bytes) and ancillary data from the socket. The *ancbufsize* argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using `CMSG_SPACE()` or `CMSG_LEN()`, and items which do not fit into the buffer might be truncated or discarded. The *flags* argument defaults to 0 and has the same meaning as for `recv()`.

The return value is a 4-tuple: `(data, ancdata, msg_flags, address)`. The *data* item is a `bytes` object holding the non-ancillary data received. The *ancdata* item is a list of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)` representing the ancillary data (control messages) received: *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a `bytes` object holding the associated data. The *msg_flags* item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, *address* is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, `sendmsg()` and `recvmsg()` can be used to pass file descriptors between processes over an `AF_UNIX` socket. When this facility is used (it is often restricted to `SOCK_STREAM` sockets), `recvmsg()` will return, in its ancillary data, items of the form `(socket.SOL_SOCKET, socket.SCM_RIGHTS, fds)`, where *fds* is a `bytes` object representing the new file descriptors as a binary array of the native C `int` type. If `recvmsg()` raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, *recvmsg()* will issue a *RuntimeWarning*, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the SCM_RIGHTS mechanism, the following function will receive up to *maxfds* file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also *sendmsg()*.

```
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")   # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen, socket.CMSG_LEN(maxfds * fds.
↪itemsize))
    for cmsg_level, cmsg_type, cmsg_data in ancdata:
        if cmsg_level == socket.SOL_SOCKET and cmsg_type == socket.SCM_RIGHTS:
            # Append data, ignoring any truncated integers at the end.
            fds.frombytes(cmsg_data[:len(cmsg_data) - (len(cmsg_data) % fds.itemsize)])
    return msg, list(fds)
```

可用性: Unix.

Most Unix platforms.

在 3.3 版被加入.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**recvmsg_into**(*buffers*[, *ancbufsize*[, *flags*]])

Receive normal data and ancillary data from the socket, behaving as *recvmsg()* would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The *buffers* argument must be an iterable of objects that export writable buffers (e.g. *bytearray* objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (*sysconf()* value SC_IOV_MAX) on the number of buffers that can be used. The *ancbufsize* and *flags* arguments have the same meaning as for *recvmsg()*.

The return value is a 4-tuple: (nbytes, ancdata, msg_flags, address), where *nbytes* is the total number of bytes of non-ancillary data written into the buffers, and *ancdata*, *msg_flags* and *address* are the same as for *recvmsg()*.

範例:

```
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'--------------')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), bytearray(b'little lamb---')]
```

可用性: Unix.

Most Unix platforms.

在 3.3 版被加入.

socket.**recvfrom_into**(*buffer*[, *nbytes*[, *flags*]])

Receive data from the socket, writing it into *buffer* instead of creating a new bytestring. The return value is

a pair `(nbytes, address)` where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family --- see above.)

socket.**recv_into**(*buffer*[, *nbytes*[, *flags*]])

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

socket.**send**(*bytes*[, *flags*])

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the socket-howto.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**sendall**(*bytes*[, *flags*])

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Unlike *send()*, this method continues to send data from *bytes* until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

在 3.5 版的變更: The socket timeout is no longer reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**sendto**(*bytes*, *address*)

socket.**sendto**(*bytes*, *flags*, *address*)

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for *recv()* above. Return the number of bytes sent. (The format of *address* depends on the address family --- see above.)

引發一個附帶引數 `self`、`address` 的稽核事件 `socket.sendto`。

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**sendmsg**(*buffers*[, *ancdata*[, *flags*[, *address*]]])

Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The *buffers* argument specifies the non-ancillary data as an iterable of *bytes-like objects* (e.g. *bytes* objects); the operating system may set a limit (*sysconf()* value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancdata* argument specifies the ancillary data (control messages) as an iterable of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)`, where *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a bytes-like object holding the associated data. Note that some systems (in particular, systems without *CMSG_SPACE()*) might support sending only one control message per call. The *flags* argument defaults to 0 and has the same meaning as for *send()*. If *address* is supplied and not `None`, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors *fds* over an *AF_UNIX* socket, on systems which support the `SCM_RIGHTS` mechanism. See also *recvmsg()*.

```
import socket, array
```

(繼續下一頁)

(繼續上一頁)

```
def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET, socket.SCM_RIGHTS, array.array("i",␣
↪fds))])
```

可用性: Unix, not WASI.

Most Unix platforms.

引發一個附帶引數 `self`、`address` 的稽核事件 `socket.sendmsg`。

在 3.3 版被加入.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.**sendmsg_afalg**([*msg*,]*, *op*[, *iv*[, *assoclen*[, *flags*]]])

Specialized version of *sendmsg()* for *AF_ALG* socket. Set mode, IV, AEAD associated data length and flags for *AF_ALG* socket.

可用性: Linux >= 2.6.38.

在 3.6 版被加入.

socket.**sendfile**(*file*, *offset=0*, *count=None*)

Send a file until EOF is reached by using high-performance *os.sendfile* and return the total number of bytes which were sent. *file* must be a regular file object opened in binary mode. If *os.sendfile* is not available (e.g. Windows) or *file* is not a regular file *send()* will be used instead. *offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case *file.tell()* can be used to figure out the number of bytes which were sent. The socket must be of *SOCK_STREAM* type. Non-blocking sockets are not supported.

在 3.5 版被加入.

socket.**set_inheritable**(*inheritable*)

Set the *inheritable flag* of the socket's file descriptor or socket's handle.

在 3.4 版被加入.

socket.**setblocking**(*flag*)

Set blocking or non-blocking mode of the socket: if *flag* is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain *settimeout()* calls:

- `sock.setblocking(True)` 等價於 `sock.settimeout(None)`
- `sock.setblocking(False)` 等價於 `sock.settimeout(0.0)`

在 3.7 版的變更: The method no longer applies *SOCK_NONBLOCK* flag on *socket.type*.

socket.**settimeout**(*value*)

Set a timeout on blocking socket operations. The *value* argument can be a nonnegative floating-point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations will raise a *timeout* exception if the timeout period *value* has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If `None` is given, the socket is put in blocking mode.

For further information, please consult the *notes on socket timeouts*.

在 3.7 版的變更: The method no longer toggles *SOCK_NONBLOCK* flag on *socket.type*.

socket.**setsockopt**(*level*, *optname*, *value: int*)

socket.**setsockopt**(*level*, *optname*, *value: buffer*)

socket.**setsockopt**(*level*, *optname*, *None*, *optlen: int*)

Set the value of the given socket option (see the Unix manual page *setsockopt(2)*). The needed symbolic constants are defined in this module (SO_* etc. <socket-unix-constants>). The value can be an integer, `None` or a *bytes-like object* representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module *struct* for a way to encode C structures as bytestrings). When *value* is set to `None`, *optlen* argument is required. It's equivalent to call `setsockopt()` C function with `optval=NULL` and `optlen=optlen`.

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

在 3.6 版的變更: setsockopt(level, optname, None, optlen: int) form added.

可用性: not WASI.

socket.**shutdown**(*how*)

Shut down one or both halves of the connection. If *how* is *SHUT_RD*, further receives are disallowed. If *how* is *SHUT_WR*, further sends are disallowed. If *how* is *SHUT_RDWR*, further sends and receives are disallowed.

可用性: not WASI.

socket.**share**(*process_id*)

Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with *process_id*. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using *fromshare()*. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

可用性: Windows.

在 3.3 版被加入.

Note that there are no methods `read()` or `write()`; use *recv()* and *send()* without *flags* argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the *socket* constructor.

socket.**family**

The socket family.

socket.**type**

The socket type.

socket.**proto**

The socket protocol.

19.2.4 Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling *setdefaulttimeout()*.

- In *blocking mode*, operations block until complete or the system returns an error (such as connection timed out).
- In *non-blocking mode*, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the *select* module can be used to know when and whether a socket is available for reading or writing.
- In *timeout mode*, operations fail if they cannot be completed within the timeout specified for the socket (they raise a *timeout* exception) or if the system returns an error.

備🄵

At the operating system level, sockets in *timeout mode* are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the *fileno()* of a socket.

Timeouts and the `connect` method

The *connect()* operation is also subject to the timeout setting, and in general it is recommended to call *settimeout()* before calling *connect()* or pass a timeout parameter to *create_connection()*. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.

Timeouts and the `accept` method

If *getdefaulttimeout()* is not *None*, sockets returned by the *accept()* method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in *blocking mode* or in *timeout mode*, the socket returned by *accept()* is in *blocking mode*;
- if the listening socket is in *non-blocking mode*, whether the socket returned by *accept()* is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.

19.2.5 范例

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence *socket()*, *bind()*, *listen()*, *accept()* (possibly repeating the *accept()* to service more than one client), while a client only needs the sequence *socket()*, *connect()*. Also note that the server does not *sendall()*/*recv()* on the socket it is listening on but on the new socket returned by *accept()*.

前兩個範例只支援 IPv4：

```
# Echo server program
import socket

HOST = ''                 # Symbolic name meaning all available interfaces
PORT = 50007              # Arbitrary non-privileged port
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.bind((HOST, PORT))
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)
```

```
# Echo client program
import socket

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the server
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to all the addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```
# Echo server program
import socket
import sys

HOST = None               # Symbolic name meaning all available interfaces
PORT = 50007              # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                              socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)
```

```
# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
with s:
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packets
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a packet
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The next example shows how to use the socket interface to communicate to a CAN network using the raw socket protocol. To use CAN with the broadcast manager protocol instead, open a socket with:

```
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.CAN_BCM)
```

After binding (`CAN_RAW`) or connecting (*`CAN_BCM`*) the socket, you can use the *`socket.send()`* and *`socket.recv()`* operations (and their counterparts) on the socket object as usual.

This last example might require special privileges:

```
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in <linux/can.h>)

can_frame_fmt = "=IB3x8s"
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc, data)

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt, frame)
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interface
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket.CAN_RAW)
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)

    print('Received: can_id=%x, can_dlc=%x, data=%s' % dissect_can_frame(cf))

    try:
```

(繼續下一頁)

(繼續上一頁)

```
        s.send(cf)
    except OSError:
        print('Error sending CAN frame')

    try:
        s.send(build_can_frame(0x01, b'\x01\x02\x03'))
    except OSError:
        print('Error sending CAN frame')
```

Running an example several times with too small delay between executions, could lead to this error:

```
OSError: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a *socket* flag to set, in order to prevent this, `socket.SO_REUSEADDR`:

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the `SO_REUSEADDR` flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

也參考

For an introduction to socket programming (in C), see the following papers:

- *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest
- *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to **RFC 3493** titled Basic Socket Interface Extensions for IPv6.

19.3 `ssl` --- socket 物件的 TLS/SSL 包裝器

原始碼： Lib/ssl.py

這個模組向用🄴端及伺服器端提供了對於網路 socket 的傳輸層安全性協定（或稱🄴「安全通訊協定 (Secure Sockets Layer)」）加密及身分驗證功能。這個模組使用 OpenSSL 套件，它可以在所有的 Unix 系統、Windows、macOS、以及其他任何可能的平台上使用，只要事先在該平台上安裝 OpenSSL。

備🄵

由於呼叫了作業系統的 socket APIs，有些行🄴會根據平台而有所不同。OpenSSL 的安裝版本也會對模組的運作🄵生影響。例如，OpenSSL 版本 1.1.1 附帶 TLSv1.3。

警告

在使用此模組之前，請🄴讀*Security considerations*。如果不這樣做，可能會🄵生錯誤的安全性認知，因🄵 ssl 模組的預設設定未必適合你的應用程式。

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

這個章節記🄵了 `ssl` 模組的物件及函式；關於 TSL、SSL、以及憑證的更多資訊，可以去參考此章節底部的「詳情」部分。

此模組提供了一個*ssl.SSLSocket* 類🄵，它是從*socket.socket* 衍生出來的，🄵且提供類似 socket 的包裝器，讓使用 SSL 進行資料傳輸時，可以進行資料的加密及解密。它也提供了一些額外的方法，如 `getpeercert()`，用於取得連結另一端的憑證；以及 `cipher()`，用於搜尋用於安全連接的加密方法 (cipher)；和 `get_verified_chain()`、`get_unverified_chain()` 能用於取得憑證鏈。

對於更🄴雜的應用程式，*ssl.SSLContext* 類🄴有助於管理設定及認證，然後可以透過*SSLContext.wrap_socket()* 方法建立的 SSL socket 繼承這些設定和認證。

在 3.5.3 版的變更: 更新以支援與 OpenSSL 1.1.0 進行連結

在 3.6 版的變更: OpenSSL 0.9.8, 1.0.0 及 1.0.1 版本已被🄴用且不再支援。在未來 ssl 模組將需要至少 OpenSSL 1.0.2 版本或 1.1.0 版本。

在 3.10 版的變更: **PEP 644** 已經被實作。ssl 模組需要 OpenSSL 1.1.1 以上的版本才能使用。

使用已經被🄴用的常數或函式將會導致🄵用警示。

19.3.1 函式、常數與例外

Socket 建立

SSLSocket 實例必須使用*SSLContext.wrap_socket()* 方法來建立。輔助函式*create_default_context()* 會回傳有安全預設設定的新語境 (context)。

使用預設語境及 IPv4/IPv6 雙協定堆🄵的用🄵端 socket 範例：

```
import socket
import ssl

hostname = 'www.python.org'
context = ssl.create_default_context()

with socket.create_connection((hostname, 443)) as sock:
    with context.wrap_socket(sock, server_hostname=hostname) as ssock:
        print(ssock.version())
```

使用自訂語境及 IPv4 的用🄵端 socket 範例：

```
hostname = 'www.python.org'
# PROTOCOL_TLS_CLIENT requires valid cert chain and hostname
context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
context.load_verify_locations('path/to/cabundle.pem')

with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0) as sock:
    with context.wrap_socket(sock, server_hostname=hostname) as ssock:
        print(ssock.version())
```

在本地 IPv4 上監聽伺服器 socket 的範例：

```
context = ssl.SSLContext(ssl.PROTOCOL_TLS_SERVER)
context.load_cert_chain('/path/to/certchain.pem', '/path/to/private.key')

with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0) as sock:
    sock.bind(('127.0.0.1', 8443))
    sock.listen(5)
    with context.wrap_socket(sock, server_side=True) as ssock:
        conn, addr = ssock.accept()
        ...
```

語境建立

一個可以幫忙建立出*SSLContext* 物件以用於一般目的的方便函式。

ssl.**create_default_context**(*purpose=Purpose.SERVER_AUTH*, *, *cafile=None*, *capath=None*, *cadata=None*)

回傳一個新的*SSLContext* 物件，使用給定 *purpose* 的預設值。這些設定是由*ssl* 選擇，通常比直接呼叫*SSLContext* 有更高的安全性。

cafile、*capath*、*cadata* 是用來選擇用於憑證認證的 CA 憑證，就像*SSLContext.load_verify_locations()* 一樣。如果三個值都是*None*，此函式會自動選擇系統預設的 CA 憑證。

這些設定包含：*PROTOCOL_TLS_CLIENT* 或*PROTOCOL_TLS_SERVER*、*OP_NO_SSLv2*、以及*OP_NO_SSLv3*，使用高等加密套件但不包含 RC4 和未經身份驗證的加密套件。如果將 *purpose* 設定🄵*SERVER_AUTH*，則會把*verify_mode* 設🄵*CERT_REQUIRED* 🄵使用設定的 CA 憑證 (當 *cafile*、*capath* 或 *cadata* 其中一個值有被設定時) 或使用預設的 CA 憑證*SSLContext.load_default_certs()* 。

當系統有支援*keylog_filename* 🄵且有設定環境變數 SSLKEYLOGFILE 時*create_default_context()* 會🄵用密鑰日🄵記🄵 (logging)。

The default settings for this context include *VERIFY_X509_PARTIAL_CHAIN* and *VERIFY_X509_STRICT*. These make the underlying OpenSSL implementation behave more like a conforming implementation of **RFC 5280**, in exchange for a small amount of incompatibility with older X.509 certificates.

備🄵

協定、選項、加密方式和其它設定可以在不舍🄵舊值的情🄵下直接更改成新的值，這些值代表了在相容性和安全性之間取得的合理平衡。

如果你的應用程式需要特殊的設定，你應該要自行建立一個*SSLContext* 🄵自行調整設定。

備🄵

如果你發現某些舊的用🄵端或伺服器常適用此函式建立的*SSLContext* 連🄵時，收到"Protocol or cipher suite mismatch" 錯誤，這可能是因🄵他們的系統僅支援 SSL3.0，然而 SSL3.0 已被此函式用*OP_NO_SSLv3* 排除。目前廣泛認🄵 SSL3.0 已經被完全破解。如果你仍然希望在允許 SSL3.0 連🄵的情🄵下使用此函式，可以使用下面的方法：

```
ctx = ssl.create_default_context(Purpose.CLIENT_AUTH)
ctx.options &= ~ssl.OP_NO_SSLv3
```

備🄵

This context enables *VERIFY_X509_STRICT* by default, which may reject pre-**RFC 5280** or malformed certificates that the underlying OpenSSL implementation otherwise would accept. While disabling this is not recommended, you can do so using:

```
ctx = ssl.create_default_context()
ctx.verify_flags &= ~ssl.VERIFY_X509_STRICT
```

在 3.4 版被加入.

在 3.4.4 版的變更: 把 RC4 從預設加密方法字串中舍🄵。

在 3.6 版的變更: 把 ChaCha20/Poly1305 加入預設加密方法字串。

把 3DES 從預設加密方法字串中舍🄵。

在 3.8 版的變更: 增加了 SSLKEYLOGFILE 對密鑰日🄵記🄵 (logging) 的支援。

在 3.10 版的變更: 目前語境使用*PROTOCOL_TLS_CLIENT* 協定或*PROTOCOL_TLS_SERVER* 協定而非通用的*PROTOCOL_TLS*。

在 3.13 版的變更: The context now uses *VERIFY_X509_PARTIAL_CHAIN* and *VERIFY_X509_STRICT* in its default verify flags.

例外

exception ssl.**SSLError**

引發由底層 SSL 實作（目前由 OpenSSL 函式庫提供）所引發的錯誤訊息。這表示在覆蓋底層網路連🄵的高階加密和身份驗證層中存在一些問題。這項錯誤是*OSError* 的一個子型🄵。*SSLError* 實例的錯誤程式代碼和訊息是由 OpenSSL 函式庫提供。

在 3.3 版的變更: *SSLError* 曾經是*socket.error* 的一個子型🄵。

library

一個字串符號 (string mnemonic)，用來指定發生錯誤的 OpenSSL 子模組，如：SSL、PEM 或 X509。可能值的範圍取🄵於 OpenSSL 的版本。

在 3.3 版被加入.

reason

一個字串符號，用來指定發生錯誤的原因，如：CERTIFICATE_VERIFY_FAILED。可能值的範圍取🄵於 OpenSSL 的版本。

在 3.3 版被加入.

exception ssl.**SSLZeroReturnError**

一個*SSLError* 的子類🄵，當嘗試去讀寫已經被完全關閉的 SSL 連🄵時會被引發。請注意，這🄵不表示底層傳輸（例如 TCP）已經被關閉。

在 3.3 版被加入.

exception ssl.**SSLWantReadError**

一個*SSLError* 的子類🄵，當嘗試去讀寫資料前，底層 TCP 傳輸需要先接收更多資料時會由非阻塞的 *SSL socket* 引發該錯誤。

在 3.3 版被加入.

exception ssl.**SSLWantWriteError**

一個*SSLError* 的子類🄵，當嘗試去讀寫資料前，底層 TCP 傳輸需要先發送更多資料時會由非阻塞的 *SSL socket* 引發該錯誤。

在 3.3 版被加入.

exception ssl.**SSLSyscallError**

一個*SSLError* 的子類🄵，當嘗試去操作 SSL socket 時有系統錯誤🄵生會引發此錯誤。不幸的是，目前🄵有任何簡單的方法可以去檢查原本的的 errno 編號。

在 3.3 版被加入.

exception ssl.**SSLEOFError**

一個*SSLError* 的子類🄵，當 SSL 連🄵被突然終止時會引發此錯誤。通常，當此錯誤發生時，你不該再去重新使用底層傳輸。

在 3.3 版被加入.

exception ssl.**SSLCertVerificationError**

當憑證驗證失敗時會引發的一個*SSLError* 子類🄵。

在 3.7 版被加入.

verify_code

一個表示驗證錯誤的錯誤數值編號。

verify_message

一個人類可讀的驗證錯誤字串。

exception ssl.**CertificateError**

SSLCertVerificationError 的🄵名。

在 3.7 版的變更: 此例外現在是*SSLCertVerificationError* 的🄵名。

隨機🄵生

ssl.**RAND_bytes**(*num*, /)

回傳 *num* 個加密性🄵的🄵隨機位元組。如果 PRNG 未使用足🄵的資料做🄵隨機種子 (seed) 或是目前的 RAND 方法不支持該操作則會導致*SSLError* 錯誤。*RAND_status()* 函式可以用來檢查 PRNG 函式，而*RAND_add()* 則可以用來🄵 PRNG 設定隨機種子。

在幾乎所有的應用程式中，*os.urandom()* 會是較好的選擇。

請🄵讀維基百科的密碼學安全🄵隨機數🄵生器 (CSPRNG)文章來了解密碼學安全🄵隨機數🄵生器的需求。

在 3.3 版被加入.

ssl.**RAND_status**()

如果 SSL 🄵隨機數🄵生器已經使用「足🄵的」隨機性進行隨機種子生成，則回傳 `True`，否則回傳 `False`。你可以使用 `ssl.RAND_egd()` 函式和*ssl.RAND_add()* 函式來增加🄵隨機數🄵生器的隨機性。

ssl.**RAND_add**(*bytes*, *entropy*, /)

將給定的 *bytes* 混進 SSL 隨機🄵隨機數🄵生器中。*entropy* 參數（float 值）是指字串中包含熵值的下限（因此你可以將其設🄵 `0.0`）。請參🄵 **RFC 1750** 了解有關熵源的更多資訊。

在 3.5 版的變更: 可寫入的類位元組物件現在可被接受。

認証處理

ssl.**cert_time_to_seconds**(*cert_time*)

回傳自紀元以來的秒數，給定的 `cert_time` 字串表示憑證的”notBefore” 或”notAfter” 日期，字串🄵用 `"%b %d %H:%M:%S %Y %Z"` 格式（C 語言區域設定）。

以下是一個範例:

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

”notBefore” 或”notAfter” 日期必須使用 GMT (**RFC 5280**)。

在 3.5 版的變更: 將輸入的時間直譯🄵 UTC 時間，如輸入字串中指定的’GMT’ 時區。在之前是使用本地的時區。回傳一個整數（在輸入格式中不包括秒的小數部分）。

ssl.**get_server_certificate**(*addr*, *ssl_version=PROTOCOL_TLS_CLIENT*, *ca_certs=None*[, *timeout*])

輸入使用 SSL 保護的伺服器的地址 `addr`，輸入形式🄵一個 pair (*hostname*, *port-number*)，取得該伺服器的憑證，🄵以 PEM 編碼字串的形式回傳。如果指定了 `ssl_version`，則使用指定的 SSL 協定來嘗試與伺服器連🄵。如果指定 *ca_certs*，則它應該是一個包含根憑證列表的檔案，🄵與*SSLContext.load_verify_locations()* 中的參數 *cafile* 所使用的格式相同。此呼叫將嘗試使用該組根憑證對伺服器憑證進行驗證，如果驗證失敗，呼叫將失敗。可以使用 `timeout` 參數指定超時時間。

在 3.3 版的變更: 此函式現在是與 IPv6 相容的。

在 3.5 版的變更: 預設的 *ssl_version* 已經從*PROTOCOL_SSLv3* 改🄵*PROTOCOL_TLS*，已確保與現今的伺服器有最大的相容性。

在 3.10 版的變更: 新增 *timeout* 參數。

ssl.**DER_cert_to_PEM_cert**(*der_cert_bytes*)

給定一個以 DER 編碼的位元組 blob 作🄵憑證，回傳以 PEM 編碼字串版本的相同憑證。

ssl.**PEM_cert_to_DER_cert**(*pem_cert_string*)

給定一個以 ASCII PEM 的字串作🄵憑證，回傳以 DER 編碼的位元組序列的相同憑證。

ssl.**get_default_verify_paths**()

回傳一個具有 OpenSSL 的預設 cafile 和 capath 路徑的附名元組。這些路徑與*SSLContext.set_default_verify_paths()* 使用的相同。回傳值是一個*named tuple* `DefaultVerifyPaths`:

- `cafile` - 解析後的 cafile 路徑，如果檔案不存在則🄵 `None`,
- `capath` - 解析後的 capath 路徑，如果目🄵不存在則🄵 `None`,
- `openssl_cafile_env` - 指向 cafile 的 OpenSSL 環境密鑰,
- `openssl_cafile` - hard coded 的 cafile 路徑,
- `openssl_capath_env` - 指向 capath 的 OpenSSL 環境密鑰,
- `openssl_capath` - hard coded 的 capath 目🄵路徑

在 3.4 版被加入.

ssl.**enum_certificates**(*store_name*)

從 Windows 的系統憑證儲存庫中搜尋憑證。*store_name* 可以是 `CA`、`ROOT` 或 `MY` 的其中一個。Windows 也可能會提供額外的憑證儲存庫。

此函式會回傳一個元組 (cert_bytes, encoding_type, trust) 串列。encoding_type 指定了 cert_bytes 的編碼格式。它可以是用來表示 X.509 ASN.1 資料的 `x509_asn` 或是用來表示 PKCS#7 ASN.1 資料的 `pkcs_7_asn`。Trust 通過一組 OIDS 來指定憑證的用途，或是如果憑證對所有用途都可以使用則回傳 `True`。

範例:

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

可用性: Windows.

在 3.4 版被加入.

ssl.**enum_crls**(*store_name*)

從 Windows 的系統憑證儲存庫中搜尋 CRLs。*store_name* 可以是 `CA`、`ROOT` 或 `MY` 的其中一個。Windows 也可能會提供額外的憑證儲存庫。

此函式會回傳一個元組 (cert_bytes, encoding_type, trust) 串列。encoding_type 指定了 cert_bytes 的編碼格式。它可以是用來表示 X.509 ASN.1 資料的 `x509_asn` 或是用來表示 PKCS#7 ASN.1 資料的 `pkcs_7_asn`。

可用性: Windows.

在 3.4 版被加入.

常數

所有的常數現在都是*enum.IntEnum* 或*enum.IntFlag* 的集合。

在 3.6 版被加入.

ssl.**CERT_NONE**

SSLContext.verify_mode 可能的值。除了*SSLContext.verify_mode* 外，這是預設的模式。對於用🄵端的 sockets，幾乎任何憑證都能被允許。驗證錯誤，像是不被信任或是過期的憑證，會被忽略🄵不會中止 TLS/SSL 握手。

在伺服器模式下，不會從用🄵端請求任何憑證，所以用🄵端不用發送任何用於用🄵端憑證身分驗證的憑證。

參🄵下方*Security considerations* 的討論。

ssl.**CERT_OPTIONAL**

SSLContext.verify_mode 可能的值。在用🄵端模式下，*CERT_OPTIONAL* 具有與*CERT_REQUIRED* 相同的含意。對於客🄵端 sockets 推薦改用*CERT_REQUIRED*。

在伺服器模式下，客🄵憑證請求會被發送給用🄵端。用🄵端可以選擇忽略請求或是選擇發送憑證來執行 TLS 用🄵端憑證身分驗證。如果用🄵端選擇發送憑證，則會對其進行驗證。任何驗證錯誤都會立刻終止 TLS 握手。

使用此設定需要將一組有效的 CA 憑證傳送給*SSLContext.load_verify_locations()*。

ssl.**CERT_REQUIRED**

SSLContext.verify_mode 可能的值。在這個模式下，需要從 socket 連🄵的另一端取得憑證；如果未提供憑證或是驗證失敗，則將會導致*SSLError*。此模式**不能**在用🄵端模式下對憑證進行驗證，因🄵它無法去配對主機名稱。*check_hostname* 也必須被開起來來驗證憑證的真實性。*PROTOCOL_TLS_CLIENT* 會使用*CERT_REQUIRED* 🄵預設開🄵*check_hostname*。

對於 socket 伺服器，此模式會提供🄵制的 TLS 用🄵端憑證驗證。用🄵端憑證請求會被發送給用🄵端🄵且用🄵端必須提供有效且被信任的憑證。

使用此設定需要將一組有效的 CA 憑證傳送給*SSLContext.load_verify_locations()*。

class ssl.**VerifyMode**

enum.IntEnum 🄵 CERT_* 常數的一個集合。

在 3.6 版被加入.

ssl.**VERIFY_DEFAULT**

SSLContext.verify_flags 可能的值。在此模式下，不會檢查憑證吊銷列表 (CRLs)。預設的 OpenSSL 🄵不會請求及驗證 CRLs。

在 3.4 版被加入.

ssl.**VERIFY_CRL_CHECK_LEAF**

SSLContext.verify_flags 可能的值。在此模式下，只會檢查同等的憑證而不會去檢查中間的 CA 憑證。此模式需要提供由對等憑證發行者 (它的直接上級 CA) 的有效的 CRL 簽名。如果🄵有用*SSLContext.load_verify_locations* 載入適當的 CRL，則會驗證失敗。

在 3.4 版被加入.

ssl.**VERIFY_CRL_CHECK_CHAIN**

SSLContext.verify_flags 可能的值。在此模式下，會檢查對等憑證🄵中所有憑證的 CRLs。

在 3.4 版被加入.

ssl.**VERIFY_X509_STRICT**

SSLContext.verify_flags 可能的值，用來禁用已損壞的 X.509 憑證的解🄵方法。

在 3.4 版被加入.

ssl.**VERIFY_ALLOW_PROXY_CERTS**

SSLContext.verify_flags 可能的值，用來🄵用憑證代理驗證。

在 3.10 版被加入.

ssl.**VERIFY_X509_TRUSTED_FIRST**

SSLContext.verify_flags 可能的值。它指示 OpenSSL 在構建信任🄵來驗證憑證時會優先使用被信任的憑證。此旗標預設開🄵。

在 3.4.4 版被加入.

ssl.**VERIFY_X509_PARTIAL_CHAIN**

SSLContext.verify_flags 可能的值。它指示 OpenSSL 接受信任儲存中的中間 CAs 作🄵信任錨，就像自簽名的根 CA 憑證。這樣就能去信任中間 CA 所頒發的憑證，而不一定非要去信任其祖先的根 CA。

在 3.10 版被加入.

class ssl.**VerifyFlags**

enum.IntFlag 🄵 VERIFY_* 常數的其中一個集合。

在 3.6 版被加入.

ssl.**PROTOCOL_TLS**

選擇用🄵端及伺服器均可以支援最高協定版本。🄵管名稱只有「TLS」，但實際上「SSL」和「TLS」均可以選擇。

在 3.6 版被加入.

在 3.10 版之後被🄵用: TLS 的用🄵端及伺服器端需要不同的預設值來實現安全通訊。通用的 TLS 協定常數已被廢除，🄵改用*PROTOCOL_TLS_CLIENT* 和*PROTOCOL_TLS_SERVER*。

ssl.**PROTOCOL_TLS_CLIENT**

自動協商用🄵端和伺服器服務器都支援的最高協定版本，🄵配置用🄵端語境連🄵。該協定預設🄵用*CERT_REQUIRED* 和*check_hostname*。

在 3.6 版被加入.

ssl.**PROTOCOL_TLS_SERVER**

自動協商用🄵端和伺服器都支援的最高協定版本，🄵配置用🄵端語境連🄵。

在 3.6 版被加入.

ssl.**PROTOCOL_SSLv23**

PROTOCOL_TLS 的🄵名。

在 3.6 版之後被🄵用: 請改用*PROTOCOL_TLS*。

ssl.**PROTOCOL_SSLv3**

選擇第三版的 SSL 做🄵通道加密協定。

如果 OpenSSL 是用 `no-ssl3` 編譯的，則此項協定無法使用。

> **⚠ 警告**
>
> 第三版的 SSL 是不安全的，🄵烈建議不要使用。

在 3.6 版之後被🄵用: OpenSSL 已經終止了所有特定版本的協定。請改用預設的*PROTOCOL_TLS_SERVER* 協定或帶有*SSLContext.minimum_version* 和*SSLContext.maximum_version* 的*PROTOCOL_TLS_CLIENT*。

ssl.**PROTOCOL_TLSv1**

選擇 1.0 版的 TLS 做🄵通道加密協定。

在 3.6 版之後被🄵用: OpenSSL 已經將所有版本特定的協定🄵用。

ssl.**PROTOCOL_TLSv1_1**

選擇 1.1 版的 TLS 做🄵通道加密協定。只有在 1.0.1 版本以上的 OpenSSL 才可以選用。

在 3.4 版被加入.

在 3.6 版之後被🄵用: OpenSSL 已經將所有版本特定的協定🄴用。

ssl.**PROTOCOL_TLSv1_2**

選擇 1.2 版的 TLS 做🄵通道加密協定。只有在 1.0.1 版本以上的 OpenSSL 才可以選用。

在 3.4 版被加入.

在 3.6 版之後被🄵用: OpenSSL 已經將所有版本特定的協定🄴用。

ssl.**OP_ALL**

🄵用對 SSL 實作時所🄵生的各種錯誤的緩解措施。此選項預設被設定。它不一定設定與 OpenSSL 的 SSL_OP_ALL 常數相同的旗標。

在 3.2 版被加入.

ssl.**OP_NO_SSLv2**

防止 SSLv2 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級 (peer) 選用 SSLv2 做🄵協定版本。

在 3.2 版被加入.

在 3.6 版之後被🄵用: SSLv2 已被🄵用

ssl.**OP_NO_SSLv3**

防止 SSLv3 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級選用 SSLv3 做🄵協定版本。

在 3.2 版被加入.

在 3.6 版之後被🄵用: SSLv3 已被🄵用

ssl.**OP_NO_TLSv1**

防止 TLSv1 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級選用 TLSv1 做🄵協定版本。

在 3.2 版被加入.

在 3.7 版之後被🄵用: 該選項自從 OpenSSL 1.1.0 以後已被🄵用，請改用新的*SSLContext.minimum_version* 及*SSLContext.maximum_version* 代替。

ssl.**OP_NO_TLSv1_1**

防止 TLSv1.1 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級選用 TLSv1.1 做🄵協定版本。只有 1.0.1 版後的 OpenSSL 版本才能使用。

在 3.4 版被加入.

在 3.7 版之後被🄵用: 此選項自 OpenSSL 1.1.0 版已被🄵用。

ssl.**OP_NO_TLSv1_2**

防止 TLSv1.2 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級選用 TLSv1.2 做🄵協定版本。只有 1.0.1 版後的 OpenSSL 版本才能使用。

在 3.4 版被加入.

在 3.7 版之後被🄵用: 此選項自 OpenSSL 1.1.0 版已被🄵用。

ssl.**OP_NO_TLSv1_3**

防止 TLSv1.3 連🄵。此選項只可以跟*PROTOCOL_TLS* 一起使用。它會防止同級選用 TLSv1.3 做🄵協定版本。TSL1.3 只適用於 1.1.1 版以後的 OpenSSL。當使用 Python 編譯舊版的 OpenSSL 時，該標志預設🄵 *0*。

在 3.6.3 版被加入.

在 3.7 版之後被🄵用: 此選項自 OpenSSL 1.1.0 以後已被🄵用。它被添加到 2.7.15 和 3.6.3 中，以向後相容 OpenSSL 1.0.2。

ssl.**OP_NO_RENEGOTIATION**

停用所有在 TLSv1.2 及更早版本的重協商 (renegotiation)。不發送 HelloRequest 訊息，🄵忽略通過 ClientHello 的重協商請求。

此選項僅適用於 OpenSSL 1.1.0h 及更新版本。

在 3.7 版被加入.

ssl.**OP_CIPHER_SERVER_PREFERENCE**

使用伺服器的加密方法名稱字串排序優先順序，而不是用🄴端的。此選項🄵不會影響到用🄴端及 SSLv2 伺服器的 sockets。

在 3.3 版被加入.

ssl.**OP_SINGLE_DH_USE**

防止對不同的 SSL 會談重🄵使用相同的 DH 密鑰。這會加🄴向前保密但需要更多的運算資源。此選項只適用於伺服器 sockets。

在 3.3 版被加入.

ssl.**OP_SINGLE_ECDH_USE**

防止對不同的 SSL 會談重🄵使用相同的 ECDH 密鑰。這會加🄴向前保密但需要更多的運算資源。此選項只適用於伺服器 sockets。

在 3.3 版被加入.

ssl.**OP_ENABLE_MIDDLEBOX_COMPAT**

在 TLS 1.3 握手中發送🄵擬的變更加密方法規範 (CCS) 消息，以使 TLS 1.3 連接看起來更像 TLS 1.2 連🄵。

此選項僅適用於 OpenSSL 1.1.1 及更新版本。

在 3.8 版被加入.

ssl.**OP_NO_COMPRESSION**

在 SSL 通道上禁用壓縮。如果應用程序協定支援自己的壓縮方案，這會很有用。

在 3.3 版被加入.

class ssl.**Options**

enum.IntFlag 🄵 OP_* 常數中的一個集合。

ssl.**OP_NO_TICKET**

防止用🄴端請求會談票據。

在 3.6 版被加入.

ssl.**OP_IGNORE_UNEXPECTED_EOF**

忽略意外關閉的 TLS 連🄵。

此選項僅適用於 OpenSSL 3.0.0 及更新版本。

在 3.10 版被加入.

ssl.**OP_ENABLE_KTLS**

允許使用 TLS 核心。要想受益於該功能，OpenSSL 必須編譯🄵支援該功能，🄵且想使用的加密套件及擴充套件也必須被該功能支援 (該功能所支援的列表可能會因平台及核心而有所差🄴)。

請注意當允許使用 TLS 核心時，一些加密操作將直接由核心執行而不是經由任何由可用的 OpenSSL 所提供的程序，而這可能🄵非你所想使用的，例如：當應用程式要求所有的加密操作由 FIPS 提供執行。

此選項僅適用於 OpenSSL 3.0.0 及更新版本。

在 3.12 版被加入.

ssl.**OP_LEGACY_SERVER_CONNECT**

只允許 OpenSSL 與未修補的伺服器進行遺留 (legacy) 不安全重協商。

在 3.12 版被加入.

ssl.**HAS_ALPN**

OpenSSL 函式庫是否🄴建支援 應用層協定協商 TLS 擴充套件，該擴充套件描述在 **RFC 7301** 中。

在 3.5 版被加入.

ssl.**HAS_NEVER_CHECK_COMMON_NAME**

OpenSSL 函式庫是否🄵建支援不檢查主題通用名稱及*SSLContext.hostname_checks_common_name* 是否可寫。

在 3.7 版被加入.

ssl.**HAS_ECDH**

OpenSSL 函式庫是否🄴建支援基於橢圓曲🄵的 (Elliptic Curve-based) Diffie-Hellman 金鑰交🄴。此回傳值應該要🄵 true 除非發布者明確禁用此功能。

在 3.3 版被加入.

ssl.**HAS_SNI**

OpenSSL 函式庫是否🄴建支援 伺服器名懲提示擴充套件 (在 **RFC 6066** 中定義)。

在 3.2 版被加入.

ssl.**HAS_NPN**

OpenSSL 函式庫是否🄴建支援 下一代協定協商該功能在應用層協定協商 中有描述。當此值🄵 true 時，你可以使用*SSLContext.set_npn_protocols()* 方法來公告你想支援的協定。

在 3.3 版被加入.

ssl.**HAS_SSLv2**

此 OpenSSL 函式庫是否🄴建支援 SSL 2.0 協定。

在 3.7 版被加入.

ssl.**HAS_SSLv3**

此 OpenSSL 函式庫是否🄴建支援 SSL 3.0 協定。

在 3.7 版被加入.

ssl.**HAS_TLSv1**

此 OpenSSL 函式庫是否🄴建支援 TLS 1.0 協定。

在 3.7 版被加入.

ssl.**HAS_TLSv1_1**

此 OpenSSL 函式庫是否🄴建支援 TLS 1.1 協定。

在 3.7 版被加入.

ssl.**HAS_TLSv1_2**

此 OpenSSL 函式庫是否🄴建支援 TLS 1.2 協定。

在 3.7 版被加入.

ssl.**HAS_TLSv1_3**

此 OpenSSL 函式庫是否🄴建支援 TLS 1.3 協定。

在 3.7 版被加入.

ssl.**HAS_PSK**

此 OpenSSL 函式庫是否🄴建支援 TLS-PSK。

在 3.13 版被加入.

ssl.**HAS_PHA**

此 OpenSSL 函式庫是否🄴建支援 TLS-PHA。

在 3.14 版被加入.

ssl.**CHANNEL_BINDING_TYPES**

支援的 TLS 通道綁定類型列表。列表中的字串可以作🄵*SSLSocket.get_channel_binding()* 的參數。

在 3.3 版被加入.

ssl.**OPENSSL_VERSION**

直譯器所加載的 OpenSSL 函式庫的版本字串:

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 1.0.2k  26 Jan 2017'
```

在 3.2 版被加入.

ssl.**OPENSSL_VERSION_INFO**

代表 OpenSSL 函式庫版本資訊的五個整數的元組:

```
>>> ssl.OPENSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

在 3.2 版被加入.

ssl.**OPENSSL_VERSION_NUMBER**

OpenSSL 函式庫的初始版本，以單一整數表示:

```
>>> ssl.OPENSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x100020bf'
```

在 3.2 版被加入.

ssl.**ALERT_DESCRIPTION_HANDSHAKE_FAILURE**

ssl.**ALERT_DESCRIPTION_INTERNAL_ERROR**

ALERT_DESCRIPTION_*

來自 **RFC 5246** 和其他文件的警報描述。IANA TLS Alert Registry 包含了此列表以及其含義定義所在的 RFC 的引用。

被用來做🄵*SSLContext.set_servername_callback()* 中回呼函式的回傳值。

在 3.4 版被加入.

class ssl.**AlertDescription**

enum.IntEnum 🄵 ALERT_DESCRIPTION_* 常數中的一個集合。

在 3.6 版被加入.

Purpose.**SERVER_AUTH**

create_default_context() 和*SSLContext.load_default_certs()* 的選項。此值表示該語境可能會用於驗證網頁伺服器 (因此它將用於建立用🄵端 socket)。

在 3.4 版被加入.

Purpose.**CLIENT_AUTH**

create_default_context() 和*SSLContext.load_default_certs()* 的選項。此值表示該語境可能會用於驗證網頁用🄵端 (因此，它將用於建立伺服器端的 socket)。

在 3.4 版被加入.

class ssl.**SSLErrorNumber**

enum.IntEnum 🄵 SSL_ERROR_* 常數中的一個集合。

在 3.6 版被加入.

class ssl.**TLSVersion**

用於*SSLContext.maximum_version* 和*SSLContext.minimum_version* 的 SSL 和 TLS 版本*enum.IntEnum* 集合。

在 3.7 版被加入.

TLSVersion.**MINIMUM_SUPPORTED**

TLSVersion.**MAXIMUM_SUPPORTED**

最低或最高支援的 SSL 或 TLS 版本。這些是特殊常數。它們的值🄵不反映可用的最低和最高 TLS/SSL 版本。

TLSVersion.**SSLv3**

TLSVersion.**TLSv1**

TLSVersion.**TLSv1_1**

TLSVersion.**TLSv1_2**

TLSVersion.**TLSv1_3**

SSL 3.0 到 TLS 1.3。

在 3.10 版之後被🄵用: 除了*TLSVersion.TLSv1_2* 和*TLSVersion.TLSv1_3* 之外，所有的*TLSVersion* 成員都已被🄵用。

19.3.2 SSL Sockets

class ssl.**SSLSocket**(*socket.socket*)

SSL sockets 提供以下*Socket 物件* 方法:

- *accept()*
- *bind()*
- *close()*
- *connect()*
- *detach()*
- *fileno()*
- *getpeername()*、*getsockname()*
- *getsockopt()*、*setsockopt()*
- *gettimeout()*、*settimeout()*、*setblocking()*
- *listen()*
- *makefile()*
- *recv()*、*recv_into()* （但不允許傳遞非零的 `flags` 引數）
- *send()*、*sendall()* （同樣不允許傳遞非零的 `flags` 引數）
- *sendfile()* （但*os.sendfile* 只能用於純文本 sockets，其余則會使用*send()*）
- *shutdown()*

然而，由於 SSL（和 TLS）協定在 TCP 之上有自己的框架，因此在某些方面，SSL sockets 的抽象可能會與普通作業系統級🄵的 sockets 規範有所不同。特🄵是請參🄵關於 *non-blocking sockets* 的🄵明。

SSLSocket 的實例必須使用*SSLContext.wrap_socket()* 方法建立。

在 3.5 版的變更: 新增 `sendfile()` 方法。

在 3.5 版的變更: `shutdown()` 不會在每次接收或發送位元組時重置 socket 超時時間。現在，socket 超時時間是關閉操作的最大總持續時間。

在 3.6 版之後被🄵用: 直接建立*SSLSocket* 實例的方式已被🄵用，請使用*SSLContext.wrap_socket()* 來包裝 socket。

在 3.7 版的變更: *SSLSocket* 實例必須使用*wrap_socket()* 建立。在較早的版本中可以直接建立實例，但這從未被記🄵或正式支援。

在 3.10 版的變更: Python 現在🄵部使用了 `SSL_read_ex` 和 `SSL_write_ex` 函式。這些函式支援讀取和寫入大於 2 GB 的資料。寫入零長度的資料不再會導致協定違規錯誤。

SSL sockets 還具有以下附加方法和屬性:

`SSLSocket.`**`read`**`(`*len=1024*, *buffer=None*`)`

從 SSL socket 讀取 *len* 位元組的資料，🄵將結果以 `bytes` 實例的形式回傳。如果指定了 *buffer*，則將資料讀入緩衝區，🄵回傳讀取的位元組。

如果 socket 是非阻塞的則會引發*SSLWantReadError* 或*SSLWantWriteError* 🄵且讀取操作將會被阻塞。

由於在任何時刻都可能發生重新協商，呼叫*read()* 也可能觸發寫入操作。

在 3.5 版的變更: 當接收或發送位元組時，socket 的超時時間將不再重置。現在，socket 超時時間是讀取最多 *len* 位元組的總最大持續時間。

在 3.6 版之後被🄵用: 請改用 `recv()` 來替🄵掉*read()*。

`SSLSocket.`**`write`**`(`*data*`)`

Write *data* to the SSL socket and return the number of bytes written. The *data* argument must be an object supporting the buffer interface.

如果 socket 是非阻塞的則會引發*SSLWantReadError* 或*SSLWantWriteError* 🄵且寫入操作將會被阻塞。

由於在任何時刻都可能發生重新協商，呼叫*write()* 也可能觸發讀取操作。

在 3.5 版的變更: The socket timeout is no longer reset each time bytes are received or sent. The socket timeout is now the maximum total duration to write *data*.

在 3.6 版之後被🄵用: 請改用 `send()` 來替🄵掉*write()*。

備🄵

read() 和*write()* 方法🄵低階層的方法，負責讀取和寫入未加密的應用層資料，🄵將其加密/解密🄵加密的寫入層資料。這些方法需要一個已建立的 SSL 連接，即握手已完成，且未呼叫*SSLSocket.unwrap()*。

通常你應該使用像*recv()* 和*send()* 這樣的 socket API 方法，而不是直接使用這些方法。

`SSLSocket.`**`do_handshake`**`(`*block=False*`)`

執行 SSL 設定握手。

If *block* is true and the timeout obtained by *gettimeout()* is zero, the socket is set in blocking mode until the handshake is performed.

在 3.4 版的變更: The handshake method also performs `match_hostname()` when the *check_hostname* attribute of the socket's *context* is true.

在 3.5 版的變更: Socket 超時時間已經不會在每次接收或傳送位元組時重置。現在，超時時間是握手過程的最大總持續時間。

在 3.7 版的變更: Hostname or IP address is matched by OpenSSL during handshake. The function `match_hostname()` is no longer used. In case OpenSSL refuses a hostname or IP address, the handshake is aborted early and a TLS alert message is sent to the peer.

`SSLSocket.`**`getpeercert`**(*binary_form=False*)

如果連🄵端🄵有證書，則回傳 `None`。如果 SSL 握手尚未完成，則引發*`ValueError`*。

如果 `binary_form` 參數🄵*`False`*，且從對等 (peer) 接收到證書，則該方法回傳一個*`dict`* 實例。如果證書未被驗證，則該字典🄵空。若證書已被驗證，則回傳的字典將包含數個鍵值，包括 `subject` (證書所簽發的對象) 和 `issuer` (簽發證書的主體)。如果證書中包含 *Subject Alternative Name* 擴充 (參考**RFC 3280**)，字典中還會有一個 `subjectAltName` 鍵。

`subject` 和 `issuer` 欄位欄位是包含相對識🄵名稱 (relative distinguished names, RDNs) 序列的元組，這些 RDN 來自證書資料結構中的相應欄位。每個 RDN 都是一組名稱與值的對。以下是現實中的範例：

```
{'issuer': ((('countryName', 'IL'),),
            (('organizationName', 'StartCom Ltd.'),),
            (('organizationalUnitName',
              'Secure Digital Certificate Signing'),),
            (('commonName',
              'StartCom Class 2 Primary Intermediate Server CA'),)),
 'notAfter': 'Nov 22 08:15:19 2013 GMT',
 'notBefore': 'Nov 21 03:09:52 2011 GMT',
 'serialNumber': '95F0',
 'subject': ((('description', '571208-SLe257oHY9fVQ07Z'),),
             (('countryName', 'US'),),
             (('stateOrProvinceName', 'California'),),
             (('localityName', 'San Francisco'),),
             (('organizationName', 'Electronic Frontier Foundation, Inc.'),),
             (('commonName', '*.eff.org'),),
             (('emailAddress', 'hostmaster@eff.org'),)),
 'subjectAltName': (('DNS', '*.eff.org'), ('DNS', 'eff.org')),
 'version': 3}
```

如果 `binary_form` 參數設定🄵*`True`*，且對等提供了證書，則該方法會以 DER 編碼形式將整個證書以位元組序列形式回傳。如果對等未提供證書，則回傳*`None`*。對等是否提供證書取🄵於 SSL socket 的🄵色：

- 對於用🄵端 SSL socket，伺服器將永遠提供證書，無論是否需要進行驗證；
- 對於伺服器 SSL socket，用🄵端僅在伺服器要求時才會提供證書；因此，如果你使用的是*`CERT_NONE`* (而非*`CERT_OPTIONAL`* 或*`CERT_REQUIRED`*)，則*`getpeercert()`* 會回傳*`None`*。

請見*`SSLContext.check_hostname`*。

在 3.2 版的變更: The returned dictionary includes additional items such as `issuer` and `notBefore`.

在 3.4 版的變更: *`ValueError`* is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and `OCSP` URIs.

在 3.9 版的變更: IPv6 address strings no longer have a trailing new line.

`SSLSocket.`**`get_verified_chain`**()

Returns verified certificate chain provided by the other end of the SSL channel as a list of DER-encoded bytes. If certificate verification was disabled method acts the same as *`get_unverified_chain()`*.

在 3.13 版被加入.

`SSLSocket.`**`get_unverified_chain`**()

Returns raw certificate chain provided by the other end of the SSL channel as a list of DER-encoded bytes.

在 3.13 版被加入.

SSLSocket.**cipher**()

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

SSLSocket.**shared_ciphers**()

Return the list of ciphers available in both the client and server. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. *shared_ciphers()* returns `None` if no connection has been established or the socket is a client socket.

在 3.5 版被加入.

SSLSocket.**compression**()

Return the compression algorithm being used as a string, or `None` if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use *OP_NO_COMPRESSION* to disable SSL-level compression.

在 3.3 版被加入.

SSLSocket.**get_channel_binding**(*cb_type='tls-unique'*)

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The *cb_type* parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the *CHANNEL_BINDING_TYPES* list. Currently only the 'tls-unique' channel binding, defined by **RFC 5929**, is supported. *ValueError* will be raised if an unsupported channel binding type is requested.

在 3.3 版被加入.

SSLSocket.**selected_alpn_protocol**()

Return the protocol that was selected during the TLS handshake. If *SSLContext.set_alpn_protocols()* was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

在 3.5 版被加入.

SSLSocket.**selected_npn_protocol**()

Return the higher-level protocol that was selected during the TLS/SSL handshake. If *SSLContext.set_npn_protocols()* was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

在 3.3 版被加入.

在 3.10 版之後被🄵用: NPN has been superseded by ALPN

SSLSocket.**unwrap**()

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

SSLSocket.**verify_client_post_handshake**()

Requests post-handshake authentication (PHA) from a TLS 1.3 client. PHA can only be initiated for a TLS 1.3 connection from a server-side socket, after the initial TLS handshake and with PHA enabled on both sides, see *SSLContext.post_handshake_auth*.

The method does not perform a cert exchange immediately. The server-side sends a CertificateRequest during the next write event and expects the client to respond with a certificate on the next read event.

If any precondition isn't met (e.g. not TLS 1.3, PHA not enabled), an *SSLError* is raised.

> **備🄵**
>
> Only available with OpenSSL 1.1.1 and TLS 1.3 enabled. Without TLS 1.3 support, the method raises *NotImplementedError*.

在 3.8 版被加入.

`SSLSocket.`**`version`**`()`

Return the actual SSL protocol version negotiated by the connection as a string, or `None` if no secure connection is established. As of this writing, possible return values include `"SSLv2"`, `"SSLv3"`, `"TLSv1"`, `"TLSv1.1"` and `"TLSv1.2"`. Recent OpenSSL versions may define more return values.

在 3.5 版被加入.

`SSLSocket.`**`pending`**`()`

Returns the number of already decrypted bytes available for read, pending on the connection.

`SSLSocket.`**`context`**

The *SSLContext* object this SSL socket is tied to.

在 3.2 版被加入.

`SSLSocket.`**`server_side`**

A boolean which is `True` for server-side sockets and `False` for client-side sockets.

在 3.2 版被加入.

`SSLSocket.`**`server_hostname`**

Hostname of the server: *str* type, or `None` for server-side socket or if the hostname was not specified in the constructor.

在 3.2 版被加入.

在 3.7 版的變更: The attribute is now always ASCII text. When `server_hostname` is an internationalized domain name (IDN), this attribute now stores the A-label form (`"xn--pythn-mua.org"`), rather than the U-label form (`"pythön.org"`).

`SSLSocket.`**`session`**

The *SSLSession* for this SSL connection. The session is available for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before *do_handshake()* has been called to reuse a session.

在 3.6 版被加入.

`SSLSocket.`**`session_reused`**

在 3.6 版被加入.

19.3.3 SSL Contexts

在 3.2 版被加入.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

`class` `ssl.`**`SSLContext`**(*protocol=None*)

Create a new SSL context. You may pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. The parameter specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server's choice. Most of the versions are not interoperable with the other versions. If not specified, the default is *PROTOCOL_TLS*; it provides the most compatibility with other versions.

Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

client / **server**	**SSLv2**	**SSLv3**	**TLS**[3]	**TLSv1**	**TLSv1.1**	**TLSv1.2**
SSLv2	yes	no	no[1]	no	no	no
SSLv3	no	yes	no[2]	no	no	no
TLS (SSLv23)[3]	no[1]	no[2]	yes	yes	yes	yes
TLSv1	no	no	yes	yes	no	no
TLSv1.1	no	no	yes	no	yes	no
TLSv1.2	no	no	yes	no	no	yes

也參考

`create_default_context()` lets the `ssl` module choose security settings for a given purpose.

在 3.6 版的變更: The context is created with secure default values. The options `OP_NO_COMPRESSION`, `OP_CIPHER_SERVER_PREFERENCE`, `OP_SINGLE_DH_USE`, `OP_SINGLE_ECDH_USE`, `OP_NO_SSLv2`, and `OP_NO_SSLv3` (except for `PROTOCOL_SSLv3`) are set by default. The initial cipher suite list contains only `HIGH` ciphers, no `NULL` ciphers and no `MD5` ciphers.

在 3.10 版之後被🄴用: `SSLContext` without protocol argument is deprecated. The context class will either require `PROTOCOL_TLS_CLIENT` or `PROTOCOL_TLS_SERVER` protocol in the future.

在 3.10 版的變更: The default cipher suites now include only secure AES and ChaCha20 ciphers with forward secrecy and security level 2. RSA and DH keys with less than 2048 bits and ECC keys with less than 224 bits are prohibited. `PROTOCOL_TLS`, `PROTOCOL_TLS_CLIENT`, and `PROTOCOL_TLS_SERVER` use TLS 1.2 as minimum TLS version.

備🄴

`SSLContext` only supports limited mutation once it has been used by a connection. Adding new certificates to the internal trust store is allowed, but changing ciphers, verification settings, or mTLS certificates may result in surprising behavior.

備🄴

`SSLContext` is designed to be shared and used by multiple connections. Thus, it is thread-safe as long as it is not reconfigured after being used by a connection.

`SSLContext` 物件具有以下方法和屬性:

`SSLContext.`**`cert_store_stats`**`()`

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

在 3.4 版被加入.

[3] TLS 1.3 protocol will be available with `PROTOCOL_TLS` in OpenSSL >= 1.1.1. There is no dedicated PROTOCOL constant for just TLS 1.3.

[1] `SSLContext` 預設會關閉 SSLv2 的`OP_NO_SSLv2`。

[2] `SSLContext` 預設會關閉 SSLv3 的`OP_NO_SSLv3`。

SSLContext.**load_cert_chain**(*certfile*, *keyfile=None*, *password=None*)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key. Otherwise the private key will be taken from *certfile* as well. See the discussion of *Certificates* for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An *SSLError* is raised if the private key doesn't match with the certificate.

在 3.3 版的變更: 新增可選引數 *password*。

SSLContext.**load_default_certs**(*purpose=Purpose.SERVER_AUTH*)

Load a set of default "certification authority" (CA) certificates from default locations. On Windows it loads CA certs from the `CA` and `ROOT` system stores. On all systems it calls *SSLContext.set_default_verify_paths()*. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings *Purpose.SERVER_AUTH* loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). *Purpose.CLIENT_AUTH* loads CA certificates for client certificate verification on the server side.

在 3.4 版被加入.

SSLContext.**load_verify_locations**(*cafile=None*, *capath=None*, *cadata=None*)

Load a set of "certification authority" (CA) certificates used to validate other peers' certificates when *verify_mode* is other than *CERT_NONE*. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, *SSLContext.verify_flags* must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of *Certificates* for more information about how to arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an OpenSSL specific layout.

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a *bytes-like object* of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

在 3.4 版的變更: 新增可選引數 *cadata*

SSLContext.**get_ca_certs**(*binary_form=False*)

Get a list of loaded "certification authority" (CA) certificates. If the `binary_form` parameter is *False* each list entry is a dict like the output of *SSLSocket.getpeercert()*. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from *capath* unless a certificate was requested and loaded by a SSL connection.

> **備🄵**
>
> Certificates in a capath directory aren't loaded unless they have been used at least once.

在 3.4 版被加入.

SSLContext.**get_ciphers**()

Get a list of enabled ciphers. The list is in order of cipher priority. See *SSLContext.set_ciphers()*.

範例:

```
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
>>> ctx.get_ciphers()
[{'aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1.2 Kx=ECDH     Au=RSA  '
                 'Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'},
 {'aead': True,
  'alg_bits': 128,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH     Au=RSA  '
                 'Enc=AESGCM(128) Mac=AEAD',
  'digest': None,
  'id': 50380847,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1.2',
  'strength_bits': 128,
  'symmetric': 'aes-128-gcm'}]
```

在 3.6 版被加入.

SSLContext.**set_default_verify_paths**()

Load a set of default "certification authority" (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there's no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

SSLContext.**set_ciphers**(*ciphers*, /)

Set the available ciphers for sockets created with this context. It should be a string in the OpenSSL cipher list format. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an *SSLError* will be raised.

> **備🄵**
>
> when connected, the *SSLSocket.cipher()* method of SSL sockets will give the currently selected cipher.
>
> TLS 1.3 cipher suites cannot be disabled with *set_ciphers()*.

SSLContext.**set_alpn_protocols**(*alpn_protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to **RFC 7301**. After a successful handshake, the *SSLSocket.selected_alpn_protocol()* method will return the agreed-upon protocol.

此方法會在*HAS_ALPN* 🄵 `False` 時引發*NotImplementedError*。

在 3.5 版被加入.

SSLContext.**set_npn_protocols**(*npn_protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the Application Layer Protocol Negotiation. After a successful handshake, the *SSLSocket.selected_npn_protocol()* method will return the agreed-upon protocol.

此方法會在*HAS_NPN* 🄵 `False` 時引發*NotImplementedError*。

在 3.3 版被加入.

在 3.10 版之後被🄵用: NPN has been superseded by ALPN

SSLContext.**sni_callback**

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in **RFC 6066** section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If *sni_callback* is set to `None` then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function will be called with three arguments; the first being the *ssl.SSLSocket*, the second is a string that represents the server name that the client is intending to communicate (or *None* if the TLS Client Hello does not contain a server name) and the third argument is the original *SSLContext*. The server name argument is text. For internationalized domain name, the server name is an IDN A-label (`"xn--pythn-mua.org"`).

A typical use of this callback is to change the *ssl.SSLSocket*'s *SSLSocket.context* attribute to a new object of type *SSLContext* representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like *SSLSocket.selected_alpn_protocol()* and *SSLSocket.context*. The *SSLSocket.getpeercert()*, *SSLSocket.get_verified_chain()*, *SSLSocket.get_unverified_chain()* *SSLSocket.cipher()* and *SSLSocket.compression()* methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not return meaningful values nor can they be called safely.

The *sni_callback* function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant *ALERT_DESCRIPTION_** can be returned. Other return values will result in a TLS fatal error with *ALERT_DESCRIPTION_INTERNAL_ERROR*.

If an exception is raised from the *sni_callback* function the TLS connection will terminate with a fatal TLS alert message *ALERT_DESCRIPTION_HANDSHAKE_FAILURE*.

This method will raise *NotImplementedError* if the OpenSSL library had OPENSSL_NO_TLSEXT defined when it was built.

在 3.7 版被加入.

SSLContext.**set_servername_callback**(*server_name_callback*)

This is a legacy API retained for backwards compatibility. When possible, you should use *sni_callback* instead. The given *server_name_callback* is similar to *sni_callback*, except that when the server hostname is an IDN-encoded internationalized domain name, the *server_name_callback* receives a decoded U-label (`"pythön.org"`).

If there is a decoding error on the server name, the TLS connection will terminate with an *ALERT_DESCRIPTION_INTERNAL_ERROR* fatal TLS alert message to the client.

在 3.4 版被加入.

SSLContext.**load_dh_params**(*dhfile*, */*)

Load the key generation parameters for Diffie-Hellman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The *dhfile* parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the *OP_SINGLE_DH_USE* option to further improve security.

在 3.3 版被加入.

SSLContext.**set_ecdh_curve**(*curve_name*, /)

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The *curve_name* parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the *OP_SINGLE_ECDH_USE* option to further improve security.

此方法在*HAS_ECDH* 🄵 `False` 時不可用。

在 3.3 版被加入.

SSL/TLS & Perfect Forward Secrecy
Vincent Bernat.

SSLContext.**wrap_socket**(*sock*, *server_side=False*, *do_handshake_on_connect=True*, *suppress_ragged_eofs=True*, *server_hostname=None*, *session=None*)

Wrap an existing Python socket *sock* and return an instance of *SSLContext.sslsocket_class* (default *SSLSocket*). The returned SSL socket is tied to the context, its settings and certificates. *sock* must be a *SOCK_STREAM* socket; other socket types are unsupported.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after `connect()` is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the `accept()` method. The method may raise *SSLError*.

On client connections, the optional parameter *server_hostname* specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying *server_hostname* will raise a *ValueError* if *server_side* is true.

The parameter `do_handshake_on_connect` specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the *SSLSocket.do_handshake()* method. Calling *SSLSocket.do_handshake()* explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the `SSLSocket.recv()` method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the exceptions back to the caller.

session, see *session*.

To wrap an *SSLSocket* in another *SSLSocket*, use *SSLContext.wrap_bio()*.

在 3.5 版的變更: Always allow a server_hostname to be passed, even if OpenSSL does not have SNI.

在 3.6 版的變更: 新增 *session* 引數。

在 3.7 版的變更: The method returns an instance of *SSLContext.sslsocket_class* instead of hard-coded *SSLSocket*.

SSLContext.**sslsocket_class**

The return type of *SSLContext.wrap_socket()*, defaults to *SSLSocket*. The attribute can be assigned to on instances of *SSLContext* in order to return a custom subclass of *SSLSocket*.

在 3.7 版被加入.

SSLContext.**wrap_bio**(*incoming*, *outgoing*, *server_side=False*, *server_hostname=None*, *session=None*)

Wrap the BIO objects *incoming* and *outgoing* and return an instance of *SSLContext.sslobject_class* (default *SSLObject*). The SSL routines will read input data from the incoming BIO and write data to the outgoing BIO.

The *server_side*, *server_hostname* and *session* parameters have the same meaning as in *SSLContext.wrap_socket()*.

在 3.6 版的變更: 新增 *session* 引數。

在 3.7 版的變更: The method returns an instance of *SSLContext.sslobject_class* instead of hard-coded *SSLObject*.

SSLContext.**sslobject_class**

The return type of *SSLContext.wrap_bio()*, defaults to *SSLObject*. The attribute can be overridden on instance of class in order to return a custom subclass of *SSLObject*.

在 3.7 版被加入.

SSLContext.**session_stats**()

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each piece of information to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

SSLContext.**check_hostname**

Whether to match the peer cert's hostname in *SSLSocket.do_handshake()*. The context's *verify_mode* must be set to *CERT_OPTIONAL* or *CERT_REQUIRED*, and you must pass *server_hostname* to *wrap_socket()* in order to match the hostname. Enabling hostname checking automatically sets *verify_mode* from *CERT_NONE* to *CERT_REQUIRED*. It cannot be set back to *CERT_NONE* as long as hostname checking is enabled. The *PROTOCOL_TLS_CLIENT* protocol enables hostname checking by default. With other protocols, hostname checking must be enabled explicitly.

範例:

```
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLSv1_2)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname='www.verisign.com')
ssl_sock.connect(('www.verisign.com', 443))
```

在 3.4 版被加入.

在 3.7 版的變更: *verify_mode* is now automatically changed to *CERT_REQUIRED* when hostname checking is enabled and *verify_mode* is *CERT_NONE*. Previously the same operation would have failed with a *ValueError*.

SSLContext.**keylog_filename**

Write TLS keys to a keylog file, whenever key material is generated or received. The keylog file is designed for debugging purposes only. The file format is specified by NSS and used by many traffic analyzers such as

Wireshark. The log file is opened in append-only mode. Writes are synchronized between threads, but not between processes.

在 3.8 版被加入.

SSLContext.**maximum_version**

A *TLSVersion* enum member representing the highest supported TLS version. The value defaults to *TLSVersion.MAXIMUM_SUPPORTED*. The attribute is read-only for protocols other than *PROTOCOL_TLS*, *PROTOCOL_TLS_CLIENT*, and *PROTOCOL_TLS_SERVER*.

The attributes *maximum_version*, *minimum_version* and *SSLContext.options* all affect the supported SSL and TLS versions of the context. The implementation does not prevent invalid combination. For example a context with *OP_NO_TLSv1_2* in *options* and *maximum_version* set to *TLSVersion.TLSv1_2* will not be able to establish a TLS 1.2 connection.

在 3.7 版被加入.

SSLContext.**minimum_version**

Like *SSLContext.maximum_version* except it is the lowest supported version or *TLSVersion.MINIMUM_SUPPORTED*.

在 3.7 版被加入.

SSLContext.**num_tickets**

Control the number of TLS 1.3 session tickets of a *PROTOCOL_TLS_SERVER* context. The setting has no impact on TLS 1.0 to 1.2 connections.

在 3.8 版被加入.

SSLContext.**options**

An integer representing the set of SSL options enabled on this context. The default value is *OP_ALL*, but you can specify other options such as *OP_NO_SSLv2* by ORing them together.

在 3.6 版的變更: *SSLContext.options* 會回傳*Options* 旗標:

```
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPRESSION: 2197947391>
```

在 3.7 版之後被🄵用: All `OP_NO_SSL*` and `OP_NO_TLS*` options have been deprecated since Python 3.7. Use *SSLContext.minimum_version* and *SSLContext.maximum_version* instead.

SSLContext.**post_handshake_auth**

Enable TLS 1.3 post-handshake client authentication. Post-handshake auth is disabled by default and a server can only request a TLS client certificate during the initial handshake. When enabled, a server may request a TLS client certificate at any time after the handshake.

When enabled on client-side sockets, the client signals the server that it supports post-handshake authentication.

When enabled on server-side sockets, *SSLContext.verify_mode* must be set to *CERT_OPTIONAL* or *CERT_REQUIRED*, too. The actual client cert exchange is delayed until *SSLSocket.verify_client_post_handshake()* is called and some I/O is performed.

在 3.8 版被加入.

SSLContext.**protocol**

The protocol version chosen when constructing the context. This attribute is read-only.

SSLContext.**hostname_checks_common_name**

Whether *check_hostname* falls back to verify the cert's subject common name in the absence of a subject alternative name extension (default: true).

在 3.7 版被加入.

在 3.10 版的變更: The flag had no effect with OpenSSL before version 1.1.1l. Python 3.8.9, 3.9.3, and 3.10 include workarounds for previous versions.

SSLContext.**security_level**

An integer representing the security level for the context. This attribute is read-only.

在 3.10 版被加入.

SSLContext.**verify_flags**

The flags for certificate verification operations. You can set flags like *VERIFY_CRL_CHECK_LEAF* by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs).

在 3.4 版被加入.

在 3.6 版的變更: *SSLContext.verify_flags* 會回傳*VerifyFlags* 旗標:

```
>>> ssl.create_default_context().verify_flags
<VerifyFlags.VERIFY_X509_TRUSTED_FIRST: 32768>
```

SSLContext.**verify_mode**

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of *CERT_NONE*, *CERT_OPTIONAL* or *CERT_REQUIRED*.

在 3.6 版的變更: *SSLContext.verify_mode* 會回傳*VerifyMode* 列舉:

```
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```

SSLContext.**set_psk_client_callback**(*callback*)

Enables TLS-PSK (pre-shared key) authentication on a client-side connection.

In general, certificate based authentication should be preferred over this method.

The parameter `callback` is a callable object with the signature: `def callback(hint: str | None) -> tuple[str | None, bytes]`. The `hint` parameter is an optional identity hint sent by the server. The return value is a tuple in the form (client-identity, psk). Client-identity is an optional string which may be used by the server to select a corresponding PSK for the client. The string must be less than or equal to `256` octets when UTF-8 encoded. PSK is a *bytes-like object* representing the pre-shared key. Return a zero length PSK to reject the connection.

Setting `callback` to *None* removes any existing callback.

備🄵

使用 TLS 1.3 時:

- `hint` 參數始終🄵*None*。
- client-identity must be a non-empty string.

範例用法:

```
context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
context.check_hostname = False
context.verify_mode = ssl.CERT_NONE
context.maximum_version = ssl.TLSVersion.TLSv1_2
context.set_ciphers('PSK')

# A simple lambda:
psk = bytes.fromhex('c0ffee')
context.set_psk_client_callback(lambda hint: (None, psk))

# A table using the hint from the server:
psk_table = { 'ServerId_1': bytes.fromhex('c0ffee'),
              'ServerId_2': bytes.fromhex('facade')
```

(繼續下一頁)

(繼續上一頁)

```
}
def callback(hint):
    return 'ClientId_1', psk_table.get(hint, b'')
context.set_psk_client_callback(callback)
```

This method will raise *NotImplementedError* if *HAS_PSK* is `False`.

在 3.13 版被加入.

`SSLContext.`**`set_psk_server_callback`**(*callback*, *identity_hint=None*)

Enables TLS-PSK (pre-shared key) authentication on a server-side connection.

In general, certificate based authentication should be preferred over this method.

The parameter `callback` is a callable object with the signature: `def callback(identity: str | None) -> bytes`. The `identity` parameter is an optional identity sent by the client which can be used to select a corresponding PSK. The return value is a *bytes-like object* representing the pre-shared key. Return a zero length PSK to reject the connection.

Setting `callback` to *None* removes any existing callback.

The parameter `identity_hint` is an optional identity hint string sent to the client. The string must be less than or equal to `256` octets when UTF-8 encoded.

> **備🄵**
>
> When using TLS 1.3 the `identity_hint` parameter is not sent to the client.

範例用法:

```
context = ssl.SSLContext(ssl.PROTOCOL_TLS_SERVER)
context.maximum_version = ssl.TLSVersion.TLSv1_2
context.set_ciphers('PSK')

# A simple lambda:
psk = bytes.fromhex('c0ffee')
context.set_psk_server_callback(lambda identity: psk)

# A table using the identity of the client:
psk_table = { 'ClientId_1': bytes.fromhex('c0ffee'),
              'ClientId_2': bytes.fromhex('facade')
}
def callback(identity):
    return psk_table.get(identity, b'')
context.set_psk_server_callback(callback, 'ServerId_1')
```

This method will raise *NotImplementedError* if *HAS_PSK* is `False`.

在 3.13 版被加入.

19.3.4 Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer

knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called "notBefore" and "notAfter".

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as "PEM" (see **RFC 1422**), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who "is" the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a "CA certs" file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling *`SSLContext.load_default_certs()`*, this is done automatically with *`create_default_context()`*.

Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to *`SSLContext.load_cert_chain()`* needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
.......++++++
..............................++++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Organization, Inc.
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

19.3.5 范例

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    ...  # do something that requires SSL support
```

Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get an error and have to adjust the location)

The *PROTOCOL_TLS_CLIENT* protocol configures the context for cert validation and hostname verification.

verify_mode is set to *CERT_REQUIRED* and *check_hostname* is set to `True`. All other protocols create SSL contexts with insecure defaults.

When you use the context to connect to a server, *CERT_REQUIRED* and *check_hostname* validate the server certificate: it ensures that the server certificate was signed with one of the CA certificates, checks the signature for correctness, and verifies other properties like validity and identity of the hostname:

```
>>> conn = context.wrap_socket(socket.socket(socket.AF_INET),
...                            server_hostname="www.python.org")
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate:

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2ExtendedValidationServerCA.crt',),
 'crlDistributionPoints': ('http://crl3.digicert.com/sha2-ev-server-g1.crl',
                           'http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': ((('countryName', 'US'),),
            (('organizationName', 'DigiCert Inc'),),
            (('organizationalUnitName', 'www.digicert.com'),),

伺服器端操作

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call `listen()` on it, and start waiting for clients to connect:

```
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.example.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call `accept()` on the socket to get the new socket from the other end, and use the context's *`SSLContext.wrap_socket()`* method to create a server-side SSL socket for the connection:

```
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```
def deal_with_client(connstream):
    data = connstream.recv(1024)
    # empty data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.recv(1024)
    # finished with client
```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in *non-blocking mode* and use an event loop).

19.3.6 Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most *SSLSocket* methods will raise either *SSLWantWriteError* or *SSLWantReadError* instead of *BlockingIOError* if an I/O operation would block. *SSLWantReadError* will be raised if a read operation on the underlying socket is necessary, and *SSLWantWriteError* for a write operation on the underlying socket. Note that attempts to *write* to an SSL socket may require *reading* from the underlying socket first, and attempts to *read* from the SSL socket may require a prior *write* to the underlying socket.

  在 3.5 版的變更: In earlier Python versions, the `SSLSocket.send()` method returned zero instead of raising *SSLWantWriteError* or *SSLWantReadError*.

- Calling *select()* tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to *select()*.

- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without *select()* being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and then only block on a *select()* call if still necessary.

  (of course, similar provisions apply when using other primitives such as *poll()*, or those in the *selectors* module)

- The SSL handshake itself will be non-blocking: the *SSLSocket.do_handshake()* method has to be retried until it returns successfully. Here is a synopsis using *select()* to wait for the socket's readiness:

```
while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
        select.select([sock], [], [])
    except ssl.SSLWantWriteError:
        select.select([], [sock], [])
```

也參考

The *asyncio* module supports *non-blocking SSL sockets* and provides a higher level *Streams API*. It polls for events using the *selectors* module and handles *SSLWantWriteError*, *SSLWantReadError* and *BlockingIOError* exceptions. It runs the SSL handshake asynchronously as well.

19.3.7 記憶體 BIO 支援

在 3.5 版被加入.

Ever since the SSL module was introduced in Python 2.6, the *SSLSocket* class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by *socket.socket*, from which *SSLSocket* also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn't. An example is async IO frameworks that want to use a different IO multiplexing model than the "select/poll on a file descriptor" (readiness based) model that is assumed by *socket.socket* and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of *SSLSocket* called *SSLObject* is provided.

class ssl.**SSLObject**

A reduced-scope variant of *SSLSocket* representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate "BIO" objects which are OpenSSL's IO abstraction layer.

This class has no public constructor. An *SSLObject* instance must be created using the *wrap_bio()* method. This method will create the *SSLObject* instance and bind it to a pair of BIOs. The *incoming* BIO is used to pass data from Python to the SSL protocol instance, while the *outgoing* BIO is used to pass data the other way around.

The following methods are available:

- *context*
- *server_side*
- *server_hostname*
- *session*
- *session_reused*
- *read()*
- *write()*
- *getpeercert()*
- *get_verified_chain()*
- *get_unverified_chain()*
- *selected_alpn_protocol()*
- *selected_npn_protocol()*
- *cipher()*
- *shared_ciphers()*
- *compression()*
- *pending()*
- *do_handshake()*
- *verify_client_post_handshake()*
- *unwrap()*
- *get_channel_binding()*
- *version()*

When compared to *SSLSocket*, this object lacks the following features:

- Any form of network IO; `recv()` and `send()` read and write only to the underlying *MemoryBIO* buffers.
- There is no *do_handshake_on_connect* machinery. You must always manually call *do_handshake()* to start the handshake.

- There is no handling of *suppress_ragged_eofs*. All end-of-file conditions that are in violation of the protocol are reported via the `SSLEOFError` exception.
- The method `unwrap()` call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The *server_name_callback* callback passed to `SSLContext.set_servername_callback()` will get an `SSLObject` instance instead of a `SSLSocket` instance as its first parameter.

Some notes related to the use of `SSLObject`:

- All IO on an `SSLObject` is *non-blocking*. This means that for example `read()` will raise an `SSLWantReadError` if it needs more data than the incoming BIO has available.

在 3.7 版的變更: `SSLObject` instances must be created with `wrap_bio()`. In earlier versions, it was possible to create instances directly. This was never documented or officially supported.

An SSLObject communicates with the outside world using memory buffers. The class `MemoryBIO` provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

class ssl.**MemoryBIO**

A memory buffer that can be used to pass data between Python and an SSL protocol instance.

pending

Return the number of bytes currently in the memory buffer.

eof

A boolean indicating whether the memory BIO is current at the end-of-file position.

read(*n=-1*, /)

Read up to *n* bytes from the memory buffer. If *n* is not specified or negative, all bytes are returned.

write(*buf*, /)

Write the bytes from *buf* to the memory BIO. The *buf* argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of *buf*.

write_eof()

Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call `write()`. The attribute `eof` will become true after all data currently in the buffer has been read.

19.3.8 SSL session

在 3.6 版被加入.

class ssl.**SSLSession**

Session object used by `session`.

time

timeout

ticket_lifetime_hint

has_ticket

19.3.9 Security considerations

Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system's trusted CA

certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the *smtplib.SMTP* class to create a trusted, secure connection to a SMTP server:

```
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with *SSLContext.load_cert_chain()*.

By contrast, if you create the SSL context by calling the *SSLContext* constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

手動設定

驗証憑証

When calling the *SSLContext* constructor directly, *CERT_NONE* is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of the time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use *CERT_REQUIRED*. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling *SSLSocket.getpeercert()*, matches the desired service. For many protocols and applications, the service can be identified by the hostname. This common check is automatically performed when *SSLContext.check_hostname* is enabled.

在 3.7 版的變更: Hostname matchings is now performed by OpenSSL. Python no longer uses `match_hostname()`.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify *CERT_REQUIRED* and similarly check the client certificate.

協定版本

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use *PROTOCOL_TLS_CLIENT* or *PROTOCOL_TLS_SERVER* as the protocol version. SSLv2 and SSLv3 are disabled by default.

```
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> client_context.minimum_version = ssl.TLSVersion.TLSv1_3
>>> client_context.maximum_version = ssl.TLSVersion.TLSv1_3
```

The SSL context created above will only allow TLSv1.3 and later (if supported by your system) connections to a server. *PROTOCOL_TLS_CLIENT* implies certificate validation and hostname checks by default. You have to load certificates into the context.

Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the *SSLContext.set_ciphers()* method. Starting from Python 3.2.3, the ssl module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the cipher list format. If you want to check which ciphers are enabled by a given cipher list, use *SSLContext.get_ciphers()* or the `openssl ciphers` command on your system.

Multi-processing

If using this module as part of a multi-processed application (using, for example the *multiprocessing* or *concurrent.futures* modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with *os.fork()*. Any successful call of *RAND_add()* or *RAND_bytes()* is sufficient.

19.3.10 TLS 1.3

在 3.7 版被加入.

The TLS 1.3 protocol behaves slightly differently than previous version of TLS/SSL. Some new TLS 1.3 features are not yet available.

- TLS 1.3 uses a disjunct set of cipher suites. All AES-GCM and ChaCha20 cipher suites are enabled by default. The method *SSLContext.set_ciphers()* cannot enable or disable any TLS 1.3 ciphers yet, but *SSLContext.get_ciphers()* returns them.
- Session tickets are no longer sent as part of the initial handshake and are handled differently. *SSLSocket.session* and *SSLSession* are not compatible with TLS 1.3.
- Client-side certificates are also no longer verified during the initial handshake. A server can request a certificate at any time. Clients process certificate requests while they send or receive application data from the server.
- TLS 1.3 features like early data, deferred TLS client cert request, signature algorithm configuration, and rekeying are not supported yet.

19.4 `select` --- 等待 I/O 完成

This module provides access to the `select()` and `poll()` functions available in most operating systems, `devpoll()` available on Solaris and derivatives, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

備🄵

The *selectors* module allows high-level and efficient I/O multiplexing, built upon the *select* module primitives. Users are encouraged to use the *selectors* module instead, unless they want precise control over the OS-level primitives used.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

The module defines the following:

exception `select.error`

A deprecated alias of *OSError*.

在 3.3 版的變更: Following **PEP 3151**, this class was made an alias of *OSError*.

`select.`**`devpoll`**`()`

(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section */dev/poll Polling Objects* below for the methods supported by devpoll objects.

`devpoll()` objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, `devpoll()` will fail. If your program increases this value, `devpoll()` may return an incomplete list of active file descriptors.

The new file descriptor is *non-inheritable*.

在 3.3 版被加入.

在 3.4 版的變更: The new file descriptor is now non-inheritable.

`select.`**`epoll`**`(`*sizehint=-1*, *flags=0*`)`

(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events.

sizehint informs epoll about the expected number of events to be registered. It must be positive, or `-1` to use the default. It is only used on older systems where `epoll_create1()` is not available; otherwise it has no effect (though its value is still checked).

flags is deprecated and completely ignored. However, when supplied, its value must be `0` or `select.EPOLL_CLOEXEC`, otherwise `OSError` is raised.

See the *Edge and Level Trigger Polling (epoll) Objects* section below for the methods supported by epolling objects.

`epoll` objects support the context management protocol: when used in a `with` statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is *non-inheritable*.

在 3.3 版的變更: 新增 *flags* 參數。

在 3.4 版的變更: Support for the `with` statement was added. The new file descriptor is now non-inheritable.

在 3.4 版之後被🄵用: The *flags* parameter. `select.EPOLL_CLOEXEC` is used by default now. Use *os.set_inheritable()* to make the file descriptor inheritable.

`select.poll()`

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section *Polling Objects* below for the methods supported by polling objects.

`select.kqueue()`

(Only supported on BSD.) Returns a kernel queue object; see section *Kqueue Objects* below for the methods supported by kqueue objects.

The new file descriptor is *non-inheritable*.

在 3.4 版的變更: The new file descriptor is now non-inheritable.

`select.kevent`(*ident*, *filter=KQ_FILTER_READ*, *flags=KQ_EV_ADD*, *fflags=0*, *data=0*, *udata=0*)

(Only supported on BSD.) Returns a kernel event object; see section *Kevent Objects* below for the methods supported by kevent objects.

`select.select`(*rlist*, *wlist*, *xlist*[, *timeout*])

This is a straightforward interface to the Unix `select()` system call. The first three arguments are iterables of 'waitable objects': either integers representing file descriptors or objects with a parameterless method named `fileno()` returning such an integer:

- *rlist*: wait until ready for reading
- *wlist*: wait until ready for writing
- *xlist*: wait for an "exceptional condition" (see the manual page for what your system considers such a condition)

Empty iterables are allowed, but acceptance of three empty iterables is platform-dependent. (It is known to work on Unix but not on Windows.) The optional *timeout* argument specifies a time-out as a floating-point number in seconds. When the *timeout* argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the iterables are Python *file objects* (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a *wrapper* class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

> **備🄵**
>
> File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don't originate from WinSock.

在 3.5 版的變更: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising `InterruptedError`.

`select.PIPE_BUF`

The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by `select()`, `poll()` or another interface in this module. This doesn't apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512.

可用性: Unix

在 3.2 版被加入.

19.4.1 `/dev/poll` Polling Objects

Solaris and derivatives have `/dev/poll`. While `select()` is *O*(*highest file descriptor*) and `poll()` is *O*(*number of file descriptors*), `/dev/poll` is *O*(*active file descriptors*).

`/dev/poll` behaviour is very close to the standard `poll()` object.

`devpoll.close()`

Close the file descriptor of the polling object.

在 3.4 版被加入.

`devpoll.closed`

`True` if the polling object is closed.

在 3.4 版被加入.

`devpoll.fileno()`

Return the file descriptor number of the polling object.

在 3.4 版被加入.

`devpoll.register`(*fd*[, *eventmask*])

Register a file descriptor with the polling object. Future calls to the *poll()* method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a *fileno()* method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for. The constants are the same that with `poll()` object. The default value is a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`.

> **警告**
>
> Registering a file descriptor that's already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with `poll()`.

`devpoll.modify`(*fd*[, *eventmask*])

This method does an *unregister()* followed by a *register()*. It is (a bit) more efficient that doing the same explicitly.

`devpoll.unregister`(*fd*)

Remove a file descriptor being tracked by a polling object. Just like the *register()* method, *fd* can be an integer or an object with a *fileno()* method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

`devpoll.poll`([*timeout*])

Polls the set of registered file descriptors, and returns a possibly empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor --- `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, -1, or *None*, the call will block until there is an event for this poll object.

在 3.5 版的變更: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.4.2 Edge and Level Trigger Polling (epoll) Objects

https://linux.die.net/man/4/epoll

eventmask

常數	含義
EPOLLIN	Available for read
EPOLLOUT	Available for write
EPOLLPRI	Urgent data for read
EPOLLERR	Error condition happened on the assoc. fd
EPOLLHUP	Hang up happened on the assoc. fd
EPOLLET	Set Edge Trigger behavior, the default is Level Trigger behavior
EPOLLONESH	Set one-shot behavior. After one event is pulled out, the fd is internally disabled
EPOLLEXCLU	Wake only one epoll object when the associated fd has an event. The default (if this flag is not set) is to wake all epoll objects polling on a fd.
EPOLLRDHUP	Stream socket peer closed connection or shut down writing half of connection.
EPOLLRDNORM	等價於 EPOLLIN
EPOLLRDBAND	Priority data band can be read.
EPOLLWRNORM	等價於 EPOLLOUT
EPOLLWRBAND	Priority data may be written.
EPOLLMSG	Ignored.
EPOLLWAKEUP	Prevents sleep during event waiting.

在 3.6 版被加入: EPOLLEXCLUSIVE was added. It's only supported by Linux Kernel 4.5 or later.

在 3.14 版被加入: EPOLLWAKEUP was added. It's only supported by Linux Kernel 3.5 or later.

epoll.**close**()

Close the control file descriptor of the epoll object.

epoll.**closed**

True if the epoll object is closed.

epoll.**fileno**()

Return the file descriptor number of the control fd.

epoll.**fromfd**(*fd*)

Create an epoll object from a given file descriptor.

epoll.**register**(*fd*[, *eventmask*])

Register a fd descriptor with the epoll object.

epoll.**modify**(*fd*, *eventmask*)

Modify a registered file descriptor.

epoll.**unregister**(*fd*)

Remove a registered file descriptor from the epoll object.

在 3.9 版的變更: The method no longer ignores the *EBADF* error.

epoll.**poll**(*timeout=None*, *maxevents=-1*)

Wait for events. timeout in seconds (float)

在 3.5 版的變更: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.4.3 Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is *O*(*highest file descriptor*), while `poll()` is *O*(*number of file descriptors*).

`poll.`**`register`**`(`*fd*[, *eventmask*]`)`

Register a file descriptor with the polling object. Future calls to the *`poll()`* method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a *`fileno()`* method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

常數	含義
`POLLIN`	There is data to read
`POLLPRI`	There is urgent data to read
`POLLOUT`	Ready for output: writing will not block
`POLLERR`	Error condition of some sort
`POLLHUP`	Hung up
`POLLRDHUP`	Stream socket peer closed connection, or shut down writing half of connection
`POLLNVAL`	Invalid request: descriptor not open

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

`poll.`**`modify`**`(`*fd*, *eventmask*`)`

Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an *`OSError`* exception with errno `ENOENT` to be raised.

`poll.`**`unregister`**`(`*fd*`)`

Remove a file descriptor being tracked by a polling object. Just like the *`register()`* method, *fd* can be an integer or an object with a *`fileno()`* method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a *`KeyError`* exception to be raised.

`poll.`**`poll`**`(`[*timeout*]`)`

Polls the set of registered file descriptors, and returns a possibly empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor --- `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, negative, or *`None`*, the call will block until there is an event for this poll object.

在 3.5 版的變更: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *`InterruptedError`*.

19.4.4 Kqueue Objects

`kqueue.`**`close`**`()`

Close the control file descriptor of the kqueue object.

`kqueue.`**`closed`**

`True` if the kqueue object is closed.

kqueue.**fileno**()

Return the file descriptor number of the control fd.

kqueue.**fromfd**(*fd*)

Create a kqueue object from a given file descriptor.

kqueue.**control**(*changelist*, *max_events*[, *timeout*]) → eventlist

Low level interface to kevent

- changelist must be an iterable of kevent objects or None
- max_events must be 0 or a positive integer
- timeout in seconds (floats possible); the default is None, to wait forever

在 3.5 版的變更: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.4.5 Kevent Objects

https://man.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2

kevent.**ident**

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a *fileno()* method. kevent stores the integer internally.

kevent.**filter**

Name of the kernel filter.

常數	含義
KQ_FILTER_READ	Takes a descriptor and returns whenever there is data available to read
KQ_FILTER_WRITE	Takes a descriptor and returns whenever there is data available to write
KQ_FILTER_AIO	AIO requests
KQ_FILTER_VNODE	Returns when one or more of the requested events watched in *fflag* occurs
KQ_FILTER_PROC	Watch for events on a process id
KQ_FILTER_NETDEV	Watch for events on a network device [not available on macOS]
KQ_FILTER_SIGNAL	Returns whenever the watched signal is delivered to the process
KQ_FILTER_TIMER	Establishes an arbitrary timer

kevent.**flags**

Filter action.

常數	含義
KQ_EV_ADD	Adds or modifies an event
KQ_EV_DELETE	Removes an event from the queue
KQ_EV_ENABLE	Permitscontrol() to returns the event
KQ_EV_DISABLE	Disablesevent
KQ_EV_ONESHOT	Removes event after first occurrence
KQ_EV_CLEAR	Reset the state after an event is retrieved
KQ_EV_SYSFLAGS	internal event
KQ_EV_FLAG1	internal event
KQ_EV_EOF	Filter specific EOF condition
KQ_EV_ERROR	See return values

kevent.**fflags**

Filter specific flags.

KQ_FILTER_READ and KQ_FILTER_WRITE filter flags:

常數	含義
KQ_NOTE_LOWAT	low water mark of a socket buffer

KQ_FILTER_VNODE filter flags:

常數	含義
KQ_NOTE_DELETE	*unlink()* was called
KQ_NOTE_WRITE	a write occurred
KQ_NOTE_EXTEND	the file was extended
KQ_NOTE_ATTRIB	an attribute was changed
KQ_NOTE_LINK	the link count has changed
KQ_NOTE_RENAME	the file was renamed
KQ_NOTE_REVOKE	access to the file was revoked

KQ_FILTER_PROC filter flags:

常數	含義
KQ_NOTE_EXIT	the process has exited
KQ_NOTE_FORK	the process has called *fork()*
KQ_NOTE_EXEC	the process has executed a new process
KQ_NOTE_PCTRLMASK	internal filter flag
KQ_NOTE_PDATAMASK	internal filter flag
KQ_NOTE_TRACK	follow a process across *fork()*
KQ_NOTE_CHILD	returned on the child process for *NOTE_TRACK*
KQ_NOTE_TRACKERR	unable to attach to a child

KQ_FILTER_NETDEV filter flags (not available on macOS):

常數	含義
KQ_NOTE_LINKUP	link is up
KQ_NOTE_LINKDOWN	link is down
KQ_NOTE_LINKINV	link state is invalid

kevent.**data**

Filter specific data.

kevent.**udata**

User defined value.

19.5 selectors --- 高階 I/O 多工

在 3.4 版被加入.

原始碼： Lib/selectors.py

19.5.1 簡介

This module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a `BaseSelector` abstract base class, along with several concrete implementations (`KqueueSelector`, `EpollSelector`...), that can be used to wait for I/O readiness notification on multiple file objects. In the following, "file object" refers to any object with a `fileno()` method, or a raw file descriptor. See *file object*.

`DefaultSelector` is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

備🄵

The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

也參考

select
Low-level I/O multiplexing module.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

19.5.2 Classes

Classes hierarchy:

```
BaseSelector
+-- SelectSelector
+-- PollSelector
+-- EpollSelector
+-- DevpollSelector
+-- KqueueSelector
```

In the following, *events* is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

常數	含義
`selectors.`**`EVENT_READ`**	Available for read
`selectors.`**`EVENT_WRITE`**	Available for write

class `selectors.`**SelectorKey**

A `SelectorKey` is a `namedtuple` used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several `BaseSelector` methods.

fileobj
File object registered.

fd

Underlying file descriptor.

events

Events that must be waited for on this file object.

data

Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors.**BaseSelector**

A *BaseSelector* is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It's an abstract base class, so cannot be instantiated. Use *DefaultSelector* instead, or one of *SelectSelector*, *KqueueSelector* etc. if you want to specifically use an implementation, and your platform supports it. *BaseSelector* and its concrete implementations support the *context manager* protocol.

abstractmethod register(*fileobj*, *events*, *data=None*)

Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a `fileno()` method. *events* is a bitwise mask of events to monitor. *data* is an opaque object.

This returns a new *SelectorKey* instance, or raises a *ValueError* in case of invalid event mask or file descriptor, or *KeyError* if the file object is already registered.

abstractmethod unregister(*fileobj*)

Unregister a file object from selection, removing it from monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.

This returns the associated *SelectorKey* instance, or raises a *KeyError* if *fileobj* is not registered. It will raise *ValueError* if *fileobj* is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

modify(*fileobj*, *events*, *data=None*)

Change a registered file object's monitored events or attached data.

This is equivalent to `BaseSelector.unregister(fileobj)` followed by `BaseSelector.register(fileobj, events, data)`, except that it can be implemented more efficiently.

This returns a new *SelectorKey* instance, or raises a *ValueError* in case of invalid event mask or file descriptor, or *KeyError* if the file object is not registered.

abstractmethod select(*timeout=None*)

Wait until some registered file objects become ready, or the timeout expires.

If `timeout > 0`, this specifies the maximum wait time, in seconds. If `timeout <= 0`, the call won't block, and will report the currently ready file objects. If *timeout* is `None`, the call will block until a monitored file object becomes ready.

This returns a list of `(key, events)` tuples, one for each ready file object.

key is the *SelectorKey* instance corresponding to a ready file object. *events* is a bitmask of events ready on this file object.

> **備🄵**
>
> This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

在 3.5 版的變更: The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see **PEP 475** for the rationale), instead of returning an empty list of events before the timeout.

close()

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

get_key(*fileobj*)

Return the key associated with a registered file object.

This returns the *SelectorKey* instance associated to this file object, or raises *KeyError* if the file object is not registered.

abstractmethod get_map()

Return a mapping of file objects to selector keys.

This returns a *Mapping* instance mapping registered file objects to their associated *SelectorKey* instance.

class selectors.**DefaultSelector**

The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.

class selectors.**SelectSelector**

select.select()-based selector.

class selectors.**PollSelector**

select.poll()-based selector.

class selectors.**EpollSelector**

select.epoll()-based selector.

fileno()

This returns the file descriptor used by the underlying *select.epoll()* object.

class selectors.**DevpollSelector**

select.devpoll()-based selector.

fileno()

This returns the file descriptor used by the underlying *select.devpoll()* object.

在 3.5 版被加入.

class selectors.**KqueueSelector**

select.kqueue()-based selector.

fileno()

This returns the file descriptor used by the underlying *select.kqueue()* object.

19.5.3 范例

Here is a simple echo server implementation:

```
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept()  # Should be ready
```

(繼續下一頁)

(繼續上一頁)

```
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000)  # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
        conn.send(data)  # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
        callback(key.fileobj, mask)
```

19.6 `signal` --- 設定非同步事件的處理函式

原始碼： Lib/signal.py

本模組提供於 Python 中使用訊號處理程式的機制。

19.6.1 一般規則

signal.signal() 函式允許定義自訂的處理程式，會在收到訊號時執行。我們安裝了少數的預設處理程式：*SIGPIPE* 會被忽略 (所以管道和 socket 上的寫入錯誤可以當作一般的 Python 例外報告)，而*SIGINT* (如果父行程🄵有改變它的話) 會被轉🄵成*KeyboardInterrupt* 例外。

特定訊號的處理程式一旦被設定，就會一直被安裝，直到被明確地重設🄵止 (不管底層的實作🄵何，Python 皆模擬出 BSD 風格的介面)，但*SIGCHLD* 的處理程式除外，它會跟隨底層的實作。

在 WebAssembly 平台上，訊號是模擬出來的，故行🄵不同。有幾個函式和訊號在這些平台上是不可用的。

Python 訊號處理程式的執行

Python 訊號處理程式不會在低階（C 語言）訊號處理程式中執行。相反地，低階訊號處理程式會設定一個旗標，告訴🄵擬機在稍後執行相對應的 Python 訊號處理程式（例如在下一個*bytecode* 指令）。這會有一些後果：

- 捕捉像*SIGFPE* 或*SIGSEGV* 這類由 C 程式碼中無效操作所引起的同步錯誤是🄵有意義的。Python 將從訊號處理程式中回傳到 C 程式碼，而 C 程式碼很可能再次引發相同的訊號，導致 Python 明顯假當機 (hang)。從 Python 3.3 開始，你可以使用*faulthandler* 模組來報告同步錯誤。
- 純粹以 C 實作的長時間計算（例如在大量文字上的正規表示式比對）可能會不間斷地運行任意長度的時間而不考慮收到的任何訊號。當計算完成時，Python 訊號處理程式會被呼叫。
- 如果處理程式引發例外，就會在主執行緒中「憑空」🄵生例外。請參🄵下面的🄵明。

訊號和執行緒

Python 訊號處理程式總是在主直譯器的主 Python 執行緒中執行，即使訊號是在另一個執行緒中接收到的。這意味著訊號不能用來做🄴執行緒間通訊的方式。你可以使用*threading* 模組的同步原語 (synchronization primitive) 來代替。

此外，只有主直譯器的主執行緒才被允許設定新的訊號處理程式。

19.6.2 模組🄵容

在 3.5 版的變更: 下面列出的訊號 (SIG*)、處理器 (*SIG_DFL*、*SIG_IGN*) 和訊號遮罩 (sigmask) (*SIG_BLOCK*、*SIG_UNBLOCK*、*SIG_SETMASK*) 的相關常數被轉🄵成*enums* (*Signals*、*Handlers* 和*Sigmasks*) 。*getsignal()*、*pthread_sigmask()*、*sigpending()* 和*sigwait()* 函式會回傳可被人類🄵讀的枚舉作🄵*Signals* 物件。

訊號模組定義了三個枚舉:

class signal.**Signals**

SIG* 常數和 CTRL_* 常數的*enum.IntEnum* 集合。

在 3.5 版被加入.

class signal.**Handlers**

SIG_DFL 和*SIG_IGN* 常數的*enum.IntEnum* 集合。

在 3.5 版被加入.

class signal.**Sigmasks**

SIG_BLOCK、*SIG_UNBLOCK* 和*SIG_SETMASK* 常數的*enum.IntEnum* 集合。

可用性: Unix.

更多資訊請見 *sigprocmask(2)* 與 *pthread_sigmask(3)* 🄵上手🄵。

在 3.5 版被加入.

在*signal* 模組中定義的變數有:

signal.**SIG_DFL**

這是兩種標準訊號處理選項之一；它會簡單地執行訊號的預設功能。例如，在大多數系統上，SIGQUIT 的預設動作是轉儲 (dump) 核心🄴退出，而*SIGCHLD* 的預設動作是直接忽略。

signal.**SIG_IGN**

這是另一個標准的訊號處理程式，會直接忽略給定的訊號。

signal.**SIGABRT**

來自 *abort(3)* 的中止訊號。

signal.**SIGALRM**

來自 *alarm(2)* 的計時器訊號。

可用性: Unix.

signal.**SIGBREAK**

從鍵盤中斷 (CTRL + BREAK)。

可用性: Windows.

signal.**SIGBUS**

匯流排錯誤（記憶體存取不良）。

可用性: Unix.

signal.**SIGCHLD**

子行程停止或終止。

可用性: Unix.

signal.**SIGCLD**

SIGCHLD 的🄵名。

可用性: not macOS.

signal.**SIGCONT**

如果目前行程是被停止的，則繼續運行

可用性: Unix.

signal.**SIGFPE**

浮點運算例外。例如除以零。

> **也參考**
>
> *ZeroDivisionError* 會在除法或模運算 (modulo operation) 的第二個引數🄵零時引發。

signal.**SIGHUP**

偵測到控制終端機🄵斷 (hangup) 或控制行程死亡。

可用性: Unix.

signal.**SIGILL**

非法指令。

signal.**SIGINT**

從鍵盤中斷 (CTRL + C)。

預設動作是引發*KeyboardInterrupt*。

signal.**SIGKILL**

殺死訊號。

它無法被捕捉、阻擋或忽略。

可用性: Unix.

signal.**SIGPIPE**

管道中斷 (broken pipe)：寫到🄵有讀取器 (reader) 的管道。

預設動作是忽略訊號。

可用性: Unix.

signal.**SIGSEGV**

記憶體區段錯誤 (segmentation fault)：無效記憶體參照。

signal.**SIGSTKFLT**

輔助處理器 (coprocessor) 上的堆🄵錯誤 (stack fault)。Linux 核心不會引發此訊號：它只能在使用者空間 (user space) 中引發。

可用性: Linux.

在訊號可用的架構上。請參🄵 *signal(7)* 🄵上手🄵以取得更多資訊。

在 3.11 版被加入.

signal.**SIGTERM**

終止訊號。

signal.**SIGUSR1**

使用者定義訊號 1。

可用性: Unix.

signal.**SIGUSR2**

使用者定義訊號 2。

可用性: Unix.

signal.**SIGWINCH**

視窗調整大小訊號。

可用性: Unix.

SIG*

所有的訊號編號都是以符號定義的。例如，🄵斷訊號被定義🄵*signal.SIGHUP*；變數名稱與 C 程式中使用的名稱相同，可在 <signal.h> 中找到。Unix 🄵上手🄵'signal()' 列出了現有的訊號（在某些系統上是 *signal(2)*，在其他系統上是在 *signal(7)* 中）。請注意，🄵非所有系統都會定義同一套訊號名稱；只有那些由系統所定義的名稱才會由這個模組定義。

signal.**CTRL_C_EVENT**

與 Ctrl+C 擊鍵 (keystroke) 事件相對應的訊號。此訊號只能與*os.kill()* 搭配使用。

可用性: Windows.

在 3.2 版被加入.

signal.**CTRL_BREAK_EVENT**

與 Ctrl+Break 擊鍵事件相對應的訊號。此訊號只能與*os.kill()* 搭配使用。

可用性: Windows.

在 3.2 版被加入.

signal.**NSIG**

比最高編號訊號的編號多一。使用*valid_signals()* 來取得有效的訊號編號。

signal.**ITIMER_REAL**

即時🄵少間隔計時器 (interval timer)，🄵在到期時送出*SIGALRM*。

signal.**ITIMER_VIRTUAL**

僅在執行行程時遞🄵間隔計時器，🄵在到期時傳送 SIGVTALRM。

signal.**ITIMER_PROF**

當行程執行或系統代表行程執行時，都會🄵少間隔計時器。與 ITIMER_VIRTUAL 配合，這個計時器通常用來分析 (profile) 應用程式在使用者空間與核心空間 (kernel space) 所花費的時間。SIGPROF 會在到期時傳送。

signal.**SIG_BLOCK**

pthread_sigmask() 的 *how* 參數的可能值，表示訊號將被阻檔。

在 3.3 版被加入.

signal.**SIG_UNBLOCK**

pthread_sigmask() 的 *how* 參數的可能值，表示訊號將被解除阻檔。

在 3.3 版被加入.

signal.**SIG_SETMASK**

pthread_sigmask() 的 *how* 參數的可能值，表示訊號遮罩 (signal mask) 要被取代。

在 3.3 版被加入.

signal 模組定義了一個例外：

exception signal.**ItimerError**

當*setitimer()* 或*getitimer()* 底層實作發生錯誤時引發訊號。如果傳給*setitimer()* 的是無效的間隔計時器或負數時間，則預期會發生此錯誤。這個錯誤是*OSError* 的子型🄵。

在 3.3 版被加入: 此錯誤過去是*IOError* 的子型🄵，現在是*OSError* 的🄵名。

signal 模組定義了下列函式：

signal.**alarm**(*time*)

如果 *time* 非零，則此函式會要求在 *time* 秒後傳送*SIGALRM* 訊號給該行程。任何先前排程 (scheduled) 的警報都會被取消（任何時候都只能排程一個警報）。回傳值是先前設定的警報原本再等多久就會被傳送的秒數。如果 *time* 🄵零，則不會去排程任何警報，且已排程的警報會被取消。如果回傳值🄵零，則代表目前未排程任何警報。

可用性: Unix.

更多資訊請見 *alarm(2)* 🄵上手🄵。

signal.**getsignal**(*signalnum*)

回傳訊號 *signalnum* 的目前訊號處理程式。回傳值可以是一個可呼叫的 Python 物件，或是特殊值*signal.SIG_IGN*、*signal.SIG_DFL* 或*None* 之一。這🄵的*signal.SIG_IGN* 表示訊號先前被忽略，*signal.SIG_DFL* 表示訊號先前使用預設的處理方式，而 None 表示先前的訊號處理程式🄵未從 Python 安裝。

signal.**strsignal**(*signalnum*)

回傳訊號 *signalnum* 的描述，例如*SIGINT* 的"Interrupt"。如果 *signalnum* 🄵有描述，則回傳*None*。如果 *signalnum* 無效則會引發*ValueError*。

在 3.8 版被加入.

signal.**valid_signals**()

回傳此平台上的有效訊號編號集合。如果某些訊號被系統保留作🄵🄵部使用，則此值可能小於 range(1, NSIG)。

在 3.8 版被加入.

signal.**pause**()

使行程休眠，直到接收到訊號；然後呼叫適當的處理程式。不會回傳任何東西。

可用性: Unix.

更多資訊請見 *signal(2)* 🄵上手🄵。

也請見*sigwait()*、*sigwaitinfo()*、*sigtimedwait()* 和*sigpending()*。

signal.**raise_signal**(*signum*)

傳送訊號至呼叫的行程。不會回傳任何東西。

在 3.8 版被加入.

signal.**pidfd_send_signal**(*pidfd*, *sig*, *siginfo=None*, *flags=0*)

傳送訊號 *sig* 到檔案描述器 *pidfd* 所指的行程。Python 目前不支援 *siginfo* 參數；它必須是 None。*flags* 引數是提供給未來的擴充；目前🄵有定義旗標值。

更多資訊請見 *pidfd_send_signal(2)* 🄵上手🄵。

可用性: Linux >= 5.1, Android >= *build-time* API level 31

在 3.9 版被加入.

signal.**pthread_kill**(*thread_id*, *signalnum*)

將訊號 *signalnum* 傳送給與呼叫者在同一行程中的另一個執行緒 *thread_id*。目標執行緒能執行任何程式碼（無論🄵 Python 與否）。但是，如果目標執行緒正執行 Python 直譯器，Python 訊號處理程式將會由主直譯器的主執行緒來執行。因此，向特定 Python 執行緒發送訊號的唯一意義是🄵制執行中的系統呼叫以*InterruptedError* 方式失敗。

使用*threading.get_ident()* 或*threading.Thread* 物件的*ident* 屬性來取得 *thread_id* 的適當值。

如果 *signalnum* 🄵 0，則不會傳送訊號，但仍會執行錯誤檢查；這可用來檢查目標執行緒是否仍在執行。

引發一個附帶引數 thread_id、signalnum 的稽核事件 signal.pthread_kill。

可用性: Unix.

更多資訊請見 *pthread_kill(3)* 🄵上手🄵。

另請參🄵*os.kill()*。

在 3.3 版被加入.

signal.**pthread_sigmask**(*how*, *mask*)

🄵取和/或變更呼叫執行緒的訊號遮罩。訊號遮罩是目前阻擋呼叫者傳送的訊號集合。將舊的訊號遮罩作🄵一組訊號集合回傳。

呼叫的行🄵取🄴於 *how* 的值，如下所示。

- *SIG_BLOCK*：被阻檔的訊號集合是目前訊號集合與 *mask* 引數的聯集。
- *SIG_UNBLOCK*：將 *mask* 中的訊號從目前阻檔的訊號集合中移除。嘗試🄵未被阻檔的訊號解除阻檔是允許的。
- *SIG_SETMASK*：將被阻檔的訊號集合設定🄵 *mask* 引數。

mask 是一組訊號編號（例如 {*signal.SIGINT*, *signal.SIGTERM*}）的集合。使用*valid_signals()* 來取得包含所有訊號的完整遮罩。

例如，`signal.pthread_sigmask(signal.SIG_BLOCK, [])` 會讀取呼叫執行緒的訊號遮罩。

SIGKILL 和 SIGSTOP 不能被阻檔。

可用性: Unix.

更多資訊請見 *sigprocmask(2)* 與 *pthread_sigmask(3)* 🄵上手🄵。

另請參🄵*pause()*、*sigpending()* 與*sigwait()*。

在 3.3 版被加入.

signal.**setitimer**(*which*, *seconds*, *interval=0.0*)

設定由 *which* 指定的間隔計時器（*signal.ITIMER_REAL*、*signal.ITIMER_VIRTUAL* 或*signal.ITIMER_PROF* 之一）🄵在 *seconds*（接受浮點數，與*alarm()* 不同）之後🄵動，在之後的每 *interval* 秒🄵動一次（如果 *interval* 非零）。*which* 指定的間隔計時器可透過將 *seconds* 設定🄵零來清除它。

當間隔計時器🄵動時，一個訊號會被傳送給行程。傳送的訊號取🄵於使用的計時器；*signal.ITIMER_REAL* 會傳送*SIGALRM*，*signal.ITIMER_VIRTUAL* 會傳送 SIGVTALRM，而*signal.ITIMER_PROF* 會傳送 SIGPROF。

舊值會以一個元組回傳：(delay, interval)。

嘗試傳入無效的間隔計時器會導致*ItimerError*。

可用性: Unix.

signal.**getitimer**(*which*)

回傳由 *which* 指定之間隔計時器的目前值。

可用性: Unix.

signal.**set_wakeup_fd**(*fd*, *, *warn_on_full_buffer=True*)

設定🄵醒檔案描述器🄵 *fd*。當接收到其處理程式已有被🄵🄵的訊號時，訊號編號會以單一位元組寫入 fd。如果你🄵有🄵你在意的訊號🄴🄵處理程式，就不會寫入到🄵醒 fd。這可被函式庫用來🄵醒輪詢 (wakeup a poll) 或 select 呼叫，讓訊號得以完全處理。

回傳舊的🄵醒 fd（如果檔案描述器🄵醒未🄵用，則回傳 -1）。如果 *fd* 🄵 -1，則會停用檔案描述器🄵醒。如果不是 -1，*fd* 必須是非阻塞的。在再次呼叫輪詢或 select 之前，由函式庫來🄵定是否移除 *fd* 中的任何位元組。

當🄵用執行緒時，這個函式只能從主直譯器的主執行緒來呼叫；嘗試從其他執行緒呼叫它將會引發*ValueError* 例外。

使用這個函式有兩種常見的方式。在這兩種方法中，當訊號抵達時，你都要使用 fd 來🄵醒，但它們的不同之處在於如何判斷哪個或哪些訊號有抵達。

在第一種方法中，我們從 fd 的緩衝區中讀取資料，而位元組值則提供訊號編號。這個方法很簡單，但在少數情F下可能會遇到問題：一般來F，fd 的緩衝區空間有限，如果太多訊號來得太快，那F緩衝區可能會滿，而有些訊號可能會遺失。如果你使用這種方法，那F你應該設定 `warn_on_full_buffer=True`，這至少會在訊號F失時將警告印出到 stderr。

在第二種方法中，我們只會將F醒 fd 用於F醒，而忽略實際的位元組值。在這種情F下，我們只在乎 fd 的緩衝區是空或非空；即便緩衝區滿了也不代表有問題。如果你使用這種方法，那F你應該設定 `warn_on_full_buffer=False`，這樣你的使用者就不會被F假的警告訊息所混淆。

在 3.5 版的變更: 在 Windows 上，此功能現在也支援 socket 處理程式。

在 3.7 版的變更: 新增 `warn_on_full_buffer` 參數。

`signal.`**`siginterrupt`**`(`*signalnum*, *flag*`)`

改變系統呼叫重新F動的行F：如果 *flag* 是*`False`*，系統呼叫會在被訊號 *signalnum* 中斷時重新F動，否則系統呼叫會被中斷。不會回傳任何東西。

可用性: Unix.

更多資訊請見 *`siginterrupt(3)`* F上手F。

請注意，使用*`signal()`* 安裝訊號處理程式，會透過隱式呼叫 `siginterrupt()` 來將重新F動的行F重設F可中斷，且指定訊號的 *flag* 值F true。

`signal.`**`signal`**`(`*signalnum*, *handler*`)`

將訊號 *signalnum* 的處理程式設定F函式 *handler*。*handler* 可以是帶兩個引數的可呼叫 Python 物件（見下面），或是特殊值*`signal.SIG_IGN`* 或*`signal.SIG_DFL`* 之一。先前的訊號處理程式將會被回傳（請參F上面*`getsignal()`* 的F明）。（更多資訊請參F Unix F上手F *`signal(2)`*）。

當F用執行緒時，這個函式只能從主直譯器的主執行緒來呼叫；嘗試從其他執行緒呼叫它將會引發*`ValueError`* 例外。

handler 被呼叫時有兩個引數：訊號編號和目前的堆F frame（`None` 或一個 frame 物件；關於 frame 物件的描述，請參F型F階層中的描述或*`inspect`* 模組中的屬性描述）。

在 Windows 上，*`signal()`* 只能在使用*`SIGABRT`*、*`SIGFPE`*、*`SIGILL`*、*`SIGINT`*、*`SIGSEGV`*、*`SIGTERM`* 或*`SIGBREAK`* 時呼叫。在其他情F下會引發*`ValueError`*。請注意，F非所有系統都定義相同的訊號名稱；如果訊號名稱F有被定義F `SIG*` 模組層級常數，則會引發*`AttributeError`* 錯誤。

`signal.`**`sigpending`**`()`

檢查待傳送至呼叫執行緒的訊號集合（即阻檔時已被提出的訊號）。回傳待定訊號的集合。

可用性: Unix.

更多資訊請見 *`sigpending(2)`* F上手F。

另請參F*`pause()`*、*`pthread_sigmask()`* 與*`sigwait()`*。

在 3.3 版被加入.

`signal.`**`sigwait`**`(`*sigset*`)`

暫停呼叫執行緒的執行，直到送出訊號集合 *sigset* 中指定的一個訊號。函式接受訊號（將其從待定訊號清單中移除），F回傳訊號編號。

可用性: Unix.

更多資訊請見 *`sigwait(3)`* F上手F。

另也請見*`pause()`*、*`pthread_sigmask()`*、*`sigpending()`*、*`sigwaitinfo()`* 和*`sigtimedwait()`*。

在 3.3 版被加入.

`signal.`**`sigwaitinfo`**`(`*sigset*`)`

暫停呼叫執行緒的執行，直到送出訊號集合 *sigset* 中指定的一個訊號。該函式接受訊號，F將其從待定訊號清單中移除。如果 *sigset* 中的一個訊號已經是呼叫執行緒的待定訊號，函式會立即回傳該訊號的相關資訊。對於已傳送的訊號，訊號處理程式不會被呼叫。如果被不在 *sigset* 中的訊號中斷，函式會引發*`InterruptedError`*。

回傳值是一個物件，代表 `siginfo_t` 結構所包含的資料，即 `si_signo`、`si_code`、`si_errno`、`si_pid`、`si_uid`、`si_status`、`si_band`。

可用性: Unix.

更多資訊請見 *sigwaitinfo(2)* 🄵上手🄵。

另請參🄵*pause()*、*sigwait()* 與*sigtimedwait()*。

在 3.3 版被加入.

在 3.5 版的變更: 現在如果被不在 *sigset* 中的訊號中斷，且訊號處理程式🄵有引發例外，則會重試函式（理由請參🄵 **PEP 475**）。

signal.**sigtimedwait**(*sigset*, *timeout*)

類似*sigwaitinfo()*，但需要額外的 *timeout* 引數指定逾時時間。如果 *timeout* 指定🄵 `0`，會執行輪詢。如果發生逾時則會回傳*None*。

可用性: Unix.

更多資訊請見 *sigtimedwait(2)* 🄵上手🄵。

另請參🄵*pause()*、*sigwait()* 與*sigwaitinfo()*。

在 3.3 版被加入.

在 3.5 版的變更: 現在如果被不在 *sigset* 中的訊號中斷，且訊號處理程式🄵有引發例外，則會使用重新計算的 *timeout* 重試函式（理由請參🄵 **PEP 475**）。

19.6.3 范例

這是一個最小範例程式。它使用*alarm()* 函式來限制等待開🄵檔案的時間；如果檔案是用於可能未開🄵的序列裝置，這會很有用，因🄵這通常會導致*os.open()* 無限期地被擱置。解🄵方法是在開🄵檔案前設定一個 5 秒的警報；如果操作時間過長，警報訊號就會被送出，而處理程式會🄵生例外。

```
import signal, os

def handler(signum, frame):
    signame = signal.Signals(signum).name
    print(f'Signal handler called with signal {signame} ({signum})')
    raise OSError("Couldn't open device!")

# 設定訊號處理程式與五秒警報
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# 這個 open() 可能無限期地被擱置
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)          # 停用警報
```

19.6.4 關於 SIGPIPE 的🄵明

將程式的輸出管道化到 *head(1)* 之類的工具，會在你的行程的標准輸出接收器提早關閉時，導致*SIGPIPE* 訊號傳送給你的行程。這會導致類似 `BrokenPipeError: [Errno 32] Broken pipe` 的例外。要處理這種情🄵，請將你的進入點包裝成如下的樣子來捕捉這個例外：

```
import os
import sys

def main():
    try:
        # 模擬大量輸出（你的程式取代此🄵圈）
        for x in range(10000):
```

(繼續下一頁)

(繼續上一頁)

```
            print("y")
        # 在這🄵清除輸出以🄵制 SIGPIPE 在這個 try 區塊
        # 中被觸發
        sys.stdout.flush()
    except BrokenPipeError:
        # Python 在退出時清除標准串流；🄵剩下的輸出重新導向
        # 至 devnull 來避免關閉時的 BrokenPipeError
        devnull = os.open(os.devnull, os.O_WRONLY)
        os.dup2(devnull, sys.stdout.fileno())
        sys.exit(1)  # Python 在 EPIPE 時以錯誤碼 1 退出

if __name__ == '__main__':
    main()
```

不要🄵了避免*BrokenPipeError* 而將*SIGPIPE* 之處置 (disposition) 設定🄵*SIG_DFL*。這樣做會導致你的程式在寫入任何 socket 連🄵時被中斷而意外退出。

19.6.5 訊號處理程式與例外的🄵明

如果訊號處理程式🄵生例外，例外會傳送到主執行緒🄵可能在任何*bytecode* 指令之後發生。最值得注意的是，*KeyboardInterrupt* 可能在執行過程中的任何時候出現。大多數 Python 程式碼，包括標准函式庫，都無法避免這種情🄵，因此*KeyboardInterrupt*（或任何其他由訊號處理程式🄵生的例外）可能會在罕見的情🄵下使程式處於預期之外的狀態。

🄵了🄵明這個問題，請參考以下程式碼：

```
class SpamContext:
    def __init__(self):
        self.lock = threading.Lock()

    def __enter__(self):
        # 如果 KeyboardInterrupt 在此發生則一切正常
        self.lock.acquire()
        # 如果 KeyboardInterrupt 在此發生，__exit__ 將不會被呼叫
        ...
        # KeyboardInterrupt 可能在函式回傳之前發生

    def __exit__(self, exc_type, exc_val, exc_tb):
        ...
        self.lock.release()
```

對許多程式來🄵，尤其是那些只想在*KeyboardInterrupt* 時退出的程式，這🄵不是問題，但是對於🄵雜或需要高可靠性的應用程式來🄵，應該避免從訊號處理程式🄵生例外。它們也應該避免將捕獲*KeyboardInterrupt* 作🄵一種優雅關閉 (gracefully shutting down) 的方式。相反地，它們應該安裝自己的*SIGINT* 處理程式。以下是 HTTP 伺服器避免*KeyboardInterrupt* 的範例：

```
import signal
import socket
from selectors import DefaultSelector, EVENT_READ
from http.server import HTTPServer, SimpleHTTPRequestHandler

interrupt_read, interrupt_write = socket.socketpair()

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    interrupt_write.send(b'\0')
signal.signal(signal.SIGINT, handler)

def serve_forever(httpd):
    sel = DefaultSelector()
```

(繼續下一頁)

(繼續上一頁)

```
    sel.register(interrupt_read, EVENT_READ)
    sel.register(httpd, EVENT_READ)

    while True:
        for key, _ in sel.select():
            if key.fileobj == interrupt_read:
                interrupt_read.recv(1)
                return
            if key.fileobj == httpd:
                httpd.handle_request()

print("Serving on port 8000")
httpd = HTTPServer(('', 8000), SimpleHTTPRequestHandler)
serve_forever(httpd)
print("Shutdown...")
```

19.7 mmap --- 記憶體對映檔案的支援

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

Memory-mapped file objects behave like both *bytearray* and like *file objects*. You can use mmap objects in most places where *bytearray* are expected; for example, you can use the *re* module to search through a memory-mapped file. You can also change a single byte by doing `obj[index] = 97`, or change a subsequence by assigning to a slice: `obj[i1:i2] = b'...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the *mmap* constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its *fileno()* method to obtain the correct value for the *fileno* parameter. Otherwise, you can open the file using the *os.open()* function, which returns a file descriptor directly (the file still needs to be closed when done).

> **備🄵**
>
> If you want to create a memory-mapping for a writable, buffered file, you should *flush()* the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, *access* may be specified as an optional keyword parameter. *access* accepts one of four values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively, or `ACCESS_DEFAULT` to defer to *prot*. *access* can be used on both Unix and Windows. If *access* is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a *TypeError* exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but does not update the underlying file.

在 3.7 版的變更: 新增 `ACCESS_DEFAULT` 常數。

To map anonymous memory, -1 should be passed as the fileno along with the length.

class mmap.**mmap**(*fileno*, *length*, *tagname=None*, *access=ACCESS_DEFAULT*, *offset=0*)

(Windows version) Maps *length* bytes from the file specified by the file handle *fileno*, and creates a mmap object. If *length* is larger than the current size of the file, the file is extended to contain *length* bytes. If *length* is `0`, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not `None`, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened,

otherwise a new tag of this name is created. If this parameter is omitted or `None`, the mapping is created without a name. Avoiding the use of the *tagname* parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of the `ALLOCATIONGRANULARITY`.

引發一個附帶引數 `fileno`、`length`、`access`、`offset` 的稽核事件 `mmap.__new__`。

class `mmap.`**mmap**(*fileno*, *length*, *flags=MAP_SHARED*, *prot=PROT_WRITE | PROT_READ*, *access=ACCESS_DEFAULT*, *offset=0*, *, *trackfd=True*)

(Unix version) Maps *length* bytes from the file specified by the file descriptor *fileno*, and returns a mmap object. If *length* is `0`, the maximum length of the map will be the current size of the file when *mmap* is called.

flags specifies the nature of the mapping. *MAP_PRIVATE* creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and *MAP_SHARED* creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is *MAP_SHARED*. Some systems have additional possible flags with the full list specified in *MAP_* constants*.

prot, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. *prot* defaults to `PROT_READ | PROT_WRITE`.

access may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of `ALLOCATIONGRANULARITY` which is equal to `PAGESIZE` on Unix systems.

If *trackfd* is `False`, the file descriptor specified by *fileno* will not be duplicated, and the resulting `mmap` object will not be associated with the map's underlying file. This means that the *size()* and *resize()* methods will fail. This mode is useful to limit the number of open file descriptors.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically synchronized with the physical backing store on macOS.

在 3.13 版的變更: The *trackfd* parameter was added.

This example shows a simple way of using *mmap*:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python!\n"
    # read content via slice notation
    print(mm[:5])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print(mm.readline())  # prints b"Hello  world!\n"
    # close the map
    mm.close()
```

mmap can also be used as a context manager in a `with` statement:

```
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!")
```

在 3.2 版被加入: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!")

pid = os.fork()

if pid == 0:  # 在子行程中
    mm.seek(0)
    print(mm.readline())

    mm.close()
```

引發一個附帶引數 `fileno`、`length`、`access`、`offset` 的稽核事件 `mmap.__new__`。

Memory-mapped file objects support the following methods:

close()

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

closed

`True` if the file is closed.

在 3.2 版被加入.

find(*sub*[, *start*[, *end*]])

Returns the lowest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

flush()

flush(*offset*, *size*, /)

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed. *offset* must be a multiple of the `PAGESIZE` or `ALLOCATIONGRANULARITY`.

`None` is returned to indicate success. An exception is raised when the call failed.

在 3.8 版的變更: Previously, a nonzero value was returned on success; zero was returned on error under Windows. A zero value was returned on success; an exception was raised on error under Unix.

madvise(*option*[, *start*[, *length*]])

Send advice *option* to the kernel about the memory region beginning at *start* and extending *length* bytes. *option* must be one of the *MADV_* constants* available on the system. If *start* and *length* are omitted, the entire mapping is spanned. On some systems (including Linux), *start* must be a multiple of the `PAGESIZE`.

Availability: Systems with the `madvise()` system call.

在 3.8 版被加入.

move(*dest*, *src*, *count*)

Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with ACCESS_READ, then calls to move will raise a *TypeError* exception.

read([*n*])

Return a *bytes* containing up to *n* bytes starting from the current file position. If the argument is omitted, None or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.

在 3.3 版的變更: Argument can be omitted or None.

read_byte()

Returns a byte at the current file position as an integer, and advances the file position by 1.

readline()

Returns a single line, starting at the current file position and up to the next newline. The file position is updated to point after the bytes that were returned.

resize(*newsize*)

Resizes the map and the underlying file, if any.

Resizing a map created with *access* of ACCESS_READ or ACCESS_COPY, will raise a *TypeError* exception. Resizing a map created with *trackfd* set to False, will raise a *ValueError* exception.

On Windows: Resizing the map will raise an *OSError* if there are other maps against the same named file. Resizing an anonymous map (ie against the pagefile) will silently create a new map with the original data copied over up to the length of the new size.

在 3.11 版的變更: Correctly fails if attempting to resize when another map is held Allows resize against an anonymous map on Windows

rfind(*sub*[, *start*[, *end*]])

Returns the highest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns -1 on failure.

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

seek(*pos*[, *whence*])

Set the file's current position. *whence* argument is optional and defaults to os.SEEK_SET or 0 (absolute file positioning); other values are os.SEEK_CUR or 1 (seek relative to the current position) and os.SEEK_END or 2 (seek relative to the file's end).

在 3.13 版的變更: Return the new absolute position instead of None.

seekable()

Return whether the file supports seeking, and the return value is always True.

在 3.13 版被加入.

size()

Return the length of the file, which can be larger than the size of the memory-mapped area.

tell()

Returns the current position of the file pointer.

write(*bytes*)

Write the bytes in *bytes* into memory at the current position of the file pointer and return the number of bytes written (never less than len(bytes), since if the write fails, a *ValueError* will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with ACCESS_READ, then writing to it will raise a *TypeError* exception.

在 3.5 版的變更: Writable *bytes-like object* is now accepted.

在 3.6 版的變更: The number of bytes written is now returned.

write_byte(*byte*)

Write the integer *byte* into memory at the current position of the file pointer; the file position is advanced by `1`. If the mmap was created with `ACCESS_READ`, then writing to it will raise a *`TypeError`* exception.

19.7.1 MADV_* 常數

mmap.**MADV_NORMAL**

mmap.**MADV_RANDOM**

mmap.**MADV_SEQUENTIAL**

mmap.**MADV_WILLNEED**

mmap.**MADV_DONTNEED**

mmap.**MADV_REMOVE**

mmap.**MADV_DONTFORK**

mmap.**MADV_DOFORK**

mmap.**MADV_HWPOISON**

mmap.**MADV_MERGEABLE**

mmap.**MADV_UNMERGEABLE**

mmap.**MADV_SOFT_OFFLINE**

mmap.**MADV_HUGEPAGE**

mmap.**MADV_NOHUGEPAGE**

mmap.**MADV_DONTDUMP**

mmap.**MADV_DODUMP**

mmap.**MADV_FREE**

mmap.**MADV_NOSYNC**

mmap.**MADV_AUTOSYNC**

mmap.**MADV_NOCORE**

mmap.**MADV_CORE**

mmap.**MADV_PROTECT**

mmap.**MADV_FREE_REUSABLE**

mmap.**MADV_FREE_REUSE**

These options can be passed to *`mmap.madvise()`*. Not every option will be present on every system.

Availability: Systems with the madvise() system call.

在 3.8 版被加入.

19.7.2 MAP_* 常數

mmap.**MAP_SHARED**

mmap.**MAP_PRIVATE**

mmap.**MAP_32BIT**

mmap.**MAP_ALIGNED_SUPER**

mmap.**MAP_ANON**

mmap.**MAP_ANONYMOUS**

mmap.**MAP_CONCEAL**

mmap.**MAP_DENYWRITE**

mmap.**MAP_EXECUTABLE**

mmap.**MAP_HASSEMAPHORE**

mmap.**MAP_JIT**

mmap.**MAP_NOCACHE**

mmap.**MAP_NOEXTEND**

mmap.**MAP_NORESERVE**

mmap.**MAP_POPULATE**

mmap.**MAP_RESILIENT_CODESIGN**

mmap.**MAP_RESILIENT_MEDIA**

mmap.**MAP_STACK**

mmap.**MAP_TPRO**

mmap.**MAP_TRANSLATED_ALLOW_EXECUTE**

mmap.**MAP_UNIX03**

These are the various flags that can be passed to *mmap.mmap()*. *MAP_ALIGNED_SUPER* is only available at FreeBSD and *MAP_CONCEAL* is only available at OpenBSD. Note that some options might not be present on some systems.

在 3.10 版的變更: 新增*MAP_POPULATE* 常數。

在 3.11 版被加入: 新增*MAP_STACK* 常數。

在 3.12 版被加入: 新增*MAP_ALIGNED_SUPER* 和*MAP_CONCEAL* 常數。

在 3.13 版被加入: Added *MAP_32BIT*, *MAP_HASSEMAPHORE*, *MAP_JIT*, *MAP_NOCACHE*, *MAP_NOEXTEND*, *MAP_NORESERVE*, *MAP_RESILIENT_CODESIGN*, *MAP_RESILIENT_MEDIA*, *MAP_TPRO*, *MAP_TRANSLATED_ALLOW_EXECUTE*, and *MAP_UNIX03* constants.

CHAPTER 20

網際網路資料處理

本章描述了支援網際網路上處理常用資料格式的模組。

20.1 `email` --- 郵件和 MIME 處理套件

原始碼： Lib/email/__init__.py

The *email* package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP (**RFC 2821**), NNTP, or other servers; those are functions of modules such as *smtplib*. The *email* package attempts to be as RFC-compliant as possible, supporting **RFC 5322** and **RFC 6532**, as well as such MIME-related RFCs as **RFC 2045**, **RFC 2046**, **RFC 2047**, **RFC 2183**, and **RFC 2231**.

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an ”object model” that represents email messages. An application interacts with the package primarily through the object model interface defined in the *message* sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the *EmailMessage* API.

The other two major components of the package are the *parser* and the *generator*. The parser takes the serialized version of an email message (a stream of bytes) and converts it into a tree of *EmailMessage* objects. The generator takes an *EmailMessage* and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the *policy* module. Every *EmailMessage*, every *generator*, and every *parser* has an associated *policy* object that controls its behavior. Usually an application only needs to specify the policy when an *EmailMessage* is created, either by directly instantiating an *EmailMessage* to create a new email, or by parsing an input stream using a *parser*. But the policy can be changed when the message is serialized using a *generator*. This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary

to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME "content types" and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.

The following sections describe the functionality of the `email` package. We start with the `message` object model, which is the primary interface an application will use, and follow that with the `parser` and `generator` components. Then we cover the `policy` controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the `parser` may detect. Then we cover the `headerregistry` and the `contentmanager` sub-components, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The foregoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the `Message` class, cover the legacy `compat32` API that deals much more directly with the details of how email messages are represented. The `compat32` API does *not* hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the `compat32` API for backward compatibility reasons.

在 3.6 版的變更: Docs reorganized and rewritten to promote the new `EmailMessage`/`EmailPolicy` API.

Contents of the `email` package documentation:

20.1.1 `email.message`：表示電子郵件訊息

原始碼： Lib/email/message.py

在 3.6 版被加入:[1]

The central class in the `email` package is the `EmailMessage` class, imported from the `email.message` module. It is the base class for the `email` object model. `EmailMessage` provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are **RFC 5322** or **RFC 6532** style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as `multipart/*` or `message/rfc822`.

The conceptual model provided by an `EmailMessage` object is that of an ordered dictionary of headers coupled with a *payload* that represents the **RFC 5322** body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for generating a serialized version of the message, and for recursively walking over the object tree.

The `EmailMessage` dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. The keys are ordered, but unlike a real dict, there can be duplicates. Additional methods are provided for working with headers that have duplicate keys.

The *payload* is either a string or bytes object, in the case of simple message objects, or a list of `EmailMessage` objects, for MIME container documents such as `multipart/*` and `message/rfc822` message objects.

[1] Originally added in 3.4 as a *provisional module*. Docs for legacy message class moved to *email.message.Message: Representing an email message using the compat32 API*.

class email.message.**EmailMessage**(*policy=default*)

If *policy* is specified use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the *default* policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `\r\n`, it uses the Python standard `\n` line endings). For more information see the *policy* documentation.

as_string(*unixfrom=False*, *maxheaderlen=None*, *policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility with the base *Message* class *maxheaderlen* is accepted, but defaults to `None`, which means that by default the line length is controlled by the *max_line_length* of the policy. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the *Generator*.

Flattening the message may trigger changes to the *EmailMessage* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See *email.generator.Generator* for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as "7 bit clean" when *utf8* is `False`, which is the default.

在 3.6 版的變更: the default behavior when *maxheaderlen* is not specified was changed from defaulting to 0 to defaulting to the value of *max_line_length* from the policy.

__str__()

Equivalent to `as_string(policy=self.policy.clone(utf8=True))`. Allows `str(msg)` to produce a string containing the serialized message in a readable format.

在 3.4 版的變更: the method was changed to use `utf8=True`, thus producing an **RFC 6531**-like message representation, instead of being a direct alias for *as_string()*.

as_bytes(*unixfrom=False*, *policy=None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the *BytesGenerator*.

Flattening the message may trigger changes to the *EmailMessage* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See *email.generator.BytesGenerator* for a more flexible API for serializing messages.

__bytes__()

Equivalent to *as_bytes()*. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

is_multipart()

Return `True` if the message's payload is a list of sub-*EmailMessage* objects, otherwise return `False`. When *is_multipart()* returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). Note that *is_multipart()* returning `True` does not necessarily mean that "msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the *EmailMessage* is of type `message/rfc822`.

set_unixfrom(*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string. (See *mboxMessage* for a brief description of this header.)

get_unixfrom()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface for accessing the message's headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()*, but in an *EmailMessage* object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

__len__()

Return the total number of headers, including duplicates.

__contains__(*name*)

Return `True` if the message object has a field named *name*. Matching is done without regard to case and *name* does not include the trailing colon. Used for the `in` operator. For example:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id'])
```

__getitem__(*name*)

Return the value of the named header field. *name* does not include the colon field separator. If the header is missing, `None` is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant headers named *name*.

Using the standard (non-`compat32`) policies, the returned value is an instance of a subclass of *email.headerregistry.BaseHeader*.

__setitem__(*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing headers.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

If the *policy* defines certain headers to be unique (as the standard policies do), this method may raise a *ValueError* when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

__delitem__(*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()

Return a list of all the message's header field names.

values()

Return a list of all the message's field values.

items()

Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj=None*)

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (*failobj* defaults to `None`).

Here are some additional useful header related methods:

get_all(*name*, *failobj=None*)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)

Extended header setting. This method is similar to *__setitem__()* except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value, `LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

以下是個範例：

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

replace_header(*_name*, *_value*)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case of the original header. If no matching header is found, raise a *KeyError*.

get_content_type()

Return the message's content type, coerced to lower case of the form *maintype/subtype*. If there is no *Content-Type* header in the message return the value returned by *get_default_type()*. If the *Content-Type* header is invalid, return `text/plain`.

(According to **RFC 2045**, messages always have a default type, *get_content_type()* will always return a value. **RFC 2045** defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.)

get_content_maintype()

Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

get_content_subtype()

Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header, so it only affects the return value of the get_content_type methods when no *Content-Type* header is present in the message.

set_param(*param*, *value*, *header='Content-Type'*, *requote=True*, *charset=None*, *language=''*, *replace=False*)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, replace its value with *value*. When *header* is Content-Type (the default) and the header does not yet exist in the message, add it, set its value to *text/plain*, and append the new parameter value. Optional *header* specifies an alternative header to *Content-Type*.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional *charset* and *language* parameters. Optional *language* specifies the **RFC 2231** language, defaulting to the empty string. Both *charset* and *language* should be strings. The default is to use the utf8 *charset* and None for the *language*.

If *replace* is False (the default) the header is moved to the end of the list of headers. If *replace* is True, the header will be updated in place.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

Note that existing parameter values of headers may be accessed through the *params* attribute of the header value (for example, msg['Content-Type'].params['charset']).

在 3.4 版的變更: replace keyword was added.

del_param(*param*, *header='content-type'*, *requote=True*)

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. Optional *header* specifies an alternative to *Content-Type*.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

get_filename(*failobj=None*)

Return the value of the filename parameter of the *Content-Disposition* header of the message. If the header does not have a filename parameter, this method falls back to looking for the name parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per *email.utils.unquote()*.

get_boundary(*failobj=None*)

Return the value of the boundary parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no boundary parameter. The returned string will always be unquoted as per *email.utils.unquote()*.

set_boundary(*boundary*)

Set the boundary parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different from deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of the *Content-Type* header in the list of headers.

get_content_charset(*failobj=None*)

Return the charset parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no charset parameter, *failobj* is returned.

get_charsets(*failobj=None*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. If the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

is_attachment()

Return `True` if there is a *Content-Disposition* header and its (case insensitive) value is `attachment`, `False` otherwise.

在 3.4.2 版的變更: is_attachment is now a method instead of a property, for consistency with *is_multipart()*.

get_content_disposition()

Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183**.

在 3.5 版被加入.

The following methods relate to interrogating and manipulating the content (payload) of the message.

walk()

The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where *is_multipart()* returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> from email.iterators import _structure
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart',
...           part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

get_body(*preferencelist=('related', 'html', 'plain')*)

Return the MIME part that is the best candidate to be the "body" of the message.

preferencelist must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in *preferencelist*, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching *`Content-ID`* is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a *`Content-Disposition`* header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in *preferencelist*, return `None`.

Notes: (1) For most applications the only *preferencelist* combinations that really make sense are `('plain',)`, `('html', 'plain')`, and the default `('related', 'html', 'plain')`. (2) Because matching starts with the object on which `get_body` is called, calling `get_body` on a `multipart/related` will return the object itself unless *preferencelist* has a non-default value. (3) Messages (or message parts) that do not specify a *`Content-Type`* or whose *`Content-Type`* header is invalid will be treated as if they are of type `text/plain`, which may occasionally cause `get_body` to return unexpected results.

iter_attachments()

Return an iterator over all of the immediate sub-parts of the message that are not candidate "body" parts. That is, skip the first occurrence of each of `text/plain`, `text/html`, `multipart/related`, or `multipart/alternative` (unless they are explicitly marked as attachments via *`Content-Disposition: attachment`*), and return all remaining parts. When applied directly to a `multipart/related`, return an iterator over the all the related parts except the root part (ie: the part pointed to by the `start` parameter, or the first part if there is no `start` parameter or the `start` parameter doesn't match the *`Content-ID`* of any of the parts). When applied directly to a `multipart/alternative` or a non-`multipart`, return an empty iterator.

iter_parts()

Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-`multipart`. (See also *`walk()`*.)

get_content(**args*, *content_manager=None*, ***kw*)

Call the *`get_content()`* method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current *`policy`*.

set_content(**args*, *content_manager=None*, ***kw*)

Call the *`set_content()`* method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current *`policy`*.

make_related(*boundary=None*)

Convert a non-`multipart` message into a `multipart/related` message, moving any existing *`Content-`* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_alternative(*boundary=None*)

Convert a non-`multipart` or a `multipart/related` into a `multipart/alternative`, moving any

existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_mixed(*boundary=None*)

Convert a non-`multipart`, a `multipart/related`, or a `multipart-alternative` into a `multipart/mixed`, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

add_related(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/related`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart`, call *make_related()* and then proceed as above. If the message is any other type of `multipart`, raise a *TypeError*. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*. If the added part has no *Content-Disposition* header, add one with the value `inline`.

add_alternative(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/alternative`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart` or `multipart/related`, call *make_alternative()* and then proceed as above. If the message is any other type of `multipart`, raise a *TypeError*. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*.

add_attachment(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/mixed`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart`, `multipart/related`, or `multipart/alternative`, call *make_mixed()* and then proceed as above. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*. If the added part has no *Content-Disposition* header, add one with the value `attachment`. This method can be used both for explicit attachments (*Content-Disposition: attachment*) and `inline` attachments (*Content-Disposition: inline*), by passing appropriate options to the `content_manager`.

clear()

Remove the payload and all of the headers.

clear_content()

Remove the payload and all of the *!Content-* headers, leaving all other headers intact and in their original order.

EmailMessage objects have the following instance attributes:

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message. As with the *preamble*, if there is no epilog text this attribute will be `None`.

defects

The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

class email.message.**MIMEPart**(*policy=default*)

This class represents a subpart of a MIME message. It is identical to *EmailMessage*, except that no *MIME-Version* headers are added when *set_content()* is called, since sub-parts do not need their own *MIME-Version* headers.

🄵解

20.1.2 email.parser：剖析電子郵件訊息

原始碼： Lib/email/parser.py

Message object structures can be created in one of two ways: they can be created from whole cloth by creating an *EmailMessage* object, adding headers using the dictionary interface, and adding payload(s) using *set_content()* and related methods, or they can be created by parsing a serialized representation of the email message.

The *email* package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a bytes, string or file object, and the parser will return to you the root *EmailMessage* instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its *is_multipart()* method, and the subparts can be accessed via the payload manipulation methods, such as *get_body()*, *iter_parts()*, and *walk()*.

There are actually two parser interfaces available for use, the *Parser* API and the incremental *FeedParser* API. The *Parser* API is most useful if you have the entire text of the message in memory, or if the entire message lives in a file on the file system. *FeedParser* is more appropriate when you are reading the message from a stream which might block waiting for more input (such as reading an email message from a socket). The *FeedParser* can consume and parse the message incrementally, and only returns the root object when you close the parser.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. All of the logic that connects the *email* package's bundled parser and the *EmailMessage* class is embodied in the *Policy* class, so a custom parser can create message object trees any way it finds necessary by implementing custom versions of the appropriate `Policy` methods.

FeedParser API

The *BytesFeedParser*, imported from the `email.feedparser` module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (such as a socket). The *BytesFeedParser* can of course be used to parse an email message fully contained in a *bytes-like object*, string, or file, but the *BytesParser* API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The *BytesFeedParser*'s API is simple; you create an instance, feed it a bunch of bytes until there's no more to feed it, then close the parser to retrieve the root message object. The *BytesFeedParser* is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's *defects* attribute with a list of any problems it found in a message. See the *email.errors* module for the list of defects that it can find.

Here is the API for the *BytesFeedParser*:

class email.parser.**BytesFeedParser**(*_factory=None*, *, *policy=policy.compat32*)

Create a *BytesFeedParser* instance. Optional *_factory* is a no-argument callable; if not specified use the *message_factory* from the *policy*. Call *_factory* whenever a new message object is needed.

If *policy* is specified use the rules it specifies to update the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package and provides *Message* as the default factory. All other policies provide *EmailMessage* as the default *_factory*. For more information on what else *policy* controls, see the *policy* documentation.

Note: **The policy keyword should always be specified**; The default will change to *email.policy.default* in a future version of Python.

在 3.2 版被加入.

在 3.3 版的變更: 新增 *policy* 關鍵字。

在 3.6 版的變更: *_factory* defaults to the policy `message_factory`.

feed(*data*)

Feed the parser some more data. *data* should be a *bytes-like object* containing one or more lines. The lines can be partial and the parser will stitch such partial lines together properly. The lines can have any of the three common line endings: carriage return, newline, or carriage return and newline (they can even be mixed).

close()

Complete the parsing of all previously fed data and return the root message object. It is undefined what happens if *feed()* is called after this method has been called.

class email.parser.**FeedParser**(*_factory=None*, *, *policy=policy.compat32*)

Works like *BytesFeedParser* except that the input to the *feed()* method must be a string. This is of limited utility, since the only way for such a message to be valid is for it to contain only ASCII text or, if *utf8* is `True`, no binary attachments.

在 3.3 版的變更: 新增 *policy* 關鍵字。

Parser API

The *BytesParser* class, imported from the *email.parser* module, provides an API that can be used to parse a message when the complete contents of the message are available in a *bytes-like object* or file. The *email.parser* module also provides *Parser* for parsing strings, and header-only parsers, *BytesHeaderParser* and *HeaderParser*, which can be used if you're only interested in the headers of the message. *BytesHeaderParser* and *HeaderParser* can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body.

class email.parser.**BytesParser**(*_class=None*, *, *policy=policy.compat32*)

Create a *BytesParser* instance. The *_class* and *policy* arguments have the same meaning and semantics as the *_factory* and *policy* arguments of *BytesFeedParser*.

Note: **The policy keyword should always be specified**; The default will change to *email.policy.default* in a future version of Python.

在 3.3 版的變更: Removed the *strict* argument that was deprecated in 2.4. Added the *policy* keyword.

在 3.6 版的變更: *_class* defaults to the policy `message_factory`.

parse(*fp*, *headersonly=False*)

Read all the data from the binary file-like object *fp*, parse the resulting bytes, and return the message object. *fp* must support both the *readline()* and the `read()` methods.

The bytes contained in *fp* must be formatted as a block of **RFC 5322** (or, if *utf8* is `True`, **RFC 6532**) style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a *Content-Transfer-Encoding* of `8bit`).

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

parsebytes(*bytes*, *headersonly=False*)

Similar to the *parse()* method, except it takes a *bytes-like object* instead of a file-like object. Calling this method on a *bytes-like object* is equivalent to wrapping *bytes* in a *BytesIO* instance first and calling *parse()*.

Optional *headersonly* is as with the *parse()* method.

在 3.2 版被加入.

class email.parser.**BytesHeaderParser**(*_class=None*, *, *policy=policy.compat32*)

Exactly like *BytesParser*, except that *headersonly* defaults to True.

在 3.3 版被加入.

class email.parser.**Parser**(*_class=None*, *, *policy=policy.compat32*)

This class is parallel to *BytesParser*, but handles string input.

在 3.3 版的變更: Removed the *strict* argument. Added the *policy* keyword.

在 3.6 版的變更: *_class* defaults to the policy message_factory.

parse(*fp*, *headersonly=False*)

Read all the data from the text-mode file-like object *fp*, parse the resulting text, and return the root message object. *fp* must support both the *readline()* and the *read()* methods on file-like objects.

Other than the text mode requirement, this method operates like *BytesParser.parse()*.

parsestr(*text*, *headersonly=False*)

Similar to the *parse()* method, except it takes a string object instead of a file-like object. Calling this method on a string is equivalent to wrapping *text* in a *StringIO* instance first and calling *parse()*.

Optional *headersonly* is as with the *parse()* method.

class email.parser.**HeaderParser**(*_class=None*, *, *policy=policy.compat32*)

Exactly like *Parser*, except that *headersonly* defaults to True.

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level *email* package namespace.

email.**message_from_bytes**(*s*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure from a *bytes-like object*. This is equivalent to BytesParser().parsebytes(s). Optional *_class* and *policy* are interpreted as with the *BytesParser* class constructor.

在 3.2 版被加入.

在 3.3 版的變更: Removed the *strict* argument. Added the *policy* keyword.

email.**message_from_binary_file**(*fp*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure tree from an open binary *file object*. This is equivalent to BytesParser().parse(fp). *_class* and *policy* are interpreted as with the *BytesParser* class constructor.

在 3.2 版被加入.

在 3.3 版的變更: Removed the *strict* argument. Added the *policy* keyword.

email.**message_from_string**(*s*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure from a string. This is equivalent to Parser().parsestr(s). *_class* and *policy* are interpreted as with the *Parser* class constructor.

在 3.3 版的變更: Removed the *strict* argument. Added the *policy* keyword.

email.**message_from_file**(*fp*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure tree from an open *file object*. This is equivalent to Parser().parse(fp). *_class* and *policy* are interpreted as with the *Parser* class constructor.

在 3.3 版的變更: Removed the *strict* argument. Added the *policy* keyword.

在 3.6 版的變更: *_class* defaults to the policy message_factory.

Here's an example of how you might use *message_from_bytes()* at an interactive Python prompt:

```
>>> import email
>>> msg = email.message_from_bytes(myBytes)
```

Additional notes

Here are some notes on the parsing semantics:

- Most non-*multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for *is_multipart()*, and *iter_parts()* will yield an empty list.
- All *multipart* type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for *is_multipart()*, and *iter_parts()* will yield a list of subparts.
- Most messages with a content type of *message/** (such as *message/delivery-status* and *message/rfc822*) will also be parsed as container object containing a list payload of length 1. Their *is_multipart()* method will return `True`. The single element yielded by *iter_parts()* will be a sub-message object.
- Some non-standards-compliant messages may not be internally consistent about their *multipart*-edness. Such messages may have a *Content-Type* header of type *multipart*, but their *is_multipart()* method may return `False`. If such messages were parsed with the *FeedParser*, they will have an instance of the *MultipartInvariantViolationDefect* class in their *defects* attribute list. See *email.errors* for details.

20.1.3 `email.generator`: 產生 MIME 文件

原始碼： Lib/email/generator.py

One of the most common tasks is to generate the flat (serialized) version of the email message represented by a message object structure. You will need to do this if you want to send your message via *smtplib.SMTP.sendmail()*, or print the message on the console. Taking a message object structure and producing a serialized representation is the job of the generator classes.

As with the *email.parser* module, you aren't limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the bytes-oriented parsing and generation operations are inverses, assuming the same non-transforming *policy* is used for both. That is, parsing the serialized byte stream via the *BytesParser* class and then regenerating the serialized byte stream using *BytesGenerator* should produce output identical to the input[1]. (On the other hand, using the generator on an *EmailMessage* constructed by program may result in changes to the *EmailMessage* object as defaults are filled in.)

The *Generator* class can be used to flatten a message into a text (as opposed to binary) serialized representation, but since Unicode cannot represent binary data directly, the message is of necessity transformed into something that contains only ASCII characters, using the standard email RFC Content Transfer Encoding techniques for encoding email messages for transport over channels that are not "8 bit clean".

To accommodate reproducible processing of SMIME-signed messages *Generator* disables header folding for message parts of type `multipart/signed` and all subparts.

class email.generator.**BytesGenerator**(*outfp*, *mangle_from_=None*, *maxheaderlen=None*, ***, *policy=None*)

Return a *BytesGenerator* object that will write any message provided to the *flatten()* method, or any surrogateescape encoded text provided to the *write()* method, to the *file-like object outfp*. *outfp* must support a `write` method that accepts binary data.

If optional *mangle_from_* is `True`, put a > character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_* defaults to the value of the *mangle_from_* setting of the *policy* (which is `True` for the *compat32* policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in Unix mbox format (see *mailbox* and WHY THE CONTENT-LENGTH FORMAT IS BAD).

[1] This statement assumes that you use the appropriate setting for `unixfrom`, and that there are no *email.policy* settings calling for automatic adjustments (for example, *refold_source* must be `none`, which is *not* the default). It is also not 100% true, since if the message does not conform to the RFC standards occasionally information about the exact original text is lost during parsing error recovery. It is a goal to fix these latter edge cases when possible.

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the *Message* or *EmailMessage* object passed to `flatten` to control the message generation. See *email.policy* for details on what *policy* controls.

在 3.2 版被加入.

在 3.3 版的變更: 新增關鍵字 *policy*。

在 3.6 版的變更: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

flatten(*msg*, *unixfrom=False*, *linesep=None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *BytesGenerator* instance was created.

If the *policy* option *cte_type* is `8bit` (the default), copy any headers in the original parsed message that have not been modified to the output with any bytes with the high bit set reproduced as in the original, and preserve the non-ASCII *Content-Transfer-Encoding* of any body parts that have them. If `cte_type` is `7bit`, convert the bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Content-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see *mailbox*) before the first of the **RFC 5322** headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

clone(*fp*)

Return an independent clone of this *BytesGenerator* instance with the exact same option settings, and *fp* as the new *outfp*.

write(*s*)

Encode *s* using the `ASCII` codec and the `surrogateescape` error handler, and pass it to the *write* method of the *outfp* passed to the *BytesGenerator*'s constructor.

As a convenience, *EmailMessage* provides the methods *as_bytes()* and `bytes(aMessage)` (a.k.a. *__bytes__()*), which simplify the generation of a serialized binary representation of a message object. For more detail, see *email.message*.

Because strings cannot represent binary data, the *Generator* class must convert any binary data in any message it flattens to an ASCII compatible format, by converting them to an ASCII compatible *Content-Transfer_Encoding*. Using the terminology of the email RFCs, you can think of this as *Generator* serializing to an I/O stream that is not "8 bit clean". In other words, most applications will want to be using *BytesGenerator*, and not *Generator*.

class email.generator.**Generator**(*outfp*, *mangle_from_=None*, *maxheaderlen=None*, ***, *policy=None*)

Return a *Generator* object that will write any message provided to the *flatten()* method, or any text provided to the *write()* method, to the *file-like object* *outfp*. *outfp* must support a `write` method that accepts string data.

If optional *mangle_from_* is `True`, put a `>` character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_* defaults to the value of the *mangle_from_* setting of the *policy* (which is `True` for the *compat32* policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in Unix mbox format (see *mailbox* and WHY THE CONTENT-LENGTH FORMAT IS BAD).

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the *Message* or *EmailMessage* object passed to `flatten` to control the message generation. See *email.policy* for details on what *policy* controls.

在 3.3 版的變更: 新增關鍵字 *policy*。

在 3.6 版的變更: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

flatten(*msg*, *unixfrom=False*, *linesep=None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *Generator* instance was created.

If the *policy* option *cte_type* is `8bit`, generate the message as if the option were set to `7bit`. (This is required because strings cannot represent non-ASCII bytes.) Convert any bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Content-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see *mailbox*) before the first of the **RFC 5322** headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

在 3.2 版的變更: Added support for re-encoding `8bit` message bodies, and the *linesep* argument.

clone(*fp*)

Return an independent clone of this *Generator* instance with the exact same options, and *fp* as the new *outfp*.

write(*s*)

Write *s* to the *write* method of the *outfp* passed to the *Generator*'s constructor. This provides just enough file-like API for *Generator* instances to be used in the *print()* function.

As a convenience, *EmailMessage* provides the methods *as_string()* and `str(aMessage)` (a.k.a. *__str__()*), which simplify the generation of a formatted string representation of a message object. For more detail, see *email.message*.

The *email.generator* module also provides a derived class, *DecodedGenerator*, which is like the *Generator* base class, except that non-*text* parts are not serialized, but are instead represented in the output stream by a string derived from a template filled in with information about the part.

class email.generator.**DecodedGenerator**(*outfp*, *mangle_from_=None*, *maxheaderlen=None*, *fmt=None*, ***, *policy=None*)

Act like *Generator*, except that for any subpart of the message passed to *Generator.flatten()*, if the subpart is of main type *text*, print the decoded payload of the subpart, and if the main type is not *text*, instead of printing it fill in the string *fmt* using information from the part and print the resulting filled-in string.

To fill in *fmt*, execute `fmt % part_info`, where `part_info` is a dictionary composed of the following keys and values:

- `type` -- Full MIME type of the non-*text* part
- `maintype` -- Main MIME type of the non-*text* part
- `subtype` -- Sub-MIME type of the non-*text* part
- `filename` -- Filename of the non-*text* part

- `description` -- Description associated with the non-*`text`* part
- `encoding` -- Content transfer encoding of the non-*`text`* part

If *fmt* is `None`, use the following default *fmt*:

"[Non-text (%(type)s) part of message omitted, filename %(filename)s]"

Optional *_mangle_from_* and *maxheaderlen* are as with the *`Generator`* base class.

🄵解

20.1.4 `email.policy`: Policy Objects

在 3.3 版被加入.

原始碼： Lib/email/policy.py

The *`email`* package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary 'body'), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main email RFCs, some do not. Even when working with email, there are times when it is desirable to break strict compliance with the RFCs, such as generating emails that interoperate with email servers that do not themselves follow the standards, or that implement extensions you want to use in ways that violate the standards.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A *`Policy`* object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. *`Policy`* instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. For all of the *`parser`* classes and the related convenience functions, and for the *`Message`* class, this is the *`Compat32`* policy, via its corresponding pre-defined instance *`compat32`*. This policy provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

This default value for the *policy* keyword to *`EmailMessage`* is the *`EmailPolicy`* policy, via its pre-defined instance *`default`*.

When a *`Message`* or *`EmailMessage`* object is created, it acquires a policy. If the message is created by a *`parser`*, a policy passed to the parser will be the policy used by the message it creates. If the message is created by the program, then the policy can be specified when it is created. When a message is passed to a *`generator`*, the generator uses the policy from the message by default, but you can also pass a specific policy to the generator that will override the one stored on the message object.

The default value for the *policy* keyword for the *`email.parser`* classes and the parser convenience functions **will be changing** in a future version of Python. Therefore you should **always specify explicitly which policy you want to use** when calling any of the classes and functions described in the *`parser`* module.

The first part of this documentation covers the features of *`Policy`*, an *abstract base class* that defines the features that are common to all policy objects, including *`compat32`*. This includes certain hook methods that are called internally by the email package, which a custom policy could override to obtain different behavior. The second part describes the concrete classes *`EmailPolicy`* and *`Compat32`*, which implement the hooks that provide the standard behavior and the backward compatible behavior and features, respectively.

`Policy` instances are immutable, but they can be cloned, accepting the same keyword arguments as the class constructor and returning a new *`Policy`* instance that is a copy of the original but with the specified attributes values changed.

As an example, the following code could be used to read an email message from a file on disk and pass it to the system `sendmail` program on a Unix system:

```
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE
>>> with open('mymsg.txt', 'rb') as f:
...     msg = message_from_binary_file(f, policy=policy.default)
...
>>> p = Popen(['sendmail', msg['To'].addresses[0]], stdin=PIPE)
>>> g = BytesGenerator(p.stdin, policy=msg.policy.clone(linesep='\r\n'))
>>> g.flatten(msg)
>>> p.stdin.close()
>>> rc = p.wait()
```

Here we are telling *BytesGenerator* to use the RFC correct line separator characters when creating the binary string to feed into `sendmail's stdin`, where the default policy would use `\n` line separators.

Some email package methods accept a *policy* keyword argument, allowing the policy to be overridden for that method. For example, the following code uses the *as_bytes()* method of the *msg* object from the previous example and writes the message to a file using the native line separators for the platform on which it is running:

```
>>> import os
>>> with open('converted.txt', 'wb') as f:
...     f.write(msg.as_bytes(policy=msg.policy.clone(linesep=os.linesep)))
17
```

Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```
>>> compat_SMTP = policy.compat32.clone(linesep='\r\n')
>>> compat_strict = policy.compat32.clone(raise_on_defect=True)
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```
>>> policy100 = policy.compat32.clone(max_line_length=100)
>>> policy80 = policy.compat32.clone(max_line_length=80)
>>> apolicy = policy100 + policy80
>>> apolicy.max_line_length
80
>>> apolicy = policy80 + policy100
>>> apolicy.max_line_length
100
```

class email.policy.**Policy**(***kw*)

This is the *abstract base class* for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the *clone()* method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

max_line_length

The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per **RFC 5322**. A value of `0` or *None* indicates that no line wrapping should be done at all.

linesep

The string to be used to terminate lines in serialized output. The default is `\n` because that's the internal end-of-line discipline used by Python, though `\r\n` is required by the RFCs.

cte_type

Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

`7bit`	all data must be "7 bit clean" (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.
`8bit`	data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see *`fold_binary()`* and *`utf8`* below for exceptions), but body parts may use the `8bit` CTE.

A `cte_type` value of `8bit` only works with `BytesGenerator`, not `Generator`, because strings cannot contain binary data. If a `Generator` is operating under a policy that specifies `cte_type=8bit`, it will act as if `cte_type` is `7bit`.

raise_on_defect

If *`True`*, any defects encountered will be raised as errors. If *`False`* (the default), defects will be passed to the *`register_defect()`* method.

mangle_from_

If *`True`*, lines starting with *"From "* in the body are escaped by putting a > in front of them. This parameter is used when the message is being serialized by a generator. Default: *`False`*.

在 3.5 版被加入.

message_factory

A factory function for constructing a new empty message object. Used by the parser when building messages. Defaults to `None`, in which case *`Message`* is used.

在 3.6 版被加入.

verify_generated_headers

If `True` (the default), the generator will raise *`HeaderWriteError`* instead of writing a header that is improperly folded or delimited, such that it would be parsed as multiple headers or joined with adjacent data. Such headers can be generated by custom header classes or bugs in the `email` module.

As it's a security feature, this defaults to `True` even in the *`Compat32`* policy. For backwards compatible, but unsafe, behavior, it must be set to `False` explicitly.

在 3.13 版被加入.

The following *`Policy`* method is intended to be called by code using the email library to create policy instances with custom settings:

clone(***kw*)

Return a new *`Policy`* instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining *`Policy`* methods are called by the email package code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

handle_defect(*obj*, *defect*)

Handle a *defect* found on *obj*. When the email package calls this method, *defect* will always be a subclass of *`MessageDefect`*.

The default implementation checks the *`raise_on_defect`* flag. If it is `True`, *defect* is raised as an exception. If it is `False` (the default), *obj* and *defect* are passed to *`register_defect()`*.

register_defect(*obj*, *defect*)

Register a *defect* on *obj*. In the email package, *defect* will always be a subclass of *`MessageDefect`*.

The default implementation calls the `append` method of the `defects` attribute of *obj*. When the email package calls *`handle_defect`*, *obj* will normally have a `defects` attribute that has an `append` method.

Custom object types used with the email package (for example, custom `Message` objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

header_max_count(*name*)

Return the maximum allowed number of headers named *name*.

Called when a header is added to an *EmailMessage* or *Message* object. If the returned value is not `0` or `None`, and there are already a number of headers with the name *name* greater than or equal to the value returned, a *ValueError* is raised.

Because the default behavior of `Message.__setitem__` is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a `Message` programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns `None` for all header names.

header_source_parse(*sourcelines*)

The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, *name* should be the case preserved name (all characters up to the ':' separator), while *value* should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.

sourcelines may contain surrogateescaped binary data.

There is no default implementation

header_store_parse(*name*, *value*)

The email package calls this method with the name and value provided by the application program when the application program is modifying a `Message` programmatically (as opposed to a `Message` created by a parser). The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the *name* and *value* should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

header_fetch_parse(*name*, *value*)

The email package calls this method with the *name* and *value* currently stored in the `Message` when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the `Message`; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.

There is no default implementation

fold(*name*, *value*)

The email package calls this method with the *name* and *value* currently stored in the `Message` for a given header. The method should return a string that represents that header "folded" correctly (according to the policy settings) by composing the *name* with the *value* and inserting *linesep* characters at the appropriate places. See **RFC 5322** for a discussion of the rules for folding email headers.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

fold_binary(*name*, *value*)

The same as *fold()*, except that the returned value should be a bytes object rather than a string.

value may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

class email.policy.**EmailPolicy**(***kw*)

This concrete *Policy* provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) **RFC 5322**, **RFC 2047**, and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are `str` subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement **RFC 2047** and **RFC 5322**.

The default value for the *message_factory* attribute is *EmailMessage*.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:

在 3.6 版被加入:[1]

utf8

If `False`, follow **RFC 5322**, supporting non-ASCII characters in headers by encoding them as "encoded words". If `True`, follow **RFC 6532** and use `utf-8` encoding for headers. Messages formatted in this way may be passed to SMTP servers that support the `SMTPUTF8` extension (**RFC 6531**).

refold_source

If the value for a header in the `Message` object originated from a *parser* (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into serialized form. The possible values are:

`none`	all source values use original folding
`long`	source values that have any line that is longer than `max_line_length` will be refolded
`all`	all values are refolded.

預設🄵 `long`。

header_factory

A callable that takes two arguments, `name` and `value`, where `name` is a header field name and `value` is an unfolded header field value, and returns a string subclass that represents that header. A default `header_factory` (see *headerregistry*) is provided that supports custom parsing for the various address and date **RFC 5322** header field types, and the major MIME header field stypes. Support for additional custom parsing will be added in the future.

content_manager

An object with at least two methods: get_content and set_content. When the *get_content()* or *set_content()* method of an *EmailMessage* object is called, it calls the corresponding method of this object, passing it the message object as its first argument, and any arguments or keywords that were passed to it as additional arguments. By default `content_manager` is set to *raw_data_manager*.

在 3.4 版被加入.

The class provides the following concrete implementations of the abstract methods of *Policy*:

header_max_count(*name*)

Returns the value of the *max_count* attribute of the specialized class used to represent the header with the given name.

[1] Originally added in 3.3 as a *provisional feature*.

header_source_parse(*sourcelines*)

The name is parsed as everything up to the ':' and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

header_store_parse(*name*, *value*)

The name is returned unchanged. If the input value has a `name` attribute and it matches *name* ignoring case, the value is returned unchanged. Otherwise the *name* and *value* are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.

header_fetch_parse(*name*, *value*)

If the value has a `name` attribute, it is returned to unmodified. Otherwise the *name*, and the *value* with any CR or LF characters removed, are passed to the `header_factory`, and the resulting header object is returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.

fold(*name*, *value*)

Header folding is controlled by the *refold_source* policy setting. A value is considered to be a 'source value' if and only if it does not have a `name` attribute (having a `name` attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the *name* and the *value* with any CR and LF characters removed to the `header_factory`. Folding of a header object is done by calling its `fold` method with the current policy.

Source values are split into lines using *splitlines()*. If the value is not to be refolded, the lines are rejoined using the `linesep` from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the `refold_source` setting, which causes the binary data to be CTE encoded using the `unknown-8bit` charset.

fold_binary(*name*, *value*)

The same as *fold()* if *cte_type* is `7bit`, except that the returned value is bytes.

If *cte_type* is `8bit`, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded, regardless of the `refold_header` setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of *EmailPolicy* provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the `HTTP` instance) may be adjusted to conform even more closely to the RFCs relevant to their domains.

`email.policy.`**default**

An instance of `EmailPolicy` with all defaults unchanged. This policy uses the standard Python `\n` line endings rather than the RFC-correct `\r\n`.

`email.policy.`**SMTP**

Suitable for serializing messages in conformance with the email RFCs. Like `default`, but with `linesep` set to `\r\n`, which is RFC compliant.

`email.policy.`**SMTPUTF8**

The same as `SMTP` except that *utf8* is `True`. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the *smtplib.SMTP.send_message()* method handles this automatically).

`email.policy.`**HTTP**

Suitable for serializing headers with for use in HTTP traffic. Like `SMTP` except that `max_line_length` is set to `None` (unlimited).

`email.policy.`**strict**

Convenience instance. The same as `default` except that `raise_on_defect` is set to `True`. This allows any policy to be made strict by writing:

```
somepolicy + policy.strict
```

With all of these *EmailPolicies*, the effective API of the email package is changed from the Python 3.2 API in the following ways:

- Setting a header on a *Message* results in that header being parsed and a header object created.
- Fetching a header value from a *Message* results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the *EmailMessage* is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in *headerregistry*.

class email.policy.**Compat32**(***kw*)

This concrete *Policy* is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The *policy* module also defines an instance of this class, *compat32*, that is used as the default policy. Thus the default behavior of the email package is to maintain compatibility with Python 3.2.

The following attributes have values that are different from the *Policy* default:

mangle_from_

The default is `True`.

The class provides the following concrete implementations of the abstract methods of *Policy*:

header_source_parse(*sourcelines*)

The name is parsed as everything up to the ':' and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

header_store_parse(*name*, *value*)

The name and value are returned unmodified.

header_fetch_parse(*name*, *value*)

If the value contains binary data, it is converted into a *Header* object using the `unknown-8bit` charset. Otherwise it is returned unmodified.

fold(*name*, *value*)

Headers are folded using the *Header* folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the `max_line_length`. Non-ASCII binary data are CTE encoded using the `unknown-8bit` charset.

fold_binary(*name*, *value*)

Headers are folded using the *Header* folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the `max_line_length`. If `cte_type` is `7bit`, non-ascii binary data is CTE encoded using the `unknown-8bit` charset. Otherwise the original source header is used, with its existing line breaks and any (RFC invalid) binary data it may contain.

email.policy.**compat32**

An instance of *Compat32*, providing backward compatibility with the behavior of the email package in Python 3.2.

🄵解

20.1.5 email.errors：例外和缺陷類🄵

原始碼： Lib/email/errors.py

The following exception classes are defined in the *email.errors* module:

exception email.errors.**MessageError**

This is the base class for all exceptions that the *email* package can raise. It is derived from the standard *Exception* class and defines no additional methods.

exception email.errors.**MessageParseError**

This is the base class for exceptions raised by the *Parser* class. It is derived from *MessageError*. This class is also used internally by the parser used by *headerregistry*.

exception email.errors.**HeaderParseError**

Raised under some error conditions when parsing the **RFC 5322** headers of a message, this class is derived from *MessageParseError*. The *set_boundary()* method will raise this error if the content type is unknown when the method is called. *Header* may raise this error for certain base64 decoding errors, and when an attempt is made to create a header that appears to contain an embedded header (that is, there is what is supposed to be a continuation line that has no leading whitespace and looks like a header).

exception email.errors.**BoundaryError**

Deprecated and no longer used.

exception email.errors.**MultipartConversionError**

Raised if the *attach()* method is called on an instance of a class derived from *MIMENonMultipart* (e.g. *MIMEImage*). *MultipartConversionError* multiply inherits from *MessageError* and the built-in *TypeError*.

exception email.errors.**HeaderWriteError**

Raised when an error occurs when the *generator* outputs headers.

exception email.errors.**MessageDefect**

This is the base class for all defects found when parsing email messages. It is derived from *ValueError*.

exception email.errors.**HeaderDefect**

This is the base class for all defects found when parsing email headers. It is derived from *MessageDefect*.

Here is the list of the defects that the *FeedParser* can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a *multipart/alternative* had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from *email.errors.MessageDefect*.

exception email.errors.**NoBoundaryInMultipartDefect**

A message claimed to be a multipart, but had no *boundary* parameter.

exception email.errors.**StartBoundaryNotFoundDefect**

The start boundary claimed in the *Content-Type* header was never found.

exception email.errors.**CloseBoundaryNotFoundDefect**

A start boundary was found, but no corresponding close boundary was ever found.

在 3.3 版被加入.

exception email.errors.**FirstHeaderLineIsContinuationDefect**

The message had a continuation line as its first header line.

exception email.errors.**MisplacedEnvelopeHeaderDefect**

A "Unix From" header was found in the middle of a header block.

exception email.errors.**MissingHeaderBodySeparatorDefect**

A line was found while parsing headers that had no leading white space but contained no ':'. Parsing continues assuming that the line represents the first line of the body.

在 3.3 版被加入.

exception email.errors.**MalformedHeaderDefect**

A header was found that was missing a colon, or was otherwise malformed.

在 3.3 版之後被🄵用: This defect has not been used for several Python versions.

exception email.errors.**MultipartInvariantViolationDefect**

A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its *is_multipart()* method may return False even though its content type claims to be *multipart*.

exception email.errors.**InvalidBase64PaddingDefect**

When decoding a block of base64 encoded bytes, the padding was not correct. Enough padding is added to perform the decode, but the resulting decoded bytes may be invalid.

exception email.errors.**InvalidBase64CharactersDefect**

When decoding a block of base64 encoded bytes, characters outside the base64 alphabet were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.

exception email.errors.**InvalidBase64LengthDefect**

When decoding a block of base64 encoded bytes, the number of non-padding base64 characters was invalid (1 more than a multiple of 4). The encoded block was kept as-is.

exception email.errors.**InvalidDateDefect**

When decoding an invalid or unparsable date field. The original value is kept as-is.

20.1.6 email.headerregistry: 自訂標頭物件

原始碼: Lib/email/headerregistry.py

在 3.6 版被加入:[1]

Headers are represented by customized subclasses of *str*. The particular class used to represent a given header is determined by the *header_factory* of the *policy* in effect when the headers are created. This section documents the particular header_factory implemented by the email package for handling **RFC 5322** compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from *EmailPolicy*, all headers are produced by *HeaderRegistry* and have *BaseHeader* as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class *UnstructuredHeader* as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the *HeaderRegistry*. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.

The sections below first document the header base classes and their attributes, followed by the API for modifying the behavior of *HeaderRegistry*, and finally the support classes used to represent the data parsed from structured headers.

class email.headerregistry.**BaseHeader**(*name*, *value*)

name and *value* are passed to BaseHeader from the *header_factory* call. The string value of any header object is the *value* fully decoded to unicode.

這個基底類🄵定義了以下唯讀屬性:

[1] Originally added in 3.3 as a *provisional module*

name

The name of the header (the portion of the field before the ':'). This is exactly the value passed in the *header_factory* call for *name*; that is, case is preserved.

defects

A tuple of *HeaderDefect* instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the *errors* module for a discussion of the types of defects that may be reported.

max_count

The maximum number of headers of this type that can have the same `name`. A value of `None` means unlimited. The `BaseHeader` value for this attribute is `None`; it is expected that specialized header classes will override this value as needed.

`BaseHeader` also provides the following method, which is called by the email library code and should not in general be called by application programs:

fold(*, *policy*)

Return a string containing *linesep* characters as required to correctly fold the header according to *policy*. A *cte_type* of `8bit` will be treated as if it were `7bit`, since headers may not contain arbitrary binary data. If *utf8* is `False`, non-ASCII data will be **RFC 2047** encoded.

`BaseHeader` by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, `BaseHeader` requires that the specialized class provide a *classmethod()* named `parse`. This method is called as follows:

```
parse(string, kwds)
```

`kwds` is a dictionary containing one pre-initialized key, `defects`. `defects` is an empty list. The parse method should append any detected defects to this list. On return, the `kwds` dictionary *must* contain values for at least the keys `decoded` and `defects`. `decoded` should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that *string* may contain content-transfer-encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.

`BaseHeader`'s `__new__` then creates the header instance, and calls its `init` method. The specialized class only needs to provide an `init` method if it wishes to set additional attributes beyond those provided by `BaseHeader` itself. Such an `init` method should look like this:

```
def init(self, /, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the `kwds` dictionary should be removed and handled, and the remaining contents of `kw` (and `args`) passed to the `BaseHeader` `init` method.

class email.headerregistry.**UnstructuredHeader**

An "unstructured" header is the default type of header in **RFC 5322**. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header is the *Subject* header.

In **RFC 5322**, an unstructured header is a run of arbitrary text in the ASCII character set. **RFC 2047**, however, has an **RFC 5322** compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a *value* containing encoded words is passed to the constructor, the `UnstructuredHeader` parser converts such encoded words into unicode, following the **RFC 2047** rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

class email.headerregistry.**DateHeader**

RFC 5322 specifies a very specific format for dates within email headers. The `DateHeader` parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes found "in the wild".

This header type provides the following additional attributes:

datetime

If the header value can be recognized as a valid date of one form or another, this attribute will contain a *datetime* instance representing that date. If the timezone of the input date is specified as `-0000` (indicating it is in UTC but contains no information about the source timezone), then *datetime* will be a naive *datetime*. If a specific timezone offset is found (including `+0000`), then *datetime* will contain an aware `datetime` that uses *datetime.timezone* to record the timezone offset.

The `decoded` value of the header is determined by formatting the `datetime` according to the **RFC 5322** rules; that is, it is set to:

```
email.utils.format_datetime(self.datetime)
```

When creating a `DateHeader`, *value* may be *datetime* instance. This means, for example, that the following code is valid and does what one would expect:

```
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of `-0000`. Much more useful is to use the *localtime()* function from the *utils* module:

```
msg['Date'] = utils.localtime()
```

This example sets the date header to the current time and date using the current timezone offset.

class email.headerregistry.**AddressHeader**

Address headers are one of the most complex structured header types. The `AddressHeader` class provides a generic interface to any address header.

This header type provides the following additional attributes:

groups

A tuple of *Group* objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address `Groups` whose *display_name* is `None`.

addresses

A tuple of *Address* objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the point where the group occurs in the value (that is, the list of addresses is "flattened" into a one dimensional list).

The `decoded` value of the header will have all encoded words decoded to unicode. *idna* encoded domain names are also decoded to unicode. The `decoded` value is set by *joining* the *str* value of the elements of the `groups` attribute with `', '`.

A list of *Address* and *Group* objects in any combination may be used to set the value of an address header. `Group` objects whose `display_name` is `None` will be interpreted as single addresses, which allows an address list to be copied with groups intact by using the list obtained from the `groups` attribute of the source header.

class email.headerregistry.**SingleAddressHeader**

A subclass of *AddressHeader* that adds one additional attribute:

address

The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default *policy*), accessing this attribute will result in a *ValueError*.

Many of the above classes also have a `Unique` variant (for example, `UniqueUnstructuredHeader`). The only difference is that in the `Unique` variant, *max_count* is set to 1.

class email.headerregistry.**MIMEVersionHeader**

There is really only one valid value for the *MIME-Version* header, and that is `1.0`. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per **RFC 2045**, then the header object will have non-`None` values for the following attributes:

version

The version number as a string, with any whitespace and/or comments removed.

major

The major version number as an integer

minor

The minor version number as an integer

class email.headerregistry.**ParameterizedMIMEHeader**

MIME headers all start with the prefix 'Content-'. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

params

A dictionary mapping parameter names to parameter values.

class email.headerregistry.**ContentTypeHeader**

A *ParameterizedMIMEHeader* class that handles the *Content-Type* header.

content_type

The content type string, in the form `maintype/subtype`.

maintype

subtype

class email.headerregistry.**ContentDispositionHeader**

A *ParameterizedMIMEHeader* class that handles the *Content-Disposition* header.

content_disposition

`inline` and `attachment` are the only valid values in common use.

class email.headerregistry.**ContentTransferEncoding**

Handles the *Content-Transfer-Encoding* header.

cte

Valid values are `7bit`, `8bit`, `base64`, and `quoted-printable`. See **RFC 2045** for more information.

class email.headerregistry.**HeaderRegistry**(*base_class=BaseHeader*, *default_class=UnstructuredHeader*, *use_default_map=True*)

This is the factory used by *EmailPolicy* by default. `HeaderRegistry` builds the class used to create a header instance dynamically, using *base_class* and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by *default_class* is used as the specialized class. When *use_default_map* is `True` (the default), the standard mapping of header names to classes is copied in to the registry during initialization. *base_class* is always the last class in the generated class's `__bases__` list.

The default mappings are:

`HeaderRegistry` 有以下方法：

map_to_type(*self*, *name*, *cls*)

name is the name of the header to be mapped. It will be converted to lower case in the registry. *cls* is the specialized class to be used, along with *base_class*, to create the class used to instantiate headers that match *name*.

__getitem__(*name*)

Construct and return a class to handle creating a *name* header.

__call__(*name*, *value*)

Retrieves the specialized header associated with *name* from the registry (using *default_class* if *name* does not appear in the registry) and composes it with *base_class* to produce a class, calls the constructed class's constructor, passing it the same argument list, and finally returns the class instance created thereby.

The following classes are the classes used to represent data parsed from structured headers and can, in general, be used by an application program to construct structured values to assign to specific headers.

class email.headerregistry.**Address**(*display_name=''*, *username=''*, *domain=''*, *addr_spec=None*)

The class used to represent an email address. The general form of an address is:

```
[display_name] <username@domain>
```

或是:

```
username@domain
```

where each part must conform to specific syntax rules spelled out in **RFC 5322**.

As a convenience *addr_spec* can be specified instead of *username* and *domain*, in which case *username* and *domain* will be parsed from the *addr_spec*. An *addr_spec* must be a properly RFC quoted string; if it is not `Address` will raise an error. Unicode characters are allowed and will be property encoded when serialized. However, per the RFCs, unicode is *not* allowed in the username portion of the address.

display_name

The display name portion of the address, if any, with all quoting removed. If the address does not have a display name, this attribute will be an empty string.

username

The `username` portion of the address, with all quoting removed.

domain

The `domain` portion of the address.

addr_spec

The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

__str__()

The `str` value of the object is the address quoted according to **RFC 5322** rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (**RFC 5321**), `Address` handles one special case: if `username` and `domain` are both the empty string (or `None`), then the string value of the `Address` is `<>`.

class email.headerregistry.**Group**(*display_name=None*, *addresses=None*)

The class used to represent an address group. The general form of an address group is:

```
display_name: [address-list];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a `Group` may also be used to represent single addresses that are not part of a group by setting *display_name* to `None` and providing a list of the single address as *addresses*.

display_name

The `display_name` of the group. If it is `None` and there is exactly one `Address` in `addresses`, then the `Group` represents a single address that is not in a group.

addresses

A possibly empty tuple of *Address* objects representing the addresses in the group.

__str__()

The `str` value of a `Group` is formatted according to **RFC 5322**, but with no Content Transfer Encoding of any non-ASCII characters. If `display_name` is none and there is a single `Address` in the `addresses` list, the `str` value will be the same as the `str` of that single `Address`.

🄵解

20.1.7 email.contentmanager：管理 MIME 🄵容

原始碼： Lib/email/contentmanager.py

在 3.6 版被加入:[1]

class email.contentmanager.**ContentManager**

Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the `get_content` and `set_content` dispatch methods.

get_content(*msg*, **args*, ***kw*)

Look up a handler function based on the `mimetype` of *msg* (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from *msg* and return an object that encodes information about the extracted data.

To find the handler, look for the following keys in the registry, stopping with the first one found:

- the string representing the full MIME type (`maintype/subtype`)
- the string representing the `maintype`
- the empty string

If none of these keys produce a handler, raise a *KeyError* for the full MIME type.

set_content(*msg*, *obj*, **args*, ***kw*)

If the `maintype` is `multipart`, raise a *TypeError*; otherwise look up a handler function based on the type of *obj* (see next paragraph), call *clear_content()* on the *msg*, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store *obj* into *msg*, possibly making other changes to *msg* as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of *obj* (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's `qualname` (`typ.__qualname__`)
- the type's `name` (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the *MRO* (`typ.__mro__`). Finally, if no other key yields a handler, check for a handler for the key `None`. If there is no handler for `None`, raise a *KeyError* for the fully qualified name of the type.

Also add a *MIME-Version* header if one is not present (see also *MIMEPart*).

add_get_handler(*key*, *handler*)

Record the function *handler* as the handler for *key*. For the possible values of *key*, see *get_content()*.

add_set_handler(*typekey*, *handler*)

Record *handler* as the function to call when an object of a type matching *typekey* is passed to *set_content()*. For the possible values of *typekey*, see *set_content()*.

[1] Originally added in 3.4 as a *provisional module*

Content Manager Instances

Currently the email package provides only one concrete content manager, *raw_data_manager*, although more may be added in the future. *raw_data_manager* is the *content_manager* provided by *EmailPolicy* and its derivatives.

email.contentmanager.**raw_data_manager**

This content manager provides only a minimum interface beyond that provided by *Message* itself: it deals only with text, raw byte strings, and *Message* objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

email.contentmanager.**get_content**(*msg*, *errors='replace'*)

Return the payload of the part as either a string (for `text` parts), an *EmailMessage* object (for `message/rfc822` parts), or a `bytes` object (for all other non-multipart types). Raise a *KeyError* if called on a `multipart`. If the part is a `text` part and *errors* is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

email.contentmanager.**set_content**(*msg*, *<'str'>*, *subtype="plain"*, *charset='utf-8'*, *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)

email.contentmanager.**set_content**(*msg*, *<'bytes'>*, *maintype*, *subtype*, *cte="base64"*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)

email.contentmanager.**set_content**(*msg*, *<'EmailMessage'>*, *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)

Add headers and payload to *msg*:

Add a *Content-Type* header with a `maintype/subtype` value.

- For `str`, set the MIME `maintype` to `text`, and set the subtype to *subtype* if it is specified, or `plain` if it is not.
- For `bytes`, use the specified *maintype* and *subtype*, or raise a *TypeError* if they are not specified.
- For *EmailMessage* objects, set the maintype to `message`, and set the subtype to *subtype* if it is specified or `rfc822` if it is not. If *subtype* is `partial`, raise an error (`bytes` objects must be used to construct `message/partial` parts).

If *charset* is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified *charset* is a known alias for a standard MIME charset name, use the standard charset instead.

If *cte* is set, encode the payload using the specified content transfer encoding, and set the *Content-Transfer-Encoding* header to that value. Possible values for *cte* are `quoted-printable`, `base64`, `7bit`, `8bit`, and `binary`. If the input cannot be encoded in the specified encoding (for example, specifying a *cte* of `7bit` for an input that contains non-ASCII values), raise a *ValueError*.

- For `str` objects, if *cte* is not set use heuristics to determine the most compact encoding. Prior to encoding, *str.splitlines()* is used to normalize all line boundaries, ensuring that each line of the payload is terminated by the current policy's *linesep* property (even if the original string did not end with one).
- For `bytes` objects, *cte* is taken to be base64 if not set, and the aforementioned newline translation is not performed.
- For *EmailMessage*, per **RFC 2046**, raise an error if a *cte* of `quoted-printable` or `base64` is requested for *subtype* `rfc822`, and for any *cte* other than `7bit` for *subtype* `external-body`. For `message/rfc822`, use `8bit` if *cte* is not specified. For all other values of *subtype*, use `7bit`.

> **備🄵**
>
> A *cte* of `binary` does not actually work correctly yet. The `EmailMessage` object as modified by `set_content` is correct, but *`BytesGenerator`* does not serialize it correctly.

If *disposition* is set, use it as the value of the *`Content-Disposition`* header. If not specified, and *filename* is specified, add the header with the value `attachment`. If *disposition* is not specified and *filename* is also not specified, do not add the header. The only valid values for *disposition* are `attachment` and `inline`.

If *filename* is specified, use it as the value of the `filename` parameter of the *`Content-Disposition`* header.

If *cid* is specified, add a *`Content-ID`* header with *cid* as its value.

If *params* is specified, iterate its `items` method and use the resulting `(key, value)` pairs to set additional parameters on the *`Content-Type`* header.

If *headers* is specified and is a list of strings of the form `headername: headervalue` or a list of `header` objects (distinguished from strings by having a `name` attribute), add the headers to *msg*.

🄵解

20.1.8 `email`：范例

Here are a few examples of how to use the *`email`* package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message (both the text content and the addresses may contain unicode characters):

```
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.message import EmailMessage

# Open the plain text file whose name is in textfile for reading.
with open(textfile) as fp:
    # Create a text/plain message
    msg = EmailMessage()
    msg.set_content(fp.read())

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = f'The contents of {textfile}'
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()
```

Parsing **RFC 822** headers can easily be done by the using the classes from the *`parser`* module:

```
# Import the email modules we'll need
#from email.parser import BytesParser
from email.parser import Parser
from email.policy import default

# If the e-mail headers are in a file, uncomment these two lines:
```

(繼續下一頁)

(繼續上一頁)

```
# with open(messagefile, 'rb') as fp:
#     headers = BytesParser(policy=default).parse(fp)

#  Or for parsing headers in a string (this is an uncommon operation), use:
headers = Parser(policy=default).parsestr(
        'From: Foo Bar <user@example.com>\n'
        'To: <someone_else@example.com>\n'
        'Subject: Test message\n'
        '\n'
        'Body would go here\n')

#  Now the header items can be accessed as a dictionary:
print('To: {}'.format(headers['to']))
print('From: {}'.format(headers['from']))
print('Subject: {}'.format(headers['subject']))

# You can also access the parts of the addresses:
print('Recipient username: {}'.format(headers['to'].addresses[0].username))
print('Sender name: {}'.format(headers['from'].addresses[0].display_name))
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```
# Import smtplib for the actual sending function.
import smtplib

# Here are the email package modules we'll need.
from email.message import EmailMessage

# Create the container email message.
msg = EmailMessage()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = ', '.join(family)
msg.preamble = 'You will not see this in a MIME-aware mail reader.\n'

# Open the files in binary mode.  You can also omit the subtype
# if you want MIMEImage to guess it.
for file in pngfiles:
    with open(file, 'rb') as fp:
        img_data = fp.read()
    msg.add_attachment(img_data, maintype='image',
                                 subtype='png')

# Send the email via our own SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

Here's an example of how to send the entire contents of a directory as an email message:[1]

```
#!/usr/bin/env python3

"""Send the contents of a directory as a MIME message."""

import os
import smtplib
# For guessing MIME type based on file name extension
```

    main()
```

Here's an example of how to unpack a MIME message like the one above, into a directory of files:

```
#!/usr/bin/env python3

"""Unpack a MIME message into a directory of files."""

import os
import email
import mimetypes

from email.policy import default

from argparse import ArgumentParser

def main():
    parser = ArgumentParser(description="""\
Unpack a MIME message into a directory of files.
""")
    parser.add_argument('-d', '--directory', required=True,
                        help="""Unpack the MIME message into the named
                        directory, which will be created if it doesn't already
                        exist.""")
    parser.add_argument('msgfile')
    args = parser.parse_args()

    with open(args.msgfile, 'rb') as fp:
        msg = email.message_from_binary_file(fp, policy=default)

    try:
        os.mkdir(args.directory)
    except FileExistsError:
        pass

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given filename so that an
        # email message can't be used to overwrite important files
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_content_type())
            if not ext:
                # Use a generic bag-of-bits extension
                ext = '.bin'
            filename = f'part-{counter:03d}{ext}'
        counter += 1
        with open(os.path.join(args.directory, filename), 'wb') as fp:
            fp.write(part.get_payload(decode=True))
```

```
if __name__ == '__main__':
    main()
```

Here's an example of how to create an HTML message with an alternative plain text version. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

```
#!/usr/bin/env python3

import smtplib

from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Pourquoi pas des asperges pour ce midi ?"
msg['From'] = Address("Pepé Le Pew", "pepe", "example.com")
msg['To'] = (Address("Penelope Pussycat", "penelope", "example.com"),
             Address("Fabrette Pussycat", "fabrette", "example.com"))
msg.set_content("""\
Salut!

Cette recette [1] sera sûrement un très bon repas.

[1] http://www.yummly.com/recipe/Roasted-Asparagus-Epicurious-203718

--Pepé
""")

# Add the html version.  This converts the message into a multipart/alternative
# container, with the original text message as the first part and the new html
# message as the second part.
asparagus_cid = make_msgid()
msg.add_alternative("""\
<html>
  <head></head>
  <body>
    <p>Salut!</p>
    <p>Cette
        <a href="http://www.yummly.com/recipe/Roasted-Asparagus-Epicurious-203718">
            recette
        </a> sera sûrement un très bon repas.
    </p>
    <img src="cid:{asparagus_cid}">
  </body>
</html>
""".format(asparagus_cid=asparagus_cid[1:-1]), subtype='html')
# note that we needed to peel the <> off the msgid for use in the html.

# Now add the related image to the html part.
with open("roasted-asparagus.jpg", 'rb') as img:
    msg.get_payload()[1].add_related(img.read(), 'image', 'jpeg',
                                     cid=asparagus_cid)

# Make a local copy of what we are going to send.
with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))
```

(繼續下一頁)

(繼續上一頁)

```
# Send the message via local SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

If we were sent the message from the last example, here is one way we could process it:

```
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

def magic_html_parser(html_text, partfiles):
    """Return safety-sanitized html linked to partfiles.

    Rewrite the href="cid:...." attributes to point to the filenames in partfiles.
    Though not trivial, this should be possible using html.parser.
    """
    raise NotImplementedError("Add the magic needed")

# In a real program you'd get the filename from the arguments.
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary, and any non-ASCII will
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content, we can extract whatever
# the least formatted payload is and print the first three lines.  Of course,
# if the message has no plain text part printing the first three lines of html
# is probably useless, but this is just a conceptual example.
simplest = msg.get_body(preferencelist=('plain', 'html'))
print()
print(''.join(simplest.get_content().splitlines(keepends=True)[:3]))

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()

# We can extract the richest alternative in order to display it:
richest = msg.get_body()
partfiles = {}
if richest['content-type'].maintype == 'text':
    if richest['content-type'].subtype == 'plain':
        for line in richest.get_content().splitlines():
            print(line)
        sys.exit()
    elif richest['content-type'].subtype == 'html':
        body = richest
    else:
        print("Don't know how to display {}".format(richest.get_content_type()))
```

(繼續下一頁)

(繼續上一頁)

```
        sys.exit()
elif richest['content-type'].content_type == 'multipart/related':
    body = richest.get_body(preferencelist=('html'))
    for part in richest.iter_attachments():
        fn = part.get_filename()
        if fn:
            extension = os.path.splitext(part.get_filename())[1]
        else:
            extension = mimetypes.guess_extension(part.get_content_type())
        with tempfile.NamedTemporaryFile(suffix=extension, delete=False) as f:
            f.write(part.get_content())
            # again strip the <> to go from email form of cid to html form.
            partfiles[part['content-id'][1:-1]] = f.name
else:
    print("Don't know how to display {}".format(richest.get_content_type()))
    sys.exit()
with tempfile.NamedTemporaryFile(mode='w', delete=False) as f:
    f.write(magic_html_parser(body.get_content(), partfiles))
webbrowser.open(f.name)
os.remove(f.name)
for fn in partfiles.values():
    os.remove(fn)

# Of course, there are lots of email messages that could break this simple
# minded program, but it will handle the most common ones.
```

Up to the prompt, the output from the above is:

```
To: Penelope Pussycat <penelope@example.com>, Fabrette Pussycat <fabrette@example.com>
From: Pepé Le Pew <pepe@example.com>
Subject: Pourquoi pas des asperges pour ce midi ?

Salut!

Cette recette [1] sera sûrement un très bon repas.
```

🄵解

Legacy API:

20.1.9 `email.message.Message`: Representing an email message using the `compat32` API

The *`Message`* class is very similar to the *`EmailMessage`* class, without the methods added by that class, and with the default behavior of certain other methods being slightly different. We also document here some methods that, while supported by the *`EmailMessage`* class, are not recommended unless you are dealing with legacy code.

The philosophy and structure of the two classes is otherwise the same.

This document describes the behavior under the default (for *`Message`*) policy *`Compat32`*. If you are going to use another policy, you should be using the *`EmailMessage`* class instead.

An email message consists of *headers* and a *payload*. Headers must be **RFC 5322** style names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as *`multipart/*`* or *`message/rfc822`*.

The conceptual model provided by a *`Message`* object is that of an ordered dictionary of headers with additional methods for accessing both specialized information from the headers, for accessing the payload, for generating a

serialized version of the message, and for recursively walking over the object tree. Note that duplicate headers are supported but special methods must be used to access them.

The *Message* pseudo-dictionary is indexed by the header names, which must be ASCII values. The values of the dictionary are strings that are supposed to contain only ASCII characters; there is some special handling for non-ASCII input, but it doesn't always produce the correct results. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. There may also be a single envelope header, also known as the *Unix-From* header or the `From_` header. The *payload* is either a string or bytes, in the case of simple message objects, or a list of *Message* objects, for MIME container documents (e.g. *multipart/** and *message/rfc822*).

Here are the methods of the *Message* class:

class email.message.**Message**(*policy=compat32*)

If *policy* is specified (it must be an instance of a *policy* class) use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the *policy* documentation.

在 3.3 版的變更: 新增 *policy* 關鍵字引數。

as_string(*unixfrom=False*, *maxheaderlen=0*, *policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility reasons, *maxheaderlen* defaults to `0`, so if you want a different value you must override it explicitly (the value specified for *max_line_length* in the policy will be ignored by this method). The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `Generator`.

Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the Unix mbox format. For more flexibility, instantiate a *Generator* instance and use its *flatten()* method directly. For example:

```
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=True, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode "unknown character" code points. (See also *as_bytes()* and *BytesGenerator*.)

在 3.4 版的變更: 新增 *policy* 關鍵字引數。

__str__()

Equivalent to *as_string()*. Allows `str(msg)` to produce a string containing the formatted message.

as_bytes(*unixfrom=False*, *policy=None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required

by the Unix mbox format. For more flexibility, instantiate a *BytesGenerator* instance and use its *flatten()* method directly. For example:

```
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

在 3.4 版被加入.

__bytes__()

Equivalent to *as_bytes()*. Allows `bytes(msg)` to produce a bytes object containing the formatted message.

在 3.4 版被加入.

is_multipart()

Return `True` if the message's payload is a list of sub-*Message* objects, otherwise return `False`. When *is_multipart()* returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). (Note that *is_multipart()* returning `True` does not necessarily mean that "msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the *Message* is of type `message/rfc822`.)

set_unixfrom(*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string.

get_unixfrom()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

attach(*payload*)

Add the given *payload* to the current payload, which must be `None` or a list of *Message* objects before the call. After the call, the payload will always be a list of *Message* objects. If you want to set the payload to a scalar object (e.g. a string), use *set_payload()* instead.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by *set_content()* and the related `make` and `add` methods.

get_payload(*i=None*, *decode=False*)

Return the current payload, which will be a list of *Message* objects when *is_multipart()* is `True`, or a string when *is_multipart()* is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument *i*, *get_payload()* will return the *i*-th element of the payload, counting from zero, if *is_multipart()* is `True`. An *IndexError* will be raised if *i* is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. *is_multipart()* is `False`) and *i* is given, a *TypeError* is raised.

Optional *decode* is a flag indicating whether the payload should be decoded or not, according to the *Content-Transfer-Encoding* header. When `True` and the message is not a multipart, the payload will be decoded if this header's value is `quoted-printable` or `base64`. If some other encoding is used, or *Content-Transfer-Encoding* header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the *decode* flag is `True`, then `None` is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added to the message's defect property (*InvalidBase64PaddingDefect* or *InvalidBase64CharactersDefect*, respectively).

When *decode* is `False` (the default) the body is returned as a string without decoding the *Content-Transfer-Encoding*. However, for a *Content-Transfer-Encoding* of 8bit, an attempt is made to decode the original bytes using the `charset` specified by the *Content-Type* header, using the `replace` error handler. If no `charset` is specified, or if the `charset` given is not recognized by the email package, the body is decoded using the default ASCII charset.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by *get_content()* and *iter_parts()*.

set_payload(*payload*, *charset=None*)

Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see *set_charset()* for details.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by *set_content()*.

set_charset(*charset*)

Set the character set of the payload to *charset*, which can either be a *Charset* instance (see *email.charset*), a string naming a character set, or `None`. If it is a string, it will be converted to a *Charset* instance. If *charset* is `None`, the `charset` parameter will be removed from the *Content-Type* header (the message will not be otherwise modified). Anything else will generate a *TypeError*.

If there is no existing *MIME-Version* header one will be added. If there is no existing *Content-Type* header, one will be added with a value of *text/plain*. Whether the *Content-Type* header already exists or not, its `charset` parameter will be set to *charset.output_charset*. If *charset.input_charset* and *charset.output_charset* differ, the payload will be re-encoded to the *output_charset*. If there is no existing *Content-Transfer-Encoding* header, then the payload will be transfer-encoded, if needed, using the specified *Charset*, and a header with the appropriate value will be added. If a *Content-Transfer-Encoding* header already exists, the payload is assumed to already be correctly encoded using that *Content-Transfer-Encoding* and is not modified.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by the *charset* parameter of the *email.message.EmailMessage.set_content()* method.

get_charset()

Return the *Charset* instance associated with the message's payload.

This is a legacy method. On the *EmailMessage* class it always returns `None`.

The following methods implement a mapping-like interface for accessing the message's **RFC 2822** headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()*, but in a *Message* object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as *Header* objects with a charset of `unknown-8bit`.

__len__()

Return the total number of headers, including duplicates.

__contains__(*name*)

Return `True` if the message object has a field named *name*. Matching is done case-insensitively and *name* should not include the trailing colon. Used for the `in` operator, e.g.:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id'])
```

__getitem__(*name*)

Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, `None` is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant named headers.

__setitem__(*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

__delitem__(*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()

Return a list of all the message's header field names.

values()

Return a list of all the message's field values.

items()

Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj=None*)

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (defaults to `None`).

Here are some additional useful methods:

get_all(*name*, *failobj=None*)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)

Extended header setting. This method is similar to *__setitem__()* except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added. If the value contains non-ASCII characters, it can be specified as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value, `LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

以下是個範例：

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1''Fu%DFballer.ppt"
```

replace_header(*_name*, *_value*)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case. If no matching header was found, a *KeyError* is raised.

get_content_type()

Return the message's content type. The returned string is coerced to lower case of the form *maintype/subtype*. If there was no *Content-Type* header in the message the default type as given by *get_default_type()* will be returned. Since according to **RFC 2045**, messages always have a default type, *get_content_type()* will always return a value.

RFC 2045 defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.

get_content_maintype()

Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

get_content_subtype()

Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

get_params(*failobj=None*, *header='content-type'*, *unquote=True*)

Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the `'='` sign. The left hand side of the `'='` is the key, while the right hand side is the value. If there is no `'='` sign in the parameter the value is the empty string, otherwise the value is as described in *get_param()* and is unquoted if optional *unquote* is `True` (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

get_param(*param*, *failobj=None*, *header='content-type'*, *unquote=True*)

Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to `None`).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was **RFC 2231** encoded. When it's a 3-tuple, the elements of the value are of the form `(CHARSET, LANGUAGE, VALUE)`. Note that both `CHARSET` and `LANGUAGE` can be `None`, in which case you should consider `VALUE` to be encoded in the `us-ascii` charset. You can usually ignore `LANGUAGE`.

If your application doesn't care whether the parameter was encoded as in **RFC 2231**, you can collapse the parameter value by calling *email.utils.collapse_rfc2231_value()*, passing in the return value from *get_param()*. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn't. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the `VALUE` item in the 3-tuple) is always unquoted, unless *unquote* is set to `False`.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

set_param(*param*, *value*, *header='Content-Type'*, *requote=True*, *charset=None*, *language=''*, *replace=False*)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, its value will be replaced with *value*. If the *Content-Type* header as not yet been defined for this message, it will be set to *text/plain* and the new parameter value will be appended as per **RFC 2045**.

Optional *header* specifies an alternative header to *Content-Type*, and all parameters will be quoted as necessary unless optional *requote* is `False` (the default is `True`).

If optional *charset* is specified, the parameter will be encoded according to **RFC 2231**. Optional *language* specifies the RFC 2231 language, defaulting to the empty string. Both *charset* and *language* should be strings.

If *replace* is `False` (the default) the header is moved to the end of the list of headers. If *replace* is `True`, the header will be updated in place.

在 3.4 版的變更: `replace` keyword was added.

del_param(*param*, *header='content-type'*, *requote=True*)

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless *requote* is `False` (the default is `True`). Optional *header* specifies an alternative to *Content-Type*.

set_type(*type*, *header='Content-Type'*, *requote=True*)

Set the main type and subtype for the *Content-Type* header. *type* must be a string in the form *maintype/subtype*, otherwise a *ValueError* is raised.

This method replaces the *Content-Type* header, keeping all the parameters in place. If *requote* is `False`, this leaves the existing header's quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the *header* argument. When the *Content-Type* header is set a *MIME-Version* header is also added.

This is a legacy method. On the *EmailMessage* class its functionality is replaced by the `make_` and `add_` methods.

get_filename(*failobj=None*)

Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per *email.utils.unquote()*.

get_boundary(*failobj=None*)

Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per *email.utils.unquote()*.

set_boundary(*boundary*)

Set the `boundary` parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of

the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

get_content_charset(*failobj=None*)

Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

Note that this method differs from *get_charset()* which returns the *Charset* instance for the default encoding of the message body.

get_charsets(*failobj=None*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

get_content_disposition()

Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183**.

在 3.5 版被加入.

walk()

The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where *is_multipart()* returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart',
...           part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the *Generator* to print a newline at the end of the file.

defects

The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

20.1.10 email.mime：從頭開始建立電子郵件和 MIME 物件

原始碼： Lib/email/mime/

This module is part of the legacy (`Compat32`) email API. Its functionality is partially replaced by the *contentmanager* in the new API, but in certain applications these classes may still be useful, even in non-legacy code.

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual *Message* objects by hand. In fact, you can also take an existing structure and add new *Message* objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating *Message* instances, adding attachments and all the appropriate headers manually. For MIME messages though, the *email* package provides some convenient subclasses to make things easier.

Here are the classes:

class email.mime.base.**MIMEBase**(*_maintype*, *_subtype*, *, *policy=compat32*, ***_params*)

模組：*email.mime.base*

This is the base class for all the MIME-specific subclasses of *Message*. Ordinarily you won't create instances specifically of *MIMEBase*, although you could. *MIMEBase* is provided primarily as a convenient base class for more specific MIME-aware subclasses.

_maintype is the *Content-Type* major type (e.g. *text* or *image*), and *_subtype* is the *Content-Type* minor type (e.g. *plain* or *gif*). *_params* is a parameter key/value dictionary and is passed directly to *Message.add_header*.

If *policy* is specified, (defaults to the *compat32* policy) it will be passed to *Message*.

The *MIMEBase* class always adds a *Content-Type* header (based on *_maintype*, *_subtype*, and *_params*), and a *MIME-Version* header (always set to `1.0`).

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.nonmultipart.**MIMENonMultipart**

模組: *email.mime.nonmultipart*

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are not *multipart*. The primary purpose of this class is to prevent the use of the *attach()* method, which only makes sense for *multipart* messages. If *attach()* is called, a *MultipartConversionError* exception is raised.

class email.mime.multipart.**MIMEMultipart**(*_subtype='mixed'*, *boundary=None*, *_subparts=None*, ***, *policy=compat32*, ***_params*)

模組: *email.mime.multipart*

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are *multipart*. Optional *_subtype* defaults to *mixed*, but can be used to specify the subtype of the message. A *Content-Type* header of *multipart/_subtype* will be added to the message object. A *MIME-Version* header will also be added.

Optional *boundary* is the multipart boundary string. When `None` (the default), the boundary is calculated when needed (for example, when the message is serialized).

_subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the *Message.attach* method.

Optional *policy* argument defaults to *compat32*.

Additional parameters for the *Content-Type* header are taken from the keyword arguments, or passed into the *_params* argument, which is a keyword dictionary.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.application.**MIMEApplication**(*_data*, *_subtype='octet-stream'*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

模組: *email.mime.application*

A subclass of *MIMENonMultipart*, the *MIMEApplication* class is used to represent MIME message objects of major type *application*. *_data* contains the bytes for the raw application data. Optional *_subtype* specifies the MIME subtype and defaults to *octet-stream*.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the *MIMEApplication* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the base class constructor.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.audio.**MIMEAudio**(*_audiodata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

模組: *email.mime.audio*

A subclass of *MIMENonMultipart*, the *MIMEAudio* class is used to create MIME message objects of major type *audio*. *_audiodata* contains the bytes for the raw audio data. If this data can be decoded as au, wav, aiff, or aifc, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the *MIMEAudio* instance. It should use

get_payload() and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the base class constructor.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.image.**MIMEImage**(*_imagedata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

模組: *email.mime.image*

A subclass of *MIMENonMultipart*, the *MIMEImage* class is used to create MIME message objects of major type *image*. *_imagedata* contains the bytes for the raw image data. If this data type can be detected (jpeg, png, gif, tiff, rgb, pbm, pgm, ppm, rast, xbm, bmp, webp, and exr attempted), then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the *MIMEImage* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the *MIMEBase* constructor.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.message.**MIMEMessage**(*_msg*, *_subtype='rfc822'*, ***, *policy=compat32*)

模組: *email.mime.message*

A subclass of *MIMENonMultipart*, the *MIMEMessage* class is used to create MIME objects of main type *message*. *_msg* is used as the payload, and must be an instance of class *Message* (or a subclass thereof), otherwise a *TypeError* is raised.

Optional *_subtype* sets the subtype of the message; it defaults to *rfc822*.

Optional *policy* argument defaults to *compat32*.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

class email.mime.text.**MIMEText**(*_text*, *_subtype='plain'*, *_charset=None*, ***, *policy=compat32*)

模組: *email.mime.text*

A subclass of *MIMENonMultipart*, the *MIMEText* class is used to create MIME objects of major type *text*. *_text* is the string for the payload. *_subtype* is the minor type and defaults to *plain*. *_charset* is the character set of the text and is passed as an argument to the *MIMENonMultipart* constructor; it defaults to `us-ascii` if the string contains only `ascii` code points, and `utf-8` otherwise. The *_charset* parameter accepts either a string or a *Charset* instance.

Unless the *_charset* argument is explicitly set to `None`, the MIMEText object created will have both a *Content-Type* header with a `charset` parameter, and a *Content-Transfer-Encoding* header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can "reset" this behavior by deleting the `Content-Transfer-Encoding` header, after which a `set_payload` call will automatically encode the new payload (and add a new *Content-Transfer-Encoding* header).

Optional *policy* argument defaults to *compat32*.

在 3.5 版的變更: *_charset* also accepts *Charset* instances.

在 3.6 版的變更: 新增僅限關鍵字參數 *policy*。

20.1.11 email.header：國際化標頭

原始碼： Lib/email/header.py

This module is part of the legacy (`Compat32`) email API. In the current API encoding and decoding of headers is handled transparently by the dictionary-like API of the *`EmailMessage`* class. In addition to uses in legacy code, this module can be useful in applications that need to completely control the character sets used when encoding headers.

The remaining text in this section is the original documentation of the module.

RFC 2822 is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**. The *`email`* package supports these standards in its *`email.header`* and *`email.charset`* modules.

If you want to include non-ASCII characters in your email headers, say in the *`Subject`* or *`To`* fields, you should use the *`Header`* class and assign the field in the *`Message`* object to an instance of *`Header`* instead of using a string for the header value. Import the *`Header`* class from the *`email.header`* module. For example:

```
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
'Subject: =?iso-8859-1?q?p=F6stal?=\n\n'
```

Notice here how we wanted the *`Subject`* field to contain a non-ASCII character? We did this by creating a *`Header`* instance and passing in the character set that the byte string was encoded in. When the subsequent *`Message`* instance was flattened, the *`Subject`* field was properly **RFC 2047** encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the *`Header`* class description:

class email.header.**Header**(*s=None*, *charset=None*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*, *errors='strict'*)

Create a MIME-compliant header that can contain strings in different character sets.

Optional *s* is the initial header value. If `None` (the default), the initial header value is not set. You can later append to the header with *`append()`* method calls. *s* may be an instance of *`bytes`* or *`str`*, but see the *`append()`* documentation for semantics.

Optional *charset* serves two purposes: it has the same meaning as the *charset* argument to the *`append()`* method. It also sets the default character set for all subsequent *`append()`* calls that omit the *charset* argument. If *charset* is not provided in the constructor (the default), the `us-ascii` character set is used both as *s*'s initial charset and as the default for subsequent *`append()`* calls.

The maximum line length can be specified explicitly via *maxlinelen*. For splitting the first line to a shorter value (to account for the field header which isn't included in *s*, e.g. *`Subject`*) pass in the name of the field in *header_name*. The default *maxlinelen* is 78, and the default value for *header_name* is `None`, meaning it is not taken into account for the first line of a long, split header.

Optional *continuation_ws* must be **RFC 2822**-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. *continuation_ws* defaults to a single space character.

Optional *errors* is passed straight through to the `append()` method.

append(*s*, *charset=None*, *errors='strict'*)

Append the string *s* to the MIME header.

Optional *charset*, if given, should be a `Charset` instance (see `email.charset`) or the name of a character set, which will be converted to a `Charset` instance. A value of `None` (the default) means that the *charset* given in the constructor is used.

s may be an instance of `bytes` or `str`. If it is an instance of `bytes`, then *charset* is the encoding of that byte string, and a `UnicodeError` will be raised if the string cannot be decoded with that character set.

If *s* is an instance of `str`, then *charset* is a hint specifying the character set of the characters in the string.

In either case, when producing an **RFC 2822**-compliant header using **RFC 2047** rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional *errors* is passed as the errors argument to the decode call if *s* is a byte string.

encode(*splitchars=';, \t'*, *maxlinelen=None*, *linesep='\n'*)

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional *splitchars* is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of **RFC 2822**'s 'higher level syntactic breaks': split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect **RFC 2047** encoded lines.

maxlinelen, if given, overrides the instance's value for the maximum line length.

linesep specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (`\n`), but `\r\n` can be specified in order to produce headers with RFC-compliant line separators.

在 3.2 版的變更: 新增引數 *linesep*。

The `Header` class also provides a number of methods to support standard operators and built-in functions.

__str__()

Returns an approximation of the `Header` as a string, using an unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of `'unknown-8bit'` are decoded as ASCII using the `'replace'` error handler.

在 3.2 版的變更: Added handling for the `'unknown-8bit'` charset.

__eq__(*other*)

This method allows you to compare two `Header` instances for equality.

__ne__(*other*)

This method allows you to compare two `Header` instances for inequality.

The `email.header` module also provides the following convenient functions.

email.header.**decode_header**(*header*)

Decode a message header value without converting the character set. The header value is in *header*.

For historical reasons, this function may return either:

1. A list of pairs containing each of the decoded parts of the header, `(decoded_bytes, charset)`, where *decoded_bytes* is always an instance of `bytes`, and *charset* is either:
   - A lower case string containing the name of the character set specified.
   - `None` for non-encoded parts of the header.

2. A list of length 1 containing a pair `(string, None)`, where *string* is always an instance of *str*.

An *email.errors.HeaderParseError* may be raised when certain decoding errors occur (e.g. a base64 decoding exception).

以下🄵範例：

```
>>> from email.header import decode_header
>>> decode_header('=?iso-8859-1?q?p=F6stal?=')
[(b'p\xf6stal', 'iso-8859-1')]
>>> decode_header('unencoded_string')
[('unencoded_string', None)]
>>> decode_header('bar =?utf-8?B?ZsOzbw==?=')
[(b'bar ', None), (b'f\xc3\xb3o', 'utf-8')]
```

備🄵

This function exists for backwards compatibility only. For new code, we recommend using *email.headerregistry.HeaderRegistry*.

email.header.**make_header**(*decoded_seq*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*)

Create a *Header* instance from a sequence of pairs as returned by *decode_header()*.

decode_header() takes a header value string and returns a sequence of pairs of the format `(decoded_string, charset)` where *charset* is the name of the character set.

This function takes one of those sequence of pairs and returns a *Header* instance. Optional *maxlinelen*, *header_name*, and *continuation_ws* are as in the *Header* constructor.

備🄵

This function exists for backwards compatibility only, and is not recommended for use in new code.

20.1.12 email.charset：字元集合的表示

原始碼： Lib/email/charset.py

此模組是舊版 (`Compat32`) email API 的其中一部份，在新版的 API 只有使用🄵名表。

此章節的其余🄵容是模組的原始🄵明文件

此模組提供一個類🄵*Charset* 來表示電子郵件訊息中的字元集合和字元集合轉🄵，也包含字元集合登🄵檔 (registry) 和其他許多運用此登🄵檔的便捷方法。*Charset* 的實例被*email* 套件中其他數個模組所使用。

從*email.charset* 模組中引入此類🄵

class email.charset.**Charset**(*input_charset=DEFAULT_CHARSET*)

將字元集合對映到其電子郵件特性 (properties)。

此類🄵提供有關於電子郵件對特定字元集合的規範資訊。考慮到適用之編解碼器 (codec) 的可用性，它還提供了在字元集合之間進行轉🄵的便利例行操作 (routine)。給定一個字元集合，它將盡量提供有關如何以符合 RFC (RFC-compliant) 的方式在電子郵件訊息中使用該字元集合的資訊。

在電子郵件標頭 (header) 或🄵文 (body) 用特定字元集合時必須使用可列印字元編碼 (quoted-printable) 或 base64 來編碼。特定字元集合不允許出現在電子郵件中、必須被徹底轉🄵。

可選的 *input_charset* 描述如下；*input_charset* 會被🄵制轉🄵 (coerced) 🄵小寫。經過🄵名標准化 (alias normalize) 後，會進到字元集合登🄵檔 (registry) 去查詢此字元集合使用的標頭編碼、🄵文編碼以及輸出轉🄵編解碼器。舉例來🄵，如果 *input_charset* 是 `iso-8859-1`，標頭跟🄵文會以可列印字元編

碼🄵且不需要輸出轉🄵編解碼器。如果 *input_charset* 是 `euc-jp`，標頭則會被編碼成 base64、🄵文不會被編碼，但輸出文字則會從 `euc-jp` 字元集合被轉🄵成 `iso-2022-jp` 字元集合。

Charset 實例有以下資料屬性：

input_charset

指定的初始字元集合。通用🄵名會被轉🄵成它們的官方電子郵件名稱（例如：`latin_1` 會被轉🄵成 `iso-8859-1`）。預設🄵 7 位元 `us-ascii`。

header_encoding

如果字元集合在被用於電子郵件標頭前必須被編碼的話，這個屬性會被設🄵 `charset.QP`（表示可列印字元編碼）、`charset.BASE64`（表示 base64 編碼格式）或是 `charset.SHORTEST` 表示最短的 QP 或是 base64 編碼格式。不然這個屬性會是 `None`。

body_encoding

與 *header_encoding* 相同，但表示郵件訊息🄵文的編碼，與上述的標頭編碼有可能不同。`charset.SHORTEST` 是不允許於 *body_encoding* 使用的。

output_charset

部分的字元集合在用於電子郵件的標頭或🄴文前必須先被轉🄵。如果 *input_charset* 是這些字元集合的其中之一，這個屬性將會包含輸出時轉🄴成的字元集合名稱。不然這個屬性則🄵 `None`。

input_codec

用於將 *input_charset* 轉🄵成 Unicode 的 Python 編解碼器的名稱。如果不需要轉🄵編解碼器，這個屬性🄵 `None`。

output_codec

用於將 Unicode 轉🄵成 *output_charset* 的 Python 編解碼器名稱。如果不需要轉🄵編解碼器，這個屬性將會與 *input_codec* 有相同的值。

Charset 實例還有以下方法：

get_body_encoding()

回傳用於🄵文編碼的🄵容傳輸編碼 (content transfer encoding)。

這可以是字串 `quoted-printable` 或 `base64`，具體取🄵於所使用的編碼，或者它也可以是一個函式，在這種情🄵下，你應該使用單個引數呼叫該函式，即正被編碼的 Message 物件。然後函式應將 *Content-Transfer-Encoding* 標頭本身設定🄵任何適當的值。

如果 *body_encoding* 🄵 `QP` 則回傳字串 `quoted-printable`，如果 *body_encoding* 🄵 `BASE64` 則回傳字串 `base64`，否則回傳字串 `7bit` 。

get_output_charset()

回傳輸出字元集合。

如果不🄵 `None` 則這會是 *output_charset* 屬性，否則它是 *input_charset*。

header_encode(*string*)

對字串 *string* 進行標頭編碼 (header-encode)。

編碼類型（base64 或可列印字元編碼）將基於 *header_encoding* 屬性。

header_encode_lines(*string*, *maxlengths*)

透過先將 *string* 轉🄵🄵位元組來對它進行標頭編碼。

這與*header_encode()* 類似，只不過字串不會超過由引數 *maxlengths* 給定的最大列長度 (maximum line length)，該引數必須是個🄴代器：從此🄴代器回傳的每個元素將提供下一個最大列長度。

body_encode(*string*)

對字串 *string* 進行🄵文編碼 (body-encode)。

編碼類型（base64 或可列印字元編碼）將基於 *body_encoding* 屬性。

Charset 類🄵也提供了許多支援標准操作和🄵建函式的方法。

__str__()
回傳🄵制轉🄵 *input_charset* 🄵小寫後的字串。__repr__() 是 __str__() 的🄵名。

__eq__(*other*)
此方法讓你比較兩個*Charset* 實例的相等性。

__ne__(*other*)
此方法讓你比較兩個*Charset* 實例的不相等性。

email.charset 模組還提供以下函式，用於將項目新增至全域字元集合、🄵名和編解碼器登🄵檔中：

email.charset.**add_charset**(*charset*, *header_enc=None*, *body_enc=None*, *output_charset=None*)
將字元特性 (properties) 新增至全域登🄵檔。

charset 是輸入的字元集合，且必須是字元集合的規範名稱 (canonical name)。

可選的 *header_enc* 和 *body_enc* 🄵 charset.QP（表示可列印字元編碼）、charset.BASE64（表示 base64 編碼）、charset.SHORTEST（表示最短的 base64 或可列印字元編碼）或 None（表示無編碼）。SHORTEST 僅在用於 *header_enc* 時有效。預設🄵 None，表示無編碼。

可選的 *output_charset* 是輸出應🄵用的字元集合。當呼叫 Charset.convert() 方法時，將從輸入字元集合轉🄵🄵 Unicode，再轉🄵🄵輸出字元集合。預設是以與輸入相同的字元集合輸出。

input_charset 和 *output_charset* 都必須在模組的字元集合到編解碼器對映 (character set-to-codec mapping) 中具有 Unicode 編解碼器項目；使用*add_codec()* 來新增模組未知的編解碼器。有關更多資訊請參🄵*codecs* 模組的文件。

全域字元集合登🄵檔保存在模組全域字典 CHARSETS 中。

email.charset.**add_alias**(*alias*, *canonical*)
新增字元集合🄵名。*alias* 是🄵名，例如 latin-1。*canonical* 是字元集合的規範名稱，例如 iso-8859-1。

全域字元集合🄵名登🄵檔保存在模組全域字典 ALIASES 中。

email.charset.**add_codec**(*charset*, *codecname*)
新增一個編解碼器，將給定字元集合中的字元與 Unicode 進行對映。

charset 是字元集合的規範名稱。*codecname* 是 Python 編解碼器的名稱，適用於*str* 的*encode()* 方法的第二個引數。

20.1.13 email.encoders：編碼器

原始碼： Lib/email/encoders.py

此模組是舊版 (Compat32) 電子郵件 API 的一部分。在新 API 中，此功能由*set_content()* 方法的 *cte* 參數提供。

此模組在 Python 3 中已🄵用。不應明確呼叫此處提供的函式，因🄵*MIMEText* 類🄴使用在該類🄵的實例化過程中傳遞的 *_subtype* 和 *_charset* 值來設定🄵容類型 (content type) 和 CTE 標頭。

本節中的其余文字是該模組的原始文件。

從零開始建立*Message* 物件時，你通常需要對負載 (payload) 進行編碼，以便透過相容的郵件伺服器進行傳輸。對於包含二進位資料的 *image/** 和 *text/** 類型的訊息尤其如此。

email 套件在其*encoders* 模組中提供了一些方便的編碼器。這些編碼器實際上由*MIMEAudio* 和*MIMEImage* 類🄵建構函式使用來提供預設編碼。所有編碼器函式都只接受一個引數，也就是要編碼的訊息物件。他們通常會提取負載、對其進行編碼，然後將負載重設🄵新編碼的值。他們也應適當地設定 *Content-Transfer-Encoding* 標頭。

請注意，這些函式對於多部分訊息 (multipart message) 🄵有意義。它們必須應用於各個子部分，如果傳遞類型🄵多部分訊息，則會引發*TypeError*。

以下是提供的編碼函式：

email.encoders.**encode_quopri**(*msg*)

將負載編碼🄵可列印字元 (quoted-printable) 形式，🄵將 *Content-Transfer-Encoding* 標頭設定🄵 `quoted-printable`[1]。當大部分負載是正常的可列印資料，但包含一些不可列印的字元時，這是一種很好的編碼。

email.encoders.**encode_base64**(*msg*)

將負載編碼🄵 base64 形式，🄵將 *Content-Transfer-Encoding* 標頭設定🄵 `base64`。當大部分負載是不可列印資料時，這是一種很好的編碼，因🄵它是比可列印字元更緊🄵的形式。Base64 編碼的缺點是它使文字無法讓人類可讀。

email.encoders.**encode_7or8bit**(*msg*)

這實際上🄵🄵有修改訊息的負載，但它確實根據負載資料將 *Content-Transfer-Encoding* 標頭設定🄵適當的 `7bit` 或 `8bit`。

email.encoders.**encode_noop**(*msg*)

這🄵有任何作用；它甚至🄵有設定 *Content-Transfer-Encoding* 標頭。

20.1.14 email.utils：雜項工具

原始碼： Lib/email/utils.py

There are a couple of useful utilities provided in the *email.utils* module:

email.utils.**localtime**(*dt=None*)

Return local time as an aware datetime object. If called without arguments, return current time. Otherwise *dt* argument should be a *datetime* instance, and it is converted to the local time zone according to the system time zone database. If *dt* is naive (that is, `dt.tzinfo` is `None`), it is assumed to be in local time.

在 3.3 版被加入.

Deprecated since version 3.12, removed in version 3.14: The *isdst* parameter.

email.utils.**make_msgid**(*idstring=None*, *domain=None*)

Returns a string suitable for an **RFC 2822**-compliant *Message-ID* header. Optional *idstring* if given, is a string used to strengthen the uniqueness of the message id. Optional *domain* if given provides the portion of the msgid after the '@'. The default is the local hostname. It is not normally necessary to override this default, but may be useful certain cases, such as a constructing distributed system that uses a consistent domain name across multiple hosts.

在 3.2 版的變更: 新增 *domain* 關鍵字。

The remaining functions are part of the legacy (`Compat32`) email API. There is no need to directly use these with the new API, since the parsing and formatting they provide is done automatically by the header parsing machinery of the new API.

email.utils.**quote**(*str*)

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

email.utils.**unquote**(*str*)

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

email.utils.**parseaddr**(*address*, ***, *strict=True*)

Parse address -- which should be the value of some address-containing field such as *To* or *Cc* -- into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of `('', '')` is returned.

If *strict* is true, use a strict parser which rejects malformed inputs.

在 3.13 版的變更: Add *strict* optional parameter and reject malformed inputs by default.

[1] 請注意，使用*encode_quopri()* 進行編碼也會對資料中的所有定位字元 (tab) 和空格字元進行編碼。

email.utils.**formataddr**(*pair*, *charset='utf-8'*)

The inverse of *parseaddr()*, this takes a 2-tuple of the form `(realname, email_address)` and returns the string value suitable for a `To` or `Cc` header. If the first element of *pair* is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the **RFC 2047** encoding of the `realname` if the `realname` contains non-ASCII characters. Can be an instance of *str* or a *Charset*. Defaults to `utf-8`.

在 3.3 版的變更: 新增 *charset* 選項。

email.utils.**getaddresses**(*fieldvalues*, *, *strict=True*)

This method returns a list of 2-tuples of the form returned by `parseaddr()`. *fieldvalues* is a sequence of header field values as might be returned by *Message.get_all*.

If *strict* is true, use a strict parser which rejects malformed inputs.

Here's a simple example that gets all the recipients of a message:

```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

在 3.13 版的變更: Add *strict* optional parameter and reject malformed inputs by default.

email.utils.**parsedate**(*date*)

Attempts to parse a date according to the rules in **RFC 2822**. however, some mailers don't follow that format as specified, so *parsedate()* tries to guess correctly in such cases. *date* is a string containing an **RFC 2822** date, such as `"Mon, 20 Nov 1995 19:12:08 -0500"`. If it succeeds in parsing the date, *parsedate()* returns a 9-tuple that can be passed directly to *time.mktime()*; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.**parsedate_tz**(*date*)

Performs the same function as *parsedate()*, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to *time.mktime()*, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time)[1]. If the input string has no timezone, the last element of the tuple returned is `0`, which represents UTC. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.**parsedate_to_datetime**(*date*)

The inverse of *format_datetime()*. Performs the same function as *parsedate()*, but on success returns a *datetime*; otherwise `ValueError` is raised if *date* contains an invalid value such as an hour greater than 23 or a timezone offset not between -24 and 24 hours. If the input date has a timezone of `-0000`, the `datetime` will be a naive `datetime`, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the `datetime` will be an aware `datetime` with the corresponding a *timezone tzinfo*.

在 3.3 版被加入.

email.utils.**mktime_tz**(*tuple*)

Turn a 10-tuple as returned by *parsedate_tz()* into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

email.utils.**formatdate**(*timeval=None*, *localtime=False*, *usegmt=False*)

Returns a date string as per **RFC 2822**, e.g.:

[1] Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows **RFC 2822**.

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional *timeval* if given is a floating-point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.

Optional *localtime* is a flag that when `True`, interprets *timeval*, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional *usegmt* is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when *localtime* is `False`. The default is `False`.

`email.utils.`**`format_datetime`**(*dt*, *usegmt=False*)

Like `formatdate`, but the input is a `datetime` instance. If it is a naive datetime, it is assumed to be "UTC with no information about the source timezone", and the conventional `-0000` is used for the timezone. If it is an aware `datetime`, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then *usegmt* may be set to `True`, in which case the string `GMT` is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

在 3.3 版被加入.

`email.utils.`**`decode_rfc2231`**(*s*)

Decode the string *s* according to **RFC 2231**.

`email.utils.`**`encode_rfc2231`**(*s*, *charset=None*, *language=None*)

Encode the string *s* according to **RFC 2231**. Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, *s* is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

`email.utils.`**`collapse_rfc2231_value`**(*value*, *errors='replace'*, *fallback_charset='us-ascii'*)

When a header parameter is encoded in **RFC 2231** format, `Message.get_param` may return a 3-tuple containing the character set, language, and value. `collapse_rfc2231_value()` turns this into a unicode string. Optional *errors* is passed to the *errors* argument of `str`'s `encode()` method; it defaults to `'replace'`. Optional *fallback_charset* specifies the character set to use if the one in the **RFC 2231** header is not known by Python; it defaults to `'us-ascii'`.

For convenience, if the *value* passed to `collapse_rfc2231_value()` is not a tuple, it should be a string and it is returned unquoted.

`email.utils.`**`decode_params`**(*params*)

Decode parameters list according to **RFC 2231**. *params* is a sequence of 2-tuples containing elements of the form `(content-type, string-value)`.

20.1.15 `email.iterators`: 代器

原始碼： Lib/email/iterators.py

Iterating over a message object tree is fairly easy with the `Message.walk` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

`email.iterators.`**`body_line_iterator`**(*msg*, *decode=False*)

This iterates over all the payloads in all the subparts of *msg*, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn't a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.

Optional *decode* is passed through to `Message.get_payload`.

email.iterators.**typed_subpart_iterator**(*msg*, *maintype='text'*, *subtype=None*)

This iterates over all the subparts of *msg*, returning only those subparts that match the MIME type specified by *maintype* and *subtype*.

Note that *subtype* is optional; if omitted, then subpart MIME type matching is done only with the main type. *maintype* is optional too; it defaults to `text`.

Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`.

The following function has been added as a useful debugging tool. It should *not* be considered part of the supported public interface for the package.

email.iterators.**_structure**(*msg*, *fp=None*, *level=0*, *include_default=False*)

Prints an indented representation of the content types of the message object structure. For example:

```
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
    text/plain
    text/plain
    multipart/digest
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
    text/plain
```

Optional *fp* is a file-like object to print the output to. It must be suitable for Python's `print()` function. *level* is used internally. *include_default*, if true, prints the default type as well.

20.2 `json` --- JSON 編碼器與解碼器

原始碼： Lib/json/__init__.py

JSON (JavaScript Object Notation) 是一個輕量化的資料交🄵格式，在 **RFC 7159**（其廢🄵了 **RFC 4627**）及 ECMA-404 🄵面有詳細🄵明，它🄵發自 JavaScript 的物件字面語法 (object literal syntax)（雖然它🄵不是 JavaScript 的嚴格子集[1]）。

[1] 如 RFC 7159 更正 所述，JSON 允許字串中出現 U+2028（列分隔符）和 U+2029（段落分隔符）字元，而 JavaScript（截至 ECMAScript 5.1 版）則不允許。

備🄵

The term ”object” in the context of JSON processing in Python can be ambiguous. All values in Python are objects. In JSON, an object refers to any data wrapped in curly braces, similar to a Python dictionary.

警告

當剖析無法信任來源的 JSON 資料時要小心。一段惡意的 JSON 字串可能會導致解碼器耗費大量 CPU 與記憶體資源。建議限制剖析資料的大小。

此模組🄵習慣標准函式庫*marshal* 與*pickle* 模組的使用者提供熟悉的 API。

對基本 Python 物件階層進行編碼：

```
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}])
'["foo", {"bar": ["baz", null, 1.0, 2]}]'
>>> print(json.dumps("\"foo\bar"))
"\"foo\bar"
>>> print(json.dumps('\u1234'))
"\u1234"
>>> print(json.dumps('\\'))
"\\"
>>> print(json.dumps({"c": 0, "b": 0, "a": 0}, sort_keys=True))
{"a": 0, "b": 0, "c": 0}
>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'["streaming API"]'
```

改用緊🄵型編碼方式：

```
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators=(',', ':'))
'[1,2,3,{"4":5,"6":7}]'
```

美化輸出：

```
>>> import json
>>> print(json.dumps({'6': 7, '4': 5}, sort_keys=True, indent=4))
{
    "4": 5,
    "6": 7
}
```

自訂 JSON 物件編碼方式：

```
>>> import json
>>> def custom_json(obj):
...     if isinstance(obj, complex):
...         return {'__complex__': True, 'real': obj.real, 'imag': obj.imag}
...     raise TypeError(f'Cannot serialize object of {type(obj)}')
...
>>> json.dumps(1 + 2j, default=custom_json)
'{"__complex__": true, "real": 1.0, "imag": 2.0}'
```

JSON 解碼：

```
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]')
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']
```

自訂 JSON 物件解碼方式：

```
>>> import json
>>> def as_complex(dct):
...     if '__complex__' in dct:
...         return complex(dct['real'], dct['imag'])
...     return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}',
...     object_hook=as_complex)
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')
```

繼承*JSONEncoder*類🄵🄵自行擴充額外的編碼方法：

```
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise the TypeError
...         return super().default(obj)
...
>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[2.0', ', 1.0', ']']
```

在 shell 使用*json*來驗證和美化印出：

```
$ echo '{"json":"obj"}' | python -m json
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json
Expecting property name enclosed in double quotes: line 1 column 2 (char 1)
```

更詳盡的文件請見命令列介面。

備🄵

JSON 語法是 YAML 1.2 語法的一種子集合。所以如果使用預設的設定的話（准確來🄴，使用預設的 *separators* 分隔符設定的話），這個模組的輸出也符合 YAML 1.0 和 1.1 的子集合規範。因此你也可以利用這個模組來當作 YAML 的序列化工具（serializer）。

備🄵

這個模組的編、解碼器預設會保存輸入與輸出資料的順序關🄵，除非一開始的輸入本身就是無序的。

20.2.1 基本用法

json.**dump**(*obj*, *fp*, *, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *cls=None*, *indent=None*, *separators=None*, *default=None*, *sort_keys=False*, ***kw*)

參考這個*Python-to-JSON 轉🄵表*將 *obj* 序列化🄵符合 JSON 格式的串流，🄵寫入到 *fp*（一個支援 `.write()` 方法的*file-like object*）

備🄵

與*pickle* 和*marshal* 不同，JSON 不具有二進位分框（binary framed）的協定，因此嘗試重🄵呼叫*dump()* 來序列化多個物件到同一個 *fp* 🄵將導致無效的 JSON 檔案。

參數

- **obj** (object) -- 要被序列化的 Python 物件。
- **fp** (*file-like object*) -- The file-like object *obj* will be serialized to. The `json` module always produces *str* objects, not *bytes* objects, therefore `fp.write()` must support *str* input.
- **skipkeys** (bool) -- If `True`, keys that are not of a basic type (*str*, *int*, *float*, *bool*, `None`) will be skipped instead of raising a *TypeError*. Default `False`.
- **ensure_ascii** (bool) -- If `True` (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `False`, these characters will be outputted as-is.
- **check_circular** (bool) -- 如🄵 `False`，則針對不同容器型🄵的循環參照 (circular reference) 檢查將會被跳過，若有循環參照則最後將引發*RecursionError*（或其他更糟的錯誤）。預設🄵 `True`。
- **allow_nan** (bool) -- 如🄵 `False`，則序列化不符合嚴格 JSON 規範的超出範圍*float* 值 (`nan`, `inf`, `-inf`) 會引發*ValueError*。如🄵 `True`（預設值），則將使用它們的 JavaScript 等效表示 (`NaN`, `Infinity`, `-Infinity`)。
- **cls** (a *JSONEncoder* subclass) -- If set, a custom JSON encoder with the *default()* method overridden, for serializing into custom datatypes. If `None` (the default), `JSONEncoder` is used.
- **indent** (*int* | *str* | *None*) -- If a positive integer or string, JSON array elements and object members will be pretty-printed with that indent level. A positive integer indents that many spaces per level; a string (such as `"\t"`) is used to indent each level. If zero, negative, or `""` (the empty string), only newlines are inserted. If `None` (the default), the most compact representation is used.
- **separators** (*tuple* | *None*) -- 一個二元組：`(item_separator, key_separator)`。如🄵 `None`（預設值）則 *separators* 被預設🄵 `(', ', ': ')`，否則預設🄵 `(',', ': ')`。想要獲得最緊🄵的 JSON 表示形式，你可以指定 `(',', ':')` 來消除空格。
- **default** (*callable* | None) -- A function that is called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a *TypeError*. If `None` (the default), `TypeError` is raised.
- **sort_keys** (bool) -- If `True`, dictionaries will be outputted sorted by key. Default `False`.

在 3.2 版的變更: 除了整數之外，*indent* 還允許使用字串作🄵輸入。

在 3.4 版的變更: 如果 *indent* 不是 `None`，則使用 `(',', ': ')` 作🄵預設值

在 3.6 版的變更: 所有可選參數現在都是僅限關鍵字參數了。

`json.`**`dumps`**(*obj*, *, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *cls=None*, *indent=None*, *separators=None*, *default=None*, *sort_keys=False*, ***kw*)

使用此轉🄵表來將 *obj* 序列化🄵 JSON 格式 *str*。這個引數的作用與 *dump()* 中的同名引數意義相同。

> **備🄵**
>
> JSON 鍵/值對中的鍵始終🄵 *str* 型🄵。當字典被轉🄵🄵 JSON 時，字典的所有鍵值資料型🄵都會被🄵制轉🄵🄵字串。因此，如果將字典先轉🄵🄵 JSON 格式然後再轉🄵回字典，則該字典可能不等於原始字典。也就是🄵，如果字典 x 含有非字串鍵值，則 `loads(dumps(x)) != x`。

`json.`**`load`**(*fp*, *, *cls=None*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *object_pairs_hook=None*, ***kw*)

使用此*JSON-to-Python 轉🄵表*將 *fp* 解碼🄵 Python 物件。

參數

- **`fp`** (*file-like object*) -- A `.read()`-supporting *text file* or *binary file* containing the JSON document to be deserialized.
- **`cls`** (a *JSONDecoder* subclass) -- If set, a custom JSON decoder. Additional keyword arguments to `load()` will be passed to the constructor of *cls*. If `None` (the default), `JSONDecoder` is used.
- **`object_hook`** (*callable* | None) -- 如果有設定，會用解碼後的 JSON 物件字面值的結果（一個 *dict*）來呼叫此函式。此函式的回傳值將用來取代 *dict*。此功能可用於實作自訂解碼器，例如 JSON-RPC 類🄵提示。預設🄵 `None`。
- **`object_pairs_hook`** (*callable* | None) -- 如果有設定，會用任何 JSON 物件字面值以有序對串列解碼的結果來呼叫此函式。此函式的回傳值將用來取代 *dict*。此功能可用於實作自訂解碼器。如果也設定了 *object_hook*，以 *object_pairs_hook* 優先。預設🄵 `None`。
- **`parse_float`** (*callable* | None) -- 如果有設定，會用每個要被解碼的 JSON 浮點數字串來呼叫此函式。如果🄵 `None`（預設值），則等同於 `float(num_str)`。此功能可用於將 JSON 浮點數剖析🄵自訂資料型🄵，例如 *decimal.Decimal*。
- **`parse_int`** (*callable* | None) -- 如果有設定，會用每個要被解碼的 JSON 整數字串來呼叫此函式。如果🄵 `None`（預設值），則等同於 `int(num_str)`。此功能可用於將 JSON 整數剖析🄵自訂資料型🄵，例如 *float*。
- **`parse_constant`** (*callable* | None) -- 如果有設定，會用以下字串之一來呼叫此函式：`'-Infinity'`、`'Infinity'` 或 `'NaN'`。此功能可用於在遇到無效的 JSON 數字時引發例外。預設🄵 `None`。

引發

- ***JSONDecodeError*** -- 當被去序列化的資料不是有效的 JSON 文件時。
- ***UnicodeDecodeError*** -- 當被去序列化的資料不包含 UTF-8、UTF-16 或 UTF-32 編碼資料時。

在 3.1 版的變更:

- 新增可選的 *object_pairs_hook* 參數。
- 遭遇'null'、'true' 或'false' 時不再以 *parse_constant* 給定的函式來處理了。

在 3.6 版的變更:

- 所有可選參數現在都是僅限關鍵字參數了。

- 現在，*fp* 可以是一個二進位檔案，前提是其編碼格式🄵 UTF-8、UTF-16 或 UTF-32。

在 3.11 版的變更: 預設 *parse_int* 使用的`int()`函式現在有限制整數字串的長度上限了，限制由直譯器的整數字串轉🄵長度限制機制來達成，這能防止阻斷服務攻擊 (Denial of Service attacks)。

`json.`**`loads`**(*s*, *, *cls=None*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *object_pairs_hook=None*, ***kw*)

與`load()`相同，但不是類檔案物件，而是使用轉🄵表將 *s*（一個包含 JSON 文件的`str`、`bytes`或`bytearray`實例）去序列化🄵 Python 物件。

在 3.6 版的變更: 現在，*s* 可以是一個二進位檔案如`bytes`或`bytearray`，前提是其編碼格式🄵 UTF-8、UTF-16 或 UTF-32。

在 3.9 版的變更: 🄵除關鍵字引數 *encoding*。

20.2.2 編碼器與解碼器

`class` `json.`**`JSONDecoder`**(*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *strict=True*, *object_pairs_hook=None*)

簡易 JSON 解碼器

預設將執行下列資料型🄵轉🄵:

JSON	Python
object	dict
array	list
string	str
number (整數)	int
number (實數)	float
true	True
false	False
null	None

雖然 `NaN`、`Infinity` 和 `-Infinity` 🄵不符合 JSON 規範，但解碼器依然能正確地將其轉🄵到相應的 Python `float` 值。

object_hook 是一個可選函式，其接受一個解碼後的 JSON 物件作🄵輸入，🄵使用其回傳值來取代原先的`dict`。這個功能可用於提供自訂的去序列化（例如支援 JSON-RPC 類🄵提示）。

object_pairs_hook is an optional function that will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the `dict`. This feature can be used to implement custom decoders. If *object_hook* is also defined, the *object_pairs_hook* takes priority.

在 3.1 版的變更: 新增對於 *object_pairs_hook* 的支援。

parse_float 🄵可選函式，每個要被解碼的 JSON 浮點數字串都會改用這個參數給定的函式來進行解碼。預設情🄵這等效於 `float(num_str)`。這個參數可用於將 JSON 中的浮點數解碼或剖析🄵另一種資料型🄵（例如`decimal.Decimal`）。

parse_int 🄵可選函式，當解碼 JSON 整數字串時會被呼叫。預設情🄵等效於 `int(num_str)`。這個參數可用於將 JSON 中的整數解碼或剖析🄵另一種資料型🄵（例如`float`）。

parse_constant 🄵可選函式，在解碼時若遭遇字串 `'-Infinity'`、`'Infinity'` 或 `'NaN'` 其中之一則會改用這個參數給定的函式來進行解碼。這也可用於使解碼過程中遇到無效的 JSON 數字時引發一個例外。

如果 *strict* 被設🄵 false（預設值🄵 `True`），那🄵字串中將允許控制字元。此語境中的控制字元指的是 ASCII 字元編碼在 0 ~ 31 範圍🄵的字元，包括 `'\t'`（tab）、'n'、'r' 和 `'\0'`。

如果被去序列化（deserialized）的資料不符合 JSON 格式，將會引發`JSONDecodeError`例外。

在 3.6 版的變更: 所有參數現在都是僅限關鍵字參數了。

decode(*s*)

回傳用 Python 型式表達的 *s*（一個含有 JSON 文件的*str* 實例）。

若給定的輸入不符合 JSON 格式會引發*JSONDecodeError* 例外。

raw_decode(*s*)

將 *s*（一個開頭部分含有合格 JSON 文件的*str*）解碼，🄵將 JSON 文件結束點的索引值（index）和解碼結果合🄵🄵一個二元組（2-tuple）後回傳。

這個方法可以用來解碼尾段可能帶有 JSON 以外資料的文字。

class json.**JSONEncoder**(*, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *sort_keys=False*, *indent=None*, *separators=None*, *default=None*)

可擴充的 Python 資料結構 JSON 編碼器。

預設可支援下列物件及型🄵:

Python	JSON
dict	object
list, tuple	array
str	string
int、float 或可作🄵整數或浮點數運算的衍生列舉（int- or float-derived Enums）	number
True	true
False	false
None	null

在 3.4 版的變更: 增加對整數（int）、浮點數（float）或可作🄵整數或浮點數運算的衍生列舉（int- or float-derived Enums）類🄵的支援性。

若要擴充此功能來識🄵其他物件，請繼承🄵實作一個*default()* 方法。此方法應回傳一個可序列化的 o 物件，否則此方法應呼叫父類🄵的 JSONEncoder.default 方法（以引發*TypeError* 例外）。

若 *skipkeys* 🄵 false（預設值），則當在編碼不是*str*、*int*、*float*、*bool* 或 `None` 的鍵值時，將引發*TypeError*。如果 *skipkeys* 🄵 true，這些項目將直接被跳過。

如果 *ensure_ascii* 被設🄵 true（預設值），則輸出時將確保所有輸入的非 ASCII 字元都會被跳🄵。若 *ensure_ascii* 🄵 false，則這些字元將照原樣輸出。

如果 *check_circular* 🄵 true（預設值），則會在編碼期間檢查串列（list）、字典（dict）和自訂編碼物件的循環參照，以防止無限遞🄵（一個會導致*RecursionError* 例外的問題）。否則不會進行此類檢查。

如果 *allow_nan* 🄵 true（預設值），則 `NaN`、`Infinity` 和 `-Infinity` 將按照原樣進行編碼。請記得此行🄵不符合標准 JSON 規範，但的確與大多數基於 JavaScript 的編碼器和解碼器一致。否則若設🄵 false，嘗試對這些浮點數進行編碼將引發*ValueError* 例外。

如果 *sort_keys* 🄵 true（預設值: `False`），則 dictionary（字典）的輸出將按鍵值排序。這項功能可確保 JSON 序列化的結果能被互相比較，能讓日常的回歸測試檢查變得方便一些。

如果 *indent* 是非負整數或字串，則 JSON 陣列元素和物件成員將使用該縮排等級進行格式美化。縮排等級 0、負數或 `""` 只會插入🄵行符號。`None`（預設值）等於是選擇最緊🄵的表示法。使用正整數縮排可以在每層縮排數量相同的空格。如果 *indent* 是一個字串（例如 `"\t"`），則該字串用於縮排每個層級。

在 3.2 版的變更: 除了整數之外，*indent* 還允許使用字串作🄵輸入。

如果有指定本引數🄵容，*separators* 應該是一個 `(item_separator, key_separator)` 二元組。如果 *indent* 🄵 `None` 則預設🄵 `(', ', ': ')`，否則預設🄵 `(',', ': ')`。想要獲得最緊🄵的 JSON 表示形式，你可以改成指定 `(',', ':')` 來消除空格。

在 3.4 版的變更: 如果 *indent* 不是 `None`，則使用 `(',', ': ')` 作🄵預設值

如果有指定本參數，*default* 會是一個遭遇無法序列化的物件時會被呼叫的函式。它應該回傳該物件的 JSON 可編碼版本或引發*TypeError*。如果未指定，則會直接引發*TypeError*。

在 3.6 版的變更: 所有參數現在都是僅限關鍵字參數了。

default(*o*)

在任意一個子類🄵🄵實作這個方法時須讓其回傳一個可序列化的物件 *o*，或呼叫原始的實作以引發 *TypeError* 例外。

舉例來🄵，想要讓編碼器支援任意🄵代器（iterator），你可以實作這樣子的*default()*：

```
def default(self, o):
   try:
       iterable = iter(o)
   except TypeError:
       pass
   else:
       return list(iterable)
   # Let the base class default method raise the TypeError
   return super().default(o)
```

encode(*o*)

回傳一個 Python 資料結構物件 *o* 的 JSON 的字串表示。例如：

```
>>> json.JSONEncoder().encode({"foo": ["bar", "baz"]})
'{"foo": ["bar", "baz"]}'
```

iterencode(*o*)

將物件 *o* 編碼，🄵將結果統整🄵一個能依序🄵生（yield）各結果字串的物件。如下例：

```
for chunk in json.JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```

20.2.3 例外

exception json.**JSONDecodeError**(*msg*, *doc*, *pos*)

ValueError 的子類🄵具有下列額外屬性：

msg

未受格式化的錯誤訊息。

doc

正在被剖析的 JSON 文件。

pos

doc 剖析失敗處的起始點的索引值。

lineno

pos 所在的列（line）數。

colno

pos 所在的行（column）數。

在 3.5 版被加入.

20.2.4 合規性與互通性（Interoperability）

JSON 格式是由 **RFC 7159** 和 ECMA-404 規範的。本節詳細🄵明了本模組對 RFC 的遵循程度。簡單起見，*JSONEncoder* 和*JSONDecoder* 子類🄵以及未明確提及的參數將不予討論。

這個模組的部份實作🄵未非常嚴格地遵循 RFC 規範。准確來🄵，下列實際實作符合 JavaScript 語法格式，但🄵不符合 JSON 格式：

- 無限（Infinite）和非數字（NaN）值會被接受。
- 同一個物件🄵可以有重🄵的名稱，但只有最後一個同名物件是有效的。

不過 RFC 准許遵循 RFC 的剖析器接受不合規的文字輸入，所以技術上來🄴若以預設設定運作，本模組的去序列化器（deserializer）是符合 RFC 規範的。

字元編碼格式

RFC 要求 JSON 必須以 UTF-8、UTF-16 或 UTF-32 格式編碼。🄵推薦以 UTF-8 編碼以達成最佳的互通性。

RFC 准許但🄵不🄵制編碼器的 *ensure_ascii=True* 行🄵是預設值，但本模組依然實作了此一選項作🄵預設，因此本模組預設會跳🄴所有非 ASCII 字元。

除了 *ensure_ascii* 選項參數之外，本模組嚴格遵循 Python 物件與*Unicode strings* 之間的轉🄵規範，因此🄵不另外處理字元編碼的問題。

RFC 禁止在文件的開頭加上端序記號（Byte Order Mark），因此本模組的序列化器（serializer）也不會在輸出中加入端序記號。RFC 允許但不🄴制 JSON 去序列化器（deserializer）忽略文件初始的端序記號，因此本模組的去序列化器將在遭遇位於文件開頭的端序記號時引發*ValueError* 例外。

RFC 🄵未明確禁止 JSON 文件包含無法對應有效 Unicode 字元的位元組序列（例如未配對的 UTF-16 代理對（surrogate pairs）），但這個特性的確可能會引起相容性問題。預設情🄴下，當原始輸入的*str* 中存在此類序列時，該模組將接受🄴輸出這些序列的編碼位置（code points）。

正負無限與非數值

RFC 不允許表現無限大或非數值（NaN）。但預設情🄴下，這個模組仍接受🄴輸出 `Infinity`、`-Infinity` 和 `NaN`，如同它們是有效的 JSON 數值字面值：

```
>>> # Neither of these calls raises an exception, but the results are not valid JSON
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```

在序列化器中，*allow_nan* 參數可以改變這個行🄵。在去序列化器中，*parse_constant* 參數可以改變這個行🄵。

物件🄵重🄵的名稱

RFC 規範僅表明 JSON 物件中的名字應該是唯一的，但🄵有🄴制要求如何處理重🄴的名字。預設情🄴下，本模組不會因此引發例外；相反的，它會忽略該名字的所有重🄴鍵值對，🄵只保留最後一個：

```
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

object_parts_hook 參數可以改變這個行🄵。

位於頂層的非物件及非列表值

由已廢🄴的 **RFC 4627** 所規範的舊版 JSON 要求 JSON 文字的頂層值必須是 JSON 物件或陣列（Python *dict* 或*list*），而且不能是 JSON 的 null、boolean、數字或字串值。**RFC 7159** 移除了這個限制，而本模組的序列化器或去串列化器中未曾實施過該限制。

如果想要最大限度地保留互通性，你可能還是會想要自行施加這個限制。

實作限制

某些 JSON 去序列化器的實作可能會造成下列限制：

- JSON 文件長度上限
- JSON 物件或陣列的最大巢狀層數（level of nesting）限制
- 數字的精准度或範圍
- JSON 字串長度上限

本模組除了 Python 資料型態本身或 Python 直譯器本身的限制以外，不會設定任何此類限制。

將資料序列化🄵 JSON 時，要注意可能會使用該 JSON 輸出的應用程式中的相關限制。特🄵要注意的是，JSON 數字常會被去序列化🄵 IEEE 754 雙精度浮點數（double），🄵因而受到其表示範圍和精度限制的影響。這在序列化極大的 Python *int* 數值、或是序列化特殊數字型🄵的實例時（例如*decimal.Decimal*）尤其重要。

20.2.5 命令列介面

原始碼： Lib/json/tool.py

The *json* module can be invoked as a script via `python -m json` to validate and pretty-print JSON objects. The *json.tool* submodule implements this interface.

如果🄵有指定可選引數 `infile` 和 `outfile`，則*sys.stdin* 和*sys.stdout* 將各自做🄵輸入和輸出的預設值。

```
$ echo '{"json": "obj"}' | python -m json
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json
Expecting property name enclosed in double quotes: line 1 column 2 (char 1)
```

在 3.5 版的變更: 現在開始輸出和輸入的資料順序會是相同的。傳入*--sort-keys* 引數以按照鍵值的字母順序對輸出進行排序。

在 3.14 版的變更: The *json* module may now be directly executed as `python -m json`. For backwards compatibility, invoking the CLI as `python -m json.tool` remains supported.

命令列選項

infile

將被用於校驗或美化呈現的 JSON 文件：

```
$ python -m json mp_films.json
[
    {
        "title": "And Now for Something Completely Different",
        "year": 1971
    },
    {
        "title": "Monty Python and the Holy Grail",
        "year": 1975
    }
]
```

如果🄵有指定 *infile* 則會從*sys.stdin* 讀取輸入。

outfile

將 *infile* 的結果寫入到給定的 *outfile*。若未提供則寫入到*sys.stdout*。

--sort-keys

按照鍵值的字母順序對輸出字典進行排序。

在 3.5 版被加入.

--no-ensure-ascii

關閉非 ASCII 字元的自動跳🄵功能。詳情請參照*json.dumps()*。

在 3.9 版被加入.

--json-lines

將每一行輸入都單獨輸出🄵一個 JSON 物件。

在 3.8 版被加入.

--indent, --tab, --no-indent, --compact

互斥的空白字元控制選項。

在 3.9 版被加入.

-h, --help

顯示🄵明訊息。

🄵解

20.3 mailbox --- 以各種格式操作郵件信箱

原始碼： Lib/mailbox.py

This module defines two classes, *Mailbox* and *Message*, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the *email.message* module's *Message* class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

也參考

***email* 模組**
Represent and manipulate messages.

20.3.1 Mailbox 物件

class mailbox.**Mailbox**

A mailbox, which may be inspected and modified.

The `Mailbox` class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from `Mailbox` and your code should instantiate a particular subclass.

The `Mailbox` interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the `Mailbox` instance with which they will be used and are only meaningful to that `Mailbox` instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a `Mailbox` instance using the set-like method *add()* and removed using a `del` statement or the set-like methods *remove()* and *discard()*.

`Mailbox` interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a *Message* instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a `Mailbox` instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the `Mailbox` instance.

The default `Mailbox` *iterator* iterates over message representations, not keys as the default `dictionary` iterator does. Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

> **警告**
>
> Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is `Maildir`; try to avoid using single-file formats such as `mbox` for concurrent writing. If you're modifying a mailbox, you *must* lock it by calling the `lock()` and `unlock()` methods *before* reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

`Mailbox` instances have the following methods:

add(*message*)

Add *message* to the mailbox and return the key that has been assigned to it.

Parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

在 3.2 版的變更: Support for binary input was added.

remove(*key*)

__delitem__(*key*)

discard(*key*)

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a `KeyError` exception is raised if the method was called as `remove()` or `__delitem__()` but no exception is raised if the method was called as `discard()`. The behavior of `discard()` may be preferred if the underlying mailbox format supports concurrent modification by other processes.

__setitem__(*key*, *message*)

Replace the message corresponding to *key* with *message*. Raise a `KeyError` exception if no message already corresponds to *key*.

As with `add()`, parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

iterkeys()

Return an *iterator* over all keys

keys()

The same as `iterkeys()`, except that a `list` is returned rather than an *iterator*

itervalues()

__iter__()

Return an *iterator* over representations of all messages. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

> **備🄵**
>
> The behavior of `__iter__()` is unlike that of dictionaries, which iterate over keys.

values()

The same as `itervalues()`, except that a `list` is returned rather than an *iterator*

iteritems()

Return an *iterator* over (*key*, *message*) pairs, where *key* is a key and *message* is a message representation. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

items()

The same as `iteritems()`, except that a `list` of pairs is returned rather than an *iterator* of pairs.

get(*key*, *default=None*)

__getitem__(*key*)

Return a representation of the message corresponding to *key*. If no such message exists, *default* is returned if the method was called as `get()` and a `KeyError` exception is raised if the method was called as `__getitem__()`. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

get_message(*key*)

Return a representation of the message corresponding to *key* as an instance of the appropriate format-specific `Message` subclass, or raise a `KeyError` exception if no such message exists.

get_bytes(*key*)

Return a byte representation of the message corresponding to *key*, or raise a `KeyError` exception if no such message exists.

在 3.2 版被加入.

get_string(*key*)

Return a string representation of the message corresponding to *key*, or raise a `KeyError` exception if no such message exists. The message is processed through `email.message.Message` to convert it to a 7bit clean representation.

get_file(*key*)

Return a *file-like* representation of the message corresponding to *key*, or raise a `KeyError` exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

在 3.2 版的變更: The file object really is a *binary file*; previously it was incorrectly returned in text mode. Also, the *file-like object* now supports the *context manager* protocol: you can use a `with` statement to automatically close it.

> **備🄵**
>
> Unlike other representations of messages, *file-like* representations are not necessarily independent of the `Mailbox` instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

__contains__(*key*)

Return `True` if *key* corresponds to a message, `False` otherwise.

__len__()

Return a count of messages in the mailbox.

clear()

Delete all messages from the mailbox.

pop(*key*, *default=None*)

Return a representation of the message corresponding to *key* and delete the message. If no such message exists, return *default*. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

popitem()

Return an arbitrary (*key*, *message*) pair, where *key* is a key and *message* is a message representation, and delete the corresponding message. If the mailbox is empty, raise a `KeyError` exception. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

update(*arg*)

Parameter *arg* should be a *key*-to-*message* mapping or an iterable of (*key*, *message*) pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using `__setitem__()`. As with `__setitem__()`, each *key* must already correspond to a message in the mailbox or else a `KeyError` exception will be raised, so in general it is incorrect for *arg* to be a `Mailbox` instance.

> **備🄵**
>
> Unlike with dictionaries, keyword arguments are not supported.

flush()

Write any pending changes to the filesystem. For some `Mailbox` subclasses, changes are always written immediately and `flush()` does nothing, but you should still make a habit of calling this method.

lock()

Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An `ExternalClashError` is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

unlock()

Release the lock on the mailbox, if any.

close()

Flush the mailbox, unlock it if necessary, and close any open files. For some `Mailbox` subclasses, this method does nothing.

`Mailbox` 物件

class mailbox.**Maildir**(*dirname*, *factory=None*, *create=True*)

A subclass of `Mailbox` for mailboxes in Maildir format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, `MaildirMessage` is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

If *create* is `True` and the *dirname* path exists, it will be treated as an existing maildir without attempting to verify its directory layout.

It is for historical reasons that *dirname* is named as such rather than *path*.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: `tmp`, `new`, and `cur`. Messages are created momentarily in the `tmp` subdirectory and then moved to the `new` subdirectory to finalize delivery. A mail user agent may subsequently move the message to the `cur` subdirectory and store information about the state of the message in a special "info" section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if `'.'` is the first character in its name. Folder names are represented by `Maildir` without the leading `'.'`. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using `'.'` to delimit levels, e.g., "Archived.2005.07".

colon

The Maildir specification requires the use of a colon (`':'`) in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (`'!'`) is a popular choice. For example:

```
import mailbox
mailbox.Maildir.colon = '!'
```

The `colon` attribute may also be set on a per-instance basis.

在 3.13 版的變更: *Maildir* now ignores files with a leading dot.

`Maildir` instances have all of the methods of *Mailbox* in addition to the following:

list_folders()

Return a list of the names of all folders.

get_folder(*folder*)

Return a `Maildir` instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

add_folder(*folder*)

Create a folder whose name is *folder* and return a `Maildir` instance representing it.

remove_folder(*folder*)

Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

clean()

Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

get_flags(*key*)

Return as a string the flags that are set on the message corresponding to *key*. This is the same as `get_message(key).get_flags()` but much faster, because it does not open the message file. Use this method when iterating over the keys to determine which messages are interesting to get.

If you do have a *MaildirMessage* object, use its *get_flags()* method instead, because changes made by the message's *set_flags()*, *add_flag()* and *remove_flag()* methods are not reflected here until the mailbox's *__setitem__()* method is called.

在 3.13 版被加入.

set_flags(*key*, *flags*)

On the message corresponding to *key*, set the flags specified by *flags* and unset all others. Calling `some_mailbox.set_flags(key, flags)` is similar to

```
one_message = some_mailbox.get_message(key)
one_message.set_flags(flags)
some_mailbox[key] = one_message
```

but faster, because it does not open the message file.

If you do have a *MaildirMessage* object, use its *set_flags()* method instead, because changes made with this mailbox method will not be visible to the message object's method, *get_flags()*.

在 3.13 版被加入.

add_flag(*key*, *flag*)

On the message corresponding to *key*, set the flags specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

Considerations for using this method versus the message object's *add_flag()* method are similar to those for *set_flags()*; see the discussion there.

在 3.13 版被加入.

remove_flag(*key*, *flag*)

On the message corresponding to *key*, unset the flags specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* may be a string of more than one character.

Considerations for using this method versus the message object's *remove_flag()* method are similar to those for *set_flags()*; see the discussion there.

在 3.13 版被加入.

get_info(*key*)

Return a string containing the info for the message corresponding to *key*. This is the same as `get_message(key).get_info()` but much faster, because it does not open the message file. Use this method when iterating over the keys to determine which messages are interesting to get.

If you do have a *MaildirMessage* object, use its *get_info()* method instead, because changes made by the message's *set_info()* method are not reflected here until the mailbox's *__setitem__()* method is called.

在 3.13 版被加入.

set_info(*key*, *info*)

Set the info of the message corresponding to *key* to *info*. Calling `some_mailbox.set_info(key, flags)` is similar to

```
one_message = some_mailbox.get_message(key)
one_message.set_info(info)
some_mailbox[key] = one_message
```

but faster, because it does not open the message file.

If you do have a *MaildirMessage* object, use its *set_info()* method instead, because changes made with this mailbox method will not be visible to the message object's method, *get_info()*.

在 3.13 版被加入.

Some *Mailbox* methods implemented by `Maildir` deserve special remarks:

add(*message*)

__setitem__(*key*, *message*)

update(*arg*)

> **⚠ 警告**
>
> These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

flush()

All changes to Maildir mailboxes are immediately applied, so this method does nothing.

lock()

unlock()

Maildir mailboxes do not support (or require) locking, so these methods do nothing.

close()

`Maildir` instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

get_file(*key*)

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

也參考

maildir man page from Courier
A specification of the format. Describes a common extension for supporting folders.

Using maildir format
Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on "info" semantics.

`mbox` 物件

class mailbox.**mbox**(*path*, *factory=None*, *create=True*)

A subclass of *Mailbox* for mailboxes in mbox format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *mboxMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are "From ".

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, `mbox` implements the original format, which is sometimes referred to as *mboxo*. This means that the *Content-Length* header, if present, is ignored and that any occurrences of "From " at the beginning of a line in a message body are transformed to ">From " when storing the message, although occurrences of ">From " are not transformed to "From " when reading the message.

Some *Mailbox* methods implemented by `mbox` deserve special remarks:

get_bytes(*key*, *from_=False*)

Note: This method has an extra parameter (*from_*) compared with other classes. The first line of an mbox file entry is the Unix "From " line. If *from_* is False, the first line of the file is dropped.

get_file(*key*, *from_=False*)

Using the file after calling *flush()* or *close()* on the `mbox` instance may yield unpredictable results or raise an exception.

Note: This method has an extra parameter (*from_*) compared with other classes. The first line of an mbox file entry is the Unix "From " line. If *from_* is False, the first line of the file is dropped.

get_string(*key*, *from_=False*)

Note: This method has an extra parameter (*from_*) compared with other classes. The first line of an mbox file entry is the Unix "From " line. If *from_* is False, the first line of the file is dropped.

lock()

unlock()

Three locking mechanisms are used---dot locking and, if available, the `flock()` and `lockf()` system calls.

mbox man page from tin
A specification of the format, with details on locking.

Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad
An argument for using the original mbox format rather than a variation.

"mbox" is a family of several mutually incompatible mailbox formats
A history of mbox variations.

MH 物件

class mailbox.**MH**(*path*, *factory=None*, *create=True*)

A subclass of *Mailbox* for mailboxes in MH format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *MHMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called *folders*) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support *sequences*, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.

The `MH` class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**'s behaviors. In particular, it does not modify and is not affected by the `context` or `.mh_profile` files that are used by **mh** to store its state and configuration.

`MH` instances have all of the methods of *Mailbox* in addition to the following:

在 3.13 版的變更: Supported folders that don't contain a `.mh_sequences` file.

list_folders()

Return a list of the names of all folders.

get_folder(*folder*)

Return an `MH` instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

add_folder(*folder*)

Create a folder whose name is *folder* and return an `MH` instance representing it.

remove_folder(*folder*)

Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

get_sequences()

Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

set_sequences(*sequences*)

Re-define the sequences that exist in the mailbox based upon *sequences*, a dictionary of names mapped to key lists, like returned by *get_sequences()*.

pack()

Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

> **備🄵**
>
> Already-issued keys are invalidated by this operation and should not be subsequently used.

Some *Mailbox* methods implemented by MH deserve special remarks:

remove(*key*)

__delitem__(*key*)

discard(*key*)

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

lock()

unlock()

Three locking mechanisms are used---dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

get_file(*key*)

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

flush()

All changes to MH mailboxes are immediately applied, so this method does nothing.

close()

MH instances do not keep any open files, so this method is equivalent to *unlock()*.

> **也參考**
>
> **nmh - Message Handling System**
> Home page of **nmh**, an updated version of the original **mh**.
>
> **MH & nmh: Email for Users & Programmers**
> A GPL-licensed book on **mh** and **nmh**, with some information on the mailbox format.

Babyl 物件

class mailbox.**Babyl**(*path*, *factory=None*, *create=True*)

A subclass of *Mailbox* for mailboxes in Babyl format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *BabylMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`'\037'`) and Control-L (`'\014'`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`'\037'`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

`Babyl` instances have all of the methods of *`Mailbox`* in addition to the following:

`get_labels`()

Return a list of the names of all user-defined labels used in the mailbox.

> **備🄵**
>
> The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some *`Mailbox`* methods implemented by `Babyl` deserve special remarks:

`get_file`(*key*)

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an *`io.BytesIO`* instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

`lock`()

`unlock`()

Three locking mechanisms are used---dot locking and, if available, the `flock()` and `lockf()` system calls.

> **也參考**
>
> **Format of Version 5 Babyl Files**
> A specification of the Babyl format.
>
> **Reading Mail with Rmail**
> The Rmail manual, with some information on Babyl semantics.

`MMDF` 物件

`class` mailbox.**`MMDF`**(*path*, *factory=None*, *create=True*)

A subclass of *`Mailbox`* for mailboxes in MMDF format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *`MMDFMessage`* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (`'\001'`) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are ”From ”, but additional occurrences of ”From ” are not transformed to ”>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some *`Mailbox`* methods implemented by `MMDF` deserve special remarks:

`get_bytes`(*key*, *from_=False*)

Note: This method has an extra parameter (*from_*) compared with other classes. The first line of an mbox file entry is the Unix ”From ” line. If *from_* is False, the first line of the file is dropped.

`get_file`(*key*, *from_=False*)

Using the file after calling *`flush()`* or *`close()`* on the `MMDF` instance may yield unpredictable results or raise an exception.

Note: This method has an extra parameter (*from_*) compared with other classes. The first line of an mbox file entry is the Unix ”From ” line. If *from_* is False, the first line of the file is dropped.

lock()

unlock()

Three locking mechanisms are used---dot locking and, if available, the `flock()` and `lockf()` system calls.

20.3.2 `Message` 物件

class mailbox.**Message**(*message=None*)

A subclass of the *email.message* module's *Message*. Subclasses of `mailbox.Message` add mailbox-format-specific state and behavior.

If *message* is omitted, the new instance is created in a default, empty state. If *message* is an *email.message.Message* instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if *message* is a `Message` instance. If *message* is a string, a byte string, or a file, it should contain an **RFC 2822**-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that `Message` instances be used to represent messages retrieved using *Mailbox* instances. In some situations, the time and memory required to generate `Message` representations might not be acceptable. For such situations, `Mailbox` instances also offer string and file-like representations, and a custom message factory may be specified when a `Mailbox` instance is initialized.

`MaildirMessage` 物件

class mailbox.**MaildirMessage**(*message=None*)

A message with Maildir-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Typically, a mail user agent application moves all of the messages in the `new` subdirectory to the `cur` subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in `cur` has an "info" section added to its file name to store information about its state. (Some mail readers may also add an "info" section to messages in `new`.) The "info" section may take one of two forms: it may contain "2," followed by a list of standardized flags (e.g., "2,FR") or it may contain "1," followed by so-called experimental information. Standard flags for Maildir messages are as follows:

Flag	含義	Explanation
D	Draft	Under composition
F	Flagged	Marked as important
P	Passed	Forwarded, resent, or bounced
R	Replied	Replied to
S	Seen	Read
T	Trashed	Marked for subsequent deletion

`MaildirMessage` instances offer the following methods:

get_subdir()

Return either ”new” (if the message should be stored in the `new` subdirectory) or ”cur” (if the message should be stored in the `cur` subdirectory).

> **備𝔽**
>
> A message is typically moved from `new` to `cur` after its mailbox has been accessed, whether or not the message has been read. A message `msg` has been read if `"S" in msg.get_flags()` is `True`.

set_subdir(*subdir*)

Set the subdirectory the message should be stored in. Parameter *subdir* must be either ”new” or ”cur”.

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of `'D'`, `'F'`, `'P'`, `'R'`, `'S'`, and `'T'`. The empty string is returned if no flags are set or if ”info” contains experimental semantics.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character. The current ”info” is overwritten whether or not it contains experimental information rather than flags.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If ”info” contains experimental information rather than flags, the current ”info” is not modified.

get_date()

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

set_date(*date*)

Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

get_info()

Return a string containing the ”info” for a message. This is useful for accessing and modifying ”info” that is experimental (i.e., not a list of flags).

set_info(*info*)

Set ”info” to *info*, which should be a string.

When a `MaildirMessage` instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

Resulting state	*mboxMessage* or *MMDFMessage* state
”cur” subdirectory	O flag
F flag	F flag
R flag	A flag
S flag	R flag
T flag	D flag

When a `MaildirMessage` instance is created based upon an *MHMessage* instance, the following conversions take place:

Resulting state	*MHMessage* state
”cur” subdirectory	”unseen” sequence
”cur” subdirectory and S flag	no ”unseen” sequence
F flag	”flagged” sequence
R flag	”replied” sequence

When a `MaildirMessage` instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
”cur” subdirectory	”unseen” label
”cur” subdirectory and S flag	no ”unseen” label
P flag	”forwarded” or ”resent” label
R flag	”answered” label
T flag	”deleted” label

`mboxMessage` 物件

class mailbox.**mboxMessage**(*message=None*)

A message with mbox-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Messages in an mbox mailbox are stored together in a single file. The sender's envelope address and the time of delivery are typically stored in a line beginning with ”From ” that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in *Status* and *X-Status* headers.

Conventional flags for mbox messages are as follows:

Flag	含義	Explanation
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The ”R” and ”O” flags are stored in the *Status* header, and the ”D”, ”F”, and ”A” flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.

`mboxMessage` instances offer the following methods:

get_from()

Return a string representing the ”From ” line that marks the start of the message in an mbox mailbox. The leading ”From ” and the trailing newline are excluded.

set_from(*from_*, *time_=None*)

Set the ”From ” line to *from_*, which should be specified without a leading ”From ” or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and appended to *from_*. If *time_* is specified, it should be a *time.struct_time* instance, a tuple suitable for passing to *time.strftime()*, or `True` (to use *time.gmtime()*).

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an `mboxMessage` instance is created based upon a *`MaildirMessage`* instance, a ”From ” line is generated based upon the *`MaildirMessage`* instance's delivery date, and the following conversions take place:

Resulting state	*`MaildirMessage`* state
R flag	S flag
O flag	”cur” subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an `mboxMessage` instance is created based upon an *`MHMessage`* instance, the following conversions take place:

Resulting state	*`MHMessage`* state
R flag and O flag	no ”unseen” sequence
O flag	”unseen” sequence
F flag	”flagged” sequence
A flag	”replied” sequence

When an `mboxMessage` instance is created based upon a *`BabylMessage`* instance, the following conversions take place:

Resulting state	*`BabylMessage`* state
R flag and O flag	no ”unseen” label
O flag	”unseen” label
D flag	”deleted” label
A flag	”answered” label

When a `mboxMessage` instance is created based upon an *`MMDFMessage`* instance, the ”From ” line is copied and all flags directly correspond:

Resulting state	*`MMDFMessage`* state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

MHMessage 物件

class mailbox.**MHMessage**(*message=None*)

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard **mh** and **nmh**) use sequences in much the same way flags are used with other formats, as follows:

Sequence	Explanation
unseen	Not read, but previously detected by MUA
replied	Replied to
flagged	Marked as important

MHMessage instances offer the following methods:

get_sequences()

Return a list of the names of sequences that include this message.

set_sequences(*sequences*)

Set the list of sequences that include this message.

add_sequence(*sequence*)

Add *sequence* to the list of sequences that include this message.

remove_sequence(*sequence*)

Remove *sequence* from the list of sequences that include this message.

When an MHMessage instance is created based upon a *MaildirMessage* instance, the following conversions take place:

Resulting state	*MaildirMessage* state
”unseen” sequence	no S flag
”replied” sequence	R flag
”flagged” sequence	F flag

When an MHMessage instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

Resulting state	*mboxMessage* or *MMDFMessage* state
”unseen” sequence	no R flag
”replied” sequence	A flag
”flagged” sequence	F flag

When an MHMessage instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
”unseen” sequence	”unseen” label
”replied” sequence	”answered” label

`BabylMessage` 物件

class mailbox.**BabylMessage**(*message=None*)

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the `Message` constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

Label	Explanation
unseen	Not read, but previously detected by MUA
deleted	Marked for subsequent deletion
filed	Copied to another file or mailbox
answered	Replied to
forwarded	Forwarded
edited	Modified by the user
resent	Resent

By default, Rmail displays only visible headers. The `BabylMessage` class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

`BabylMessage` instances offer the following methods:

get_labels()

Return a list of labels on the message.

set_labels(*labels*)

Set the list of labels on the message to *labels*.

add_label(*label*)

Add *label* to the list of labels on the message.

remove_label(*label*)

Remove *label* from the list of labels on the message.

get_visible()

Return a `Message` instance whose headers are the message's visible headers and whose body is empty.

set_visible(*visible*)

Set the message's visible headers to be the same as the headers in *message*. Parameter *visible* should be a `Message` instance, an `email.message.Message` instance, a string, or a file-like object (which should be open in text mode).

update_visible()

When a `BabylMessage` instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of `Date`, `From`, `Reply-To`, `To`, `CC`, and `Subject` that are present in the original headers but not the visible headers are added to the visible headers.

When a `BabylMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:

Resulting state	`MaildirMessage` state
"unseen" label	no S flag
"deleted" label	T flag
"answered" label	R flag
"forwarded" label	P flag

When a `BabylMessage` instance is created based upon an *`mboxMessage`* or *`MMDFMessage`* instance, the *`Status`* and *`X-Status`* headers are omitted and the following conversions take place:

Resulting state	*`mboxMessage`* or *`MMDFMessage`* state
”unseen” label	no R flag
”deleted” label	D flag
”answered” label	A flag

When a `BabylMessage` instance is created based upon an *`MHMessage`* instance, the following conversions take place:

Resulting state	*`MHMessage`* state
”unseen” label	”unseen” sequence
”answered” label	”replied” sequence

`MMDFMessage` 物件

class mailbox.**MMDFMessage**(*message=None*)

A message with MMDF-specific behaviors. Parameter *message* has the same meaning as with the *`Message`* constructor.

As with message in an mbox mailbox, MMDF messages are stored with the sender’s address and the delivery date in an initial line beginning with ”From ”. Likewise, flags that indicate the state of the message are typically stored in *`Status`* and *`X-Status`* headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

Flag	含義	Explanation
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The ”R” and ”O” flags are stored in the *`Status`* header, and the ”D”, ”F”, and ”A” flags are stored in the *`X-Status`* header. The flags and headers typically appear in the order mentioned.

`MMDFMessage` instances offer the following methods, which are identical to those offered by *`mboxMessage`*:

get_from()

Return a string representing the ”From ” line that marks the start of the message in an mbox mailbox. The leading ”From ” and the trailing newline are excluded.

set_from(*from_*, *time_=None*)

Set the ”From ” line to *from_*, which should be specified without a leading ”From ” or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and appended to *from_*. If *time_* is specified, it should be a *`time.struct_time`* instance, a tuple suitable for passing to *`time.strftime()`*, or `True` (to use *`time.gmtime()`*).

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an `MMDFMessage` instance is created based upon a *`MaildirMessage`* instance, a ”From ” line is generated based upon the *`MaildirMessage`* instance's delivery date, and the following conversions take place:

Resulting state	*`MaildirMessage`* state
R flag	S flag
O flag	”cur” subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an `MMDFMessage` instance is created based upon an *`MHMessage`* instance, the following conversions take place:

Resulting state	*`MHMessage`* state
R flag and O flag	no ”unseen” sequence
O flag	”unseen” sequence
F flag	”flagged” sequence
A flag	”replied” sequence

When an `MMDFMessage` instance is created based upon a *`BabylMessage`* instance, the following conversions take place:

Resulting state	*`BabylMessage`* state
R flag and O flag	no ”unseen” label
O flag	”unseen” label
D flag	”deleted” label
A flag	”answered” label

When an `MMDFMessage` instance is created based upon an *`mboxMessage`* instance, the ”From ” line is copied and all flags directly correspond:

Resulting state	*`mboxMessage`* state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

20.3.3 例外

The following exception classes are defined in the `mailbox` module:

exception mailbox.**Error**

The based class for all other module-specific exceptions.

exception mailbox.**NoSuchMailboxError**

Raised when a mailbox is expected but is not found, such as when instantiating a *Mailbox* subclass with a path that does not exist (and with the *create* parameter set to `False`), or when opening a folder that does not exist.

exception mailbox.**NotEmptyError**

Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception mailbox.**ExternalClashError**

Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely generated file name already exists.

exception mailbox.**FormatError**

Raised when the data in a file cannot be parsed, such as when an *MH* instance attempts to read a corrupted `.mh_sequences` file.

20.3.4 范例

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```
import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']       # 可能🄵 None.
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-bugs')

boxes = {name: mailbox.mbox('~/email/%s' % name) for name in list_names}
inbox = mailbox.Maildir('~/Maildir', factory=None)

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue                # The message is malformed. Just leave it.

    for name in list_names:
        list_id = message['list-id']
        if list_id and name in list_id:
            # Get mailbox to use
            box = boxes[name]
```

(繼續下一頁)

(繼續上一頁)

```
            # Write copy to disk before removing original.
            # If there's a crash, you might duplicate a message, but
            # that's better than losing a message completely.
            box.lock()
            box.add(message)
            box.flush()
            box.unlock()

            # Remove original message
            inbox.lock()
            inbox.discard(key)
            inbox.flush()
            inbox.unlock()
            break               # Found destination, so stop looking.

for box in boxes.itervalues():
    box.close()
```

20.4 `mimetypes` --- 將檔案名稱對映到 MIME 類型

原始碼： Lib/mimetypes.py

The *mimetypes* module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call *init()* if they rely on the information *init()* sets up.

`mimetypes.`**guess_type**(*url*, *strict=True*)

Guess the type of a file based on its filename, path or URL, given by *url*. URL can be a string or a *path-like object*.

The return value is a tuple `(type, encoding)` where *type* is `None` if the type can't be guessed (missing or unknown suffix) or a string of the form `'type/subtype'`, usable for a MIME *content-type* header.

encoding is `None` for no encoding or the name of the program used to encode (e.g. **compress** or **gzip**). The encoding is suitable for use as a *Content-Encoding* header, **not** as a *Content-Transfer-Encoding* header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

The optional *strict* argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA. However, the behavior of this module also depends on the underlying operating system. Only file types recognized by the OS or explicitly registered with Python's internal database can be identified. When *strict* is `True` (the default), only the IANA types are supported; when *strict* is `False`, some additional non-standard but commonly used MIME types are also recognized.

在 3.8 版的變更: 新增 *url* 做🄵*path-like object* 的支援。

在 3.13 版之後被🄵用: Passing a file path instead of URL is *soft deprecated*. Use *guess_file_type()* for this.

`mimetypes.`**guess_file_type**(*path*, *, *strict=True*)

Guess the type of a file based on its path, given by *path*. Similar to the *guess_type()* function, but accepts a path instead of URL. Path can be a string, a bytes object or a *path-like object*.

在 3.13 版被加入.

mimetypes.**guess_all_extensions**(*type*, *strict=True*)

Guess the extensions for a file based on its MIME type, given by *type*. The return value is a list of strings giving all possible filename extensions, including the leading dot (`'.'`). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by *guess_type()* and *guess_file_type()*.

The optional *strict* argument has the same meaning as with the *guess_type()* function.

mimetypes.**guess_extension**(*type*, *strict=True*)

Guess the extension for a file based on its MIME type, given by *type*. The return value is a string giving a filename extension, including the leading dot (`'.'`). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by *guess_type()* and *guess_file_type()*. If no extension can be guessed for *type*, `None` is returned.

The optional *strict* argument has the same meaning as with the *guess_type()* function.

Some additional functions and data items are available for controlling the behavior of the module.

mimetypes.**init**(*files=None*)

Initialize the internal data structures. If given, *files* must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from *knownfiles*; on Windows, the current registry settings are loaded. Each file named in *files* or *knownfiles* takes precedence over those named before it. Calling *init()* repeatedly is allowed.

Specifying an empty list for *files* will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

If *files* is `None` the internal data structure is completely rebuilt to its initial default value. This is a stable operation and will produce the same results when called multiple times.

在 3.2 版的變更: Previously, Windows registry settings were ignored.

mimetypes.**read_mime_types**(*filename*)

Load the type map given in the file *filename*, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot (`'.'`), to strings of the form `'type/subtype'`. If the file *filename* does not exist or cannot be read, `None` is returned.

mimetypes.**add_type**(*type*, *ext*, *strict=True*)

Add a mapping from the MIME type *type* to the extension *ext*. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is `True` (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

mimetypes.**inited**

Flag indicating whether or not the global data structures have been initialized. This is set to `True` by *init()*.

mimetypes.**knownfiles**

List of type map file names commonly installed. These files are typically named `mime.types` and are installed in different locations by different packages.

mimetypes.**suffix_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

mimetypes.**encodings_map**

Dictionary mapping filename extensions to encoding types.

mimetypes.**types_map**

Dictionary mapping filename extensions to MIME types.

mimetypes.**common_types**

Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

模組的使用範例：

```
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
'gzip'
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```

20.4.1 MimeTypes 物件

The *MimeTypes* class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the *mimetypes* module.

class mimetypes.**MimeTypes**(*filenames=()*, *strict=True*)

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the *read()* or *readfp()* methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional *filenames* parameter can be used to cause additional files to be loaded "on top" of the default database.

suffix_map

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global *suffix_map* defined in the module.

encodings_map

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global *encodings_map* defined in the module.

types_map

Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common_types* and *types_map*.

types_map_inv

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common_types* and *types_map*.

guess_extension(*type*, *strict=True*)

Similar to the *guess_extension()* function, using the tables stored as part of the object.

guess_type(*url*, *strict=True*)

Similar to the *guess_type()* function, using the tables stored as part of the object.

guess_file_type(*path*, ***, *strict=True*)

Similar to the *guess_file_type()* function, using the tables stored as part of the object.

在 3.13 版被加入.

guess_all_extensions(*type*, *strict=True*)

Similar to the *guess_all_extensions()* function, using the tables stored as part of the object.

read(*filename*, *strict=True*)

Load MIME information from a file named *filename*. This uses *readfp()* to parse the file.

If *strict* is `True`, information will be added to list of standard types, else to the list of non-standard types.

readfp(*fp*, *strict=True*)

Load MIME type information from an open file *fp*. The file must have the format of the standard `mime.types` files.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

read_windows_registry(*strict=True*)

Load MIME type information from the Windows registry.

可用性: Windows.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

在 3.2 版被加入.

add_type(*type*, *ext*, *strict=True*)

Add a mapping from the MIME type *type* to the extension *ext*. Valid extensions start with a '.' or are empty. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is `True` (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

Deprecated since version 3.14, will be removed in version 3.16: Invalid, undotted extensions will raise a *ValueError* in Python 3.16.

20.4.2 Command-line usage

The `mimetypes` module can be executed as a script from the command line.

```
python -m mimetypes [-h] [-e] [-l] type [type ...]
```

The following options are accepted:

-h

--help

Show the help message and exit.

-e

--extension

Guess extension instead of type.

-l

--lenient

Additionally search for some common, but non-standard types.

By default the script converts MIME types to file extensions. However, if `--extension` is specified, it converts file extensions to MIME types.

For each `type` entry, the script writes a line into the standard output stream. If an unknown type occurs, it writes an error message into the standard error stream and exits with the return code `1`.

20.4.3 Command-line example

Here are some examples of typical usage of the `mimetypes` command-line interface:

```
$ # get a MIME type by a file name
$ python -m mimetypes filename.png
type: image/png encoding: None

$ # get a MIME type by a URL
$ python -m mimetypes https://example.com/filename.txt
type: text/plain encoding: None

$ # get a complex MIME type
$ python -m mimetypes filename.tar.gz
type: application/x-tar encoding: gzip

$ # get a MIME type for a rare file extension
$ python -m mimetypes filename.pict
error: unknown extension of filename.pict

$ # now look in the extended database built into Python
$ python -m mimetypes --lenient filename.pict
type: image/pict encoding: None

$ # get a file extension by a MIME type
$ python -m mimetypes --extension text/javascript
.js

$ # get a file extension by a rare MIME type
$ python -m mimetypes --extension text/xul
error: unknown type text/xul

$ # now look in the extended database again
$ python -m mimetypes --extension --lenient text/xul
.xul

$ # try to feed an unknown file extension
$ python -m mimetypes filename.sh filename.nc filename.xxx filename.txt
type: application/x-sh encoding: None
type: application/x-netcdf encoding: None
error: unknown extension of filename.xxx

$ # try to feed an unknown MIME type
$ python -m mimetypes --extension audio/aac audio/opus audio/future audio/x-wav
.aac
.opus
error: unknown type audio/future
```

20.5 `base64` --- Base16、Base32、Base64、Base85 資料編碼

原始碼： Lib/base64.py

這個模組提供將二進位資料編碼成可顯示 ASCII 字元以及解碼回原始資料的功能。這包括了 **RFC 4648** 中指定的編碼（Base64、Base32 和 Base16）和非標準的*Base85 編碼*。

該模組提供了兩個介面。新介面支援將類位元組物件 編碼成 ASCII *bytes*，🄵將包含 ASCII 的類位元組物件或字串解碼🄵*bytes*。支援 **RFC 4648** 中定義的兩種 base-64 字母表（常見和 URL 安全 (URL-safe) 及檔案系統安全 (filesystem-safe) 字母表）。

舊版介面不支援從字串解碼，但它提供對檔案物件進行編碼和解碼的函式。它僅支援 Base64 標準字母表，🄵且按照 **RFC 2045** 每 76 個字元添加🄵行字元。請注意，如果你需要 **RFC 2045** 的支援，你可能會

需要*email* 函式庫。

在 3.3 版的變更: 新介面的解碼功能現在接受 ASCII-only 的 Unicode 字串。

在 3.4 版的變更: 任何類位元組物件現在被該模組中的所有編碼和解碼函式接受。新增了對 Ascii85/Base85 的支援。

20.5.1 RFC 4648 編碼

RFC 4648 編碼適合對二進位資料進行編碼來使得電子郵件、URL 或是 HTTP POST 🄵容等傳輸管道能🄵安全地傳遞資料。

base64.**b64encode**(*s*, *altchars=None*)

使用 Base64 對類位元組物件 *s* 進行編碼🄵回傳編碼過的*bytes*。

可選的 *altchars* 必須是一個長度🄵 2 的類位元組物件，用來指定替代的字母表，以替🄵 + 和 / 字元。這使得應用程式可以生成對 URL 或檔案系統安全的 Base64 字串。預設值🄵 `None`，即使用標準的 Base64 字母表。

如果 *altchars* 的長度不是 2，可以斷言或引發*ValueError*。如果 *altchars* 不是類位元組物件，則會引發*TypeError*。

base64.**b64decode**(*s*, *altchars=None*, *validate=False*)

將經過 Base64 編碼的類位元組物件或 ASCII 字串 *s* 解碼，🄵回傳解碼後的*bytes*。

可選的 *altchars* 必須是長度🄵 2 的類位元組物件或 ASCII 字串，用於指定替代字母表，取代 + 和 / 字元。

如果 *s* 填充 (pad) 不正確，將引發*binascii.Error* 例外。

如果 *validate* 🄵 `False`（預設值），在 padding check（填充檢查）之前，不屬於標準 base-64 字母表和替代字母表的字元將被🄵🄵。如果 *validate* 🄵 `True`，輸入中的這些非字母表字元將導致引發*binascii.Error*。

有關嚴格的 base64 檢查的更多資訊，請參🄵*binascii.a2b_base64()*。

如果 *altchars* 的長度不是 2，可能會斷言或引發*ValueError*。

base64.**standard_b64encode**(*s*)

使用標準 Base64 字母表對類位元組物件 *s* 進行編碼，🄵回傳編碼後的*bytes*。

base64.**standard_b64decode**(*s*)

使用標準 Base64 字母表對類位元組物件或 ASCII 字串 *s* 進行解碼，🄵回傳解碼後的*bytes*。

base64.**urlsafe_b64encode**(*s*)

使用 URL 安全和檔案系統安全的字母表對類位元組物件 *s* 進行編碼，該字母表將標準 Base64 字母表中的 + 替🄵🄵 -，/ 替🄵🄵 _，🄵回傳編碼後的*bytes*。結果仍可能包含 =。

base64.**urlsafe_b64decode**(*s*)

使用 URL 安全和檔案系統安全字母表對類位元組物件或 ASCII 字串 *s* 進行解碼，該字母表將標準 Base64 字母表中的 + 替🄵🄵 -，/ 替🄵🄵 _，🄵回傳解碼後的*bytes*。

base64.**b32encode**(*s*)

使用 Base32 對類位元組物件 *s* 進行編碼，🄵回傳編碼後的*bytes*。

base64.**b32decode**(*s*, *casefold=False*, *map01=None*)

解碼經過 Base32 編碼的類位元組物件或 ASCII 字串 *s*，🄵回傳解碼後的*bytes*。

可選的 *casefold* 是一個是否接受小寫字母表作🄵輸入的旗標。出於安全性考量，預設值🄵 `False`。

RFC 4648 允許將數字 0 選擇性地對應對映🄵字母 O，🄵且允許將數字 1 選擇性地對映🄵字母 I 或字母 L。當可選的引數 *map01* 不🄵 `None` 時，指定數字 1 應該對映🄵哪個字母（當 *map01* 不🄵 `None` 時，數字 0 總是對映🄵字母 O）。出於安全性考量，預設值🄵 `None`，因此不允許在輸入中使用數字 0 和 1。

如果 *s* 的填充不正確或輸入中存在非字母表字元，將引發*binascii.Error*。

base64.**b32hexencode**(*s*)

類似於*b32encode()*，但使用在 **RFC 4648** 中定義的擴展十六進位字母表 (Extended Hex Alphabet)。

在 3.10 版被加入.

base64.**b32hexdecode**(*s*, *casefold=False*)

類似於*b32encode()*，但使用在 **RFC 4648** 中定義的擴展十六進位字母表。

這個版本不允許將數字 0 對映🄵字母 O，以及將數字 1 對映🄵字母 I 或字母 L，所有這些字元都包含在擴展十六進位字母表中，🄵且不能互🄵使用。

在 3.10 版被加入.

base64.**b16encode**(*s*)

使用 Base16 對類位元組物件 *s* 進行編碼，🄵回傳編碼後的*bytes*。

base64.**b16decode**(*s*, *casefold=False*)

解碼經過 Base16 編碼的類位元組物件或 ASCII 字串 *s*，🄵回傳解碼後的*bytes*。

可選的 *casefold* 是一個是否接受小寫字母表作🄵輸入的旗標。出於安全性考量，預設值🄵 `False`。

如果 *s* 的填充不正確或輸入中存在非字母表字元，將引發*binascii.Error*。

20.5.2 Base85 編碼

Base85 encoding is not formally specified but rather a de facto standard, thus different systems perform the encoding differently.

The *a85encode()* and *b85encode()* functions in this module are two implementations of the de facto standard. You should call the function with the Base85 implementation used by the software you intend to work with.

The two functions present in this module differ in how they handle the following:

- Whether to include enclosing <~ and ~> markers
- Whether to include newline characters
- The set of ASCII characters used for encoding
- Handling of null bytes

Refer to the documentation of the individual functions for more information.

base64.**a85encode**(*b*, ***, *foldspaces=False*, *wrapcol=0*, *pad=False*, *adobe=False*)

使用 Ascii85 對類位元組物件 *b* 進行編碼，🄵回傳編碼後的*bytes*。

foldspaces 是一個可選的旗標，它使用特殊的短序列'y' 來替代連續的 4 個空格 (ASCII 0x20)，這是由'btoa' 支援的功能。這個特性不被「標准」的 Ascii85 編碼所支援。

wrapcol 控制輸出是否應該包含🄵行字元 (`b'\n'`)。如果這個值不🄵零，每行輸出的長度將不超過這個字元長度（不包含後面的🄵行符號）。

pad 控制是否在編碼之前將輸入填充🄵 4 的倍數。請注意，`btoa` 實作始終會填充。

adobe 控制編碼的位元組序列前後是否加上 <~ 和 ~>，這是 Adobe 實作中使用的。

在 3.4 版被加入.

base64.**a85decode**(*b*, ***, *foldspaces=False*, *adobe=False*, *ignorechars=b' \t\n\r\x0b'*)

解碼經過 Ascii85 編碼的類位元組物件或 ASCII 字串 *b*，🄵回傳解碼後的*bytes*。

foldspaces 是一個旗標，指定是否應該將短序列'y' 視🄵 4 個連續的空格 (ASCII 0x20) 的簡寫。這個功能不受「標准」Ascii85 編碼的支援。

adobe 控制輸入序列是否符合 Adobe Ascii85 格式（即前後加上 <~ 和 ~>）。

ignorechars 是一個包含要從輸入中忽略的字元的類位元組物件或 ASCII 字串。這只包含空格字元，預設情🄵下包含 ASCII 中的所有空格字元。

在 3.4 版被加入.

base64.**b85encode**(*b*, *pad=False*)

使用 Base85（例如，git 風格的二進位差🄵 (binary diff)）對類位元組物件 *b* 進行編碼，🄵回傳編碼後的*bytes*。

如果 *pad* 🄵 true，則在編碼之前，輸入將使用 `b'\0'` 進行填充，以使其長度🄵 4 的倍數。

在 3.4 版被加入.

base64.**b85decode**(*b*)

解碼經過 base85 編碼的類位元組物件或 ASCII 字串 *b*，🄵回傳解碼後的*bytes*。必要時會隱式移除填充。

在 3.4 版被加入.

base64.**z85encode**(*s*)

使用 Z85（如用於 ZeroMQ）對類位元組物件 *s* 進行編碼，🄵回傳編碼後的*bytes*。有關更多資訊，請參🄵 Z85 規格。

在 3.13 版被加入.

base64.**z85decode**(*s*)

解碼經 Z85 編碼的類位元組物件或 ASCII 字串 *s*，🄵回傳解碼後的*bytes*。有關更多資訊，請參🄵 Z85 規格。

在 3.13 版被加入.

20.5.3 舊版介面

base64.**decode**(*input*, *output*)

解碼二進位檔案 *input* 的🄵容，🄵將結果的二進位資料寫入 *output* 檔案。*input* 和 *output* 必須是檔案物件。*input* 將被讀取，直到 `input.readline()` 回傳一個空的 bytes 物件🄵止。

base64.**decodebytes**(*s*)

解碼必須包含一行或多行的 base64 編碼資料類位元組物件 *s*，🄵回傳解碼後的*bytes*。

在 3.1 版被加入.

base64.**encode**(*input*, *output*)

編碼二進位檔案 *input* 的🄵容，🄵將結果的 base64 編碼資料寫入 *output* 檔案。*input* 和 *output* 必須是檔案物件。*input* 將被讀取，直到 `input.read()` 回傳一個空的 bytes 物件🄵止。*encode()* 會在輸出的每 76 個位元組之後插入一個🄵行字元 (`b'\n'`)，🄵確保輸出始終以🄵行字元結尾，符合 **RFC 2045** (MIME) 的規定。

base64.**encodebytes**(*s*)

對包含任意二進位資料的類位元組物件 *s* 進行編碼，🄵回傳包含 base64 編碼資料*bytes*，在每 76 個輸出位元組後插入🄵行字元 (`b'\n'`)，🄵確保有尾隨🄵行字元，符合 **RFC 2045** (MIME) 的規定。

在 3.1 版被加入.

模組的一個範例用法：

```
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded')
>>> encoded
b'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
b'data to be encoded'
```

20.5.4 安全性注意事項

RFC 4648（第 12 節）中添加了一個新的安全性考量部分；建議對部署到正式環境的任何程式碼進行安全性部分的審查。

也參考

***binascii* 模組**
支援模組中包含 ASCII 到二進位 (ASCII-to-binary) 和二進位到 ASCII (binary-to-ASCII) 的轉🄵功能。

RFC 1521 - MIME（多用途網際網路郵件擴展）第一部分：指定和描述網際網路主體格式的機制。
第 5.2 節，”Base64 Content-Transfer-Encoding”，提供了 base64 編碼的定義。

20.6 `binascii` --- 在二進位制和 ASCII 之間轉🄵

The *binascii* module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like *base64* instead. The *binascii* module contains low-level functions written in C for greater speed that are used by the higher-level modules.

備🄵

`a2b_*` functions accept Unicode strings containing only ASCII characters. Other functions only accept *bytes-like objects* (such as *bytes*, *bytearray* and other objects that support the buffer protocol).

在 3.3 版的變更: ASCII-only unicode strings are now accepted by the `a2b_*` functions.

binascii 模組定義了以下函式：

`binascii.`**`a2b_uu`**(*string*)

Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

`binascii.`**`b2a_uu`**(*data*, *, *backtick=False*)

Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of *data* should be at most 45. If *backtick* is true, zeros are represented by `'`` '` instead of spaces.

在 3.7 版的變更: 新增 *backtick* 參數。

`binascii.`**`a2b_base64`**(*string*, /, *, *strict_mode=False*)

Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

If *strict_mode* is true, only valid base64 data will be converted. Invalid base64 data will raise *binascii.Error*.

Valid base64:

- Conforms to RFC 3548.
- Contains only characters from the base64 alphabet.
- Contains no excess data after padding (including excess padding, newlines, etc.).
- Does not start with a padding.

在 3.11 版的變更: 新增 *strict_mode* 參數。

binascii.**b2a_base64**(*data*, ***, *newline=True*)

Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char if *newline* is true. The output of this function conforms to **RFC 3548**.

在 3.6 版的變更: 新增 *newline* 參數。

binascii.**a2b_qp**(*data*, *header=False*)

Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument *header* is present and true, underscores will be decoded as spaces.

binascii.**b2a_qp**(*data*, *quotetabs=False*, *istext=True*, *header=False*)

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument *quotetabs* is present and true, all tabs and spaces will be encoded. If the optional argument *istext* is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument *header* is present and true, spaces will be encoded as underscores per **RFC 1522**. If the optional argument *header* is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

binascii.**crc_hqx**(*data*, *value*)

Compute a 16-bit CRC value of *data*, starting with *value* as the initial CRC, and return the result. This uses the CRC-CCITT polynomial $x^{16} + x^{12} + x^5 + 1$, often represented as 0x1021. This CRC is used in the binhex4 format.

binascii.**crc32**(*data*[, *value*])

Compute CRC-32, the unsigned 32-bit checksum of *data*, starting with an initial CRC of *value*. The default initial CRC is zero. The algorithm is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc)
print('crc32 = {:#010x}'.format(crc))
```

在 3.0 版的變更: The result is always unsigned.

binascii.**b2a_hex**(*data*[, *sep*[, *bytes_per_sep=1*]])

binascii.**hexlify**(*data*[, *sep*[, *bytes_per_sep=1*]])

Return the hexadecimal representation of the binary *data*. Every byte of *data* is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of *data*.

Similar functionality (but returning a text string) is also conveniently accessible using the *bytes.hex()* method.

If *sep* is specified, it must be a single character str or bytes object. It will be inserted in the output after every *bytes_per_sep* input bytes. Separator placement is counted from the right end of the output by default, if you wish to count from the left, supply a negative *bytes_per_sep* value.

```
>>> import binascii
>>> binascii.b2a_hex(b'\xb9\x01\xef')
b'b901ef'
>>> binascii.hexlify(b'\xb9\x01\xef', '-')
b'b9-01-ef'
>>> binascii.b2a_hex(b'\xb9\x01\xef', b'_', 2)
b'b9_01ef'
>>> binascii.b2a_hex(b'\xb9\x01\xef', b' ', -2)
b'b901 ef'
```

在 3.8 版的變更: 新增 *sep* 與 *bytes_per_sep* 參數。

binascii.**a2b_hex**(*hexstr*)

binascii.**unhexlify**(*hexstr*)

Return the binary data represented by the hexadecimal string *hexstr*. This function is the inverse of `b2a_hex()`. *hexstr* must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise an `Error` exception is raised.

Similar functionality (accepting only text string arguments, but more liberal towards whitespace) is also accessible using the `bytes.fromhex()` class method.

exception binascii.**Error**

Exception raised on errors. These are usually programming errors.

exception binascii.**Incomplete**

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

也參考

***base64* 模組**
Support for RFC compliant base64-style encoding in base 16, 32, 64, and 85.

***quopri* 模組**
Support for quoted-printable encoding used in MIME email messages.

20.7 quopri --- 編碼和解碼 MIME 可列印字元資料

原始碼： Lib/quopri.py

該模組根據 **RFC 1521**：「MIME（多功能網際網路郵件擴充）第一部分：指定和描述網際網路訊息正文格式的機制」中的定義來執行可列印字元 (quoted-printable) 傳輸編碼和解碼。可列印字元編碼是🄵不可列印字元相對較少的資料而設計的；如果存在許多此類字元（例如發送圖形檔案時），則透過`base64` 模組提供的 Base64 編碼方案會更加簡潔。

quopri.**decode**(*input*, *output*, *header=False*)

解碼 *input* 檔案的🄵容🄵將解碼後的二進位資料寫入 *output* 檔案。*input* 和 *output* 必須是二進位檔案物件。如果可選參數 *header* 存在且🄵 true，則底🄵將被解碼🄵空格。這用於解碼如 **RFC 1522**：「MIME（多功能網際網路郵件擴充）第二部分：非 ASCII 文字的訊息標頭擴充」中所述的"Q" 編碼標頭。

quopri.**encode**(*input*, *output*, *quotetabs*, *header=False*)

對 *input* 檔案的🄵容進行編碼，🄵將生成的可列印字元資料寫入 *output* 檔案。*input* 和 *output* 必須是二進位檔案物件。*quotetabs*，一個非可選旗標，控制是否對嵌入的空格和🄵表符號 (tab) 進行編碼；當🄵 true 時，它將對此類嵌入的空白進行編碼，當🄵 false 時，它將不對它們進行編碼。請注意，出現在列尾的空格和🄵表符號都會按照 **RFC 1521** 進行編碼。*header* 是一個旗標，用於控制空格是否按照 **RFC 1522** 編碼🄵底🄵。

quopri.**decodestring**(*s*, *header=False*)

與`decode()` 類似，不同之處在於它接受來源的`bytes` 🄵回傳相應的已解碼`bytes`。

quopri.**encodestring**(*s*, *quotetabs=False*, *header=False*)

與`encode()` 類似，不同之處在於它接受來源的`bytes` 🄵回傳相應的已編碼`bytes`。預設情🄵下，它向`encode()` 函式的 *quotetabs* 參數發送一個 `False` 值。

***base64* 模組**
對 MIME Base64 資料進行編碼和解碼

CHAPTER 21

結構化標記處理工具

Python 支援多種模組來處理各種形式的結構化資料標記。這包括用於處理標準通用標記語言 (SGML, Standard Generalized Markup Language) 和超文本標記語言 (HTML, Hypertext Markup Language) 的模組，以及用於處理可擴展標記語言 (XML, Extensible Markup Language) 的幾個介面。

21.1 `html` --- 超文本標記語言 (HTML) 支援

原始碼： Lib/html/__init__.py

此模組定義了操作 HTML 的工具。

`html.`**`escape`**(*s*, *quote=True*)

將字串 *s* 中的 `&`、< 和 > 字元轉🄵🄵在 HTML 中安全的序列 (sequence)。如果你需要在 HTML 中顯示可能包含這些字元的文字，可以使用這個函式。如果選擇性的旗標 *quote* 🄵 true（預設），則 (") 與 (') 字元也會被轉🄵；這樣能包含在 HTML 中，被引號分隔的屬性值，如 `<a href="...">` 。如果 *quote* 設🄵 false，則 (") 與 (') 字元不會被轉🄵。

在 3.2 版被加入.

`html.`**`unescape`**(*s*)

將字串 *s* 中所有附名 (named) 且🄵數值的 (numeric) 字元參照（如：`>`、`>`、`>` ）轉🄵🄵對應的 Unicode 字元。此函式針對有效及無效的字元參照，皆使用 HTML 5 標準所定義的規則，以及*HTML 5 附名字元參照清單* 。

在 3.4 版被加入.

`html` 套件中的子模組🄵:

- *`html.parser`* -- 帶有寬松剖析模式的 HTML/XHTML 剖析器
- *`html.entities`* -- HTML 實體的定義

21.2 `html.parser` --- 簡單的 HTML 和 XHTML 剖析器

原始碼： Lib/html/parser.py

該模組定義了一個類🄴*HTMLParser*，是剖析 (parse) HTML（HyperText Mark-up Language、超文本標記語言）和 XHTML 格式文本檔案的基礎。

class html.parser.**HTMLParser**(*, *convert_charrefs=True*)

建立一個能🄵剖析無效標記的剖析器實例。

如果 *convert_charrefs* 🄵 `True`（預設值），所有字元參照 (reference)（`script`/`style` 元素中的參照除外）將自動轉🄵🄵相應的 Unicode 字元。

HTMLParser 實例被提供 HTML 資料，🄴在遇到開始標🄴、結束標🄴、文本、🄴解和其他標記元素時呼叫處理程式 (handler) 方法。使用者應該繼承*HTMLParser* 🄴覆蓋其方法以實作所需的行🄴。

此剖析器不檢查結束標🄴是否與開始標🄴匹配，也不會🄴透過結束外部元素來隱晦地被結束的元素呼叫結束標🄴處理程式。

在 3.4 版的變更: 新增關鍵字引數 *convert_charrefs*。

在 3.5 版的變更: 引數 *convert_charrefs* 的預設值現在是 `True`。

21.2.1 HTML 剖析器應用程式范例

以下的基礎範例是一個簡單的 HTML 剖析器，它使用*HTMLParser* 類🄴，當遇到開始標🄴、結束標🄴和資料時將它們印出：

```
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)

    def handle_endtag(self, tag):
        print("Encountered an end tag :", tag)

    def handle_data(self, data):
        print("Encountered some data  :", data)

parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>'
            '<body><h1>Parse me!</h1></body></html>')
```

輸出將是：

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data  : Test
Encountered an end tag : title
Encountered an end tag : head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data  : Parse me!
Encountered an end tag : h1
Encountered an end tag : body
Encountered an end tag : html
```

21.2.2 HTMLParser 方法

HTMLParser 實例具有以下方法：

HTMLParser.**feed**(*data*)

向剖析器提供一些文本。只要它由完整的元素組成，它就會被處理；不完整的資料會被緩衝，直到輸入更多資料或呼叫*close()*。*data* 必須是*str*。

HTMLParser.**close**()

F制處理所有緩衝資料，如同它後面跟有文件結束標F一樣。此方法可能有被衍生類F重新定義，以在輸入末尾定義額外的處理，但重新定義的版本仍應要呼叫*HTMLParser* 基底類F方法*close()*。

HTMLParser.**reset**()

重置實例。FF所有未處理的資料。這在實例化時被會隱晦地呼叫。

HTMLParser.**getpos**()

回傳目前列號 (line number) 和偏移量 (offset)。

HTMLParser.**get_starttag_text**()

回傳最近開F (open) 的開始標F的文本。這對於結構化處理通常不必要，但在處理「已部署」的 HTML 或以最少的更改重新生成輸入（可以保留屬性之間的空白等）時可能很有用。

當遇到資料或標記元素時將呼叫以下方法，F且它們應在子類F中被覆蓋。基底類F實作什F都不做（除了*handle_startendtag()*）：

HTMLParser.**handle_starttag**(*tag*, *attrs*)

呼叫此方法來處理元素的開始標F（例如 `<div id="main">`）。

tag 引數是轉FF小寫的標F名稱。*attrs* 引數是一個 `(name, value)` 對的列表，包含在標F的 `<>` 括號F找到的屬性。*name* 將被轉成小寫，*value* 中的引號會被F除，字元和實體參照也會被替F。

例如，對於標F `<A HREF="https://www.cwi.nl/">`，這個方法會以 `handle_starttag('a', [('href', 'https://www.cwi.nl/')])` 的形式被呼叫。

在屬性值中來自*html.entities* 的所有實體參照都會被替F。

HTMLParser.**handle_endtag**(*tag*)

呼叫此方法來處理元素的結束標F（例如 `</div>`）。

tag 引數是轉FF小寫的標F名稱。

HTMLParser.**handle_startendtag**(*tag*, *attrs*)

與*handle_starttag()* 類似，但在剖析器遇到 XHTML 樣式的空標F (`<img ... />`) 時呼叫。這個方法可能被需要這個特定詞F資訊 (lexical information) 的子類F覆蓋；預設實作只是呼叫*handle_starttag()* 和*handle_endtag()*。

HTMLParser.**handle_data**(*data*)

呼叫此方法來處理任意資料（例如文本節點與 `<script>...</script>` 和 `<style>...</style>` 的F容）。

HTMLParser.**handle_entityref**(*name*)

呼叫此方法來處理形式F `&name;`（例如 `>`）的附名字元參照，其中 *name* 是一般實體參照（例如 `'gt'`）。如果 *convert_charrefs* F `True`，則永遠不會呼叫此方法。

HTMLParser.**handle_charref**(*name*)

呼叫此方法來處理 `&#`*NNN*`;` 和 `&#x`*NNN*`;` 形式的十進位和十六進位數字字元參照。例如，`>` 的十進位等效F `>`，而十六進位F `>`；在這種情F下，該方法將收到 `'62'` 或 `'x3E'`。如果 *convert_charrefs* F `True`，則永遠不會呼叫此方法。

HTMLParser.**handle_comment**(*data*)

當遇到F解時呼叫此方法（例如 `<!--comment-->`）。

舉例來F，F解 `<!-- comment -->` 會使得此方法被以引數 `' comment '` 來呼叫。

Internet Explorer 條件式🄵解（conditional comments, condcoms）的🄵容也會被發送到這個方法，故以 `<!--[if IE 9]>IE9-specific content<![endif]-->` 🄵例，這個方法將會收到 `'[if IE 9]>IE9-specific content<![endif]'`。

`HTMLParser.`**`handle_decl`**(*decl*)

呼叫此方法來處理 HTML 文件類型聲明 (doctype declaration)（例如 `<!DOCTYPE html>`）。

decl 參數將是 `<!...>` 標記🄵聲明部分的全部🄵容（例如 `'DOCTYPE html'`）。

`HTMLParser.`**`handle_pi`**(*data*)

遇到處理指示 (processing instruction) 時會呼叫的方法。*data* 參數將包含整個處理指示。例如，對於處理指示 `<?proc color='red'>`，這個方法將以 `handle_pi("proc color='red'")` 形式被呼叫。它旨在被衍生類🄵覆蓋；基底類🄵實作中什🄵都不做。

> **備🄵**
>
> *`HTMLParser`* 類🄵使用 SGML 語法規則來處理指示。使用有 `?` 跟隨在後面的 XHTML 處理指示將導致 `?` 被包含在 *data* 中。

`HTMLParser.`**`unknown_decl`**(*data*)

當剖析器讀取無法識🄵的聲明時會呼叫此方法。

data 參數將是 `<![...]>` 標記🄵聲明的全部🄵容。有時被衍生類🄵被覆蓋會是好用的。在基底類🄵實作中什🄵都不做。

21.2.3 范例

以下類🄵實作了一個剖析器，將用於解🄵更多範例：

```
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("     attr:", attr)

    def handle_endtag(self, tag):
        print("End tag  :", tag)

    def handle_data(self, data):
        print("Data     :", data)

    def handle_comment(self, data):
        print("Comment  :", data)

    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)

    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
        else:
            c = chr(int(name))
        print("Num ent  :", c)

    def handle_decl(self, data):
        print("Decl     :", data)
```

(繼續下一頁)

(繼續上一頁)

```
parser = MyHTMLParser()
```

剖析文件類型：

```
>>> parser.feed('<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" '
...             '"http://www.w3.org/TR/html4/strict.dtd">')
Decl     : DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/
↪strict.dtd"
```

剖析一個具有一些屬性和標題的元素：

```
>>> parser.feed('<img src="python-logo.png" alt="The Python logo">')
Start tag: img
     attr: ('src', 'python-logo.png')
     attr: ('alt', 'The Python logo')
>>>
>>> parser.feed('<h1>Python</h1>')
Start tag: h1
Data     : Python
End tag  : h1
```

`script` 和 `style` 元素的🄴容按原樣回傳，無需進一步剖析：

```
>>> parser.feed('<style type="text/css">#python { color: green }</style>')
Start tag: style
     attr: ('type', 'text/css')
Data     : #python { color: green }
End tag  : style

>>> parser.feed('<script type="text/javascript">'
...             'alert("<strong>hello!</strong>");</script>')
Start tag: script
     attr: ('type', 'text/javascript')
Data     : alert("<strong>hello!</strong>");
End tag  : script
```

剖析🄴解：

```
>>> parser.feed('<!--a comment-->'
...             '<!--[if IE 9]>IE-specific content<![endif]-->')
Comment  : a comment
Comment  : [if IE 9]>IE-specific content<![endif]
```

剖析附名 (named) 且🄴數值的 (numeric) 字元參照，🄴將它們轉🄵🄴正確的字元（注意：這 3 個參照都等同於 `'>'`）：

```
>>> parser = MyHTMLParser()
>>> parser.feed('&gt;&#62;&#x3E;')
Data     : >>>

>>> parser = MyHTMLParser(convert_charrefs=False)
>>> parser.feed('&gt;&#62;&#x3E;')
Named ent: >
Num ent  : >
Num ent  : >
```

將不完整的區塊提供給*`feed()`* 是可行的，但是*`handle_data()`* 可能會被多次呼叫（除非 *convert_charrefs* 設定🄴 `True`）：

```
>>> for chunk in ['<sp', 'an>buff', 'ered', ' text</s', 'pan>']:
...     parser.feed(chunk)
...
Start tag: span
Data     : buff
Data     : ered
Data     :  text
End tag  : span
```

也能🄵剖析無效的 HTML（例如未加引號的屬性）：

```
>>> parser.feed('<p><a class=link href=#main>tag soup</p ></a>')
Start tag: p
Start tag: a
     attr: ('class', 'link')
     attr: ('href', '#main')
Data     : tag soup
End tag  : p
End tag  : a
```

21.3 `html.entities` --- HTML 一般實體的定義

原始碼： Lib/html/entities.py

該 module（模組）定義了四個字典：*html5*、*name2codepoint*、*codepoint2name* 以及*entitydefs*。

`html.entities.`**`html5`**

將 HTML5 命名字元引用[1] 對映到同等 Unicode 字元的字典，例如 `html5['gt;'] == '>'`。請注意，後面的的分號包含在名稱中（例如 `'gt;'`），但有些名稱即使🄵有分號也會被此標準接受：在這種情🄵下，名稱可帶有或不帶有 `';'`。請見*html.unescape()*。

在 3.3 版被加入.

`html.entities.`**`entitydefs`**

將 XHTML 1.0 實體定義對映到 ISO Latin-1 中的替🄵文字的字典。

`html.entities.`**`name2codepoint`**

將 HTML4 實體名稱對映到 Unicode 程式點的字典。

`html.entities.`**`codepoint2name`**

將 Unicode 程式點對映到 HTML4 實體名稱的字典。

🄵解

21.4 XML 處理模組

原始碼： Lib/xml/

Python 處理 XML 的介面被歸類於 `xml` 套件中。

備🄵

如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

[1] 請見 https://html.spec.whatwg.org/multipage/named-characters.html#named-character-references

請務必注意*xml* 套件中的模組要求至少有一個可用的 SAX 相容 XML 剖析器。Expat 剖析器包含在 Python 中，所以總是可以使用*xml.parsers.expat* 模組。

xml.dom 和*xml.sax* 套件的文件🄵 DOM 和 SAX 介面的 Python 🄵結的定義。

以下是 XML 處理子模組：

- *xml.etree.ElementTree*：ElementTree API，一個簡單且輕量級的 XML 處理器
- *xml.dom*：DOM API 定義
- *xml.dom.minidom*：最小的 DOM 實作
- *xml.dom.pulldom*：支援建置部分 DOM 樹
- *xml.sax*：SAX2 基底類🄵和便利函式
- *xml.parsers.expat*：Expat 剖析器🄵結

21.4.1 XML 安全性

攻擊者可以濫用 XML 功能來執行阻斷服務攻擊 (denial of service attack)、存取本地檔案、生成與其他機器的網路連接或繞過防火🄵。

Expat versions lower than 2.6.0 may be vulnerable to "billion laughs", "quadratic blowup" and "large tokens". Python may be vulnerable if it uses such older versions of Expat as a system-provided library. Check `pyexpat.EXPAT_VERSION`.

xmlrpc 容易受到「解壓縮炸彈」攻擊。

十億笑聲 / 指數實體擴展
: 十億笑聲攻擊（也稱🄵指數實體擴展 (exponential entity expansion)）使用多層巢狀實體。每個實體多次引用另一個實體，最終的實體定義包含一個小字串。指數擴展會🄵生數 GB 的文本，🄵消耗大量記憶體和 CPU 時間。

二次爆炸實體擴展
: 二次爆炸攻擊類似於十億笑聲攻擊；它也濫用實體擴展。它不是巢狀實體，而是一遍又一遍地重🄵一個具有幾千個字元的大型實體。該攻擊不如指數擴展那🄵有效率，但它不會觸發那些用來防止深度巢狀實體的剖析器對策。

解壓縮炸彈 (decompression bomb)
: 解壓縮炸彈（又名 ZIP bomb）適用於所有可以剖析壓縮 XML 串流（例如 gzip 壓縮的 HTTP 串流或 LZMA 壓縮檔案）的 XML 函式庫。對於攻擊者來🄵，它可以將傳輸的資料量🄵少三個或更多數量級。

大型 token
: Expat 需要重新剖析未完成的 token；如果🄵有 Expat 2.6.0 中引入的保護，這可能會導致二次 runtime 而導致剖析 XML 的應用程式出現阻斷服務。此問題記🄵於 **CVE 2023-52425**。

21.5 `xml.etree.cElementTree` --- ElementTree XML API

原始碼： Lib/xml/etree/ElementTree.py

The *xml.etree.ElementTree* module implements a simple and efficient API for parsing and creating XML data.

在 3.3 版的變更: This module will use a fast implementation whenever available.

在 3.3 版之後被🄵用: `xml.etree.cElementTree` 模組已被🄵用。

備🄵

如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

21.5.1 教學

This is a short tutorial for using *xml.etree.ElementTree* (ET in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. ET has two classes for this purpose - *ElementTree* represents the whole XML document as a tree, and *Element* represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the *ElementTree* level. Interactions with a single XML element and its sub-elements are done on the *Element* level.

剖析 XML

We'll be using the fictive `country_data.xml` XML document as the sample data for this section:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank>1</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank>4</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank>68</rank>
        <year>2011</year>
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
</data>
```

We can import this data by reading from a file:

```
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```
root = ET.fromstring(country_data_as_string)
```

fromstring() parses XML from a string directly into an *Element*, which is the root element of the parsed tree. Other parsing functions may create an *ElementTree*. Check the documentation to be sure.

As an *Element*, `root` has a tag and a dictionary of attributes:

```
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:

```
>>> for child in root:
...     print(child.tag, child.attrib)
...
country {'name': 'Liechtenstein'}
country {'name': 'Singapore'}
country {'name': 'Panama'}
```

Children are nested, and we can access specific child nodes by index:

```
>>> root[0][1].text
'2008'
```

備🄵

Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom *TreeBuilder* instance to the *XMLParser* constructor.

Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an *XMLParser* and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed *Element* objects.

The most powerful tool for doing this is *XMLPullParser*. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with *XMLPullParser.feed()* calls. To get the parsed XML elements, call *XMLPullParser.read_events()*. Here is an example:

```
>>> parser = ET.XMLPullParser(['start', 'end'])
>>> parser.feed('<mytag>sometext')
>>> list(parser.read_events())
[('start', <Element 'mytag' at 0x7fa66db2be58>)]
>>> parser.feed(' more text</mytag>')
>>> for event, elem in parser.read_events():
...     print(event)
...     print(elem.tag, 'text=', elem.text)
...
end
mytag text= sometext more text
```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, *XMLPullParser* can be inconvenient to use for simpler use-cases. If you don't mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at *iterparse()*. It can be useful when you're reading a large XML document and don't want to hold it wholly in memory.

Where *immediate* feedback through events is wanted, calling method *XMLPullParser.flush()* can help reduce delay; please make sure to study the related security notes.

Finding interesting elements

Element has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For example, *Element.iter()*:

```
>>> for neighbor in root.iter('neighbor'):
...     print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

Element.findall() finds only elements with a tag which are direct children of the current element. *Element.find()* finds the *first* child with a particular tag, and *Element.text* accesses the element's text content. *Element.get()* accesses the element's attributes:

```
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print(name, rank)
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using *XPath*.

改動 XML 檔案

ElementTree provides a simple way to build XML documents and write them to files. The *ElementTree.write()* method serves this purpose.

Once created, an *Element* object may be manipulated by directly changing its fields (such as *Element.text*), adding and modifying attributes (*Element.set()* method), as well as adding new children (for example with *Element.append()*).

Let's say we want to add one to each country's rank, and add an `updated` attribute to the rank element:

```
>>> for rank in root.iter('rank'):
...     new_rank = int(rank.text) + 1
...     rank.text = str(new_rank)
...     rank.set('updated', 'yes')
...
>>> tree.write('output.xml')
```

XML 現在看起來像這樣：

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
```

(繼續下一頁)

(繼續上一頁)

```
    </country>
    <country name="Panama">
        <rank updated="yes">69</rank>
        <year>2011</year>
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
</data>
```

We can remove elements using *Element.remove()*. Let's say we want to remove all countries with a rank higher than 50:

```
>>> for country in root.findall('country'):
...     # 使用 root.findall() 來避免在遍歷時移除
...     rank = int(country.find('rank').text)
...     if rank > 50:
...         root.remove(country)
...
>>> tree.write('output.xml')
```

Note that concurrent modification while iterating can lead to problems, just like when iterating and modifying Python lists or dicts. Therefore, the example first collects all matching elements with `root.findall()`, and only then iterates over the list of matches.

XML 現在看起來像這樣:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
</data>
```

建立 XML 文件

The *SubElement()* function also provides a convenient way to create new sub-elements for a given element:

```
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /><c><d /></c></a>
```

Parsing XML with Namespaces

If the XML input has namespaces, tags and attributes with prefixes in the form `prefix:sometag` get expanded to `{uri}sometag` where the *prefix* is replaced by the full *URI*. Also, if there is a default namespace, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix ”fictional” and the other serving as the default namespace:

```
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
        xmlns="http://people.example.com">
    <actor>
        <name>John Cleese</name>
        <fictional:character>Lancelot</fictional:character>
        <fictional:character>Archie Leach</fictional:character>
    </actor>
    <actor>
        <name>Eric Idle</name>
        <fictional:character>Sir Robin</fictional:character>
        <fictional:character>Gunther</fictional:character>
        <fictional:character>Commander Clement</fictional:character>
    </actor>
</actors>
```

One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a *find()* or *findall()*:

```
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name')
    print(name.text)
    for char in actor.findall('{http://characters.example.com}character'):
        print(' |-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns)
    print(name.text)
    for char in actor.findall('role:character', ns):
        print(' |-->', char.text)
```

These two approaches both output:

```
John Cleese
 |--> Lancelot
 |--> Archie Leach
Eric Idle
 |--> Sir Robin
 |--> Gunther
 |--> Commander Clement
```

21.5.2 XPath 支援

This module provides limited support for XPath expressions for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

范例

Here’s an example that demonstrates some of the XPath capabilities of the module. We’ll be using the `countrydata` XML document from the *Parsing XML* section:

```
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children of the top-level
# elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall(".//year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall(".//*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of their parent
root.findall(".//neighbor[2]")
```

For XML with namespaces, use the usual qualified `{namespace}tag` notation:

```
# All dublin-core "title" tags in the document
root.findall(".//{http://purl.org/dc/elements/1.1/}title")
```

支援的 XPath 語法

語法	意義
`tag`	Selects all child elements with the given tag. For example, `spam` selects all child elements named `spam`, and `spam/egg` selects all grandchildren named `egg` in all children named `spam`. `{namespace}*` selects all tags in the given namespace, `{*}spam` selects tags named `spam` in any (or no) namespace, and `{}*` only selects tags that are not in a namespace. 在 3.8 版的變更: 新增對星號萬用字元的支援。
`*`	Selects all child elements, including comments and processing instructions. For example, `*/egg` selects all grandchildren named `egg`.
`.`	Selects the current node. This is mostly useful at the beginning of the path, to indicate that it's a relative path.
`//`	Selects all subelements, on all levels beneath the current element. For example, `.//egg` selects all `egg` elements in the entire tree.
`..`	Selects the parent element. Returns `None` if the path attempts to reach the ancestors of the start element (the element `find` was called on).
`[@attrib]`	選擇所有具有給定屬性的元素。
`[@attrib='value']`	Selects all elements for which the given attribute has the given value. The value cannot contain quotes.
`[@attrib!='value']`	Selects all elements for which the given attribute does not have the given value. The value cannot contain quotes. 在 3.10 版被加入.
`[tag]`	Selects all elements that have a child named `tag`. Only immediate children are supported.
`[.='text']`	Selects all elements whose complete text content, including descendants, equals the given `text`. 在 3.7 版被加入.
`[.!='text']`	Selects all elements whose complete text content, including descendants, does not equal the given `text`. 在 3.10 版被加入.
`[tag='text']`	Selects all elements that have a child named `tag` whose complete text content, including descendants, equals the given `text`.
`[tag!='text']`	Selects all elements that have a child named `tag` whose complete text content, including descendants, does not equal the given `text`. 在 3.10 版被加入.
`[position]`	Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression `last()` (for the last position), or a position relative to the last position (e.g. `last()-1`).

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another predicate. `position` predicates must be preceded by a tag name.

21.5.3 Reference

函式

`xml.etree.ElementTree.`**`canonicalize`**(*xml_data=None*, *, *out=None*, *from_file=None*, ***options*)

C14N 2.0 transformation function.

Canonicalization is a way to normalise XML output in a way that allows byte-by-byte comparisons and digital signatures. It reduces the freedom that XML serializers have and instead generates a more constrained XML representation. The main restrictions regard the placement of namespace declarations, the ordering of attributes, and ignorable whitespace.

This function takes an XML data string (*xml_data*) or a file path or file-like object (*from_file*) as input, converts it to the canonical form, and writes it out using the *out* file(-like) object, if provided, or returns it as a text string if not. The output file receives text, not bytes. It should therefore be opened in text mode with `utf-8` encoding.

Typical uses:

```
xml_data = "<root>...</root>"
print(canonicalize(xml_data))

with open("c14n_output.xml", mode='w', encoding='utf-8') as out_file:
    canonicalize(xml_data, out=out_file)

with open("c14n_output.xml", mode='w', encoding='utf-8') as out_file:
    canonicalize(from_file="inputfile.xml", out=out_file)
```

The configuration *options* are as follows:

- *with_comments*: set to true to include comments (default: false)
- ***strip_text*: set to true to strip whitespace before and after text content**
  (default: false)
- ***rewrite_prefixes*: set to true to replace namespace prefixes by "n{number}"**
  (default: false)
- ***qname_aware_tags*: a set of qname aware tag names in which prefixes**
  should be replaced in text content (default: empty)
- ***qname_aware_attrs*: a set of qname aware attribute names in which prefixes**
  should be replaced in text content (default: empty)
- *exclude_attrs*: a set of attribute names that should not be serialised
- *exclude_tags*: a set of tag names that should not be serialised

In the option list above, "a set" refers to any collection or iterable of strings, no ordering is expected.

在 3.8 版被加入.

xml.etree.ElementTree.**Comment**(*text=None*)

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. *text* is a string containing the comment string. Returns an element instance representing a comment.

Note that *XMLParser* skips over comments in the input instead of creating comment objects for them. An *ElementTree* will only contain comment nodes if they have been inserted into to the tree using one of the *Element* methods.

xml.etree.ElementTree.**dump**(*elem*)

Writes an element tree or element structure to sys.stdout. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

elem is an element tree or an individual element.

在 3.8 版的變更: The *dump()* function now preserves the attribute order specified by the user.

xml.etree.ElementTree.**fromstring**(*text*, *parser=None*)

Parses an XML section from a string constant. Same as *XML()*. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

xml.etree.ElementTree.**fromstringlist**(*sequence*, *parser=None*)

Parses an XML document from a sequence of string fragments. *sequence* is a list or other sequence containing XML data fragments. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

在 3.2 版被加入.

xml.etree.ElementTree.**indent**(*tree*, *space=' '*, *level=0*)

Appends whitespace to the subtree to indent the tree visually. This can be used to generate pretty-printed XML output. *tree* can be an Element or ElementTree. *space* is the whitespace string that will be inserted for each indentation level, two space characters by default. For indenting partial subtrees inside of an already indented tree, pass the initial indentation level as *level*.

在 3.9 版被加入.

xml.etree.ElementTree.**iselement**(*element*)

Check if an object appears to be a valid element object. *element* is an element instance. Return `True` if this is an element object.

xml.etree.ElementTree.**iterparse**(*source*, *events=None*, *parser=None*)

Parses an XML section into an element tree incrementally, and reports what's going on to the user. *source* is a filename or *file object* containing XML data. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"comment"`, `"pi"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. *parser* must be a subclass of *XMLParser* and can only use the default *TreeBuilder* as a target. Returns an *iterator* providing `(event, elem)` pairs; it has a `root` attribute that references the root element of the resulting XML tree once *source* is fully read. The iterator has the `close()` method that closes the internal file object if *source* is a filename.

Note that while *iterparse()* builds the tree incrementally, it issues blocking reads on *source* (or the file it names). As such, it's unsuitable for applications where blocking reads can't be made. For fully non-blocking parsing, see *XMLPullParser*.

> **備🄵**
>
> *iterparse()* only guarantees that it has seen the ">" character of a starting tag when it emits a "start" event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.
>
> If you need a fully populated element, look for "end" events instead.

在 3.4 版之後被🄵用: *parser* 引數。

在 3.8 版的變更: 新增 *context* 與 *check_hostname* 事件。

在 3.13 版的變更: 新增 `close()` 方法。

xml.etree.ElementTree.**parse**(*source*, *parser=None*)

Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *ElementTree* instance.

xml.etree.ElementTree.**ProcessingInstruction**(*target*, *text=None*)

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that *XMLParser* skips over processing instructions in the input instead of creating PI objects for them. An *ElementTree* will only contain processing instruction nodes if they have been inserted into to the tree using one of the *Element* methods.

xml.etree.ElementTree.**register_namespace**(*prefix*, *uri*)

Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

在 3.2 版被加入.

xml.etree.ElementTree.**SubElement**(*parent*, *tag*, *attrib={}*, ***extra*)

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.**tostring**(*element*, *encoding='us-ascii'*, *method='xml'*, ***, *xml_declaration=None*, *default_namespace=None*, *short_empty_elements=True*)

Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*[1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). *xml_declaration*, *default_namespace* and *short_empty_elements* has the same meaning as in *ElementTree.write()*. Returns an (optionally) encoded string containing the XML data.

在 3.4 版的變更: 新增 *short_empty_elements* 參數。

在 3.8 版的變更: 新增 *xml_declaration* 與 *default_namespace* 參數。

在 3.8 版的變更: The *tostring()* function now preserves the attribute order specified by the user.

xml.etree.ElementTree.**tostringlist**(*element*, *encoding='us-ascii'*, *method='xml'*, ***, *xml_declaration=None*, *default_namespace=None*, *short_empty_elements=True*)

Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*[1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). *xml_declaration*, *default_namespace* and *short_empty_elements* has the same meaning as in *ElementTree.write()*. Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that `b"".join(tostringlist(element)) == tostring(element)`.

在 3.2 版被加入.

在 3.4 版的變更: 新增 *short_empty_elements* 參數。

在 3.8 版的變更: 新增 *xml_declaration* 與 *default_namespace* 參數。

在 3.8 版的變更: The *tostringlist()* function now preserves the attribute order specified by the user.

xml.etree.ElementTree.**XML**(*text*, *parser=None*)

Parses an XML section from a string constant. This function can be used to embed "XML literals" in Python code. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

xml.etree.ElementTree.**XMLID**(*text*, *parser=None*)

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns a tuple containing an *Element* instance and a dictionary.

21.5.4 XInclude support

This module provides limited support for XInclude directives, via the *xml.etree.ElementInclude* helper module. This module can be used to insert subtrees and text strings into element trees, based on information in the tree.

[1] The encoding string included in XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

范例

Here's an example that demonstrates use of the XInclude module. To include an XML document in the current document, use the `{http://www.w3.org/2001/XInclude}include` element and set the **parse** attribute to `"xml"`, and use the **href** attribute to specify the document to include.

```
<?xml version="1.0"?>
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  <xi:include href="source.xml" parse="xml" />
</document>
```

By default, the **href** attribute is treated as a file name. You can use custom loaders to override this behaviour. Also note that the standard helper does not support XPointer syntax.

To process this file, load it as usual, and pass the root element to the *xml.etree.ElementTree* module:

```
from xml.etree import ElementTree, ElementInclude

tree = ElementTree.parse("document.xml")
root = tree.getroot()

ElementInclude.include(root)
```

The ElementInclude module replaces the `{http://www.w3.org/2001/XInclude}include` element with the root element from the **source.xml** document. The result might look something like this:

```
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  <para>This is a paragraph.</para>
</document>
```

If the **parse** attribute is omitted, it defaults to "xml". The href attribute is required.

To include a text document, use the `{http://www.w3.org/2001/XInclude}include` element, and set the **parse** attribute to "text":

```
<?xml version="1.0"?>
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  Copyright (c) <xi:include href="year.txt" parse="text" />.
</document>
```

The result might look something like:

```
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  Copyright (c) 2003.
</document>
```

21.5.5 Reference

函式

`xml.etree.ElementInclude.`**`default_loader`**(*href*, *parse*, *encoding=None*)

Default loader. This default loader reads an included resource from disk. *href* is a URL. *parse* is for parse mode either "xml" or "text". *encoding* is an optional text encoding. If not given, encoding is `utf-8`. Returns the expanded resource. If the parse mode is `"xml"`, this is an *Element* instance. If the parse mode is `"text"`, this is a string. If the loader fails, it can return `None` or raise an exception.

`xml.etree.ElementInclude.`**`include`**(*elem*, *loader=None*, *base_url=None*, *max_depth=6*)

This function expands XInclude directives in-place in tree pointed by *elem*. *elem* is either the root *Element* or an *ElementTree* instance to find such element. *loader* is an optional resource loader. If omitted, it defaults to *default_loader()*. If given, it should be a callable that implements the same interface as *default_loader()*. *base_url* is base URL of the original file, to resolve relative include file references.

max_depth is the maximum number of recursive inclusions. Limited to reduce the risk of malicious content explosion. Pass `None` to disable the limitation.

在 3.9 版的變更: 新增 *base_url* 與 *max_depth* 參數。

Element 物件

class `xml.etree.ElementTree.`**Element**(*tag*, *attrib={}*, ***extra*)

Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *tag* is the element name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments.

tag

A string identifying what kind of data this element represents (the element type, in other words).

text

tail

These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the *text* attribute holds either the text between the element's start tag and its first child or end tag, or `None`, and the *tail* attribute holds either the text between the element's end tag and the next tag, or `None`. For the XML data

```
<a><b>1<c>2<d/>3</c></b>4</a>
```

the *a* element has `None` for both *text* and *tail* attributes, the *b* element has *text* `"1"` and *tail* `"4"`, the *c* element has *text* `"2"` and *tail* `None`, and the *d* element has *text* `None` and *tail* `"3"`.

To collect the inner text of an element, see *itertext()*, for example `"".join(element.itertext())`.

Applications may store arbitrary objects in these attributes.

attrib

A dictionary containing the element's attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

clear()

Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

get(*key*, *default=None*)

Gets the element attribute named *key*.

Returns the attribute value, or *default* if the attribute was not found.

items()

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

keys()

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

set(*key*, *value*)

Set the attribute *key* on the element to *value*.

The following methods work on the element's children (subelements).

append(*subelement*)

Adds the element *subelement* to the end of this element's internal list of subelements. Raises *TypeError* if *subelement* is not an *Element*.

extend(*subelements*)

Appends *subelements* from an iterable of elements. Raises *TypeError* if a subelement is not an *Element*.

在 3.2 版被加入.

find(*match*, *namespaces=None*)

Finds the first subelement matching *match*. *match* may be a tag name or a *path*. Returns an element instance or `None`. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

findall(*match*, *namespaces=None*)

Finds all matching subelements, by tag name or *path*. Returns a list containing all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

findtext(*match*, *default=None*, *namespaces=None*)

Finds text for the first subelement matching *match*. *match* may be a tag name or a *path*. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

insert(*index*, *subelement*)

Inserts *subelement* at the given position in this element. Raises *TypeError* if *subelement* is not an *Element*.

iter(*tag=None*)

Creates a tree *iterator* with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not `None` or `'*'`, only elements whose tag equals *tag* are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

在 3.2 版被加入.

iterfind(*match*, *namespaces=None*)

Finds all matching subelements, by tag name or *path*. Returns an iterable yielding all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name.

在 3.2 版被加入.

itertext()

Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

在 3.2 版被加入.

makeelement(*tag*, *attrib*)

Creates a new element object of the same type as this element. Do not call this method, use the *SubElement()* factory function instead.

remove(*subelement*)

Removes *subelement* from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

Element objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`.

Caution: Elements with no subelements will test as `False`. In a future release of Python, all elements will test as `True` regardless of whether subelements exist. Instead, prefer explicit `len(elem)` or `elem is not None` tests.:

```
element = root.find('foo')

if not element:  # careful!
    print("element not found, or element has no subelements")

if element is None:
    print("element not found")
```

在 3.12 版的變更: Testing the truth value of an Element emits *DeprecationWarning*.

Prior to Python 3.8, the serialisation order of the XML attributes of elements was artificially made predictable by sorting the attributes by their name. Based on the now guaranteed ordering of dicts, this arbitrary reordering was removed in Python 3.8 to preserve the order in which attributes were originally parsed or created by user code.

In general, user code should try not to depend on a specific ordering of attributes, given that the XML Information Set explicitly excludes the attribute order from conveying information. Code should be prepared to deal with any ordering on input. In cases where deterministic XML output is required, e.g. for cryptographic signing or test data sets, canonical serialisation is available with the *canonicalize()* function.

In cases where canonical output is not applicable but a specific attribute order is still desirable on output, code should aim for creating the attributes directly in the desired order, to avoid perceptual mismatches for readers of the code. In cases where this is difficult to achieve, a recipe like the following can be applied prior to serialisation to enforce an order independently from the Element creation:

```
def reorder_attributes(root):
    for el in root.iter():
        attrib = el.attrib
        if len(attrib) > 1:
            # adjust attribute order, e.g. by sorting
            attribs = sorted(attrib.items())
            attrib.clear()
            attrib.update(attribs)
```

ElementTree 物件

class xml.etree.ElementTree.**ElementTree**(*element=None*, *file=None*)

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

element is the root element. The tree is initialized with the contents of the XML *file* if given.

_setroot(*element*)

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. *element* is an element instance.

find(*match*, *namespaces=None*)

Same as *Element.find()*, starting at the root of the tree.

findall(*match*, *namespaces=None*)

Same as *Element.findall()*, starting at the root of the tree.

findtext(*match*, *default=None*, *namespaces=None*)

Same as *Element.findtext()*, starting at the root of the tree.

getroot()

Returns the root element for this tree.

iter(*tag=None*)

Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. *tag* is the tag to look for (default is to return all elements).

iterfind(*match*, *namespaces=None*)

Same as `Element.iterfind()`, starting at the root of the tree.

在 3.2 版被加入.

parse(*source*, *parser=None*)

Loads an external XML section into this element tree. *source* is a file name or *file object*. *parser* is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns the section root element.

write(*file*, *encoding='us-ascii'*, *xml_declaration=None*, *default_namespace=None*, *method='xml'*, ***, *short_empty_elements=True*)

Writes the element tree to a file, as XML. *file* is a file name, or a *file object* opened for writing. *encoding*[Page 1375, 1] is the output encoding (default is US-ASCII). *xml_declaration* controls if an XML declaration should be added to the file. Use `False` for never, `True` for always, `None` for only if not US-ASCII or UTF-8 or Unicode (default is `None`). *default_namespace* sets the default XML namespace (for "xmlns"). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). The keyword-only *short_empty_elements* parameter controls the formatting of elements that contain no content. If `True` (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (`str`) or binary (`bytes`). This is controlled by the *encoding* argument. If *encoding* is `"unicode"`, the output is a string; otherwise, it's binary. Note that this may conflict with the type of *file* if it's an open *file object*; make sure you do not try to write a string to a binary stream and vice versa.

在 3.4 版的變更: 新增 *short_empty_elements* 參數。

在 3.8 版的變更: The `write()` method now preserves the attribute order specified by the user.

This is the XML file that is going to be manipulated:

```
<html>
    <head>
        <title>Example page</title>
    </head>
    <body>
        <p>Moved to <a href="http://example.org/">example.org</a>
        or <a href="http://example.com/">example.com</a>.</p>
    </body>
</html>
```

Example of changing the attribute "target" of every link in first paragraph:

```
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")      # Finds first occurrence of tag p in body
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))    # Returns list of all links
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ec1cc>]
>>> for i in links:             # Iterates through all found links
...     i.attrib["target"] = "blank"
...
>>> tree.write("output.xhtml")
```

QName 物件

class xml.etree.ElementTree.**QName**(*text_or_uri*, *tag=None*)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. *text_or_uri* is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If *tag* is given, the first argument is interpreted as a URI, and this argument is interpreted as a local name. *QName* instances are opaque.

TreeBuilder 物件

class xml.etree.ElementTree.**TreeBuilder**(*element_factory=None*, *, *comment_factory=None*, *pi_factory=None*, *insert_comments=False*, *insert_pis=False*)

Generic element structure builder. This builder converts a sequence of start, data, end, comment and pi method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format.

element_factory, when given, must be a callable accepting two positional arguments: a tag and a dict of attributes. It is expected to return a new element instance.

The *comment_factory* and *pi_factory* functions, when given, should behave like the *Comment()* and *ProcessingInstruction()* functions to create comments and processing instructions. When not given, the default factories will be used. When *insert_comments* and/or *insert_pis* is true, comments/pis will be inserted into the tree if they appear within the root element (but not outside of it).

close()

Flushes the builder buffers, and returns the toplevel document element. Returns an *Element* instance.

data(*data*)

Adds text to the current element. *data* is a string. This should be either a bytestring, or a Unicode string.

end(*tag*)

Closes the current element. *tag* is the element name. Returns the closed element.

start(*tag*, *attrs*)

Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

comment(*text*)

Creates a comment with the given *text*. If `insert_comments` is true, this will also add it to the tree.

在 3.8 版被加入.

pi(*target*, *text*)

Creates a process instruction with the given *target* name and *text*. If `insert_pis` is true, this will also add it to the tree.

在 3.8 版被加入.

In addition, a custom *TreeBuilder* object can provide the following methods:

doctype(*name*, *pubid*, *system*)

Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default *TreeBuilder* class.

在 3.2 版被加入.

start_ns(*prefix*, *uri*)

Is called whenever the parser encounters a new namespace declaration, before the `start()` callback for the opening element that defines it. *prefix* is `''` for the default namespace and the declared namespace prefix name otherwise. *uri* is the namespace URI.

在 3.8 版被加入.

end_ns(*prefix*)

Is called after the `end()` callback of an element that declared a namespace prefix mapping, with the name of the *prefix* that went out of scope.

在 3.8 版被加入.

class xml.etree.ElementTree.**C14NWriterTarget**(*write*, *, *with_comments=False*, *strip_text=False*, *rewrite_prefixes=False*, *qname_aware_tags=None*, *qname_aware_attrs=None*, *exclude_attrs=None*, *exclude_tags=None*)

A C14N 2.0 writer. Arguments are the same as for the *canonicalize()* function. This class does not build a tree but translates the callback events directly into a serialised form using the *write* function.

在 3.8 版被加入.

XMLParser 物件

class xml.etree.ElementTree.**XMLParser**(*, *target=None*, *encoding=None*)

This class is the low-level building block of the module. It uses *xml.parsers.expat* for efficient, event-based parsing of XML. It can be fed XML data incrementally with the *feed()* method, and parsing events are translated to a push API - by invoking callbacks on the *target* object. If *target* is omitted, the standard *TreeBuilder* is used. If *encoding*[Page 1375, 1] is given, the value overrides the encoding specified in the XML file.

在 3.8 版的變更: Parameters are now *keyword-only*. The *html* argument is no longer supported.

close()

Finishes feeding data to the parser. Returns the result of calling the `close()` method of the *target* passed during construction; by default, this is the toplevel document element.

feed(*data*)

Feeds data to the parser. *data* is encoded data.

flush()

Triggers parsing of any previously fed unparsed data, which can be used to ensure more immediate feedback, in particular with Expat >=2.6.0. The implementation of *flush()* temporarily disables reparse deferral with Expat (if currently enabled) and triggers a reparse. Disabling reparse deferral has security consequences; please see *xml.parsers.expat.xmlparser.SetReparseDeferralEnabled()* for details.

Note that *flush()* has been backported to some prior releases of CPython as a security fix. Check for availability of *flush()* using *hasattr()* if used in code running across a variety of Python versions.

在 3.13 版被加入.

XMLParser.feed() calls *target*'s `start(tag, attrs_dict)` method for each opening tag, its `end(tag)` method for each closing tag, and data is processed by method `data(data)`. For further supported callback methods, see the *TreeBuilder* class. *XMLParser.close()* calls *target*'s method `close()`. *XMLParser* can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:                     # The target object of the parser
...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib):   # Called for each opening tag.
...         self.depth += 1
...         if self.depth > self.maxDepth:
...             self.maxDepth = self.depth
...     def end(self, tag):             # Called for each closing tag.
...         self.depth -= 1
...     def data(self, data):
```

(繼續下一頁)

(繼續上一頁)

```
...         pass            # We do not need to do anything with data.
...     def close(self):    # Called when all data has been parsed.
...         return self.maxDepth
...
>>> target = MaxDepth()
>>> parser = XMLParser(target=target)
>>> exampleXml = """
... <a>
...   <b>
...   </b>
...   <b>
...     <c>
...       <d>
...       </d>
...     </c>
...   </b>
... </a>"""
>>> parser.feed(exampleXml)
>>> parser.close()
4
```

XMLPullParser 物件

class xml.etree.ElementTree.**XMLPullParser**(*events=None*)

A pull parser suitable for non-blocking applications. Its input-side API is similar to that of *XMLParser*, but instead of pushing calls to a callback target, *XMLPullParser* collects an internal list of parsing events and lets the user read from it. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"comment"`, `"pi"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported.

feed(*data*)

Feed the given bytes data to the parser.

flush()

Triggers parsing of any previously fed unparsed data, which can be used to ensure more immediate feedback, in particular with Expat >=2.6.0. The implementation of *flush()* temporarily disables reparse deferral with Expat (if currently enabled) and triggers a reparse. Disabling reparse deferral has security consequences; please see *xml.parsers.expat.xmlparser.SetReparseDeferralEnabled()* for details.

Note that *flush()* has been backported to some prior releases of CPython as a security fix. Check for availability of *flush()* using *hasattr()* if used in code running across a variety of Python versions.

在 3.13 版被加入.

close()

Signal the parser that the data stream is terminated. Unlike *XMLParser.close()*, this method always returns *None*. Any events not yet retrieved when the parser is closed can still be read with *read_events()*.

read_events()

Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields `(event, elem)` pairs, where *event* is a string representing the type of event (e.g. `"end"`) and *elem* is the encountered *Element* object, or other context value as follows.

- `start`、`end`: 目前的 Element。
- `comment`, `pi`: the current comment / processing instruction
- `start-ns`: a tuple `(prefix, uri)` naming the declared namespace mapping.
- `end-ns`: *None* (this may change in a future version)

Events provided in a previous call to *read_events()* will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel over iterators obtained from *read_events()* will have unpredictable results.

> **備🄵**
>
> *XMLPullParser* only guarantees that it has seen the ">" character of a starting tag when it emits a "start" event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.
>
> If you need a fully populated element, look for "end" events instead.

在 3.4 版被加入.

在 3.8 版的變更: 新增 *context* 與 *check_hostname* 事件。

例外

class xml.etree.ElementTree.**ParseError**

XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

code

A numeric error code from the expat parser. See the documentation of *xml.parsers.expat* for the list of error codes and their meanings.

position

A tuple of *line*, *column* numbers, specifying where the error occurred.

🄵解

21.6 xml.dom --- Document 物件模型 API

原始碼： Lib/xml/dom/__init__.py

The Document Object Model, or "DOM," is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program's position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or "levels" in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a `DOMImplementation` object class which provides access to `Document` creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing `Document` object. In Python, each DOM implementation will provide a function *getDOMImplementation()*.

DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section *Conformance* for a detailed discussion of mapping requirements.

Document Object Model (DOM) Level 1 Specification
The W3C recommendation for the DOM supported by *xml.dom.minidom*.

Python Language Mapping Specification
This specifies the mapping from OMG IDL to Python.

21.6.1 模組🄵容

The *xml.dom* contains the following functions:

xml.dom.**registerDOMImplementation**(*name*, *factory*)

Register the *factory* function with the name *name*. The factory function should return an object which implements the DOMImplementation interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

xml.dom.**getDOMImplementation**(*name=None*, *features=()*)

Return a suitable DOM implementation. The *name* is either well-known, the module name of a DOM implementation, or None. If it is not None, imports the corresponding module and returns a DOMImplementation object if the import succeeds. If no name is given, and if the environment variable PYTHON_DOM is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an *ImportError*. The features list must be a sequence of (feature, version) pairs which are passed to the hasFeature() method on available DOMImplementation objects.

Some convenience constants are also provided:

xml.dom.**EMPTY_NAMESPACE**

The value used to indicate that no namespace is associated with a node in the DOM. This is typically found as the namespaceURI of a node, or used as the *namespaceURI* parameter to a namespaces-specific method.

xml.dom.**XML_NAMESPACE**

The namespace URI associated with the reserved prefix xml, as defined by Namespaces in XML (section 4).

xml.dom.**XMLNS_NAMESPACE**

The namespace URI for namespace declarations, as defined by Document Object Model (DOM) Level 2 Core Specification (section 1.1.8).

xml.dom.**XHTML_NAMESPACE**

The URI of the XHTML namespace as defined by XHTML 1.0: The Extensible HyperText Markup Language (section 3.1.1).

In addition, *xml.dom* contains a base Node class and the DOM exception classes. The Node class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM

implementations must provide those. The `Node` class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete `Node` objects; they are located within the class rather than at the module level to conform with the DOM specifications.

21.6.2 Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

Interface	Section	Purpose
`DOMImplementation`	*DOMImplementation 物件*	Interface to the underlying implementation.
`Node`	*Node Objects*	Base interface for most objects in a document.
`NodeList`	*NodeList 物件*	Interface for a sequence of nodes.
`DocumentType`	*DocumentType 物件*	Information about the declarations needed to process a document.
`Document`	*Document Objects*	Object which represents an entire document.
`Element`	*Element Objects*	Element nodes in the document hierarchy.
`Attr`	*Attr Objects*	Attribute value nodes on element nodes.
`Comment`	*Comment Objects*	Representation of comments in the source document.
`Text`	*Text and CDATASection Objects*	Nodes containing textual content from the document.
`ProcessingInstructi`	*ProcessingInstruction 物件*	Processing instruction representation.

An additional section describes the exceptions defined for working with the DOM in Python.

DOMImplementation 物件

The `DOMImplementation` interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new `Document` and `DocumentType` objects using the `DOMImplementation` as well.

`DOMImplementation.`**`hasFeature`**(*feature*, *version*)

Return `True` if the feature identified by the pair of strings *feature* and *version* is implemented.

`DOMImplementation.`**`createDocument`**(*namespaceUri*, *qualifiedName*, *doctype*)

Return a new `Document` object (the root of the DOM), with a child `Element` object having the given *namespaceUri* and *qualifiedName*. The *doctype* must be a `DocumentType` object created by *`createDocumentType()`*, or `None`. In the Python DOM API, the first two arguments can also be `None` in order to indicate that no `Element` child is to be created.

`DOMImplementation.`**`createDocumentType`**(*qualifiedName*, *publicId*, *systemId*)

Return a new `DocumentType` object that encapsulates the given *qualifiedName*, *publicId*, and *systemId* strings, representing the information contained in an XML document type declaration.

Node Objects

All of the components of an XML document are subclasses of `Node`.

`Node.`**`nodeType`**

An integer representing the node type. Symbolic constants for the types are on the `Node` object: `ELEMENT_NODE`, `ATTRIBUTE_NODE`, `TEXT_NODE`, `CDATA_SECTION_NODE`, `ENTITY_NODE`, `PROCESSING_INSTRUCTION_NODE`, `COMMENT_NODE`, `DOCUMENT_NODE`, `DOCUMENT_TYPE_NODE`, `NOTATION_NODE`. This is a read-only attribute.

`Node.`**`parentNode`**

The parent of the current node, or `None` for the document node. The value is always a `Node` object or `None`.

For `Element` nodes, this will be the parent element, except for the root element, in which case it will be the `Document` object. For `Attr` nodes, this is always `None`. This is a read-only attribute.

`Node.`**`attributes`**

A `NamedNodeMap` of attribute objects. Only elements have actual values for this; others provide `None` for this attribute. This is a read-only attribute.

`Node.`**`previousSibling`**

The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the *self* element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be `None`. This is a read-only attribute.

`Node.`**`nextSibling`**

The node that immediately follows this one with the same parent. See also *`previousSibling`*. If this is the last child of the parent, this attribute will be `None`. This is a read-only attribute.

`Node.`**`childNodes`**

A list of nodes contained within this node. This is a read-only attribute.

`Node.`**`firstChild`**

The first child of the node, if there are any, or `None`. This is a read-only attribute.

`Node.`**`lastChild`**

The last child of the node, if there are any, or `None`. This is a read-only attribute.

`Node.`**`localName`**

The part of the `tagName` following the colon if there is one, else the entire `tagName`. The value is a string.

`Node.`**`prefix`**

The part of the `tagName` preceding the colon if there is one, else the empty string. The value is a string, or `None`.

`Node.`**`namespaceURI`**

The namespace associated with the element name. This will be a string or `None`. This is a read-only attribute.

`Node.`**`nodeName`**

This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the `tagName` property for elements or the `name` property for attributes. For all node types, the value of this attribute will be either a string or `None`. This is a read-only attribute.

`Node.`**`nodeValue`**

This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with *`nodeName`*. The value is a string or `None`.

`Node.`**`hasAttributes`**`()`

Return `True` if the node has any attributes.

`Node.`**`hasChildNodes`**`()`

Return `True` if the node has any child nodes.

`Node.`**`isSameNode`**`(`*other*`)`

Return `True` if *other* refers to the same node as this node. This is especially useful for DOM implementations which use any sort of proxy architecture (because more than one object can refer to the same node).

> **備🄵**
>
> This is based on a proposed DOM Level 3 API which is still in the "working draft" stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node.**appendChild**(*newChild*)

Add a new child node to this node at the end of the list of children, returning *newChild*. If the node was already in the tree, it is removed first.

Node.**insertBefore**(*newChild*, *refChild*)

Insert a new child node before an existing child. It must be the case that *refChild* is a child of this node; if not, *ValueError* is raised. *newChild* is returned. If *refChild* is None, it inserts *newChild* at the end of the children's list.

Node.**removeChild**(*oldChild*)

Remove a child node. *oldChild* must be a child of this node; if not, *ValueError* is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its unlink() method should be called.

Node.**replaceChild**(*newChild*, *oldChild*)

Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, *ValueError* is raised.

Node.**normalize**()

Join adjacent text nodes so that all stretches of text are stored as single Text instances. This simplifies processing text from a DOM tree for many applications.

Node.**cloneNode**(*deep*)

Clone this node. Setting *deep* means to clone all child nodes as well. This returns the clone.

NodeList 物件

A NodeList represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: an Element object provides one as its list of child nodes, and the getElementsByTagName() and getElementsByTagNameNS() methods of Node return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

NodeList.**item**(*i*)

Return the *i*'th item from the sequence, if there is one, or None. The index *i* is not allowed to be less than zero or greater than or equal to the length of the sequence.

NodeList.**length**

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow NodeList objects to be used as Python sequences. All NodeList implementations must include support for __len__() and __getitem__(); this allows iteration over the NodeList in for statements and proper support for the *len()* built-in function.

If a DOM implementation supports modification of the document, the NodeList implementation must also support the __setitem__() and __delitem__() methods.

DocumentType 物件

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a DocumentType object. The DocumentType for a document is available from the Document object's doctype attribute; if there is no DOCTYPE declaration for the document, the document's doctype attribute will be set to None instead of an instance of this interface.

DocumentType is a specialization of Node, and adds the following attributes:

DocumentType.**publicId**

The public identifier for the external subset of the document type definition. This will be a string or None.

DocumentType.**systemId**

The system identifier for the external subset of the document type definition. This will be a URI as a string, or None.

DocumentType.**internalSubset**

A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be None.

DocumentType.**name**

The name of the root element as given in the DOCTYPE declaration, if present.

DocumentType.**entities**

This is a NamedNodeMap giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no entities are defined.

DocumentType.**notations**

This is a NamedNodeMap giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no notations are defined.

Document Objects

A Document represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from Node.

Document.**documentElement**

The one and only root element of the document.

Document.**createElement**(*tagName*)

Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as insertBefore() or appendChild().

Document.**createElementNS**(*namespaceURI*, *tagName*)

Create and return a new element with a namespace. The *tagName* may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as insertBefore() or appendChild().

Document.**createTextNode**(*data*)

Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document.**createComment**(*data*)

Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document.**createProcessingInstruction**(*target*, *data*)

Create and return a processing instruction node containing the *target* and *data* passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

Document.**createAttribute**(*name*)

Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use setAttributeNode() on the appropriate Element object to use the newly created attribute instance.

Document.**createAttributeNS**(*namespaceURI*, *qualifiedName*)

Create and return an attribute node with a namespace. The *tagName* may have a prefix. This method does not associate the attribute node with any particular element. You must use setAttributeNode() on the appropriate Element object to use the newly created attribute instance.

Document.**getElementsByTagName**(*tagName*)

Search for all descendants (direct children, children's children, etc.) with a particular element type name.

Document.**getElementsByTagNameNS**(*namespaceURI*, *localName*)

Search for all descendants (direct children, children's children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

Element Objects

`Element` is a subclass of `Node`, so inherits all the attributes of that class.

`Element`.**tagName**

The element type name. In a namespace-using document it may have colons in it. The value is a string.

`Element`.**getElementsByTagName**(*tagName*)

Same as equivalent method in the `Document` class.

`Element`.**getElementsByTagNameNS**(*namespaceURI*, *localName*)

Same as equivalent method in the `Document` class.

`Element`.**hasAttribute**(*name*)

Return `True` if the element has an attribute named by *name*.

`Element`.**hasAttributeNS**(*namespaceURI*, *localName*)

Return `True` if the element has an attribute named by *namespaceURI* and *localName*.

`Element`.**getAttribute**(*name*)

Return the value of the attribute named by *name* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

`Element`.**getAttributeNode**(*attrname*)

Return the `Attr` node for the attribute named by *attrname*.

`Element`.**getAttributeNS**(*namespaceURI*, *localName*)

Return the value of the attribute named by *namespaceURI* and *localName* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

`Element`.**getAttributeNodeNS**(*namespaceURI*, *localName*)

Return an attribute value as a node, given a *namespaceURI* and *localName*.

`Element`.**removeAttribute**(*name*)

Remove an attribute by name. If there is no matching attribute, a *`NotFoundErr`* is raised.

`Element`.**removeAttributeNode**(*oldAttr*)

Remove and return *oldAttr* from the attribute list, if present. If *oldAttr* is not present, *`NotFoundErr`* is raised.

`Element`.**removeAttributeNS**(*namespaceURI*, *localName*)

Remove an attribute by name. Note that it uses a localName, not a qname. No exception is raised if there is no matching attribute.

`Element`.**setAttribute**(*name*, *value*)

Set an attribute value from a string.

`Element`.**setAttributeNode**(*newAttr*)

Add a new attribute node to the element, replacing an existing attribute if necessary if the `name` attribute matches. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, *`InuseAttributeErr`* will be raised.

`Element`.**setAttributeNodeNS**(*newAttr*)

Add a new attribute node to the element, replacing an existing attribute if necessary if the `namespaceURI` and `localName` attributes match. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, *`InuseAttributeErr`* will be raised.

`Element`.**setAttributeNS**(*namespaceURI*, *qname*, *value*)

Set an attribute value from a string, given a *namespaceURI* and a *qname*. Note that a qname is the whole attribute name. This is different than above.

Attr Objects

`Attr` inherits from `Node`, so inherits all its attributes.

`Attr.`**`name`**

The attribute name. In a namespace-using document it may include a colon.

`Attr.`**`localName`**

The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.

`Attr.`**`prefix`**

The part of the name preceding the colon if there is one, else the empty string.

`Attr.`**`value`**

The text value of the attribute. This is a synonym for the `nodeValue` attribute.

NamedNodeMap 物件

`NamedNodeMap` does *not* inherit from `Node`.

`NamedNodeMap.`**`length`**

The length of the attribute list.

`NamedNodeMap.`**`item`**(*index*)

Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the `Element` objects.

Comment Objects

`Comment` represents a comment in the XML document. It is a subclass of `Node`, but cannot have child nodes.

`Comment.`**`data`**

The content of the comment as a string. The attribute contains all characters between the leading `<!--` and trailing `-->`, but does not include them.

Text and CDATASection Objects

The `Text` interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in `CDATASection` objects. These two interfaces are identical, but provide different values for the `nodeType` attribute.

These interfaces extend the `Node` interface. They cannot have child nodes.

`Text.`**`data`**

The content of the text node as a string.

> **備🄵**
>
> The use of a `CDATASection` node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent `CDATASection` nodes represent different CDATA marked sections.

ProcessingInstruction 物件

Represents a processing instruction in the XML document; this inherits from the `Node` interface and cannot have child nodes.

ProcessingInstruction.**target**

The content of the processing instruction up to the first whitespace character. This is a read-only attribute.

ProcessingInstruction.**data**

The content of the processing instruction following the first whitespace character.

例外

The DOM Level 2 recommendation defines a single exception, *DOMException*, and a number of constants that allow applications to determine what sort of error occurred. *DOMException* instances carry a *code* attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the *code* attribute.

exception xml.dom.**DOMException**

Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception xml.dom.**DomstringSizeErr**

Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception xml.dom.**HierarchyRequestErr**

Raised when an attempt is made to insert a node where the node type is not allowed.

exception xml.dom.**IndexSizeErr**

Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.**InuseAttributeErr**

Raised when an attempt is made to insert an `Attr` node that is already present elsewhere in the document.

exception xml.dom.**InvalidAccessErr**

Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.**InvalidCharacterErr**

This exception is raised when a string parameter contains a character that is not permitted in the context it's being used in by the XML 1.0 recommendation. For example, attempting to create an `Element` node with a space in the element type name will cause this error to be raised.

exception xml.dom.**InvalidModificationErr**

Raised when an attempt is made to modify the type of a node.

exception xml.dom.**InvalidStateErr**

Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.**NamespaceErr**

If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.**NotFoundErr**

Exception when a node does not exist in the referenced context. For example, `NamedNodeMap.removeNamedItem()` will raise this if the node passed in does not exist in the map.

exception xml.dom.**NotSupportedErr**

Raised when the implementation does not support the requested type of object or operation.

exception xml.dom.**NoDataAllowedErr**

This is raised if data is specified for a node which does not support data.

exception xml.dom.**NoModificationAllowedErr**

Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

exception xml.dom.**SyntaxErr**

Raised when an invalid or illegal string is specified.

exception xml.dom.**WrongDocumentErr**

Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

常數	例外
DOMSTRING_SIZE_ERR	*DomstringSizeErr*
HIERARCHY_REQUEST_ERR	*HierarchyRequestErr*
INDEX_SIZE_ERR	*IndexSizeErr*
INUSE_ATTRIBUTE_ERR	*InuseAttributeErr*
INVALID_ACCESS_ERR	*InvalidAccessErr*
INVALID_CHARACTER_ERR	*InvalidCharacterErr*
INVALID_MODIFICATION_ERR	*InvalidModificationErr*
INVALID_STATE_ERR	*InvalidStateErr*
NAMESPACE_ERR	*NamespaceErr*
NOT_FOUND_ERR	*NotFoundErr*
NOT_SUPPORTED_ERR	*NotSupportedErr*
NO_DATA_ALLOWED_ERR	*NoDataAllowedErr*
NO_MODIFICATION_ALLOWED_ERR	*NoModificationAllowedErr*
SYNTAX_ERR	*SyntaxErr*
WRONG_DOCUMENT_ERR	*WrongDocumentErr*

21.6.3 Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

IDL Type	Python Type
boolean	bool 或 int
int	int
long int	int
unsigned int	int
DOMString	str 或 bytes
null	None

Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL `attribute` declarations in much the way the Java mapping does. Mapping the IDL declarations

```
readonly attribute string someValue;
         attribute string anotherValue;
```

yields three accessor functions: a "get" method for `someValue` (`_get_someValue()`), and "get" and "set" methods for `anotherValue` (`_get_anotherValue()` and `_set_anotherValue()`). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: `object.someValue` is *not* required to work, and may raise an *AttributeError*.

The Python DOM API, however, *does* require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared `readonly` may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. "Set" accessors should never be provided for `readonly` attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of `getElementsByTagName()`, being "live". The Python DOM API does not require implementations to enforce such requirements.

21.7 `xml.dom.minidom` --- 最小的 DOM 實作

原始碼： Lib/xml/dom/minidom.py

`xml.dom.minidom` is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the *`xml.etree.ElementTree`* module for their XML processing instead.

> **備🄵**
>
> 如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

DOM applications typically start by parsing some XML into a DOM. With *`xml.dom.minidom`*, this is done through the parse functions:

```
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\\temp\\mydata.xml')  # 以檔名來剖析 XML 檔案

datasource = open('c:\\temp\\mydata.xml')
dom2 = parse(datasource)  # 剖析開🄵的檔案

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

`parse()` 函式可以接受一個檔案名稱或開🄵的檔案物件。

xml.dom.minidom.**parse**(*filename_or_file*, *parser=None*, *bufsize=None*)

Return a `Document` from the given input. *filename_or_file* may be either a file name, or a file-like object. *parser*, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

如果你有一個字串中的 XML，你可以使用*`parseString()`* 函式來代替：

xml.dom.minidom.**parseString**(*string*, *parser=None*)

Return a `Document` that represents the *string*. This method creates an *`io.StringIO`* object for the string and passes that on to *`parse()`*.

這兩個函式都會回傳一個 `Document` 物件，表示文件的🄵容。

What the *`parse()`* and *`parseString()`* functions do is connect an XML parser with a "DOM builder" that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it's simply that these functions do not provide a parser implementation themselves.

You can also create a `Document` by calling a method on a "DOM Implementation" object. You can get this object either by calling the `getDOMImplementation()` function in the *xml.dom* package or the *xml.dom.minidom* module. Once you have a `Document`, you can add child nodes to it to populate the DOM:

```
from xml.dom.minidom import getDOMImplementation

impl = getDOMImplementation()

newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the `unlink()` method to encourage early cleanup of the now-unneeded objects. `unlink()` is an *xml.dom.minidom*-specific extension to the DOM API that renders the node and its descendants essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

也參考

Document Object Model (DOM) Level 1 Specification
W3C 對*xml.dom.minidom* DOM 支援的建議。

21.7.1 DOM 物件

The definition of the DOM API for Python is given as part of the *xml.dom* module documentation. This section lists the differences between the API and *xml.dom.minidom*.

`Node.`**`unlink`**`()`

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the `Document` object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the `with` statement. The following code will automatically unlink *dom* when the `with` block is exited:

```
with xml.dom.minidom.parse(datasource) as dom:
    ... # 使用 dom。
```

`Node.`**`writexml`**`(`*writer*, *indent=''*, *addindent=''*, *newl=''*, *encoding=None*, *standalone=None*`)`

Write XML to the writer object. The writer receives texts but not bytes as input, it should have a `write()` method which matches that of the file object interface. The *indent* parameter is the indentation of the current node. The *addindent* parameter is the incremental indentation to use for subnodes of the current one. The *newl* parameter specifies the string to use to terminate newlines.

For the `Document` node, an additional keyword argument *encoding* can be used to specify the encoding field of the XML header.

Similarly, explicitly stating the *standalone* argument causes the standalone document declarations to be added to the prologue of the XML document. If the value is set to `True`, `standalone="yes"` is added, otherwise it is set to `"no"`. Not stating the argument will omit the declaration from the document.

在 3.8 版的變更: The *writexml()* method now preserves the attribute order specified by the user.

在 3.9 版的變更: 新增 *standalone* 參數。

Node.**toxml**(*encoding=None*, *standalone=None*)

Return a string or byte string containing the XML represented by the DOM node.

With an explicit *encoding*[1] argument, the result is a byte string in the specified encoding. With no *encoding* argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

The *standalone* argument behaves exactly as in *writexml()*.

在 3.8 版的變更: 現在*toxml()* 方法會保留使用者指定的屬性順序。

在 3.9 版的變更: 新增 *standalone* 參數。

Node.**toprettyxml**(*indent='\t'*, *newl='\n'*, *encoding=None*, *standalone=None*)

Return a pretty-printed version of the document. *indent* specifies the indentation string and defaults to a tabulator; *newl* specifies the string emitted at the end of each line and defaults to `\n`.

The *encoding* argument behaves like the corresponding argument of *toxml()*.

The *standalone* argument behaves exactly as in *writexml()*.

在 3.8 版的變更: The *toprettyxml()* method now preserves the attribute order specified by the user.

在 3.9 版的變更: 新增 *standalone* 參數。

21.7.2 DOM 范例

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```
import xml.dom.minidom

document = """\
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
</slideshow>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)
```

(繼續下一頁)

[1] The encoding name included in the XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not valid in an XML document's declaration, even though Python accepts it as an encoding name. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

        print(f"<p>{getText(title.childNodes)}</p>")

handleSlideshow(dom)
```

21.7.3 minidom 和 DOM 標準

The *xml.dom.minidom* module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the `Document` object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short int`, `unsigned int`, `unsigned long long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. *xml.dom.minidom* supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.

- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- `DOMException` is currently not supported in *xml.dom.minidom*. Instead, *xml.dom.minidom* uses standard Python exceptions such as *TypeError* and *AttributeError*.
- `NodeList` objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more "Pythonic" than the interface defined in the W3C recommendations.

The following interfaces have no implementation in *xml.dom.minidom*:

- `DOMTimeStamp`
- `EntityReference`

Most of these reflect information in the XML document that is not of general utility to most DOM users.

21.8 `xml.dom.pulldom` --- 支援建置部分 DOM 樹

原始碼： Lib/xml/dom/pulldom.py

The *xml.dom.pulldom* module provides a "pull parser" which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling "events" from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

> **備🄵**
>
> 如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

在 3.7.1 版的變更: The SAX parser no longer processes general external entities by default to increase security by default. To enable processing of external entities, pass a custom parser instance in:

```
from xml.dom.pulldom import parse
from xml.sax import make_parser
from xml.sax.handler import feature_external_ges

parser = make_parser()
parser.setFeature(feature_external_ges, True)
parse(filename, parser=parser)
```

範例：

```
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName == 'item':
        if int(node.getAttribute('price')) > 50:
            doc.expandNode(node)
            print(node.toxml())
```

`event` 是一個常數，可以是以下其中一個：

- `START_ELEMENT`
- `END_ELEMENT`
- `COMMENT`

- START_DOCUMENT
- END_DOCUMENT
- CHARACTERS
- PROCESSING_INSTRUCTION
- IGNORABLE_WHITESPACE

node is an object of type xml.dom.minidom.Document, xml.dom.minidom.Element or xml.dom.minidom.Text.

Since the document is treated as a "flat" stream of events, the document "tree" is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the *DOMEventStream.expandNode()* method and switch to DOM-related processing.

class xml.dom.pulldom.**PullDom**(*documentFactory=None*)

xml.sax.handler.ContentHandler 的子類🄵。

class xml.dom.pulldom.**SAX2DOM**(*documentFactory=None*)

xml.sax.handler.ContentHandler 的子類🄵。

xml.dom.pulldom.**parse**(*stream_or_string*, *parser=None*, *bufsize=None*)

Return a *DOMEventStream* from the given input. *stream_or_string* may be either a file name, or a file-like object. *parser*, if given, must be an *XMLReader* object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the *parseString()* function instead:

xml.dom.pulldom.**parseString**(*string*, *parser=None*)

回傳一個表示 (Unicode) *string* 的*DOMEventStream*。

xml.dom.pulldom.**default_bufsize**

Default value for the *bufsize* parameter to *parse()*.

The value of this variable can be changed before calling *parse()* and the new value will take effect.

21.8.1 DOMEventStream 物件

class xml.dom.pulldom.**DOMEventStream**(*stream*, *parser*, *bufsize*)

在 3.11 版的變更: 已移除對 __getitem__() 方法的支援。

getEvent()

Return a tuple containing *event* and the current *node* as xml.dom.minidom.Document if event equals START_DOCUMENT, xml.dom.minidom.Element if event equals START_ELEMENT or END_ELEMENT or xml.dom.minidom.Text if event equals CHARACTERS. The current node does not contain information about its children, unless *expandNode()* is called.

expandNode(*node*)

展開 *node* 的所有子節點到 *node*。範例:

```
from xml.dom import pulldom

xml = '<html><title>Foo</title> <p>Some text <div>and more</div></p> </html>'
doc = pulldom.parseString(xml)
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName == 'p':
        # 以下陳述式只會印出 '<p/>'
        print(node.toxml())
        doc.expandNode(node)
```

(繼續下一頁)

(繼續上一頁)

```
        # 以下陳述式會印出包含所有子節點的節點 '<p>Some text <div>and more</div></
↪p>'
        print(node.toxml())
```

reset()

21.9 xml.sax --- SAX2 剖析器支援

原始碼： Lib/xml/sax/__init__.py

The *xml.sax* package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

> **備🄵**
>
> 如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

在 3.7.1 版的變更: The SAX parser no longer processes general external entities by default to increase security. Before, the parser created network connections to fetch remote files or loaded local files from the file system for DTD and entities. The feature can be enabled again with method *setFeature()* on the parser object and argument *feature_external_ges*.

The convenience functions are:

xml.sax.**make_parser**(*parser_list=[]*)

Create and return a SAX *XMLReader* object. The first parser found will be used. If *parser_list* is provided, it must be an iterable of strings which name modules that have a function named create_parser(). Modules listed in *parser_list* will be used before modules in the default list of parsers.

在 3.8 版的變更: The *parser_list* argument can be any iterable, not just a list.

xml.sax.**parse**(*filename_or_stream*, *handler*, *error_handler=handler.ErrorHandler()*)

Create a SAX parser and use it to parse a document. The document, passed in as *filename_or_stream*, can be a filename or a file object. The *handler* parameter needs to be a SAX *ContentHandler* instance. If *error_handler* is given, it must be a SAX *ErrorHandler* instance; if omitted, *SAXParseException* will be raised on all errors. There is no return value; all work must be done by the *handler* passed in.

xml.sax.**parseString**(*string*, *handler*, *error_handler=handler.ErrorHandler()*)

Similar to *parse()*, but parses from a buffer *string* received as a parameter. *string* must be a *str* instance or a *bytes-like object*.

在 3.5 版的變更: 新增*str* 實例的支援。

A typical SAX application uses three kinds of objects: readers, handlers and input sources. "Reader" in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The *InputSource*, *Locator*, Attributes, AttributesNS, and *XMLReader* interfaces are defined in the module *xml.sax.xmlreader*. The handler interfaces are defined in *xml.sax.handler*. For convenience, *InputSource* (which is often instantiated directly) and the handler classes are also available from *xml.sax*. These interfaces are described below.

In addition to these classes, *xml.sax* provides the following exception classes.

exception xml.sax.**SAXException**(*msg*, *exception=None*)

Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the *ErrorHandler* interface receive instances of this exception, it is not required to actually raise the exception --- it is also useful as a container for information.

When instantiated, *msg* should be a human-readable description of the error. The optional *exception* parameter, if given, should be `None` or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

exception xml.sax.**SAXParseException**(*msg*, *exception*, *locator*)

Subclass of *SAXException* raised on parse errors. Instances of this class are passed to the methods of the SAX *ErrorHandler* interface to provide information about the parse error. This class supports the SAX *Locator* interface as well as the *SAXException* interface.

exception xml.sax.**SAXNotRecognizedException**(*msg*, *exception=None*)

Subclass of *SAXException* raised when a SAX *XMLReader* is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

exception xml.sax.**SAXNotSupportedException**(*msg*, *exception=None*)

Subclass of *SAXException* raised when a SAX *XMLReader* is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

21.9.1 SAXException 物件

The *SAXException* exception class supports the following methods:

SAXException.**getMessage**()

Return a human-readable message describing the error condition.

SAXException.**getException**()

Return an encapsulated exception object, or `None`.

21.10 `xml.sax.handler` --- SAX 處理函式的基本類🄵

原始碼： Lib/xml/sax/handler.py

The SAX API defines five kinds of handlers: content handlers, DTD handlers, error handlers, entity resolvers and lexical handlers. Applications normally only need to implement those interfaces whose events they are interested in;

they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module *xml.sax.handler*, so that all methods get default implementations.

class xml.sax.handler.**ContentHandler**

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

class xml.sax.handler.**DTDHandler**

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

class xml.sax.handler.**EntityResolver**

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

class xml.sax.handler.**ErrorHandler**

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

class xml.sax.handler.**LexicalHandler**

Interface used by the parser to represent low frequency events which may not be of interest to many applications.

In addition to these classes, *xml.sax.handler* provides symbolic constants for the feature and property names.

xml.sax.handler.**feature_namespaces**

value: "http://xml.org/sax/features/namespaces"

true: Perform Namespace processing.

false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**feature_namespace_prefixes**

value: "http://xml.org/sax/features/namespace-prefixes"

true: Report the original prefixed names and attributes used for Namespace declarations.

false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**feature_string_interning**

value: "http://xml.org/sax/features/string-interning"

true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.

false: Names are not necessarily interned, although they may be (default).

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**feature_validation**

value: "http://xml.org/sax/features/validation"

true: Report all validation errors (implies external-general-entities and external-parameter-entities).

false: Do not report validation errors.

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**feature_external_ges**

value: "http://xml.org/sax/features/external-general-entities"

true: Include all external general (text) entities.

false: Do not include external general entities.

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**feature_external_pes**

value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**all_features**

List of all features.

xml.sax.handler.**property_lexical_handler**

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.handler.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.**property_declaration_handler**

value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.**property_dom_node**

value: "http://xml.org/sax/properties/dom-node"
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**property_xml_string**

value: "http://xml.org/sax/properties/xml-string"
data type: Bytes
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.**all_properties**

List of all known property names.

21.10.1 ContentHandler 物件

Users are expected to subclass *ContentHandler* to support their application. The following methods are called by the parser on the appropriate events in the input document:

ContentHandler.**setDocumentLocator**(*locator*)

Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

ContentHandler.**startDocument**()

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for *setDocumentLocator()*).

ContentHandler.**endDocument**()

Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler.**startPrefixMapping**(*prefix*, *uri*)

Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the `feature_namespaces` feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the *startPrefixMapping()* and *endPrefixMapping()* events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that *startPrefixMapping()* and *endPrefixMapping()* events are not guaranteed to be properly nested relative to each-other: all *startPrefixMapping()* events will occur before the corresponding *startElement()* event, and all *endPrefixMapping()* events will occur after the corresponding *endElement()* event, but their order is not guaranteed.

ContentHandler.**endPrefixMapping**(*prefix*)

End the scope of a prefix-URI mapping.

See *startPrefixMapping()* for details. This event will always occur after the corresponding *endElement()* event, but the order of *endPrefixMapping()* events is not otherwise guaranteed.

ContentHandler.**startElement**(*name*, *attrs*)

Signals the start of an element in non-namespace mode.

The *name* parameter contains the raw XML 1.0 name of the element type as a string and the *attrs* parameter holds an object of the *Attributes* interface containing the attributes of the element. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

ContentHandler.**endElement**(*name*)

Signals the end of an element in non-namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElement()* event.

ContentHandler.**startElementNS**(*name*, *qname*, *attrs*)

Signals the start of an element in namespace mode.

The *name* parameter contains the name of the element type as a `(uri, localname)` tuple, the *qname* parameter contains the raw XML 1.0 name used in the source document, and the *attrs* parameter holds an instance of the *AttributesNS* interface containing the attributes of the element. If no namespace is associated with the element, the *uri* component of *name* will be `None`. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

Parsers may set the *qname* parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

ContentHandler.**endElementNS**(*name*, *qname*)

Signals the end of an element in namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElementNS()* method, likewise the *qname* parameter.

ContentHandler.**characters**(*content*)

Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

content may be a string or bytes instance; the `expat` reader module always produces strings.

> **備🄵**
>
> The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use *content* instead of slicing content with the old *offset* and *length* parameters.

ContentHandler.**ignorableWhitespace**(*whitespace*)

Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

ContentHandler.**processingInstruction**(*target*, *data*)

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

ContentHandler.**skippedEntity**(*name*)

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.

21.10.2 DTDHandler 物件

DTDHandler instances provide the following methods:

DTDHandler.**notationDecl**(*name*, *publicId*, *systemId*)

Handle a notation declaration event.

DTDHandler.**unparsedEntityDecl**(*name*, *publicId*, *systemId*, *ndata*)

Handle an unparsed entity declaration event.

21.10.3 EntityResolver 物件

EntityResolver.**resolveEntity**(*publicId*, *systemId*)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns *systemId*.

21.10.4 ErrorHandler 物件

Objects with this interface are used to receive error and warning information from the *XMLReader*. If you create an object that implements this interface, then register the object with your *XMLReader*, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a *SAXParseException* as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

ErrorHandler.**error**(*exception*)

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

ErrorHandler.**fatalError**(*exception*)

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

ErrorHandler.**warning**(*exception*)

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.

21.10.5 LexicalHandler 物件

Optional SAX2 handler for lexical events.

This handler is used to obtain lexical information about an XML document. Lexical information includes information describing the document encoding used and XML comments embedded in the document, as well as section boundaries for the DTD and for any CDATA sections. The lexical handlers are used in the same manner as content handlers.

Set the LexicalHandler of an XMLReader by using the setProperty method with the property identifier `'http://xml.org/sax/properties/lexical-handler'`.

LexicalHandler.**comment**(*content*)

Reports a comment anywhere in the document (including the DTD and outside the document element).

LexicalHandler.**startDTD**(*name*, *public_id*, *system_id*)

Reports the start of the DTD declarations if the document has an associated DTD.

LexicalHandler.**endDTD**()

Reports the end of DTD declaration.

LexicalHandler.**startCDATA**()

Reports the start of a CDATA marked section.

The contents of the CDATA marked section will be reported through the characters handler.

LexicalHandler.**endCDATA**()

Reports the end of a CDATA marked section.

21.11 `xml.sax.saxutils` --- SAX 工具程式

原始碼： Lib/xml/sax/saxutils.py

模組*xml.sax.saxutils*包含了許多在建立 SAX 應用程式時非常有用的類🄵和函式，這些類🄵和函式可以直接使用，也可以作🄵基底類🄵。

xml.sax.saxutils.**escape**(*data*, *entities={}*)

在資料字串中跳🄴 `'&'`、`'<'` 及 `'>'`。

你可以透過傳入字典作🄵可選的 *entities* 參數，來跳🄴其他資料字串。鍵和值都必須是字串；每個鍵都會被對應的值取代。即使提供 *entities*，`'&'`、`'<'` 和 `'>'` 字元始終會被跳🄴。

> **備🄵**
>
> 這個函式只能用來跳🄴 XML 中無法直接使用的字元。請勿將此函式用作一般的字串轉🄵函式。

xml.sax.saxutils.**unescape**(*data*, *entities={}*)

取消跳🄵資料字串中的 `'&'`、`'<'` 和 `'>'`。

你可以透過傳入字典作🄵可選的 *entities* 參數，來取消其他字串的資料。鍵和值都必須是字串；每個鍵都會被對應的值取代。即使提供了 *entities*，`'&amp'`、`'<'` 和 `'>'` 總是會取消跳🄴。

xml.sax.saxutils.**quoteattr**(*data*, *entities={}*)

類似於*escape()*，但也准備 *data* 作🄵屬性值。*quoteattr()* 會根據 *data* 的🄵容選擇引號字元，嘗試避免在字串中編碼任何引號字元。如果 *data* 中已經有單引號和雙引號字元，雙引號字元將被編碼，而 *data* 將被雙引號包覆。結果字串可直接用作屬性值：

```
>>> print("<element attr=%s>" % quoteattr("ab ' cd \" ef"))
<element attr="ab ' cd &quot; ef">
```

當使用參考具體語法🄵 HTML 或任何 SGML 🄵生屬性值時，此功能非常有用。

class xml.sax.saxutils.**XMLGenerator**(*out=None*, *encoding='iso-8859-1'*, *short_empty_elements=False*)

這個類🄵透過將 SAX 事件寫回 XML 文件來實作*ContentHandler* 介面。🄵句話🄵，使用*XMLGenerator* 作🄵🄵容處理器將會重現被剖析的原始文件。*out* 應該是類檔案物件，預設🄵 *sys.stdout*。*encoding* 是輸出串流的編碼，預設🄵 `'iso-8859-1'`。*short_empty_elements* 控制不包含🄵容的元素的格式：如果設定🄵 `False`（預設值），它們會以一對開始/結束（start/end）標🄵的形式輸出；如果設定🄵 `True`，它們會以單一自封（self-closed）標🄵的形式輸出。

在 3.2 版的變更: 新增 *short_empty_elements* 參數。

class xml.sax.saxutils.**XMLFilterBase**(*base*)

這個類🄵的設計是在*XMLReader* 與用🄵端應用程式的事件處理程式之間。預設情🄵下，它什🄵都不做，只是將要求傳送到🄵讀器，🄵將事件未經修改地傳送到處理程式，但子類🄵可以覆寫特定的方法，以在傳送它們的時候修改事件串流或配置請求。

xml.sax.saxutils.**prepare_input_source**(*source*, *base=''*)

這個函式接收一個輸入來源和一個可選的基底 URL，🄵回傳一個完全解析的*InputSource* 物件，以准備讀取。輸入來源可以是字串、類檔案物件或*InputSource* 物件；剖析器會使用這個函式來實作它們的*parse()* 方法的多型 *source* 引數。

21.12 xml.sax.xmlreader --- XML 剖析器的介面

原始碼： Lib/xml/sax/xmlreader.py

SAX parsers implement the *XMLReader* interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by *xml.sax.make_parser()* with no arguments to create a new parser object.

class xml.sax.xmlreader.**XMLReader**

Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.**IncrementalParser**

In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after parse has been called and before it returns.

By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

class xml.sax.xmlreader.**Locator**

Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return `None`.

class xml.sax.xmlreader.**InputSource**(*system_id=None*)

Encapsulation of the information needed by the *XMLReader* to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the *XMLReader.parse()* method and for returning from EntityResolver.resolveEntity.

An *InputSource* belongs to the application, the *XMLReader* is not allowed to modify *InputSource* objects passed to it from the application, although it may make copies and modify those.

class xml.sax.xmlreader.**AttributesImpl**(*attrs*)

This is an implementation of the `Attributes` interface (see section *The Attributes Interface*). This is a dictionary-like object which represents the element attributes in a `startElement()` call. In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; *attrs* must be a dictionary-like object containing a mapping from attribute names to attribute values.

class xml.sax.xmlreader.**AttributesNSImpl**(*attrs*, *qnames*)

Namespace-aware variant of *AttributesImpl*, which will be passed to `startElementNS()`. It is derived from *AttributesImpl*, but understands attribute names as two-tuples of *namespaceURI* and *localname*. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the `AttributesNS` interface (see section *The AttributesNS Interface*).

21.12.1 XMLReader 物件

The *XMLReader* interface supports the following methods:

XMLReader.**parse**(*source*)

Process an input source, producing SAX events. The *source* object can be a system identifier (a string identifying the input source -- typically a file name or a URL), a *pathlib.Path* or *path-like* object, or an *InputSource* object. When *parse()* returns, the input is completely processed, and the parser object can be discarded or reset.

在 3.5 版的變更: 新增對字元串流的支援。

在 3.8 版的變更: 新增對類路徑物件的支援。

XMLReader.**getContentHandler**()

Return the current *ContentHandler*.

XMLReader.**setContentHandler**(*handler*)

Set the current *ContentHandler*. If no *ContentHandler* is set, content events will be discarded.

XMLReader.**getDTDHandler**()

Return the current *DTDHandler*.

XMLReader.**setDTDHandler**(*handler*)

Set the current *DTDHandler*. If no *DTDHandler* is set, DTD events will be discarded.

XMLReader.**getEntityResolver**()

Return the current *EntityResolver*.

XMLReader.**setEntityResolver**(*handler*)

Set the current *EntityResolver*. If no *EntityResolver* is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

XMLReader.**getErrorHandler**()

Return the current *ErrorHandler*.

XMLReader.**setErrorHandler**(*handler*)

Set the current error handler. If no *ErrorHandler* is set, errors will be raised as exceptions, and warnings will be printed.

XMLReader.**setLocale**(*locale*)

Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

XMLReader.**getFeature**(*featurename*)

Return the current setting for feature *featurename*. If the feature is not recognized, `SAXNotRecognizedException` is raised. The well-known featurenames are listed in the module *xml.sax.handler*.

XMLReader.**setFeature**(*featurename*, *value*)

Set the *featurename* to *value*. If the feature is not recognized, `SAXNotRecognizedException` is raised. If the feature or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

XMLReader.**getProperty**(*propertyname*)

Return the current setting for property *propertyname*. If the property is not recognized, a `SAXNotRecognizedException` is raised. The well-known propertynames are listed in the module *xml.sax.handler*.

XMLReader.**setProperty**(*propertyname*, *value*)

Set the *propertyname* to *value*. If the property is not recognized, `SAXNotRecognizedException` is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

21.12.2 IncrementalParser 物件

Instances of *IncrementalParser* offer the following additional methods:

IncrementalParser.**feed**(*data*)

Process a chunk of *data*.

IncrementalParser.**close**()

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser.**reset**()

This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.

21.12.3 Locator Objects

Instances of *Locator* provide these methods:

Locator.**getColumnNumber**()

Return the column number where the current event begins.

Locator.**getLineNumber**()

Return the line number where the current event begins.

Locator.**getPublicId**()

Return the public identifier for the current event.

Locator.**getSystemId**()

Return the system identifier for the current event.

21.12.4 InputSource 物件

InputSource.**setPublicId**(*id*)

Sets the public identifier of this *InputSource*.

InputSource.**getPublicId**()

Returns the public identifier of this *InputSource*.

InputSource.**setSystemId**(*id*)

Sets the system identifier of this *InputSource*.

InputSource.**getSystemId**()

Returns the system identifier of this *InputSource*.

InputSource.**setEncoding**(*encoding*)

Sets the character encoding of this *InputSource*.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the *InputSource* is ignored if the *InputSource* also contains a character stream.

InputSource.**getEncoding**()

Get the character encoding of this InputSource.

InputSource.**setByteStream**(*bytefile*)

Set the byte stream (a *binary file*) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.

If the application knows the character encoding of the byte stream, it should set it with the setEncoding method.

InputSource.**getByteStream**()

Get the byte stream for this input source.

The getEncoding method will return the character encoding for this byte stream, or `None` if unknown.

InputSource.**setCharacterStream**(*charfile*)

Set the character stream (a *text file*) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

InputSource.**getCharacterStream**()

Get the character stream for this input source.

21.12.5 The `Attributes` Interface

`Attributes` objects implement a portion of the *mapping protocol*, including the methods `copy()`, `get()`, `__contains__()`, `items()`, `keys()`, and `values()`. The following methods are also provided:

`Attributes.`**`getLength`**`()`

Return the number of attributes.

`Attributes.`**`getNames`**`()`

Return the names of the attributes.

`Attributes.`**`getType`**`(`*name*`)`

Returns the type of the attribute *name*, which is normally `'CDATA'`.

`Attributes.`**`getValue`**`(`*name*`)`

Return the value of attribute *name*.

21.12.6 The `AttributesNS` Interface

This interface is a subtype of the `Attributes` interface (see section *The Attributes Interface*). All methods supported by that interface are also available on `AttributesNS` objects.

The following methods are also available:

`AttributesNS.`**`getValueByQName`**`(`*name*`)`

Return the value for a qualified name.

`AttributesNS.`**`getNameByQName`**`(`*name*`)`

Return the `(namespace, localname)` pair for a qualified *name*.

`AttributesNS.`**`getQNameByName`**`(`*name*`)`

Return the qualified name for a `(namespace, localname)` pair.

`AttributesNS.`**`getQNames`**`()`

Return the qualified names of all attributes.

21.13 `xml.parsers.expat` --- 使用 Expat 進行快速 XML 剖析

備🄵

如果你需要剖析不受信任或未經驗證的資料，請參🄵*XML 安全性*。

The *`xml.parsers.expat`* module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the `pyexpat` module to provide access to the Expat parser. Direct use of the `pyexpat` module is deprecated.

這個模組提供一個例外和一個型🄵物件：

`exception` `xml.parsers.expat.`**`ExpatError`**

The exception raised when Expat reports an error. See section *ExpatError 例外* for more information on interpreting Expat errors.

`exception` `xml.parsers.expat.`**`error`**

`ExpatError` 的🄵名。

xml.parsers.expat.**XMLParserType**

The type of the return values from the *ParserCreate()* function.

xml.parsers.expat 模組包含兩個函式：

xml.parsers.expat.**ErrorString**(*errno*)

回傳一個給定錯誤編號 *errno* 的解釋字串。

xml.parsers.expat.**ParserCreate**(*encoding=None*, *namespace_separator=None*)

Creates and returns a new xmlparser object. *encoding*, if specified, must be a string naming the encoding used by the XML data. Expat doesn't support as many encodings as Python does, and its repertoire of encodings can't be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If *encoding*[1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for *namespace_separator*. The value must be a one-character string; a *ValueError* will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers StartElementHandler and EndElementHandler will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (chr(0)) then the namespace URI and the local part will be concatenated without any separator.

For example, if *namespace_separator* is set to a space character (' ') and the following document is parsed:

```
<?xml version="1.0"?>
<root xmlns    = "http://default-namespace.org/"
      xmlns:py = "http://www.python.org/ns/">
  <py:elem1 />
  <elem2 xmlns="" />
</root>
```

StartElementHandler 將會收到每個元素的以下字串：

```
http://default-namespace.org/ root
http://www.python.org/ns/ elem1
elem2
```

Due to limitations in the Expat library used by pyexpat, the xmlparser instance returned can only be used to parse a single XML document. Call ParserCreate for each document to provide unique parser instances.

Expat 專案的首頁。

21.13.1 XMLParser 物件

xmlparser 物件擁有以下方法：

xmlparser.**Parse**(*data*[, *isfinal*])

Parses the contents of the string *data*, calling the appropriate handler functions to process the parsed data. *isfinal* must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. *data* can be the empty string at any time.

xmlparser.**ParseFile**(*file*)

Parse XML data reading from the object *file*. *file* only needs to provide the read(nbytes) method, returning the empty string when there's no more data.

[1] The encoding string included in XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

xmlparser.**SetBase**(*base*)

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the *base* argument to the *ExternalEntityRefHandler()*, *NotationDeclHandler()*, and *UnparsedEntityDeclHandler()* functions.

xmlparser.**GetBase**()

Returns a string containing the base set by a previous call to *SetBase()*, or None if *SetBase()* hasn't been called.

xmlparser.**GetInputContext**()

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is None.

xmlparser.**ExternalEntityParserCreate**(*context*[, *encoding*])

Create a "child" parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The *context* parameter should be the string passed to the *ExternalEntityRefHandler()* handler function, described below. The child parser is created with the *ordered_attributes* and *specified_attributes* set to the values of this parser.

xmlparser.**SetParamEntityParsing**(*flag*)

Control parsing of parameter entities (including the external DTD subset). Possible *flag* values are XML_PARAM_ENTITY_PARSING_NEVER, XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE and XML_PARAM_ENTITY_PARSING_ALWAYS. Return true if setting the flag was successful.

xmlparser.**UseForeignDTD**([*flag*])

Calling this with a true value for *flag* (the default) will cause Expat to call the *ExternalEntityRefHandler* with *None* for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the *ExternalEntityRefHandler* will still be called, but the *StartDoctypeDeclHandler* and *EndDoctypeDeclHandler* will not be called.

Passing a false value for *flag* will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the *Parse()* or *ParseFile()* methods are called; calling it after either of those have been called causes *ExpatError* to be raised with the *code* attribute set to errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING].

xmlparser.**SetReparseDeferralEnabled**(*enabled*)

> **⚠ 警告**
>
> Calling SetReparseDeferralEnabled(False) has security implications, as detailed below; please make sure to understand these consequences prior to using the SetReparseDeferralEnabled method.

Expat 2.6.0 introduced a security mechanism called "reparse deferral" where instead of causing denial of service through quadratic runtime from reparsing large tokens, reparsing of unfinished tokens is now delayed by default until a sufficient amount of input is reached. Due to this delay, registered handlers may —depending of the sizing of input chunks pushed to Expat —no longer be called right after pushing new input to the parser. Where immediate feedback and taking over responsibility of protecting against denial of service from large tokens are both wanted, calling SetReparseDeferralEnabled(False) disables reparse deferral for the current Expat parser instance, temporarily or altogether. Calling SetReparseDeferralEnabled(True) allows re-enabling reparse deferral.

Note that *SetReparseDeferralEnabled()* has been backported to some prior releases of CPython as a security fix. Check for availability of *SetReparseDeferralEnabled()* using *hasattr()* if used in code running across a variety of Python versions.

在 3.13 版被加入.

xmlparser.**GetReparseDeferralEnabled**()

Returns whether reparse deferral is currently enabled for the given Expat parser instance.

在 3.13 版被加入.

xmlparser 物件擁有以下屬性:

xmlparser.**buffer_size**

The size of the buffer used when *buffer_text* is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

xmlparser.**buffer_text**

Setting this to true causes the xmlparser object to buffer textual content returned by Expat to avoid multiple calls to the *CharacterDataHandler()* callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time. Note that when it is false, data that does not contain newlines may be chunked too.

xmlparser.**buffer_used**

If *buffer_text* is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when *buffer_text* is false.

xmlparser.**ordered_attributes**

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false; it may be changed at any time.

xmlparser.**specified_attributes**

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an xmlparser object, and will only have correct values once a call to Parse() or ParseFile() has raised an *xml.parsers.expat.ExpatError* exception.

xmlparser.**ErrorByteIndex**

Byte index at which an error occurred.

xmlparser.**ErrorCode**

Numeric code specifying the problem. This value can be passed to the *ErrorString()* function, or compared to one of the constants defined in the errors object.

xmlparser.**ErrorColumnNumber**

Column number at which an error occurred.

xmlparser.**ErrorLineNumber**

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an xmlparser object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

xmlparser.**CurrentByteIndex**

Current byte index in the parser input.

xmlparser.**CurrentColumnNumber**

Current column number in the parser input.

xmlparser.**CurrentLineNumber**

Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object *o*, use `o.handlername = func`. *handlername* must be taken from the following list, and *func* must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

xmlparser.**XmlDeclHandler**(*version*, *encoding*, *standalone*)

Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional "standalone" declaration. *version* and *encoding* will be strings, and *standalone* will be `1` if the document is declared standalone, `0` if it is declared not to be standalone, or `-1` if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

xmlparser.**StartDoctypeDeclHandler**(*doctypeName*, *systemId*, *publicId*, *has_internal_subset*)

Called when Expat begins parsing the document type declaration (`<!DOCTYPE ...`). The *doctypeName* is provided exactly as presented. The *systemId* and *publicId* parameters give the system and public identifiers if specified, or `None` if omitted. *has_internal_subset* will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

xmlparser.**EndDoctypeDeclHandler**()

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

xmlparser.**ElementDeclHandler**(*name*, *model*)

Called once for each element type declaration. *name* is the name of the element type, and *model* is a representation of the content model.

xmlparser.**AttlistDeclHandler**(*elname*, *attname*, *type*, *default*, *required*)

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. *elname* is the name of the element to which the declaration applies and *attname* is the name of the attribute declared. The attribute type is a string passed as *type*; the possible values are `'CDATA'`, `'ID'`, `'IDREF'`, ... *default* gives the default value for the attribute used when the attribute is not specified by the document instance, or `None` if there is no default value (`#IMPLIED` values). If the attribute is required to be given in the document instance, *required* will be true. This requires Expat version 1.95.0 or newer.

xmlparser.**StartElementHandler**(*name*, *attributes*)

Called for the start of every element. *name* is a string containing the element name, and *attributes* is the element attributes. If *ordered_attributes* is true, this is a list (see *ordered_attributes* for a full description). Otherwise it's a dictionary mapping names to values.

xmlparser.**EndElementHandler**(*name*)

Called for the end of every element.

xmlparser.**ProcessingInstructionHandler**(*target*, *data*)

Called for every processing instruction.

xmlparser.**CharacterDataHandler**(*data*)

Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the *StartCdataSectionHandler*, *EndCdataSectionHandler*, and *ElementDeclHandler* callbacks to collect the required information. Note that the character data may be chunked even if it is short and so you may receive more than one call to *CharacterDataHandler()*. Set the *buffer_text* instance attribute to `True` to avoid that.

xmlparser.**UnparsedEntityDeclHandler**(*entityName*, *base*, *systemId*, *publicId*, *notationName*)

Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use *EntityDeclHandler* instead. (The underlying function in the Expat library has been declared obsolete.)

xmlparser.**EntityDeclHandler**(*entityName*, *is_parameter_entity*, *value*, *base*, *systemId*, *publicId*, *notationName*)

Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be `None` for external entities. The *notationName* parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. *is_parameter_entity* will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

`xmlparser.`**`NotationDeclHandler`**(*notationName*, *base*, *systemId*, *publicId*)

Called for notation declarations. *notationName*, *base*, and *systemId*, and *publicId* are strings if given. If the public identifier is omitted, *publicId* will be `None`.

`xmlparser.`**`StartNamespaceDeclHandler`**(*prefix*, *uri*)

Called when an element contains a namespace declaration. Namespace declarations are processed before the *`StartElementHandler`* is called for the element on which declarations are placed.

`xmlparser.`**`EndNamespaceDeclHandler`**(*prefix*)

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the *`StartNamespaceDeclHandler`* was called to indicate the start of each namespace declaration's scope. Calls to this handler are made after the corresponding *`EndElementHandler`* for the end of the element.

`xmlparser.`**`CommentHandler`**(*data*)

Called for comments. *data* is the text of the comment, excluding the leading `'<!--'` and trailing `'-->'`.

`xmlparser.`**`StartCdataSectionHandler`**()

Called at the start of a CDATA section. This and *`EndCdataSectionHandler`* are needed to be able to identify the syntactical start and end for CDATA sections.

`xmlparser.`**`EndCdataSectionHandler`**()

在 CDATA 區塊結束時呼叫。

`xmlparser.`**`DefaultHandler`**(*data*)

Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

`xmlparser.`**`DefaultHandlerExpand`**(*data*)

This is the same as the *`DefaultHandler()`*, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

`xmlparser.`**`NotStandaloneHandler`**()

Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns `0`, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

`xmlparser.`**`ExternalEntityRefHandler`**(*context*, *base*, *systemId*, *publicId*)

Called for references to external entities. *base* is the current base, as set by a previous call to *`SetBase()`*. The public and system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be `None`. The *context* value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns `0`, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the *`DefaultHandler`* callback, if provided.

21.13.2 ExpatError 例外

`ExpatError` exceptions have a number of interesting attributes:

ExpatError.**code**

Expat's internal error number for the specific error. The *errors.messages* dictionary maps these error numbers to Expat's error messages. For example:

```
from xml.parsers.expat import ParserCreate, ExpatError, errors

p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

The *errors* module also provides error message constants and a dictionary *codes* mapping these messages back to the error codes, see below.

ExpatError.**lineno**

Line number on which the error was detected. The first line is numbered `1`.

ExpatError.**offset**

Character offset into the line where the error occurred. The first column is numbered `0`.

21.13.3 范例

The following program defines three handlers that just print out their arguments.

```
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()

p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

這個程式的輸出是:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
```

21.13.4 Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the *xml.parsers.expat.model* module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

xml.parsers.expat.model.**XML_CTYPE_ANY**

The element named by the model name was declared to have a content model of `ANY`.

xml.parsers.expat.model.**XML_CTYPE_CHOICE**

The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

xml.parsers.expat.model.**XML_CTYPE_EMPTY**

Elements which are declared to be `EMPTY` have this model type.

xml.parsers.expat.model.**XML_CTYPE_MIXED**

xml.parsers.expat.model.**XML_CTYPE_NAME**

xml.parsers.expat.model.**XML_CTYPE_SEQ**

Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:

xml.parsers.expat.model.**XML_CQUANT_NONE**

No modifier is given, so it can appear exactly once, as for `A`.

xml.parsers.expat.model.**XML_CQUANT_OPT**

The model is optional: it can appear once or not at all, as for `A?`.

xml.parsers.expat.model.**XML_CQUANT_PLUS**

The model must occur one or more times (like `A+`).

xml.parsers.expat.model.**XML_CQUANT_REP**

The model must occur zero or more times, as for `A*`.

21.13.5 Expat 錯誤常數

The following constants are provided in the *xml.parsers.expat.errors* module. These constants are useful in interpreting some of the attributes of the `ExpatError` exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error *message* and not the numeric error *code*, you do this by comparing its *code* attribute with `errors.codes[errors.XML_ERROR_`*CONSTANT_NAME*`]`.

`errors` 模組有以下屬性：

xml.parsers.expat.errors.**codes**

A dictionary mapping string descriptions to their error codes.

在 3.2 版被加入.

xml.parsers.expat.errors.**messages**

A dictionary mapping numeric error codes to their string descriptions.

在 3.2 版被加入.

xml.parsers.expat.errors.**XML_ERROR_ASYNC_ENTITY**

xml.parsers.expat.errors.**XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF**

An entity reference in an attribute value referred to an external entity instead of an internal entity.

xml.parsers.expat.errors.**XML_ERROR_BAD_CHAR_REF**

A character reference referred to a character which is illegal in XML (for example, character `0`, or '`&#0;`').

xml.parsers.expat.errors.**XML_ERROR_BINARY_ENTITY_REF**

An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

xml.parsers.expat.errors.**XML_ERROR_DUPLICATE_ATTRIBUTE**

An attribute was used more than once in a start tag.

xml.parsers.expat.errors.**XML_ERROR_INCORRECT_ENCODING**

xml.parsers.expat.errors.**XML_ERROR_INVALID_TOKEN**

Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value `0`) in a UTF-8 input stream.

xml.parsers.expat.errors.**XML_ERROR_JUNK_AFTER_DOC_ELEMENT**

Something other than whitespace occurred after the document element.

xml.parsers.expat.errors.**XML_ERROR_MISPLACED_XML_PI**

An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.errors.**XML_ERROR_NO_ELEMENTS**

The document contains no elements (XML requires all documents to contain exactly one top-level element)..

xml.parsers.expat.errors.**XML_ERROR_NO_MEMORY**

Expat was not able to allocate memory internally.

xml.parsers.expat.errors.**XML_ERROR_PARAM_ENTITY_REF**

A parameter entity reference was found where it was not allowed.

xml.parsers.expat.errors.**XML_ERROR_PARTIAL_CHAR**

An incomplete character was found in the input.

xml.parsers.expat.errors.**XML_ERROR_RECURSIVE_ENTITY_REF**

An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.**XML_ERROR_SYNTAX**

Some unspecified syntax error was encountered.

xml.parsers.expat.errors.**XML_ERROR_TAG_MISMATCH**

An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.**XML_ERROR_UNCLOSED_TOKEN**

Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.**XML_ERROR_UNDEFINED_ENTITY**

A reference was made to an entity which was not defined.

xml.parsers.expat.errors.**XML_ERROR_UNKNOWN_ENCODING**

The document encoding is not supported by Expat.

xml.parsers.expat.errors.**XML_ERROR_UNCLOSED_CDATA_SECTION**

A CDATA marked section was not closed.

xml.parsers.expat.errors.**XML_ERROR_EXTERNAL_ENTITY_HANDLING**

xml.parsers.expat.errors.**XML_ERROR_NOT_STANDALONE**

The parser determined that the document was not "standalone" though it declared itself to be in the XML declaration, and the `NotStandaloneHandler` was set and returned `0`.

xml.parsers.expat.errors.**XML_ERROR_UNEXPECTED_STATE**

xml.parsers.expat.errors.**XML_ERROR_ENTITY_DECLARED_IN_PE**

xml.parsers.expat.errors.**XML_ERROR_FEATURE_REQUIRES_XML_DTD**

An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the *xml.parsers.expat* module.

xml.parsers.expat.errors.**XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING**

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by `UseForeignDTD()`.

xml.parsers.expat.errors.**XML_ERROR_UNBOUND_PREFIX**

An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.errors.**XML_ERROR_UNDECLARING_PREFIX**

The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.errors.**XML_ERROR_INCOMPLETE_PE**

A parameter entity contained incomplete markup.

xml.parsers.expat.errors.**XML_ERROR_XML_DECL**

The document contained no document element at all.

xml.parsers.expat.errors.**XML_ERROR_TEXT_DECL**

There was an error parsing a text declaration in an external entity.

xml.parsers.expat.errors.**XML_ERROR_PUBLICID**

Characters were found in the public id that are not allowed.

xml.parsers.expat.errors.**XML_ERROR_SUSPENDED**

The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.**XML_ERROR_NOT_SUSPENDED**

An attempt to resume the parser was made when the parser had not been suspended.

xml.parsers.expat.errors.**XML_ERROR_ABORTED**

This should not be reported to Python applications.

xml.parsers.expat.errors.**XML_ERROR_FINISHED**

The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.**XML_ERROR_SUSPEND_PE**

xml.parsers.expat.errors.**XML_ERROR_RESERVED_PREFIX_XML**

An attempt was made to undeclare reserved namespace prefix `xml` or to bind it to another namespace URI.

xml.parsers.expat.errors.**XML_ERROR_RESERVED_PREFIX_XMLNS**

An attempt was made to declare or undeclare reserved namespace prefix `xmlns`.

xml.parsers.expat.errors.**XML_ERROR_RESERVED_NAMESPACE_URI**

An attempt was made to bind the URI of one the reserved namespace prefixes `xml` and `xmlns` to another namespace prefix.

xml.parsers.expat.errors.**XML_ERROR_INVALID_ARGUMENT**

This should not be reported to Python applications.

xml.parsers.expat.errors.**XML_ERROR_NO_BUFFER**

This should not be reported to Python applications.

xml.parsers.expat.errors.**XML_ERROR_AMPLIFICATION_LIMIT_BREACH**

The limit on input amplification factor (from DTD and entities) has been breached.

xml.parsers.expat.errors.**XML_ERROR_NOT_STARTED**

The parser was tried to be stopped or suspended before it started.

在 3.14 版被加入.

🄵解

CHAPTER 22

網路協定 (Internet protocols) 及支援

這個章節講述的模組實作了網路協定及相關技術的支援；他們全都是用 Python 實作的。這🄵的大多數模組都需要相依於系統的模組*socket*，目前普遍的平台都支援該模組。以下🄵概述：

22.1 webbrowser --- 方便的網頁🄵覽器控制器

原始碼： Lib/webbrowser.py

webbrowser 模組提供了一個高階介面，允許向使用者顯示基於網頁的文件。在大多數情🄵下，只需從此模組呼叫*open()* 函式即可完成正確的操作。

在 Unix 下，X11 下首選圖形🄵覽器，但如果圖形🄵覽器不可用或 X11 顯示不可用，則將使用文字模式🄵覽器。如果使用文字模式🄵覽器，則呼叫程序將會阻塞 (block)，直到使用者退出🄵覽器。

如果環境變數 BROWSER 存在，它會被直譯🄵以*os.pathsep* 分隔的🄵覽器串列，以在平台預設值之前嘗試。當串列部分的值包含字串 `%s` 時，它會被直譯🄵字面🄵覽器命令列，🄵使用引數 URL 替🄵 `%s`；如果值是指向已🄵🄵🄵覽器之一的單個字，則此🄵覽器會被新增到搜尋串列的前面；如果該部分不包含 `%s`，則它僅被直譯🄵要🄵動的🄵覽器的名稱。[1]

在 3.14 版的變更: The BROWSER variable can now also be used to reorder the list of platform defaults. This is particularly useful on macOS where the platform defaults do not refer to command-line tools on PATH.

對於非 Unix 平台，或當 Unix 上有可用的遠端🄵覽器時，控制行程不會等待使用者以完成🄵覽器，而是允許遠端🄵覽器在顯示器上維護自己的視窗。如果遠端🄵覽器在 Unix 上不可用，控制行程將🄵動新的🄵覽器🄵等待。

在 iOS 上，BROWSER 環境變數以及控制自動引發 (autoraise)、🄵覽器設定和新分頁/視窗建立的任何引數都將被忽略。網頁將始終在使用者偏好的🄵覽器中的新分頁中開🄵，🄵將🄵覽器帶到前台。在 iOS 上使用*webbrowser* 模組需要*ctypes* 模組。如果*ctypes* 不可用，則呼叫*open()* 將會失敗。

🄵本 **webbrowser** 可以用作模組的命令列介面。它接受 URL 作🄵引數。它接受以下可選參數：

-n, --new-window

如果可能的話會在新的🄵覽器視窗中開🄵 URL。

[1] 此處命名的無完整路徑可執行檔將在 PATH 環境變數中給定的目🄵中被搜尋。

-t, --new-tab

會在新的🄴覽器分頁 (”tab”) 中開🄵 URL。

這些選項自然是相互排斥的。用法範例如下：

```
python -m webbrowser -t "https://www.python.org"
```

可用性: not WASI, not Android.

以下例外有被定義於該模組：

exception webbrowser.**Error**

當🄴覽器控制項發生錯誤時引發例外。

以下函式有被定義於該模組：

webbrowser.**open**(*url*, *new=0*, *autoraise=True*)

使用預設🄴覽器顯示 *url*。如果 *new* 🄵 0，則盡可能在同一🄴覽器視窗中開🄵 *url*。如果 *new* 🄵 1，則盡可能開🄵一個新的🄴覽器視窗。如果 *new* 🄵 2，則盡可能開🄵一個新的🄴覽器分頁 (”tab”)。如果 *autoraise* 🄵 `True`，則盡可能提升視窗（請注意，無論此變數的設定如何，許多視窗管理器下都會發生這種情🄵）。

如果🄴覽器成功🄴動則回傳 `True`，否則回傳 `False`。

請注意，在某些平台上，嘗試使用此函式開🄴檔案名稱可能能🄴運作🄵🄵動作業系統的關聯程式。然而這既不支援也不可移植。

引發一個附帶引數 `url` 的稽核事件 `webbrowser.open`。

webbrowser.**open_new**(*url*)

盡可能在預設🄴覽器的新視窗中開🄵 *url*，否則在唯一的🄴覽器視窗中開🄵 *url*。

如果🄴覽器成功🄴動則回傳 `True`，否則回傳 `False`。

webbrowser.**open_new_tab**(*url*)

盡可能在預設🄴覽器的新分頁 (”tab”) 中開🄵 *url*，否則相當於*open_new()*。

如果🄴覽器成功🄴動則回傳 `True`，否則回傳 `False`。

webbrowser.**get**(*using=None*)

回傳🄴覽器類型使用 *（以引數 **using* 給定）的控制器物件。如果 *using* 🄵 `None`，則回傳適合呼叫者環境的預設🄴覽器控制器。

webbrowser.**register**(*name*, *constructor*, *instance=None*, *, *preferred=False*)

🄵🄵🄵覽器類型名稱 *（以引數 **name* 給定）。一旦🄵🄵了🄵覽器類型，*get()* 函式就可以回傳該🄵覽器類型的控制器。如果🄵有提供 *instance* 或🄵 `None`，則會在需要時不帶參數地呼叫 *constructor* 來建立實例。如果提供了 *instance*，*constructor* 將永遠不會被呼叫，🄵且可能🄵 `None`。

將 *preferred* 設🄵 `True` 會使該🄴覽器成🄵不帶引數的*get()* 呼叫的偏好結果。否則只有當你計劃設定 `BROWSER` 變數或使用與你宣告的處理程序名稱相符的非空引數呼叫*get()* 時，此入口點才會有用。

在 3.7 版的變更: 新增了 *preferred* 僅限關鍵字參數。

預先定義了多種🄴覽器類型。此表給出了可以傳遞給*get()* 函式的類型名稱以及控制器類🄴的相應實例化方式，這些都定義於此模組中。

類型名懲	類🄵名懲	🄵解
'mozilla'	Mozilla('mozilla')	
'firefox'	Mozilla('mozilla')	
'epiphany'	Epiphany('epiphany')	
'kfmclient'	Konqueror()	(1)
'konqueror'	Konqueror()	(1)
'kfm'	Konqueror()	(1)
'opera'	Opera()	
'links'	GenericBrowser('links')	
'elinks'	Elinks('elinks')	
'lynx'	GenericBrowser('lynx')	
'w3m'	GenericBrowser('w3m')	
'windows-default'	WindowsDefault	(2)
'macosx'	MacOSXOSAScript('default')	(3)
'safari'	MacOSXOSAScript('safari')	(3)
'google-chrome'	Chrome('google-chrome')	
'chrome'	Chrome('chrome')	
'chromium'	Chromium('chromium')	
'chromium-browser'	Chromium('chromium-browser')	
'iosbrowser'	IOSBrowser	(4)

🄵解:

(1) "Konqueror" 是 Unix 的 KDE 桌面環境的檔案管理器，只有在 KDE 運作時才有意義。最好能有某種可靠的 KDE 檢測方法；僅有 `KDEDIR` 變數是不🄵的。另請注意，即使在 KDE 2 中使用 **konqueror** 命令時，也會使用"kfm" 名稱 --- 該實作會選擇執行 Konqueror 的最佳策略。

(2) 僅在 Windows 平台上。

(3) 僅在 macOS 上。

(4) 僅在 iOS 上。

在 3.2 版被加入: 新增了 `MacOSXOSAScript` 類🄵🄵於 Mac 上使用，而非使用先前的 `MacOSX` 類🄵。這增加了對開🄵目前未設定🄵作業系統預設之🄵覽器的支援。

在 3.3 版被加入: 新增了對 Chrome/Chromium 的支援。

在 3.12 版的變更: 對多個過時🄵覽器的支援已被🄵除。已🄵除的🄵覽器包括 Grail、Mosaic、Netscape、Galeon、Skipstone、Iceape 和 Firefox 35 及以下版本。

在 3.13 版的變更: 新增了對 iOS 的支援。

以下是一些簡單範例:

```
url = 'https://docs.python.org/'

# 如果🄵覽器視窗已打開，則在新分頁中開🄵 URL。
webbrowser.open_new_tab(url)

# 在新視窗中開🄵 URL，如果可能的話提升視窗。
webbrowser.open_new(url)
```

22.1.1 🄵覽器控制器物件

🄵覽器控制器提供了*name* 屬性和以下三個與模組層級便利函式相同的方法:

`controller.`**`name`**

🄵覽器的系統相依名稱 (system-dependent name)。

controller.**open**(*url*, *new=0*, *autoraise=True*)

使用此控制器處理的🄵覽器顯示 *url*。如果 *new* 🄵 1，則盡可能開🄵一個新的🄵覽器視窗。如果 *new* 🄵 2，則盡可能開🄵一個新的🄵覽器分頁 (”tab”)。

controller.**open_new**(*url*)

盡可能在此控制器處理的🄵覽器的新視窗中開🄵 *url*，否則在唯一的🄵覽器視窗中開🄵 *url*。🄵名🄵*open_new()*。

controller.**open_new_tab**(*url*)

盡可能在此控制器處理的🄵覽器的新分頁 (”tab”) 中開🄵 *url*，否則相當於*open_new()*。

22.2 wsgiref --- WSGI 工具與參考實作

原始碼： Lib/wsgiref

網頁伺服器閘道介面 (WSGI) 是一個標准介面，用於連接網頁伺服器軟體與使用 Python 撰寫的網頁應用程式，擁有一個標准介面使得支援 WSGI 的應用程式可以與多個不同的網頁伺服器運行。

只有網頁伺服器與程式框架的作者需要🄵解 WSGI 設計的每個細節與邊角案例，你🄵不需要🄵了安裝 WSGI 應用程式或是使用現有框架撰寫網頁應用程式而必須理解每個細節。

wsgiref 是 WSGI 規格的參考實作，可用於新增 WSGI 來支援網頁伺服器或框架，它提供操作 WSGI 環境變數以及回應標頭的工具，用於實作 WSGI 伺服器的基本類🄵，提供用於示範 HTTP 伺服器的 WSGI 應用程式、🄵態型🄵檢查、以及驗證 WSGI 伺服器與應用程式是否符合 WSGI 規格的驗證工具 (**PEP 3333**)。

參🄵 wsgi.readthedocs.io 更多 WSGI 相關資訊，以及教學連結與其他資源。

22.2.1 wsgiref.util -- WSGI 環境工具

這個模組提供許多用於處理 WSGI 環境運作的功能。WSGI 環境是一個包含 HTTP 請求變數的字典，如 **PEP 3333** 所述。所有接受 *environ* 的參數的函式都需要提供符合 WSGI 標准的字典；請參🄵 **PEP 3333** 取得詳細規格，以及*WSGIEnvironment* 取得可用於使用型🄵🄵釋的型🄵🄵名。

wsgiref.util.**guess_scheme**(*environ*)

透過檢查 *environ* 字典中的 HTTPS 環境變數，回傳 wsgi.url_scheme 應該是”http” 或”https” 的猜測。回傳值🄵一個字串。

當建立一個包裝 CGI 或類似 FastCGI 的 CGI-like 協定閘道時，此函式非常有用。例如 FastCGI，通常提供這類協定的伺服器在通過 SSL 接收到請求時會包含”1”，”yes”，或”on” 的 HTTPS 變數，因此，如果找到這樣的值，此函式回傳”https”，否則回傳”http”。

wsgiref.util.**request_uri**(*environ*, *include_query=True*)

根據 **PEP 3333** 中”URL Reconstruction” 章節所找到的演算法，回傳完整的請求 URI，可選擇性的包含查詢字串，如果 *include_query* 設🄵 false，查詢字串不會被包含在結果的 URI 中。

wsgiref.util.**application_uri**(*environ*)

類似於*request_uri()*，但忽略 PATH_INFO 和 QUERY_STRING 變數。結果是請求地址的應用程式物件的的基本 URI。

wsgiref.util.**shift_path_info**(*environ*)

將單一名稱從 PATH_INFO 移到 SCRIPT_NAME 🄵回傳該名稱。*environ* 字典會在適當時機被 *modified*；如果你需要保留原始完好無損的 PATH_INFO 或 SCRIPT_NAME 請使用副本。

如果在 PATH_INFO 中🄵有剩余的路徑片段，則回傳 None。

通常，此程式用於處理請求 URI 的每一部分路徑，例如將路徑視🄵一系列的字典鍵此程式會修改傳入的環境，使其適用於呼叫位於目標 URI 的 WSGI 應用程式。例如，如果在 /foo 上有一個 WSGI 應用程式且請求 URI 路徑🄵 /foo/bar/baz，🄵且位於 /foo 的 WSGI 應用程式呼叫*shift_path_info()*，它將接收字串”bar”，而環境將被更新🄵適用於傳遞給位於 /foo/bar 的 WSGI 應用程式。🄵句話🄵，SCRIPT_NAME 將從 /foo 變更🄵 /foo/bar，而 PATH_INFO 將從 /bar/baz 變更🄵 /baz。

當 PATH_INFO 只是一個"/" 時，此程式會回傳一個空字串，🄴在 SCRIPT_NAME 後添加尾部斜號，即使空路徑片段通常是被忽略的，而且 SCRIPT_NAME 通常不會以斜號結尾。這是刻意行🄴，以確保應用程式在使用這個程式進行物件遍歷時可以區分結尾🄴 /x 和結尾🄴 /x/ 的 URIs。

wsgiref.util.**setup_testing_defaults**(*environ*)

🄴測試目的，以簡單的預設值更新 *environ* 。

這個程式新增 WSGI 所需的各種參數，包括 HTTP_HOST、SERVER_NAME、SERVER_PORT、REQUEST_METHOD、SCRIPT_NAME、PATH_INFO，以及所有 **PEP 3333** 定義的 wsgi.* 變數，它只提供預設值，🄴且不會取代現有的這些變數設定。

這個程式目的🄴了讓 WSGI 伺服器和應用程式的單元測試更容易建置🄵擬環境。實際的 WSGI 伺服器或應用程式不應該使用它，因🄴所🄴生的數據是假的！

Example usage (see also *demo_app()* for another example):

```
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print out the
# environment dictionary after being updated by setup_testing_defaults
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charset=utf-8')]

    start_response(status, headers)

    ret = [("%s: %s\n" % (key, value)).encode("utf-8")
           for key, value in environ.items()]
    return ret

with make_server('', 8000, simple_app) as httpd:
    print("Serving on port 8000...")
    httpd.serve_forever()
```

除了上述的環境功能外，*wsgiref.util* 模組還提供以下各類工具：

wsgiref.util.**is_hop_by_hop**(*header_name*)

如果'header_name' 是根據 **RFC 2616** 所定義的 HTTP/1.1 "Hop-by-Hop" 標頭，則回傳 True。

class wsgiref.util.**FileWrapper**(*filelike*, *blksize=8192*)

wsgiref.types.FileWrapper 協定的具體實作，用於將類檔案物件轉🄵🄵*iterator*。🄴生的物件是*iterable*。當物件進行🄴代時，將可選的 *blksize* 引數重🄴傳遞給 *filelike* 物件的 read() 方法來獲得將🄵生（yield）的位元組字串。當 read() 回傳一個空位元組字串，代表🄵代已結束且無法回復。

如果 *filelike* 有 close() 方法，則回傳的物件也會具有 close() 方法，🄴在呼叫時叫用 *filelike* 物件的 close() 方法。

用法範例：

```
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object"*10)
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
```

在 3.11 版的變更: 已移除對 __getitem__() 方法的支援。

22.2.2 `wsgiref.headers` -- WSGI 回應標頭工具

這個模組提供單一類🄴*Headers*，用於使用類似對映的介面方便地操作 WSGI 回應標頭。

class wsgiref.headers.**Headers**(*[headers]*)

建立一個類似對映物件🄴包裝 *headers*，🄴且必須是符合 **PEP 3333** 描述的 name/value 元組的標頭串列。*headers* 的預設值是一個空串列。

Headers 物件支援典型對映操作包括 `__getitem__()`、*get()*、`__setitem__()`、*setdefault()*、`__delitem__()` 以及 `__contains__()`。對於這些方法中的每一個，鍵是標頭名稱（以不區分大小寫方式處理），而值則是與該標頭名稱關聯的第一個值。設定標頭會🄴除該標頭的所有現有值，然後將新值添加到包裝的標頭串列末尾。標頭的現有順序通常保持不變，新標頭會添加到包裝串列的末尾。

不同於字典，當你嘗試取得或🄴除包裝的標頭串列不存在的鍵，*Headers* 物件不會引發例外錯誤。取得不存在的標頭只會回傳 `None`，而🄴除不存在的標頭則不會有任何效果。

Headers 物件還支援 `keys()`、`value()`、和 `items()` 方法。由 `keys()` 和 `items()` 回傳的串列在存在多值標頭時可能會包含相同的鍵。*Headers* 物件的 `len()` 與 `items()` 的長度相同，也與包裝標頭串列的長度相同。實際上，`items()` 方法只是回傳包裝的標頭串列的副本。

對 `Header` 物件呼叫 `bytes()` 會回傳適合作🄵 HTTP 傳輸回應標頭的格式化的位元組字串。每個標頭都與其值一起置於一行上，由冒號與空格分隔。每行以回車（carriage return）和🄵行（line feed）結束，而該位元組字串則以空行結束。

除了對映介面和格式化功能外，*Headers* 物件還具有以下查詢及附加多值標頭的以及附加 MIME 參數標頭的方法：

get_all(*name*)

回傳指定標頭的所有值的串列。

回傳的串列按照它們在在原始的標頭串列出現的順序或是被添加到此實例的順序進行排序，🄵且可能包含重🄵的🄵容。任何被🄵除🄵重新插入的欄位都會被添加到標頭串列的末尾。如果不存在指定名稱的欄位，則回傳空串列。

add_header(*name*, *value*, ***_params*)

添加一個（可能是多值的）標頭，可通過關鍵字引數來指定選擇性的 MIME 參數。

name 是要添加的標頭欄位。關鍵字引數可使於設定標頭欄位的 MIME 參數。每一個參數必須是字串或是 `None`。由於破折號在 Python 識🄵符中是非法的，但是許多 MIME 參數名稱包含破折號，因此參數名稱的底🄵會轉🄵成破折號。如果參數值是字串，則以 `name="value"` 的形式添加到標頭值參數中。如果它是 `None`，則僅添加參數名稱。（這使用於🄵有值的 MIME 參數）使用範例：

```
h.add_header('content-disposition', 'attachment', filename='bud.gif')
```

上述操作將添加看起來像這樣的標頭：

```
Content-Disposition: attachment; filename="bud.gif"
```

在 3.5 版的變更: *headers* 參數是可選的。

22.2.3 `wsgiref.simple_server` -- 一個簡單的 WSGI HTTP 伺服器

這個模組實作一個簡單的的 HTTP 伺服器（基於*http.server*）用於提供 WSGI 應用程式。每個伺服器執行個體在特定的主機與埠提供單一的 WSGI 應用程式。如果你想要在單一主機與埠上提供多個應用程式，你應該建立一個 WSGI 應用程式以剖析 `PATH_INFO` 去選擇🄵每個請求叫用哪個應用程式。（例如，使用來自*wsgiref.util* 的 `shift_path_info()` 函式。）

wsgiref.simple_server.**make_server**(*host*, *port*, *app*, *server_class=WSGIServer*, *handler_class=WSGIRequestHandler*)

建立一個新的 WSGI 伺服器監聽 *host* 和 *port*，接受 *app* 的連🄵。回傳值是提供 *server_class* 的實例，🄵將使用指定的 *handler_class* 處理請求。*app* 必須是一個 WSGI 應用程式物件，如 **PEP 3333** 所定義。

用法範例：

```
from wsgiref.simple_server import make_server, demo_app

with make_server('', 8000, demo_app) as httpd:
    print("Serving HTTP on port 8000...")

    # Respond to requests until process is killed
    httpd.serve_forever()

    # Alternative: serve one request, then exit
    httpd.handle_request()
```

wsgiref.simple_server.**demo_app**(*environ*, *start_response*)

這個函式是一個簡單但完整的 WSGI 應用程式，它回傳一個包含訊息"Hello world!" 和在 *environ* 參數中提供的鍵值對串列的文字頁面。這對於驗證 WSGI 伺服器（例如*wsgiref.simple_server*）是否能正確執行簡單的 WSGI 應用程式非常有用。

The *start_response* callable should follow the *StartResponse* protocol.

class wsgiref.simple_server.**WSGIServer**(*server_address*, *RequestHandlerClass*)

建立一個*WSGIServer* 實例。*server_address* 應該是一個 (host, port) 元組，而 *RequestHandlerClass* 應該是*http.server.BaseHTTPRequestHandler* 的子類🄵，將用於處理請求。

通常你不需要呼叫這個建構函式（constructor），因🄵*make_server()* 函式可以🄵你處理所有細節。

WSGIServer 是*http.server.HTTPServer* 的子類🄵，因此它的所有方法（例如 serve_forever() 和 handle_request()）都可用。*WSGIServer* 也提供這些特定於 WSGI 的方法：

set_app(*application*)

將可呼叫的 *application* 設定🄵接收請求的 WSGI 應用程式。

get_app()

回傳目前設定應用程式的可呼叫物件。

然而，通常情🄵下你不需要去使用這些額外方法，因🄵*set_app()* 通常會被*make_server()* 呼叫而*get_app()* 主要存在於請求處理程式（handler）實例的好處上。

class wsgiref.simple_server.**WSGIRequestHandler**(*request*, *client_address*, *server*)

🄵給定的 *request** (即一個 *socket*)、**client_address** (一個 *"(host,port)"* 位元組)、**server* (*WSGIServer* 實例) 建立一個 HTTP 處理程式（handler）。

你不需要直接建立這個類🄵的實例；它們會在需要時由*WSGIServer* 物件自動建立。不過，你可以建立這個類🄵的子類🄵🄵將其作🄵 *handler_class* 提供給*make_server()* 函式。一些可能相關的方法可以在子類🄵中進行覆寫：

get_environ()

唯一個請求回傳一個*WSGIEnvironment* 字典。預設的實作會🄵🄵*WSGIServer* 物件的 base_environ 字典屬性的🄵容以及添加從 HTTP 請求中衍生的各種標頭。每次呼叫這個方法都應該回傳一個包含所有如 **PEP 3333** 所指定的相關 CGI 環境變數的新字典。

get_stderr()

回傳的物件應該被用作 wsgi.errors 串流。預設實作只會回傳 sys.stderr。

handle()

處理 HTTP 請求。預設實作會使用 wsgiref.handler 類🄵來建立處置程式（handler）實例來實作實際 WSGI 應用程式介面。

22.2.4 wsgiref.validate --- WSGI 符合性檢查

當建立新的 WSGI 應用程式物件、框架、伺服器、或是中介軟體 (middleware) 時，使用*wsgiref.validate* 來驗證新程式碼的符合性可能會很有用。這個模組提供一個函式用於建立 WSGI 應用程式物件，🄵用於驗證 WSGI 伺服器或是閘道與 WSGI 應用程式物件之間的通訊，以檢查雙方協定的符合性。

請注意這個工具🄵不保證完全符合 **PEP 3333**；這個模組中的錯誤不一定代表不存在錯誤。但是，如果如果這個模組🄵生錯誤，那🄵幾乎可以確定伺服器或應用程式不是 100% 符合標準。

這個模組基於 Ian Bicking 的"Python Paste" 函式庫的 `paste.lint` 模組。

`wsgiref.validate.`**`validator`**(*application*)

包裝 *application* 🄵回傳一個新的 WSGI 應用程式物件。回傳的應用程式將轉發所有請求給原始的 *application*，🄵檢查 *application* 和呼叫它的伺服器是否符合 WSGI 規範和 **RFC 2616**。

任何在*AssertionError* 中偵測不符合結果都會發起例外；但請注意，如何處理這些錯誤取🄵於伺服器。例如，基於*wsgiref.handlers* 的*wsgiref.simple_server* 以及其他伺服器（未覆蓋錯誤處理方法以執行其他操作的伺服器）將僅輸出一條錯誤訊息，指示發生錯誤，🄵將回溯訊息輸出到 `sys.stderr` 或是其他錯誤串流。

這個包裝器也可以使用*warnings* 模組生成輸出去指示一些可能有疑慮但實際上可能不會被 **PEP 3333** 禁止的行🄵。除非使用 Python 命令列選項或*warnings* API，抑制了這些警告，否則這類警告將被寫入到 `sys.stderr`（*not* `wsgi.errors`，除非它們碰巧是相同的物件）。

用法範例：

```
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not compliant to the
# standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and
    # the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

with make_server('', 8000, validator_app) as httpd:
    print("Listening on port 8000....")
    httpd.serve_forever()
```

22.2.5 `wsgiref.handlers` -- 伺服器 / 閘道基本類🄵

這個模組提供實作 WSGI 伺服器和閘道的基礎處理程式（handler）類🄵。這些基底類🄵處理程式大部分與 WSGI 應用程式通訊的工作，只要它們被提供 CGI-like 環境，以及輸入、輸出和錯誤串流。

`class` `wsgiref.handlers.`**`CGIHandler`**

這是基於 CGI 的呼叫方式🄵透過 `sys.stdin`、`sys.stdout`、`sys.stderr` 和 `os.environ`。當你擁有一個 WSGI 應用程式🄵希望將其作🄵 CGI 🄵本運行時是很有用的。只需叫用 `CGIHandler().run(app)`，其中 `app` 是你希望叫用的 WSGI 應用程式物件。

這個類🄵是*BaseCGIHandler* 的子類🄵將 `wsgi.run_once` 設置🄵 true，`wsgi.multithread` 設置🄵 false，🄵將 `wsgi.multiprocess` 設置🄵 true，🄵且始終使用*sys* 和*os* 來取得所需的 CGI 串流以及環境。

`class` `wsgiref.handlers.`**`IISCGIHandler`**

這是用於在 Microsoft 的 IIS 網頁伺服器上部署時使用的*CGIHandler* 的一個專門替代選擇，無需設置 config 的 allowPathInfo 選項（IIS>=7），或 metabase 的 allowPathInfoForScriptMappings 選項（IIS<7）。

預設情🄵下，IIS 提供的 `PATH_INFO` 會在前面🄵🄵 `SCRIPT_NAME`，對於希望實作路由的 WSGI 應用程式造成問題。這個處理程式（handler）會移除任何這樣的重🄵路徑。

IIS 可以配置去傳遞正確的 `PATH_INFO`，但這會導致 `PATH_TRANSLATED` 是錯誤的問題。幸運的是這個變數很少被使用🄵且不受 WSGI 保證。然而，在 IIS<7 上，這個設置只能在🄵擬主機層級進行，

影響所有其他🄵本的對映，其中許多在暴露 PATH_TRANSLATED 問題時會中斷。由於這個原因幾乎從不會使用修復的 IIS<7（即使是 IIS7 也很少使用它，因🄵它仍然🄵有相應的 UI）。

CGI 程式碼無法知道是否已設置該選項，因此提供了一個獨立的處理程式（handler）類🄵。它的使用方式與*CGIHandler* 相同，即透過呼叫 IISCGIHandler().run(app) 來使用，其中 app 是你希望叫用的 WSGI 應用程式物件。

在 3.2 版被加入.

class wsgiref.handlers.**BaseCGIHandler**(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

類似於*CGIHandler*，但不是使用*sys* 和*os* 模組，而是明確指定 CGI 環境與 I/O 串流。*multithread* 和 *multiprocess* 值用於設置由處理程式（handler）實例運行的任何應用程式的旗標。

這個類🄵是專門🄵除了 HTTP "origin servers" 以外的軟體一起使用的*SimpleHandler* 的子類🄵。如果你正在撰寫一個使用 Status: 標頭來發送 HTTP 狀態的閘道協定實作（例如 CGI、FastCGI、SCGI 等），你可能會想要子類化這個類🄵來替代*SimpleHandler*。

class wsgiref.handlers.**SimpleHandler**(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

類似於*BaseCGIHandler*，但是被設計使用在 HTTP origin 伺服器。如果你正在撰寫 HTTP 伺服器的實作，你可能會想要子類🄵化這個類🄵來替代*BaseCGIHandler*。

這個類🄵是*BaseHandler* 的子類🄵。它透過建構函式去覆寫 __init__()、*get_stdin()*、*get_stderr()*、*add_cgi_vars()*、*_write()*、和*_flush()* 方法來明確提供設置環境與串流。提供的環境與串流被儲存在 stdin、stdout、stderr、和 environ 環境中。

stdout 的*write()* 方法應該完整地寫入每個塊（chunk），像是*io.BufferedIOBase*。

class wsgiref.handlers.**BaseHandler**

這是一個運行 WSGI 應用程式的抽象基底類🄵。每個實例將處理單個 HTTP 請求，🄵管原則上你可以建立一個可重用於多個請求的子類🄵。

BaseHandler 實例只有一個供外部使用的方法：

run(*app*)

運行指定 WSGI 應用程式，*app*。

此方法在運行應用程式的過程中叫用了所有其他*BaseHandler* 的方法，因此這些方法主要存在是🄵了允許自定義整個過程。

以下方法必須在子類🄵中覆寫：

_write(*data*)

緩衝要傳送給用🄵端的位元組 *data*。如果這個方法實際上傳送了數據也是可以的；當底層系統實際具有這種區分時，*BaseHandler* 🄵了更好的效能進而分離寫入和刷新操作。

_flush()

🄵制將緩衝數據傳送到用🄵端。如果這是一個無操作（no-op）的方法（即，如果*_write()* 實際上發送了數據），那🄵是可以的。

get_stdin()

回傳一個與*InputStream* 相容的物件🄵適用於用作目前正在處理請求的 wsgi.input。

get_stderr()

回傳一個與*ErrorStream* 相容的物件🄵適用於用作目前正在處理請求的 wsgi.errors。

add_cgi_vars()

將目前請求的 CGI 變數插入到 environ 屬性中。

以下是你可能希望覆寫的其他方法和屬性。這個列表只是一個摘要，然而，不包括可以被覆寫的每個方法。在嘗試建立自定義的*BaseHandler* 子類🄵之前，你應該參考文件🄵明和原始碼以獲得更多資訊。

用於自定義 WSGI 環境的屬性和方法：

wsgi_multithread

用於 wsgi.multithread 環境變數的值。在*BaseHandler* 中預設🄵 true，但在其他子類🄵中可能有不同的預設值（或由建構函式設置）。

wsgi_multiprocess

用於 wsgi.multiprocess 環境變數的值。在*BaseHandler* 中預設🄵 true，但在其他子類🄵中可能有不同的預設值（或由建構函式設置）。

wsgi_run_once

用於 wsgi.run_once 環境變數的值。在*BaseHandler* 中預設🄵 false，但*CGIHandler* 預設將其設置🄵 true。

os_environ

預設環境變數包含在每一個請求的 WSGI 環境中。預設情🄵下，這是在載入*wsgiref.handlers* 時的 os.environ 副本，但子類🄵可以在類🄵或實例層級建立自己的副本。注意字典應該被視🄵唯讀，因🄵預設值在多個類🄵與實例中共享。

server_software

如果設置*origin_server* 屬性，則此屬性的值將用於設置預設的 SERVER_SOFTWARE WSGI 環境變數，🄵且還將用於設置 HTTP 回應中的預設 Server: 標頭。對於不是 HTTP origin 伺服器的處置程式（例如*BaseCGIHandler* 和*CGIHandler*），此屬性將被忽略。

在 3.3 版的變更: 將術語”Python” 替🄵🄵特定實作的術語，如”CPython”、”Jython” 等。

get_scheme()

回傳用於目前請求的 URL scheme。預設的實作使用*wsgiref.util* 中的 guess_scheme() 函式去猜測 scheme 是”http” 或是”https”，基於目前請求的 environ 變數。

setup_environ()

將 environ 屬性設置🄵完全填充的 WSGI 環境。預設的實作使用上述所有方法和屬性，以及*get_stdin()*、*get_stderr()* 和*add_cgi_vars()* 方法以及*wsgi_file_wrapper* 屬性。如果不呈現它也會插入一個 SERVER_SOFTWARE 關鍵字，只要*origin_server* 屬性是一個 true 值🄵且*server_software* 屬性被設置。

用於自定義例外處理的屬性和方法：

log_exception(*exc_info*)

將 *exc_info* 元組記🄵到伺服器日🄵中。*exc_info* 是一個 (type, value, traceback) 元組。預設實作只是將追🄵資訊寫入到請求的 wsgi.errors 串流中🄵刷新它。子類🄵可以覆蓋此方法以更改格式或重新定向輸出，將追🄵資訊發送給管理員，或執行其他被認🄵合適的操作。

traceback_limit

預設的*log_exception()* 方法追🄵輸出中包含的最大幀數。如果🄵 None，則包含所有幀。

error_output(*environ*, *start_response*)

這個方法是一個🄵使用者去🄵生錯誤頁面的 WSGI 應用程式。只有在標頭傳送給用🄵端前如果發生錯誤才會被叫用。

此方法使用 sys.exception() 存取目前的錯誤，當呼叫它（如 **PEP 3333** 的”Error Handling” 部分所描述）時應該傳遞資訊給 *start_response*。特🄵是 *start_response* 可呼叫物件應該遵循*StartResponse* 協定。

預設的實作只是使用*error_status*、*error_headers* 和*error_body* 屬性🄵生輸出頁面。子類🄵可以覆蓋此方法以生成更動態的錯誤輸出。

然而，從安全的角度🄵不建議向任何普通使用者顯示診斷資訊；理想情🄵下，你應該需要🄵取特殊措施才能🄵用診斷輸出，這就是預設實作不包括任何診斷資訊的原因。

error_status

用於錯誤回應的 HTTP 狀態。這應該是一個按照 **PEP 3333** 定義的狀態字串；預設🄵 500 狀態碼和訊息。

error_headers

用於錯誤回應的 HTTP 標頭。這應該是一個 WSGI 回應標頭的串列（`(name, value)` 元組），如 **PEP 3333** 中所描述。預設串列只設置🄵容種類🄵 `text/plain`。

error_body

錯誤回應的主體。這應該是一個 HTTP 回應🄵容的位元組字串。預設🄵純文字"A server error occurred. Please contact the administrator."

用於 **PEP 3333** 中的"Optional Platform-Specific File Handling" 功能的方法和屬性：

wsgi_file_wrapper

一個 `wsgi.file_wrapper` 工廠函式（factory），與*wsgiref.types.FileWrapper* 相容，或者🄵 `None`。這個屬性的預設值是*wsgiref.util.FileWrapper* 類🄵。

sendfile()

覆蓋以實作特定平台的檔案傳輸。只有當應用程式的回傳值是由*wsgi_file_wrapper* 屬性指定的類🄵實例時才會呼叫此方法。如果它能🄵成功傳輸檔案應該回傳一個 true 值，以便不執行預設的傳輸程式碼。該方法的預設實作只回傳一個 false 值。

其他方法和屬性：

origin_server

這個屬性應該被設置🄵 true 值，如果處理程式（handler）的*_write()* 和*_flush()* 被用於直接與用🄵端通訊，而不是透過 CGI-like 的閘道協定希望 HTTP 狀態在特殊的 `Status:` 標頭中。

這個屬性在*BaseCGIHandler* 預設值🄵 true，但是在*BaseCGIHandler* 和*CGIHandler* 🄵 false。

http_version

如果*origin_server* 🄵 true，則此字串屬性用於設定傳送給用🄵端的回應的 HTTP 版本。預設🄵 `"1.0"`。

wsgiref.handlers.**read_environ**()

從 `os.environ` 轉碼 CGI 變數到 **PEP 3333** 中的"bytes in unicode" 字串，🄵回傳一個新字典。這個函式被*CGIHandler* 和*IISCGIHandler* 使用來直接替代 `os.environ`，在所有平台和使用 Python 3 的網頁伺服器上不一定符合 WSGI 標准，具體來🄵，在 OS 的實際環境是 Unicode（例如 Windows）的情🄵下，或者在環境是位元組的情🄵下，但 Python 用於解碼它的系統編碼不是 ISO-8859-1 （例如使用 UTF-8 的 Unix 系統）。

如果你自己正在實作 CGI-based 處理程式（handler），你可能想要使用這個函式來替🄵單純直接從 `os.environ` 中🄵🄵值。

在 3.2 版被加入.

22.2.6 wsgiref.types -- 用於🄵態型🄵檢查的 WSGI 型🄵

這個模組提供在 **PEP 3333** 中所描述的各種用於🄵態型🄵檢查的型🄵。

在 3.11 版被加入.

class wsgiref.types.**StartResponse**

一個描述 **start_response()** 可呼叫物件的*typing.Protocol* (**PEP 3333**)。

wsgiref.types.**WSGIEnvironment**

一個描述 WSGI 環境字典的型🄵🄵名。

wsgiref.types.**WSGIApplication**

一個描述 WSGI 應用程式可呼叫物件的型🄵🄵名。

class wsgiref.types.**InputStream**

一個描述 **WSGI 輸入串流**的*typing.Protocol*。

class wsgiref.types.**ErrorStream**

一個描述 **WSGI 錯誤串流**的*typing.Protocol*。

class wsgiref.types.**FileWrapper**

一個描述**檔案包裝器**的*typing.Protocol*。請參🄵*wsgiref.util.FileWrapper* 來🄵解此協定的具體實作。

22.2.7 范例

This is a working "Hello World" WSGI application, where the *start_response* callable should follow the *StartResponse* protocol:

```
"""
Every WSGI application must have an application object - a callable
object that accepts two arguments. For that purpose, we're going to
use a function (note that you're not limited to a function, you can
use a class for example). The first argument passed to the function
is a dictionary containing CGI-style environment variables and the
second variable is the callable object.
"""
from wsgiref.simple_server import make_server

def hello_world_app(environ, start_response):
    status = "200 OK"  # HTTP Status
    headers = [("Content-type", "text/plain; charset=utf-8")]  # HTTP Headers
    start_response(status, headers)

    # The returned object is going to be printed
    return [b"Hello World"]

with make_server("", 8000, hello_world_app) as httpd:
    print("Serving on port 8000...")

    # Serve until process is killed
    httpd.serve_forever()
```

提供目前目🄵的 WSGI 應用程式範例，🄵接受命令列上的可選目🄵和埠號（預設：8000）：

```
"""
Small wsgiref based web server. Takes a path to serve from and an
optional port number (defaults to 8000), then tries to serve files.
MIME types are guessed from the file names, 404 errors are raised
if the file is not found.
"""
import mimetypes
import os
import sys
from wsgiref import simple_server, util

def app(environ, respond):
    # Get the file name and MIME type
    fn = os.path.join(path, environ["PATH_INFO"][1:])
    if "." not in fn.split(os.path.sep)[-1]:
        fn = os.path.join(fn, "index.html")
    mime_type = mimetypes.guess_file_type(fn)[0]

    # Return 200 OK if file exists, otherwise 404 Not Found
    if os.path.exists(fn):
        respond("200 OK", [("Content-Type", mime_type)])
        return util.FileWrapper(open(fn, "rb"))
    else:
        respond("404 Not Found", [("Content-Type", "text/plain")])
        return [b"not found"]
```

(繼續下一頁)

(繼續上一頁)

```
if __name__ == "__main__":
    # Get the path and port from command-line arguments
    path = sys.argv[1] if len(sys.argv) > 1 else os.getcwd()
    port = int(sys.argv[2]) if len(sys.argv) > 2 else 8000

    # Make and start the server until control-c
    httpd = simple_server.make_server("", port, app)
    print(f"Serving {path} on port {port}, control-C to stop")
    try:
        httpd.serve_forever()
    except KeyboardInterrupt:
        print("Shutting down.")
        httpd.server_close()
```

22.3 `urllib` --- URL 處理模組

原始碼： Lib/urllib/

`urllib` 是一個🄵集了許多處理 URLs 的 module（模組）的 package（套件）：

- *`urllib.request`* 用來開🄵和讀取 URLs
- *`urllib.error`* 包含了*`urllib.request`* 所引發的例外
- *`urllib.parse`* 用來剖析 URLs
- *`urllib.robotparser`* 用來剖析 `robots.txt` 檔案

22.4 `urllib.request` --- 用來開🄵 URLs 的可擴充函式庫

原始碼： Lib/urllib/request.py

`urllib.request` module（模組）定義了一些函式與 class（類🄵）用以開🄵 URLs（大部分是 HTTP），🄵處理各式🄵雜情🄵如：basic 驗證與 digest 驗證、重新導向、cookies。

也參考

有關於更高階的 HTTP 用🄵端介面，推薦使用 Requests 套件。

警告

On macOS it is unsafe to use this module in programs using *`os.fork()`* because the *`getproxies()`* implementation for macOS uses a higher-level system API. Set the environment variable `no_proxy` to `*` to avoid this problem (e.g. `os.environ["no_proxy"] = "*"`).

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

`urllib.request` module 定義下列函式：

urllib.request.**urlopen**(*url*, *data=None*, [*timeout*,]*, *context=None*)

打開 *url*，其值可以是一個包含有效且適當編碼 URL 的字串或是一個*Request* 物件。

data 必須是一個包含傳送給伺服器額外資料的物件，若不需要傳送額外資料則指定🄵 None。更多細節請見*Request*。

urllib.request module 使用 HTTP/1.1 🄵包含 Connection:close header（標頭）在其 HTTP 請求中。

透過選擇性參數 *timeout* 來指定 blocking operations（阻塞性操作，如：嘗試連接）的 timeout（超時時間），以秒🄵單位。若🄵有指定值，則會使用全域預設超時時間設定。實際上，此參數僅作用於 HTTP、HTTPS 以及 FTP 的連接。

若 *context* 有被指定時，它必須是一個*ssl.SSLContext* 的實例🄵描述著各種 SSL 選項。更多細節請見*HTTPSConnection*。

這個函式總是回傳一個可作🄵*context manager* 使用的物件，🄵有著特性 (property) *url*、*headers* 與 *status*。欲知更多這些特性細節請參見*urllib.response.addinfourl*。

對於 HTTP 與 HTTPS 的 URLs，這個函式回傳一個稍有不同的*http.client.HTTPResponse* 物件。除了上述提到的三個方法外，另有 msg 屬性🄵有著與*reason* 相同的資訊 --- 由伺服器回傳的原因🄵述 (reason phrase)，而不是在*HTTPResponse* 文件中提到的回應 headers。

對於 FTP、檔案及資料的 URLs，這個函式會回傳一個*urllib.response.addinfourl* 物件。

當遇到協定上的錯誤時會引發*URLError*。

請注意若🄵有 handler 處理請求時，None 值將會被回傳。（即使有預設的全域類🄵*OpenerDirector* 使用*UnknownHandler* 來確保這種情🄵不會發生）

另外，若有偵測到代理服務的設定（例如當 *_proxy 環境變數像是：:envvar:!http_proxy‘ 有被設置時），*ProxyHandler* 會被預設使用以確保請求有透過代理服務來處理。

Python 2.6 或更早版本的遺留函式 urllib.urlopen 已經不再被維護；新函式*urllib.request.urlopen()* 對應到舊函式 urllib2.urlopen。有關代理服務的處理，以往是透過傳遞 dictionary（字典）參數給 urllib.urlopen 來取得的，現在則可以透過*ProxyHandler* 物件來取得。

預設的 opener 會觸發一個*auditing event* urllib.Request 與其從請求物件中所獲得的引數 fullurl、data、headers、method。

在 3.2 版的變更: 新增 *cafile* 與 *capath*。

HTTPS 🄵擬主機 (virtual hosts) 現已支援，只要*ssl.HAS_SNI* 的值🄵 true。

data 可以是一個可🄵代物件。

在 3.3 版的變更: *cadefault* 被新增。

在 3.4.3 版的變更: *context* 被新增。

在 3.10 版的變更: 當 *context* 🄵有被指定時，HTTPS 連🄵現在會傳送一個帶有協定指示器 http/1.1 的 ALPN 擴充 (extension)。自訂的 *context* 應該利用*set_alpn_protocols()* 來自行設定 ALPN 協定。

在 3.13 版的變更: Remove *cafile*, *capath* and *cadefault* parameters: use the *context* parameter instead.

urllib.request.**install_opener**(*opener*)

安裝一個*OpenerDirector* 實例作🄵預設的全域 opener。僅在當你想要讓 urlopen 使用該 opener 時安裝一個 opener，否則的話應直接呼叫*OpenerDirector.open()* 而非*urlopen()*。程式碼不會檢查 class 是否真的🄵*OpenerDirector*，而是任何具有正確介面的 class 都能適用。

urllib.request.**build_opener**([*handler*, ...])

回傳一個*OpenerDirector* 實例，以給定的順序把 handlers 串接起來。*handler*s 可以是*BaseHandler* 的實例，亦或是*BaseHandler* 的 subclasses（這個情🄵下必須有不帶參數的建構函式能🄵被呼叫）。以下 classes 的實例順位會在 *handler*s 之前，除非 *handler*s 已經包含它們，是它們的實例，或是它們的 subclasses：*ProxyHandler*（如果代理服務設定被偵測到）、*UnknownHandler*、*HTTPHandler*、*HTTPDefaultErrorHandler*、*HTTPRedirectHandler*、*FTPHandler*、*FileHandler*、*HTTPErrorProcessor*。

如果 Python 安裝時已帶有 SSL 支援（如果*ssl* module 能🄴被 import），則*HTTPSHandler* 也在上述 class 之中。

一個*BaseHandler* 的 subclass 可能透過改變其 `handler_order` 屬性來調整它在 handlers list 中的位置。

`urllib.request.`**`pathname2url`**(*path*, *, *add_scheme=False*)

Convert the given local path to a `file:` URL. This function uses *quote()* function to encode the path.

If *add_scheme* is false (the default), the return value omits the `file:` scheme prefix. Set *add_scheme* to true to return a complete URL.

This example shows the function being used on Windows:

```
>>> from urllib.request import pathname2url
>>> path = 'C:\\Program Files'
>>> pathname2url(path, add_scheme=True)
'file:///C:/Program%20Files'
```

在 3.14 版的變更: Windows drive letters are no longer converted to uppercase, and `:` characters not following a drive letter no longer cause an *OSError* exception to be raised on Windows.

在 3.14 版的變更: Paths beginning with a slash are converted to URLs with authority sections. For example, the path `/etc/hosts` is converted to the URL `///etc/hosts`.

在 3.14 版的變更: The *add_scheme* parameter was added.

`urllib.request.`**`url2pathname`**(*url*, *, *require_scheme=False*, *resolve_host=False*)

Convert the given `file:` URL to a local path. This function uses *unquote()* to decode the URL.

If *require_scheme* is false (the default), the given value should omit a `file:` scheme prefix. If *require_scheme* is set to true, the given value should include the prefix; a *URLError* is raised if it doesn't.

The URL authority is discarded if it is empty, `localhost`, or the local hostname. Otherwise, if *resolve_host* is set to true, the authority is resolved using *socket.gethostbyname()* and discarded if it matches a local IP address (as per **RFC 8089 §3**). If the authority is still unhandled, then on Windows a UNC path is returned, and on other platforms a *URLError* is raised.

This example shows the function being used on Windows:

```
>>> from urllib.request import url2pathname
>>> url = 'file:///C:/Program%20Files'
>>> url2pathname(url, require_scheme=True)
'C:\\Program Files'
```

在 3.14 版的變更: Windows drive letters are no longer converted to uppercase, and `:` characters not following a drive letter no longer cause an *OSError* exception to be raised on Windows.

在 3.14 版的變更: The URL authority is discarded if it matches the local hostname. Otherwise, if the authority isn't empty or `localhost`, then on Windows a UNC path is returned (as before), and on other platforms a *URLError* is raised.

在 3.14 版的變更: The URL query and fragment components are discarded if present.

在 3.14 版的變更: The *require_scheme* and *resolve_host* parameters were added.

`urllib.request.`**`getproxies`**()

這個輔助函式 (helper function) 回傳一個代理伺服器 URL mappings（對映）的 dictionary。在所有的作業系統中，它首先掃描環境中有著 `<scheme>_proxy` 名稱的變數（忽略大小寫的），如果找不到的話就會在 macOS 中的系統設定 (System Configuration) 或是 Windows 系統中的 Windows Systems Registry 尋找代理服務設定。如果大小寫的環境變數同時存在且值有不同，小寫的環境變數會被選用。

> **備🄵**
>
> 如果環境變數 REQUEST_METHOD 有被設置（通常這代表著你的 script 是運行在一個共用閘道介面 (CGI) 環境中），那🄵環境變數 HTTP_PROXY （大寫的 _PROXY）將被忽略。這是因🄵變數可以透過使用"Proxy:" HTTP header 被注入。如果需要在共用閘道介面環境中使用 HTTP 代理服務，可以明確使用 ProxyHandler，亦或是確認變數名稱是小寫的（或至少 _proxy 後綴是小寫的）。

提供了以下的 classes：

class urllib.request.**Request**(*url*, *data=None*, *headers={}*, *origin_req_host=None*, *unverifiable=False*, *method=None*)

這個 class 是一個 URL 請求的抽象 class。

url 是一個包含有效且適當編碼的 URL 字串。

data 必須是一個包含要送到伺服器的附加資料的物件，若不需帶附加資料則其值應🄵 None。目前 HTTP 請求是唯一有使用 *data* 參數的，其支援的物件型🄵包含位元組、類檔案物件 (file-like objects)、以及可🄵代的類位元組串物件 (bytes-like objects)。如果🄵有提供 Content-Length 及 Transfer-Encoding headers 欄位，*HTTPHandler* 將會根據 *data* 的型🄵設置這些 header。Content-Length 會被用來傳送位元組串物件，而 **RFC 7230** 章節 3.3.1 所定義的 Transfer-Encoding: chunked 則會被用來傳送檔案或是其它可🄵代物件 (iterables)。

對於一個 HTTP POST 請求方法，*data* 應🄵一個標准 *application/x-www-form-urlencoded* 格式的 buffer。*urllib.parse.urlencode()* 方法接受一個 mapping 或是 sequence（序列）的 2-tuples，🄵回傳一個對應格式的 ASCII 字串。在被作🄵 *data* 參數前它應該被編碼成位元組串。

headers 必須是一個 dictionary，🄵會被視🄵如同每對 key 和 value 作🄵引數來呼叫*add_header()*。經常用於「🄵裝」User-Agent header 的值，這個 header 是用來讓一個🄵覽器向伺服器表明自己的身分 --- 有些 HTTP 伺服器僅允許來自普通🄵覽器的請求，而不接受來自程式🄵本的請求。例如，Mozilla Firefox 會將 header 的值設🄵 "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11"，而*urllib* 的值則是 "Python-urllib/2.6"（在 Python 2.6 上）。所有 header 的鍵都會以 camel case（駝峰式大小寫）來傳送。

當有給定 *data* 引數時，一個適當的 Content-Type header 應該被設置。如果這個 header 🄵有被提供且 *data* 也不🄵 None 時，預設值 Content-Type: application/x-www-form-urlencoded 會被新增至請求中。

接下來的兩個引數的介紹提供給那些有興趣正確處理第三方 HTTP cookies 的使用者：

origin_req_host 應🄵原始傳輸互動的請求主機 (request-host)，如同在 **RFC 2965** 中的定義。預設值🄵 http.cookiejar.request_host(self)。這是使用者發起的原始請求的主機名稱或是 IP 位址。例如當請求是要求一個 HTML 文件中的一個影像，則這個屬性應🄵請求包含影像頁面的請求主機。

unverifiable 應該標示一個請求是否是無法驗證的，如同在 **RFC 2965** 中的定義。其預設值🄵 False。一個無法驗證的請求是指使用者🄵有機會去批准請求的 URL，例如一個對於 HTML 文件中的影像所做的請求，而使用者🄵有機會去批准是否能自動🄵取影像，則這個值應該🄵 true。

method 應🄵一個標示 HTTP 請求方法的字串（例如：'HEAD'）。如果有提供值，則會被存在*method* 屬性中且被*get_method()* 所使用。當 *data* 是 None 時，其預設值🄵 'GET'，否則預設值🄵 'POST'。Subclasses 可以透過設置其*method* 屬性來設定不一樣的預設請求方法。

> **備🄵**
>
> 如果資料物件無法重🄵提供其🄵容（例如一個檔案或是只能🄵生一次🄵容的可🄵代物件）且請求因🄵 HTTP 重導向 (redirects) 或是 HTTP 驗證 (authentication) 而被重新嘗試傳送，則該請求不會正常運作。*data* 會接在 headers 之後被送至 HTTP 伺服器。此函式庫🄵有支援 100-continue expectation。

在 3.3 版的變更: 新增*Request.method* 引數到 Request class。

在 3.4 版的變更: 能🄵在 class 中設置預設的*Request.method*。

在 3.6 版的變更: 如果 Content-Length 尚未被提供且 *data* 既不是 None 也不是一個位元組串物件，則不會觸發錯誤，🄵 fall back（後備）使用分塊傳輸編碼 (chunked transfer encoding)。

class urllib.request.**OpenerDirector**

The *OpenerDirector* class opens URLs via *BaseHandler*s chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.**BaseHandler**

This is the base class for all registered handlers --- and handles only the simple mechanics of registration.

class urllib.request.**HTTPDefaultErrorHandler**

A class which defines a default handler for HTTP error responses; all responses are turned into *HTTPError* exceptions.

class urllib.request.**HTTPRedirectHandler**

A class to handle redirections.

class urllib.request.**HTTPCookieProcessor**(*cookiejar=None*)

A class to handle HTTP Cookies.

class urllib.request.**ProxyHandler**(*proxies=None*)

Cause requests to go through a proxy. If *proxies* is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables <protocol>_proxy. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a macOS environment proxy information is retrieved from the System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

The no_proxy environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with :port appended, for example cern.ch,ncsa.uiuc.edu,some.host:8080.

> **備🄵**
>
> HTTP_PROXY will be ignored if a variable REQUEST_METHOD is set; see the documentation on *getproxies()*.

class urllib.request.**HTTPPasswordMgr**

Keep a database of (realm, uri) -> (user, password) mappings.

class urllib.request.**HTTPPasswordMgrWithDefaultRealm**

Keep a database of (realm, uri) -> (user, password) mappings. A realm of None is considered a catch-all realm, which is searched if no other realm fits.

class urllib.request.**HTTPPasswordMgrWithPriorAuth**

A variant of *HTTPPasswordMgrWithDefaultRealm* that also has a database of uri -> is_authenticated mappings. Can be used by a BasicAuth handler to determine when to send authentication credentials immediately instead of waiting for a 401 response first.

在 3.5 版被加入.

class urllib.request.**AbstractBasicAuthHandler**(*password_mgr=None*)

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported. If *passwd_mgr* also provides is_authenticated and update_authenticated methods (see *HTTPPasswordMgrWithPriorAuth 物件*), then the handler will use the is_authenticated result for a given URI to determine whether or not to send authentication credentials with the request. If is_authenticated returns True for the URI, credentials are sent. If is_authenticated is False, credentials are not sent, and then if a 401 response is received the request is re-sent with the authentication credentials. If authentication succeeds, update_authenticated

is called to set `is_authenticated` `True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

在 3.5 版被加入: 新增 `is_authenticated` 的支援。

class urllib.request.**HTTPBasicAuthHandler**(*password_mgr=None*)

Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported. HTTPBasicAuthHandler will raise a *ValueError* when presented with a wrong Authentication scheme.

class urllib.request.**ProxyBasicAuthHandler**(*password_mgr=None*)

Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported.

class urllib.request.**AbstractDigestAuthHandler**(*password_mgr=None*)

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported.

在 3.14 版的變更: Added support for HTTP digest authentication algorithm `SHA-256`.

class urllib.request.**HTTPDigestAuthHandler**(*password_mgr=None*)

Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a *ValueError* when presented with an authentication scheme other than Digest or Basic.

在 3.3 版的變更: Raise *ValueError* on unsupported Authentication Scheme.

class urllib.request.**ProxyDigestAuthHandler**(*password_mgr=None*)

Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr 物件* for information on the interface that must be supported.

class urllib.request.**HTTPHandler**

A class to handle opening of HTTP URLs.

class urllib.request.**HTTPSHandler**(*debuglevel=0*, *context=None*, *check_hostname=None*)

A class to handle opening of HTTPS URLs. *context* and *check_hostname* have the same meaning as in *http.client.HTTPSConnection*.

在 3.2 版的變更: 新增 *context* 與 *check_hostname*。

class urllib.request.**FileHandler**

Open local files.

class urllib.request.**DataHandler**

Open data URLs.

在 3.4 版被加入.

class urllib.request.**FTPHandler**

打開 FTP URLs。

class urllib.request.**CacheFTPHandler**

Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib.request.**UnknownHandler**

A catch-all class to handle unknown URLs.

class urllib.request.**HTTPErrorProcessor**

Process HTTP error responses.

22.4.1 Request 物件

The following methods describe *Request*'s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request.**full_url**

The original URL passed to the constructor.

在 3.4 版的變更.

Request.full_url is a property with setter, getter and a deleter. Getting *full_url* returns the original request URL with the fragment, if it was present.

Request.**type**

The URI scheme.

Request.**host**

The URI authority, typically a host, but may also contain a port separated by a colon.

Request.**origin_req_host**

The original host for the request, without port.

Request.**selector**

The URI path. If the *Request* uses a proxy, then selector will be the full URL that is passed to the proxy.

Request.**data**

The entity body for the request, or None if not specified.

在 3.4 版的變更: Changing value of *Request.data* now deletes "Content-Length" header if it was previously set or calculated.

Request.**unverifiable**

boolean, indicates whether the request is unverifiable as defined by **RFC 2965**.

Request.**method**

The HTTP request method to use. By default its value is *None*, which means that *get_method()* will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in *get_method()*) either by providing a default value by setting it at the class level in a *Request* subclass, or by passing a value in to the *Request* constructor via the *method* argument.

在 3.3 版被加入.

在 3.4 版的變更: A default value can now be set in subclasses; previously it could only be set via the constructor argument.

Request.**get_method**()

Return a string indicating the HTTP request method. If *Request.method* is not None, return its value, otherwise return 'GET' if *Request.data* is None, or 'POST' if it's not. This is only meaningful for HTTP requests.

在 3.3 版的變更: get_method now looks at the value of *Request.method*.

Request.**add_header**(*key*, *val*)

Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the *key* collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header. Note that headers added using this method are also added to redirected requests.

Request.**add_unredirected_header**(*key*, *header*)

Add a header that will not be added to a redirected request.

Request.**has_header**(*header*)

Return whether the instance has the named header (checks both regular and unredirected).

Request.**remove_header**(*header*)

Remove named header from the request instance (both from regular and unredirected headers).

在 3.4 版被加入.

Request.**get_full_url**()

Return the URL given in the constructor.

在 3.4 版的變更.

回傳*Request.full_url*

Request.**set_proxy**(*host*, *type*)

Prepare the request by connecting to a proxy server. The *host* and *type* will replace those of the instance, and the instance's selector will be the original URL given in the constructor.

Request.**get_header**(*header_name*, *default=None*)

Return the value of the given header. If the header is not present, return the default value.

Request.**header_items**()

Return a list of tuples (header_name, header_value) of the Request headers.

在 3.4 版的變更: The request methods add_data, has_data, get_data, get_type, get_host, get_selector, get_origin_req_host and is_unverifiable that were deprecated since 3.3 have been removed.

22.4.2 OpenerDirector 物件

OpenerDirector 物件有以下的方法:

OpenerDirector.**add_handler**(*handler*)

handler should be an instance of *BaseHandler*. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case). Note that, in the following, *protocol* should be replaced with the actual protocol to handle, for example `http_response()` would be the HTTP protocol response handler. Also *type* should be replaced with the actual HTTP code, for example `http_error_404()` would handle HTTP 404 errors.

- `<protocol>_open()` --- signal that the handler knows how to open *protocol* URLs.

  更多資訊請見*BaseHandler.<protocol>_open()*。

- `http_error_<type>()` --- signal that the handler knows how to handle HTTP errors with HTTP error code *type*.

  更多資訊請見*BaseHandler.http_error_<nnn>()*。

- `<protocol>_error()` --- signal that the handler knows how to handle errors from (non-`http`) *protocol*.

- `<protocol>_request()` --- signal that the handler knows how to pre-process *protocol* requests.

  更多資訊請見*BaseHandler.<protocol>_request()*。

- `<protocol>_response()` --- signal that the handler knows how to post-process *protocol* responses.

  更多資訊請見*BaseHandler.<protocol>_response()*。

OpenerDirector.**open**(*url*, *data=None*[, *timeout*])

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of *urlopen()* (which simply calls the *open()* method on the currently installed global *OpenerDirector*). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections.

OpenerDirector.**error**(*proto*, **args*)

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the `http_error_<type>()` methods of the handler classes.

Return values and exceptions raised are the same as those of *urlopen()*.

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like `<protocol>_request()` has that method called to pre-process the request.
2. Handlers with a method named like `<protocol>_open()` are called to handle the request. This stage ends when a handler either returns a non-*None* value (ie. a response), or raises an exception (usually *URLError*). Exceptions are allowed to propagate.

   In fact, the above algorithm is first tried for methods named *default_open()*. If all such methods return *None*, the algorithm is repeated for methods named like `<protocol>_open()`. If all such methods return *None*, the algorithm is repeated for methods named *unknown_open()*.

   Note that the implementation of these methods may involve calls of the parent *OpenerDirector* instance's *open()* and *error()* methods.
3. Every handler with a method named like `<protocol>_response()` has that method called to post-process the response.

22.4.3 BaseHandler 物件

BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

BaseHandler.**add_parent**(*director*)

Add a director as parent.

BaseHandler.**close**()

Remove any parents.

The following attribute and methods should only be used by classes derived from *BaseHandler*.

> **備🄵**
>
> The convention has been adopted that subclasses defining `<protocol>_request()` or `<protocol>_response()` methods are named `*Processor`; all others are named `*Handler`.

BaseHandler.**parent**

A valid *OpenerDirector*, which can be used to open using a different protocol, or handle errors.

BaseHandler.**default_open**(*req*)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent *OpenerDirector*. It should return a file-like object as described in the return value of the *open()* method of *OpenerDirector*, or `None`. It should raise *URLError*, unless a truly exceptional thing happens (for example, *MemoryError* should not be mapped to *URLError*).

This method will be called before any protocol-specific open method.

BaseHandler.<protocol>_open(req)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. Return values should be the same as for *default_open()*.

BaseHandler.**unknown_open**(*req*)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the *parent* *OpenerDirector*. Return values should be the same as for *default_open()*.

BaseHandler.**http_error_default**(*req*, *fp*, *code*, *msg*, *hdrs*)

This method is *not* defined in *BaseHandler*, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the *OpenerDirector* getting the error, and should not normally be called in other circumstances.

OpenerDirector 會以五個位置引數呼叫此方法：

1. 一個*Request* 物件
2. 一個類檔案物件，包含 HTTP 錯誤主體，
3. HTTP 錯誤的三位數代號字串，
4. HTTP 錯誤代號的使用者可見解釋字串，以及
5. HTTP 錯誤的標頭，🄵一個對映物件。

Return values and exceptions raised should be the same as those of *urlopen()*.

BaseHandler.http_error_<nnn>(req, fp, code, msg, hdrs)

nnn should be a three-digit HTTP error code. This method is also not defined in *BaseHandler*, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code *nnn* occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for *http_error_default()*.

BaseHandler.<protocol>_request(req)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. The return value should be a *Request* object.

BaseHandler.<protocol>_response(req, response)

This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. *response* will be an object implementing the same interface as the return value of *urlopen()*. The return value should implement the same interface as the return value of *urlopen()*.

22.4.4 HTTPRedirectHandler 物件

備🄵

Some HTTP redirections require action from this module's client code. If this is the case, *HTTPError* is raised. See **RFC 2616** for details of the precise meanings of the various redirection codes.

An *HTTPError* exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected URL which is not an HTTP, HTTPS or FTP URL.

HTTPRedirectHandler.**redirect_request**(*req*, *fp*, *code*, *msg*, *hdrs*, *newurl*)

Return a *Request* or `None` in response to a redirect. This is called by the default implementations of the `http_error_30*()` methods when a redirection is received from the server. If a redirection should take place, return a new *Request* to allow `http_error_30*()` to perform the redirect to *newurl*. Otherwise, raise *HTTPError* if no other handler should try to handle this URL, or return `None` if you can't but another handler might.

> **備🄵**
>
> The default implementation of this method does not strictly follow **RFC 2616**, which says that 301 and 302 responses to `POST` requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a `GET`, and the default implementation reproduces this behavior.

HTTPRedirectHandler.**http_error_301**(*req*, *fp*, *code*, *msg*, *hdrs*)

Redirect to the `Location:` or `URI:` URL. This method is called by the parent *OpenerDirector* when getting an HTTP 'moved permanently' response.

HTTPRedirectHandler.**http_error_302**(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as *http_error_301()*, but called for the 'found' response.

HTTPRedirectHandler.**http_error_303**(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as *http_error_301()*, but called for the 'see other' response.

HTTPRedirectHandler.**http_error_307**(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as *http_error_301()*, but called for the 'temporary redirect' response. It does not allow changing the request method from `POST` to `GET`.

HTTPRedirectHandler.**http_error_308**(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as *http_error_301()*, but called for the 'permanent redirect' response. It does not allow changing the request method from `POST` to `GET`.

在 3.11 版被加入.

22.4.5 HTTPCookieProcessor 物件

HTTPCookieProcessor 實例有一個屬性:

HTTPCookieProcessor.**cookiejar**

存放 cookies 的*http.cookiejar.CookieJar*。

22.4.6 ProxyHandler 物件

ProxyHandler.<protocol>_open(request)

The *ProxyHandler* will have a method `<protocol>_open()` for every *protocol* which has a proxy in the *proxies* dictionary given in the constructor. The method will modify requests to go through the proxy, by calling `request.set_proxy()`, and call the next handler in the chain to actually execute the protocol.

22.4.7 HTTPPasswordMgr 物件

These methods are available on *HTTPPasswordMgr* and *HTTPPasswordMgrWithDefaultRealm* objects.

HTTPPasswordMgr.**add_password**(*realm*, *uri*, *user*, *passwd*)

uri can be either a single URI, or a sequence of URIs. *realm*, *user* and *passwd* must be strings. This causes `(user, passwd)` to be used as authentication tokens when authentication for *realm* and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.**find_user_password**(*realm*, *authuri*)

Get user/password for given realm and URI, if any. This method will return `(None, None)` if there is no matching user/password.

For *HTTPPasswordMgrWithDefaultRealm* objects, the realm `None` will be searched if the given *realm* has no matching user/password.

22.4.8 HTTPPasswordMgrWithPriorAuth 物件

This password manager extends *HTTPPasswordMgrWithDefaultRealm* to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.**add_password**(*realm*, *uri*, *user*, *passwd*, *is_authenticated=False*)

realm, *uri*, *user*, *passwd* are as for *HTTPPasswordMgr.add_password()*. *is_authenticated* sets the initial value of the `is_authenticated` flag for the given URI or list of URIs. If *is_authenticated* is specified as `True`, *realm* is ignored.

HTTPPasswordMgrWithPriorAuth.**find_user_password**(*realm*, *authuri*)

Same as for *HTTPPasswordMgrWithDefaultRealm* objects

HTTPPasswordMgrWithPriorAuth.**update_authenticated**(*self*, *uri*, *is_authenticated=False*)

Update the `is_authenticated` flag for the given *uri* or list of URIs.

HTTPPasswordMgrWithPriorAuth.**is_authenticated**(*self*, *authuri*)

Returns the current state of the `is_authenticated` flag for the given URI.

22.4.9 AbstractBasicAuthHandler 物件

AbstractBasicAuthHandler.**http_error_auth_reqed**(*authreq*, *host*, *req*, *headers*)

Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

host is either an authority (e.g. `"python.org"`) or a URL containing an authority component (e.g. `"http://python.org/"`). In either case, the authority must not contain a userinfo component (so, `"python.org"` and `"python.org:80"` are fine, `"joe:password@python.org"` is not).

22.4.10 HTTPBasicAuthHandler 物件

HTTPBasicAuthHandler.**http_error_401**(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

22.4.11 ProxyBasicAuthHandler 物件

ProxyBasicAuthHandler.**http_error_407**(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

22.4.12 AbstractDigestAuthHandler 物件

AbstractDigestAuthHandler.**http_error_auth_reqed**(*authreq*, *host*, *req*, *headers*)

authreq should be the name of the header where the information about the realm is included in the request, *host* should be the host to authenticate to, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

22.4.13 HTTPDigestAuthHandler 物件

`HTTPDigestAuthHandler.`**`http_error_401`**(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

22.4.14 ProxyDigestAuthHandler 物件

`ProxyDigestAuthHandler.`**`http_error_407`**(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

22.4.15 HTTPHandler 物件

`HTTPHandler.`**`http_open`**(*req*)

Send an HTTP request, which can be either GET or POST, depending on `req.data`.

22.4.16 HTTPSHandler 物件

`HTTPSHandler.`**`https_open`**(*req*)

Send an HTTPS request, which can be either GET or POST, depending on `req.data`.

22.4.17 FileHandler 物件

`FileHandler.`**`file_open`**(*req*)

Open the file locally, if there is no host name, or the host name is `'localhost'`.

在 3.2 版的變更: This method is applicable only for local hostnames. When a remote hostname is given, a *URLError* is raised.

22.4.18 DataHandler 物件

`DataHandler.`**`data_open`**(*req*)

Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in **RFC 2397**. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don't mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise a *ValueError* in that case.

22.4.19 FTPHandler 物件

`FTPHandler.`**`ftp_open`**(*req*)

Open the FTP file indicated by *req*. The login is always done with empty username and password.

22.4.20 CacheFTPHandler 物件

CacheFTPHandler objects are *FTPHandler* objects with the following additional methods:

`CacheFTPHandler.`**`setTimeout`**(*t*)

Set timeout of connections to *t* seconds.

`CacheFTPHandler.`**`setMaxConns`**(*m*)

Set maximum number of cached connections to *m*.

22.4.21 UnknownHandler 物件

`UnknownHandler.`**`unknown_open`**()

Raise a *URLError* exception.

22.4.22 HTTPErrorProcessor 物件

`HTTPErrorProcessor.`**`http_response`**(*request*, *response*)

Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the `http_error_<type>()` handler methods, via *`OpenerDirector.error()`*. Eventually, *`HTTPDefaultErrorHandler`* will raise an *`HTTPError`* if no other handler handles the error.

`HTTPErrorProcessor.`**`https_response`**(*request*, *response*)

Process HTTPS error responses.

The behavior is same as *`http_response()`*.

22.4.23 范例

In addition to the examples below, more examples are given in urllib-howto.

This example gets the python.org main page and displays the first 300 bytes of it:

```
>>> import urllib.request
>>> with urllib.request.urlopen('http://www.python.org/') as f:
...     print(f.read(300))
...
b'<!doctype html>\n<!--[if lt IE 7]>   <html class="no-js ie6 lt-ie7 lt-ie8 lt-ie9">   <!
↪[endif]-->\n<!--[if IE 7]>      <html class="no-js ie7 lt-ie8 lt-ie9">          <![endif]--
↪>\n<!--[if IE 8]>      <html class="no-js ie8 lt-ie9">
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the HTTP server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following HTML spec document, https://html.spec.whatwg.org/#charset, lists the various ways in which an HTML or an XML document could have specified its encoding information.

For additional information, see the W3C document: https://www.w3.org/International/questions/qa-html-encoding-declarations.

As the python.org website uses *utf-8* encoding as specified in its meta tag, we will use the same for decoding the bytes object:

```
>>> with urllib.request.urlopen('http://www.python.org/') as f:
...     print(f.read(100).decode('utf-8'))
...
<!doctype html>
<!--[if lt IE 7]>   <html class="no-js ie6 lt-ie7 lt-ie8 lt-ie9">   <![endif]-->
<!-
```

It is also possible to achieve the same result without using the *context manager* approach:

```
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/')
>>> try:
...     print(f.read(100).decode('utf-8'))
... finally:
...     f.close()
...
<!doctype html>
<!--[if lt IE 7]>   <html class="no-js ie6 lt-ie7 lt-ie8 lt-ie9">   <![endif]-->
<!--
```

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/cgi-bin/test.cgi',
...                       data=b'This data is passed to stdin of the CGI')
>>> with urllib.request.urlopen(req) as f:
...     print(f.read().decode('utf-8'))
...
Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is:

```
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain\n\nGot Data: "%s"' % data)
```

Here is an example of doing a `PUT` request using *Request*:

```
import urllib.request
DATA = b'some data'
req = urllib.request.Request(url='http://localhost:8080', data=DATA, method='PUT')
with urllib.request.urlopen(req) as f:
    pass
print(f.status)
print(f.reason)
```

使用基本 HTTP 認證:

```
import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                          uri='https://mahler:8092/site-updates.py',
                          user='klem',
                          passwd='kadidd!ehopper')
opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urlopen.
urllib.request.install_opener(opener)
with urllib.request.urlopen('http://www.example.com/login.html') as f:
    print(f.read().decode('utf-8'))
```

build_opener() provides many handlers by default, including a *ProxyHandler*. By default, *ProxyHandler* uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the `http_proxy` environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default *ProxyHandler* with one that uses programmatically supplied proxy URLs, and adds proxy authorization support with *ProxyBasicAuthHandler*.

```
proxy_handler = urllib.request.ProxyHandler({'http': 'http://www.example.com:3128/'})
proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password')

opener = urllib.request.build_opener(proxy_handler, proxy_auth_handler)
# 這次我們直接使用它而不安裝 OpenerDirector:
with opener.open('http://www.example.com/login.html') as f:
   print(f.read().decode('utf-8'))
```

添加 HTTP 標頭:

使用*Request* 建構函式的 *headers* 引數，或:

```
import urllib.request
req = urllib.request.Request('http://www.example.com/')
```

(繼續下一頁)

(繼續上一頁)

```
req.add_header('Referer', 'http://www.python.org/')
# 自訂預設的使用者代理標頭值:
req.add_header('User-Agent', 'urllib-example/0.1 (Contact: . . .)')
with urllib.request.urlopen(req) as f:
    print(f.read().decode('utf-8'))
```

OpenerDirector automatically adds a *User-Agent* header to every *Request*. To change this:

```
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
with opener.open('http://www.example.com/') as f:
   print(f.read().decode('utf-8'))
```

Also, remember that a few standard headers (*Content-Length*, *Content-Type* and *Host*) are added when the *Request* is passed to *urlopen()* (or *OpenerDirector.open()*).

Here is an example session that uses the `GET` method to retrieve a URL containing parameters:

```
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> url = "http://www.musi-cal.com/cgi-bin/query?%s" % params
>>> with urllib.request.urlopen(url) as f:
...     print(f.read().decode('utf-8'))
...
```

The following example uses the `POST` method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> data = data.encode('ascii')
>>> with urllib.request.urlopen("http://requestb.in/xrbl82xr", data) as f:
...     print(f.read().decode('utf-8'))
...
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.build_opener(urllib.request.ProxyHandler(proxies))
>>> with opener.open("http://www.python.org") as f:
...     f.read().decode('utf-8')
...
```

The following example uses no proxies at all, overriding environment settings:

```
>>> import urllib.request
>>> opener = urllib.request.build_opener(urllib.request.ProxyHandler({}))
>>> with opener.open("http://www.python.org/") as f:
...     f.read().decode('utf-8')
...
```

22.4.24 遺留介面

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

urllib.request.**urlretrieve**(*url*, *filename=None*, *reporthook=None*, *data=None*)

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple `(filename, headers)` where *filename* is the local file name under which the object can be found, and *headers* is whatever the `info()` method of the object returned by *urlopen()* returned (for a remote object). Exceptions are the same as for *urlopen()*.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a callable that will be called once on establishment of the network connection and once after each block read thereafter. The callable will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve('http://python.org/')
>>> html = open(local_filename)
>>> html.close()
```

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a `POST` request (normally the request type is `GET`). The *data* argument must be a bytes object in standard *application/x-www-form-urlencoded* format; see the *urllib.parse.urlencode()* function.

urlretrieve() will raise *ContentTooShortError* when it detects that the amount of data available was less than the expected amount (which is the size reported by a *Content-Length* header). This can occur, for example, when the download is interrupted.

The *Content-Length* is treated as a lower bound: if there's more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no *Content-Length* header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

urllib.request.**urlcleanup**()

Cleans up temporary files that may have been left behind by previous calls to *urlretrieve()*.

22.4.25 `urllib.request` 限制

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  在 3.4 版的變更: Added support for data URLs.

- The caching feature of *urlretrieve()* has been disabled until someone finds the time to hack proper processing of Expiration time headers.
- There should be a function to query whether a particular URL is in the cache.
- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.
- The *urlopen()* and *urlretrieve()* functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive web client using these functions without using threads.
- The data returned by *urlopen()* or *urlretrieve()* is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the *Content-Type* header. If the returned data is HTML, you can use the module *html.parser* to parse it.
- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL

ends in a /, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the *ftplib* module.

22.5 urllib.response --- Response classes used by urllib

The *urllib.response* module defines functions and classes which define a minimal file-like interface, including read() and readline(). Functions defined by this module are used internally by the *urllib.request* module. The typical response object is a *urllib.response.addinfourl* instance:

class urllib.response.**addinfourl**

url

URL of the resource retrieved, commonly used to determine if a redirect was followed.

headers

Returns the headers of the response in the form of an *EmailMessage* instance.

status

在 3.9 版被加入.

伺服器回傳的狀態碼。

geturl()

在 3.9 版之後被🄵用: 已被*status* 取代而🄵用。

22.6 urllib.parse --- 將 URL 剖析成元件

原始碼： Lib/urllib/parse.py

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a "relative URL" to an absolute URL given a "base URL."

The module has been designed to match the internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: file, ftp, gopher, hdl, http, https, imap, itms-services, mailto, mms, news, nntp, prospero, rsync, rtsp, rtsps, rtspu, sftp, shttp, sip, sips, snews, svn, svn+ssh, telnet, wais, ws, wss.

CPython 實作細節： The inclusion of the itms-services URL scheme can prevent an app from passing Apple's App Store review process for the macOS and iOS App Stores. Handling for the itms-services scheme is always removed on iOS; on macOS, it *may* be removed if CPython has been built with the --with-app-store-compliance option.

The *urllib.parse* module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.

This module's functions use the deprecated term `netloc` (or `net_loc`), which was introduced in **RFC 1808**. However, this term has been obsoleted by **RFC 3986**, which introduced the term `authority` as its replacement. The use of `netloc` is continued for backward compatibility.

22.6.1 URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

`urllib.parse.`**`urlparse`**(*urlstring*, *scheme=''*, *allow_fragments=True*)

Parse a URL into six components, returning a 6-item *named tuple*. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up into smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the *path* component, which is retained if present. For example:

```
>>> from urllib.parse import urlparse
>>> urlparse("scheme://netloc/path;parameters?query#fragment")
ParseResult(scheme='scheme', netloc='netloc', path='/path;parameters', params='',
            query='query', fragment='fragment')
>>> o = urlparse("http://docs.python.org:80/3/library/urllib.parse.html?"
...              "highlight=params#url-parsing")
>>> o
ParseResult(scheme='http', netloc='docs.python.org:80',
            path='/3/library/urllib.parse.html', params='',
            query='highlight=params', fragment='url-parsing')
>>> o.scheme
'http'
>>> o.netloc
'docs.python.org:80'
>>> o.hostname
'docs.python.org'
>>> o.port
80
>>> o._replace(fragment="").geturl()
'http://docs.python.org:80/3/library/urllib.parse.html?highlight=params'
```

Following the syntax specifications in **RFC 1808**, urlparse recognizes a netloc only if it is properly introduced by '//'. Otherwise the input is presumed to be a relative URL and thus to start with a path component.

```
>>> from urllib.parse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', params='',
            query='', fragment='')
```

The *scheme* argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as *urlstring*, except that the default value `''` is always allowed, and is automatically converted to `b''` if appropriate.

If the *allow_fragments* argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and `fragment` is set to the empty string in the return value.

The return value is a *named tuple*, which means that its items can be accessed by index or as named attributes, which are:

屬性	Index	Value	Value if not present
`scheme`	0	URL scheme specifier	*scheme* parameter
`netloc`	1	Network location part	empty string
`path`	2	Hierarchical path	empty string
`params`	3	Parameters for last path element	empty string
`query`	4	Query component	empty string
`fragment`	5	Fragment identifier	empty string
`username`		User name	*None*
`password`		Password	*None*
`hostname`		Host name (lower case)	*None*
`port`		Port number as integer, if present	*None*

Reading the `port` attribute will raise a *ValueError* if an invalid port is specified in the URL. See section *Structured Parse Results* for more information on the result object.

Unmatched square brackets in the `netloc` attribute will raise a *ValueError*.

Characters in the `netloc` attribute that decompose under NFKC normalization (as used by the IDNA encoding) into any of `/`, `?`, `#`, `@`, or `:` will raise a *ValueError*. If the URL is decomposed before parsing, no error will be raised.

As is the case with all named tuples, the subclass has a few additional methods and attributes that are particularly useful. One such method is `_replace()`. The `_replace()` method will return a new ParseResult object replacing specified fields with new values.

```
>>> from urllib.parse import urlparse
>>> u = urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
>>> u
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> u._replace(scheme='http')
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
```

警告

urlparse() does not perform validation. See *URL parsing security* for details.

在 3.2 版的變更: 新增剖析 IPv6 URL 的能力。

在 3.3 版的變更: The fragment is now parsed for all URL schemes (unless *allow_fragments* is false), in accordance with **RFC 3986**. Previously, an allowlist of schemes that support fragments existed.

在 3.6 版的變更: Out-of-range port numbers now raise *ValueError*, instead of returning *None*.

在 3.8 版的變更: Characters that affect netloc parsing under NFKC normalization will now raise *ValueError*.

`urllib.parse.`**`parse_qs`**(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*, *max_num_fields=None*, *separator='&'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a *ValueError* exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

The optional argument *max_num_fields* is the maximum number of fields to read. If set, then throws a `ValueError` if there are more than *max_num_fields* fields read.

The optional argument *separator* is the symbol to use for separating the query arguments. It defaults to `&`.

Use the `urllib.parse.urlencode()` function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

在 3.2 版的變更: 新增 *encoding* 和 *errors* 參數。

在 3.8 版的變更: 新增 *max_num_fields* 參數。

在 3.10 版的變更: Added *separator* parameter with the default value of `&`. Python versions earlier than Python 3.10 allowed using both `;` and `&` as query parameter separator. This has been changed to allow only a single separator key, with `&` as the default separator.

在 3.14 版之後被🄴用: Accepting objects with false values (like `0` and `[]`) except empty strings and byte-like objects and `None` is now deprecated.

`urllib.parse.`**`parse_qsl`**(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*, *max_num_fields=None*, *separator='&'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a list of name, value pairs.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

The optional argument *max_num_fields* is the maximum number of fields to read. If set, then throws a `ValueError` if there are more than *max_num_fields* fields read.

The optional argument *separator* is the symbol to use for separating the query arguments. It defaults to `&`.

Use the `urllib.parse.urlencode()` function to convert such lists of pairs into query strings.

在 3.2 版的變更: 新增 *encoding* 和 *errors* 參數。

在 3.8 版的變更: 新增 *max_num_fields* 參數。

在 3.10 版的變更: Added *separator* parameter with the default value of `&`. Python versions earlier than Python 3.10 allowed using both `;` and `&` as query parameter separator. This has been changed to allow only a single separator key, with `&` as the default separator.

`urllib.parse.`**`urlunparse`**(*parts*)

Construct a URL from a tuple as returned by `urlparse()`. The *parts* argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a `?` with an empty query; the RFC states that these are equivalent).

`urllib.parse.`**`urlsplit`**(*urlstring*, *scheme=''*, *allow_fragments=True*)

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the *path* portion of the URL (see **RFC 2396**) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-item *named tuple*:

```
(addressing scheme, network location, path, query, fragment identifier).
```

The return value is a *named tuple*, its items can be accessed by index or as named attributes:

屬性	Index	Value	Value if not present
`scheme`	0	URL scheme specifier	*scheme* parameter
`netloc`	1	Network location part	empty string
`path`	2	Hierarchical path	empty string
`query`	3	Query component	empty string
`fragment`	4	Fragment identifier	empty string
`username`		User name	*None*
`password`		Password	*None*
`hostname`		Host name (lower case)	*None*
`port`		Port number as integer, if present	*None*

Reading the `port` attribute will raise a *ValueError* if an invalid port is specified in the URL. See section *Structured Parse Results* for more information on the result object.

Unmatched square brackets in the `netloc` attribute will raise a *ValueError*.

Characters in the `netloc` attribute that decompose under NFKC normalization (as used by the IDNA encoding) into any of `/`, `?`, `#`, `@`, or `:` will raise a *ValueError*. If the URL is decomposed before parsing, no error will be raised.

Following some of the WHATWG spec that updates RFC 3986, leading C0 control and space characters are stripped from the URL. `\n`, `\r` and tab `\t` characters are removed from the URL at any position.

警告

urlsplit() does not perform validation. See *URL parsing security* for details.

在 3.6 版的變更: Out-of-range port numbers now raise *ValueError*, instead of returning *None*.

在 3.8 版的變更: Characters that affect netloc parsing under NFKC normalization will now raise *ValueError*.

在 3.10 版的變更: ASCII newline and tab characters are stripped from the URL.

在 3.12 版的變更: Leading WHATWG C0 control and space characters are stripped from the URL.

`urllib.parse.`**`urlunsplit`**(*parts*)

Combine the elements of a tuple as returned by *urlsplit()* into a complete URL as a string. The *parts* argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

`urllib.parse.`**`urljoin`**(*base*, *url*, *allow_fragments=True*)

Construct a full ("absolute") URL by combining a "base URL" (*base*) with another URL (*url*). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The *allow_fragments* argument has the same meaning and default as for *urlparse()*.

備🄵

If *url* is an absolute URL (that is, it starts with `//` or `scheme://`), the *url*'s hostname and/or scheme will be present in the result. For example:

```
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html',
...         '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the *url* with `urlsplit()` and `urlunsplit()`, removing possible *scheme* and *netloc* parts.

警告

Because an absolute URL may be passed as the `url` parameter, it is generally **not secure** to use `urljoin` with an attacker-controlled `url`. For example in, `urljoin("https://website.com/users/", username)`, if `username` can contain an absolute URL, the result of `urljoin` will be the absolute URL.

在 3.5 版的變更: Behavior updated to match the semantics defined in **RFC 3986**.

`urllib.parse.`**`urldefrag`**(*url*)

If *url* contains a fragment identifier, return a modified version of *url* with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in *url*, return *url* unmodified and an empty string.

The return value is a *named tuple*, its items can be accessed by index or as named attributes:

屬性	Index	Value	Value if not present
`url`	0	URL with no fragment	empty string
`fragment`	1	Fragment identifier	empty string

See section *Structured Parse Results* for more information on the result object.

在 3.2 版的變更: Result is a structured object rather than a simple 2-tuple.

`urllib.parse.`**`unwrap`**(*url*)

Extract the url from a wrapped URL (that is, a string formatted as `<URL:scheme://host/path>`, `<scheme://host/path>`, `URL:scheme://host/path` or `scheme://host/path`). If *url* is not a wrapped URL, it is returned without changes.

22.6.2 URL parsing security

The `urlsplit()` and `urlparse()` APIs do not perform **validation** of inputs. They may not raise errors on inputs that other applications consider invalid. They may also succeed on some inputs that might not be considered URLs elsewhere. Their purpose is for practical functionality rather than purity.

Instead of raising an exception on unusual input, they may instead return some component parts as empty strings. Or components may contain more than perhaps they should.

We recommend that users of these APIs where the values may be used anywhere with security implications code defensively. Do some verification within your code before trusting a returned component part. Does that `scheme` make sense? Is that a sensible `path`? Is there anything strange about that `hostname`? etc.

What constitutes a URL is not universally well defined. Different applications have different needs and desired constraints. For instance the living WHATWG spec describes what user facing web clients such as a web browser require. While **RFC 3986** is more general. These functions incorporate some aspects of both, but cannot be claimed compliant with either. The APIs and existing user code with expectations on specific behaviors predate both standards leading us to be very cautious about making API behavior changes.

22.6.3 Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on *bytes* and *bytearray* objects in addition to *str* objects.

If *str* data is passed in, the result will also contain only *str* data. If *bytes* or *bytearray* data is passed in, the result will contain only *bytes* data.

Attempting to mix *str* data with *bytes* or *bytearray* in a single function call will result in a *TypeError* being raised, while attempting to pass in non-ASCII byte values will trigger *UnicodeDecodeError*.

To support easier conversion of result objects between *str* and *bytes*, all return values from URL parsing functions provide either an `encode()` method (when the result contains *str* data) or a `decode()` method (when the result contains *bytes* data). The signatures of these methods match those of the corresponding *str* and *bytes* methods (except that the default encoding is `'ascii'` rather than `'utf-8'`). Each produces a value of a corresponding type that contains either *bytes* data (for `encode()` methods) or *str* data (for `decode()` methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.

The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

在 3.2 版的變更: URL parsing functions now accept ASCII encoded byte sequences

22.6.4 Structured Parse Results

The result objects from the *urlparse()*, *urlsplit()* and *urldefrag()* functions are subclasses of the *tuple* type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

`urllib.parse.SplitResult.`**`geturl`**`()`

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For *urldefrag()* results, only empty fragment identifiers will be removed. For *urlsplit()* and *urlparse()* results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured parse results when operating on *str* objects:

`class` `urllib.parse.`**`DefragResult`**(*url*, *fragment*)

Concrete class for *urldefrag()* results containing *str* data. The `encode()` method returns a *DefragResultBytes* instance.

在 3.2 版被加入.

`class` `urllib.parse.`**`ParseResult`**(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for *urlparse()* results containing *str* data. The `encode()` method returns a *ParseResultBytes* instance.

class urllib.parse.**SplitResult**(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for *urlsplit()* results containing *str* data. The `encode()` method returns a *SplitResultBytes* instance.

The following classes provide the implementations of the parse results when operating on *bytes* or *bytearray* objects:

class urllib.parse.**DefragResultBytes**(*url*, *fragment*)

Concrete class for *urldefrag()* results containing *bytes* data. The `decode()` method returns a *DefragResult* instance.

在 3.2 版被加入.

class urllib.parse.**ParseResultBytes**(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for *urlparse()* results containing *bytes* data. The `decode()` method returns a *ParseResult* instance.

在 3.2 版被加入.

class urllib.parse.**SplitResultBytes**(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for *urlsplit()* results containing *bytes* data. The `decode()` method returns a *SplitResult* instance.

在 3.2 版被加入.

22.6.5 URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

urllib.parse.**quote**(*string*, *safe='/'*, *encoding=None*, *errors=None*)

Replace special characters in *string* using the `%xx` escape. Letters, digits, and the characters `'_.-~'` are never quoted. By default, this function is intended for quoting the path section of a URL. The optional *safe* parameter specifies additional ASCII characters that should not be quoted --- its default value is `'/'`.

string may be either a *str* or a *bytes* object.

在 3.7 版的變更: Moved from **RFC 2396** to **RFC 3986** for quoting URL strings. "~" is now included in the set of unreserved characters.

The optional *encoding* and *errors* parameters specify how to deal with non-ASCII characters, as accepted by the *str.encode()* method. *encoding* defaults to `'utf-8'`. *errors* defaults to `'strict'`, meaning unsupported characters raise a *UnicodeEncodeError*. *encoding* and *errors* must not be supplied if *string* is a *bytes*, or a *TypeError* is raised.

Note that `quote(string, safe, encoding, errors)` is equivalent to `quote_from_bytes(string.encode(encoding, errors), safe)`.

Example: `quote('/El Niño/')` yields `'/El%20Ni%C3%B1o/'`.

urllib.parse.**quote_plus**(*string*, *safe=''*, *encoding=None*, *errors=None*)

Like *quote()*, but also replace spaces with plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in *safe*. It also does not have *safe* default to `'/'`.

Example: `quote_plus('/El Niño/')` yields `'%2FEl+Ni%C3%B1o%2F'`.

urllib.parse.**quote_from_bytes**(*bytes*, *safe='/'*)

Like *quote()*, but accepts a *bytes* object rather than a *str*, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields `'a%26%EF'`.

urllib.parse.**unquote**(*string*, *encoding='utf-8'*, *errors='replace'*)

Replace `%xx` escapes with their single-character equivalent. The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

string may be either a `str` or a `bytes` object.

encoding defaults to `'utf-8'`. *errors* defaults to `'replace'`, meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields `'/El Niño/'`.

在 3.9 版的變更: *string* parameter supports bytes and str objects (previously only str).

urllib.parse.**unquote_plus**(*string*, *encoding='utf-8'*, *errors='replace'*)

Like `unquote()`, but also replace plus signs with spaces, as required for unquoting HTML form values.

string must be a `str`.

Example: `unquote_plus('/El+Ni%C3%B1o/')` yields `'/El Niño/'`.

urllib.parse.**unquote_to_bytes**(*string*)

Replace `%xx` escapes with their single-octet equivalent, and return a `bytes` object.

string may be either a `str` or a `bytes` object.

If it is a `str`, unescaped non-ASCII characters in *string* are encoded into UTF-8 bytes.

Example: `unquote_to_bytes('a%26%EF')` yields `b'a&\xef'`.

urllib.parse.**urlencode**(*query*, *doseq=False*, *safe=''*, *encoding=None*, *errors=None*, *quote_via=quote_plus*)

Convert a mapping object or a sequence of two-element tuples, which may contain `str` or `bytes` objects, to a percent-encoded ASCII text string. If the resultant string is to be used as a *data* for POST operation with the `urlopen()` function, then it should be encoded to bytes, otherwise it would result in a `TypeError`.

The resulting string is a series of `key=value` pairs separated by `'&'` characters, where both *key* and *value* are quoted using the *quote_via* function. By default, `quote_plus()` is used to quote the values, which means spaces are quoted as a `'+'` character and '/' characters are encoded as `%2F`, which follows the standard for GET requests (`application/x-www-form-urlencoded`). An alternate function that can be passed as *quote_via* is `quote()`, which will encode spaces as `%20` and not encode '/' characters. For maximum control of what is quoted, use `quote` and specify a value for *safe*.

When a sequence of two-element tuples is used as the *query* argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter *doseq* evaluates to `True`, individual `key=value` pairs separated by `'&'` are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

The *safe*, *encoding*, and *errors* parameters are passed down to *quote_via* (the *encoding* and *errors* parameters are only passed when a query element is a `str`).

To reverse this encoding process, `parse_qs()` and `parse_qsl()` are provided in this module to parse query strings into Python data structures.

Refer to *urllib examples* to find out how the `urllib.parse.urlencode()` method can be used for generating the query string of a URL or data for a POST request.

在 3.2 版的變更: *query* supports bytes and string objects.

在 3.5 版的變更: 新增 *quote_via* 參數。

在 3.14 版之後被🄵用: Accepting objects with false values (like `0` and `[]`) except empty strings and byte-like objects and `None` is now deprecated.

22.7 `urllib.error` --- urllib.request 引發的例外類🄵

原始碼： Lib/urllib/error.py

---

urllib.error module（模組）🄵*urllib.request* 所引發的例外定義了例外 (exception) 類🄵。基礎例外類🄵是*URLError*。

下列例外會被*urllib.error* 適時引發：

exception urllib.error.**URLError**
處理程式 (handler) 在遇到問題時會引發此例外（或其衍生例外）。它是*OSError* 的一個子類🄵。

reason
此錯誤的原因。它可以是一個訊息字串或另一個例外實例。

在 3.3 版的變更: *URLError* 過去是*OSError* 的子類🄵，但現在🄵*OSError* 的🄵名。

exception urllib.error.**HTTPError**(*url*, *code*, *msg*, *hdrs*, *fp*)
雖然是一個例外（*URLError* 的一個子類🄵），*HTTPError* 也可以作🄵一個非例外的類檔案回傳值（與*urlopen()* 所回傳的物件相同）。這適用於處理特殊 HTTP 錯誤，例如🄵請求認證。

url
包含請求 URL。*filename* 屬性的🄵名。

code
一個 HTTP 狀態碼，具體定義見 **RFC 2616**。這個數值會對應到存放在*http.server.BaseHTTPRequestHandler.responses* 程式碼 dictionary 中的某個值。

reason
這通常是一個解釋本次錯誤原因的字串。🄵 *msg* 屬性的🄵名。

headers
導致*HTTPError* 的特定 HTTP 請求的 HTTP 回應 header。🄵 *hdrs* 屬性的🄵名。

在 3.4 版被加入.

fp

一個類檔案物件，可以從中讀取 HTTP 錯誤主體 (body)。

exception urllib.error.**ContentTooShortError**(*msg*, *content*)

此例外會在*urlretrieve()* 函式檢查到已下載的資料量小於期待的資料量（由 *Content-Length* header 給定）時被引發。

content

已下載（可能已被截斷）的資料。

22.8 urllib.robotparser --- robots.txt 的剖析器

原始碼： Lib/urllib/robotparser.py

此模組 (module) 提供了一個單獨的類🄵 (class) *RobotFileParser*，它可以知道某個特定 user agent（使用者代理）是否能在有發布 robots.txt 文件的網站 fetch（🄵取）特定 URL。有關 robots.txt 文件結構的更多細節，請參🄵 http://www.robotstxt.org/orig.html。

class urllib.robotparser.**RobotFileParser**(*url=''*)

此類🄵提供了一些方法可以讀取、剖析和回答關於 *url* 上的 robots.txt 文件的問題。

set_url(*url*)

設置指向 robots.txt 文件的 URL。

read()

讀取 robots.txt URL 🄵將其輸入到剖析器。

parse(*lines*)

剖析 lines 引數。

can_fetch(*useragent*, *url*)

根據從 robots.txt 文件中剖析出的規則，如果 *useragent* 被允許 fetch *url* 的話，則回傳 True。

mtime()

回傳最近一次 fetch robots.txt 文件的時間。這適用於需要定期檢查 robots.txt 文件更新情🄵的長時間運行網頁爬蟲。

modified()

將最近一次 fetch robots.txt 文件的時間設置🄵目前時間。

crawl_delay(*useragent*)

針對指定的 *useragent* 從 robots.txt 回傳 Crawl-delay 參數的值。如果此參數不存在、不適用於指定的 *useragent*，或是此參數在 robots.txt 中所指的條目含有無效語法，則回傳 None。

在 3.6 版被加入.

request_rate(*useragent*)

以*named tuple* RequestRate(requests, seconds) 的形式從 robots.txt 回傳 Request-rate 參數的🄵容。如果此參數不存在、不適用於指定的 *useragent*，或是此參數在 robots.txt 中所指的條目含有無效語法，則回傳 None。

在 3.6 版被加入.

site_maps()

以*list()* 的形式從 robots.txt 回傳 Sitemap 參數的🄵容。如果此參數不存在或此參數在 robots.txt 中所指的條目含有無效語法，則回傳 None。

在 3.8 版被加入.

下面的範例展示了*RobotFileParser* 類🄵的基本用法：

```
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rrate = rp.request_rate("*")
>>> rrate.requests
3
>>> rrate.seconds
20
>>> rp.crawl_delay("*")
6
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```

22.9 `http` --- HTTP 模組

原始碼： Lib/http/__init__.py

---

http 是一個收集了多個用於處理超文本傳輸協定 (HyperText Transfer Protocol) 之模組 (module) 的套件：

- *http.client* 是一個低階的 HTTP 協定用🄵端；對於高階的 URL 存取請使用*urllib.request*
- *http.server* 包含基於*socketserver* 的基本 HTTP 伺服器類🄵
- *http.cookies* 包含通過 cookies 實作狀態管理的工具程式 (utilities)
- *http.cookiejar* 提供了 cookies 的持續留存 (persistence)

The *http* module also defines the following enums that help you work with http related code:

class http.**HTTPStatus**

在 3.5 版被加入.

enum.IntEnum 的子類🄵，它定義了一組 HTTP 狀態碼、原理短語 (reason phrase) 以及英文長描述。

用法：

```
>>> from http import HTTPStatus
>>> HTTPStatus.OK
HTTPStatus.OK
>>> HTTPStatus.OK == 200
True
>>> HTTPStatus.OK.value
200
>>> HTTPStatus.OK.phrase
'OK'
>>> HTTPStatus.OK.description
'Request fulfilled, document follows'
>>> list(HTTPStatus)
[HTTPStatus.CONTINUE, HTTPStatus.SWITCHING_PROTOCOLS, ...]
```

22.9.1 HTTP 狀態碼

http.HTTPStatus 當中，已支援🄵且有於 IANA 🄵🄵的狀態碼有：

狀態碼	列舉名懲	詳情
100	CONTINUE	HTTP Semantics **RFC 9110**, Section 15.2.1
101	SWITCHING_PROTOCOLS	HTTP Semantics **RFC 9110**, Section 15.2.2
102	PROCESSING	WebDAV **RFC 2518**，10.1 節
103	EARLY_HINTS	用於指定提示 (Indicating Hints) **RFC 8297** 的 HTTP 狀態碼
200	OK	HTTP Semantics **RFC 9110**, Section 15.3.1
201	CREATED	HTTP Semantics **RFC 9110**, Section 15.3.2
202	ACCEPTED	HTTP Semantics **RFC 9110**, Section 15.3.3
203	NON_AUTHORITATIVE_INFORMATION	HTTP Semantics **RFC 9110**, Section 15.3.4
204	NO_CONTENT	HTTP Semantics **RFC 9110**, Section 15.3.5
205	RESET_CONTENT	HTTP Semantics **RFC 9110**, Section 15.3.6
206	PARTIAL_CONTENT	HTTP Semantics **RFC 9110**, Section 15.3.7
207	MULTI_STATUS	WebDAV **RFC 4918**，11.1 節
208	ALREADY_REPORTED	WebDAV 🄵結擴充 (Binding Extensions) **RFC 5842**，7.1 節（實驗性）
226	IM_USED	HTTP 中的差分編碼 **RFC 3229**，10.4.1 節
300	MULTIPLE_CHOICES	HTTP Semantics **RFC 9110**, Section 15.4.1
301	MOVED_PERMANENTLY	HTTP Semantics **RFC 9110**, Section 15.4.2
302	FOUND	HTTP Semantics **RFC 9110**, Section 15.4.3
303	SEE_OTHER	HTTP Semantics **RFC 9110**, Section 15.4.4
304	NOT_MODIFIED	HTTP Semantics **RFC 9110**, Section 15.4.5
305	USE_PROXY	HTTP Semantics **RFC 9110**, Section 15.4.6
307	TEMPORARY_REDIRECT	HTTP Semantics **RFC 9110**, Section 15.4.8
308	PERMANENT_REDIRECT	HTTP Semantics **RFC 9110**, Section 15.4.9
400	BAD_REQUEST	HTTP Semantics **RFC 9110**, Section 15.5.1
401	UNAUTHORIZED	HTTP Semantics **RFC 9110**, Section 15.5.2
402	PAYMENT_REQUIRED	HTTP Semantics **RFC 9110**, Section 15.5.3
403	FORBIDDEN	HTTP Semantics **RFC 9110**, Section 15.5.4
404	NOT_FOUND	HTTP Semantics **RFC 9110**, Section 15.5.5
405	METHOD_NOT_ALLOWED	HTTP Semantics **RFC 9110**, Section 15.5.6
406	NOT_ACCEPTABLE	HTTP Semantics **RFC 9110**, Section 15.5.7
407	PROXY_AUTHENTICATION_REQUIRED	HTTP Semantics **RFC 9110**, Section 15.5.8
408	REQUEST_TIMEOUT	HTTP Semantics **RFC 9110**, Section 15.5.9
409	CONFLICT	HTTP Semantics **RFC 9110**, Section 15.5.10
410	GONE	HTTP Semantics **RFC 9110**, Section 15.5.11
411	LENGTH_REQUIRED	HTTP Semantics **RFC 9110**, Section 15.5.12
412	PRECONDITION_FAILED	HTTP Semantics **RFC 9110**, Section 15.5.13
413	CONTENT_TOO_LARGE	HTTP Semantics **RFC 9110**, Section 15.5.14
414	URI_TOO_LONG	HTTP Semantics **RFC 9110**, Section 15.5.15
415	UNSUPPORTED_MEDIA_TYPE	HTTP Semantics **RFC 9110**, Section 15.5.16
416	RANGE_NOT_SATISFIABLE	HTTP Semantics **RFC 9110**, Section 15.5.17
417	EXPECTATION_FAILED	HTTP Semantics **RFC 9110**, Section 15.5.18
418	IM_A_TEAPOT	HTCPCP/1.0 **RFC 2324**，Section 2.3.2
421	MISDIRECTED_REQUEST	HTTP Semantics **RFC 9110**, Section 15.5.20
422	UNPROCESSABLE_CONTENT	HTTP Semantics **RFC 9110**, Section 15.5.21
423	LOCKED	WebDAV **RFC 4918**，11.3 節
424	FAILED_DEPENDENCY	WebDAV **RFC 4918**，11.4 節
425	TOO_EARLY	使用 HTTP 中的早期資料 **RFC 8470**
426	UPGRADE_REQUIRED	HTTP Semantics **RFC 9110**, Section 15.5.22
428	PRECONDITION_REQUIRED	額外的 HTTP 狀態碼 **RFC 6585**
429	TOO_MANY_REQUESTS	額外的 HTTP 狀態碼 **RFC 6585**
431	REQUEST_HEADER_FIELDS_TOO_LARGE	額外的 HTTP 狀態碼 **RFC 6585**
451	UNAVAILABLE_FOR_LEGAL_REASONS	一個用來回報合法性障礙 (Legal Obstacles) 的 HTTP 狀態碼 **RFC 7725**
500	INTERNAL_SERVER_ERROR	HTTP Semantics **RFC 9110**, Section 15.6.1
501	NOT_IMPLEMENTED	HTTP Semantics **RFC 9110**, Section 15.6.2
502	BAD_GATEWAY	HTTP Semantics **RFC 9110**, Section 15.6.3
503	SERVICE_UNAVAILABLE	HTTP Semantics **RFC 9110**, Section 15.6.4

表格 1 – 繼續上一頁

狀態碼	列舉名懲	詳情
504	GATEWAY_TIMEOUT	HTTP Semantics RFC 9110, Section 15.6.5
505	HTTP_VERSION_NOT_SUPPORTED	HTTP Semantics RFC 9110, Section 15.6.6
506	VARIANT_ALSO_NEGOTIATES	HTTP 中的透明🄵容協商 (Transparent Content Negotiation) RFC 2295,
507	INSUFFICIENT_STORAGE	WebDAV RFC 4918，11.5 節
508	LOOP_DETECTED	WebDAV 🄵結擴充 RFC 5842，7.2 節（實驗性）
510	NOT_EXTENDED	一個 HTTP 擴充框架 RFC 2774，7 節（實驗性）
511	NETWORK_AUTHENTICATION_REQUIRED	額外的 HTTP 狀態碼 RFC 6585，6 節

🄵了向後相容性，列舉值也以常數形式出現在*http.client* 模組中。列舉名稱等於常數名稱（例如 http.HTTPStatus.OK 也可以是 http.client.OK）。

在 3.7 版的變更: 新增 421 MISDIRECTED_REQUEST 狀態碼。

在 3.8 版被加入: 新增 451 UNAVAILABLE_FOR_LEGAL_REASONS 狀態碼。

在 3.9 版被加入: 新增 103 EARLY_HINTS、418 IM_A_TEAPOT 與 425 TOO_EARLY 狀態碼。

在 3.13 版的變更: Implemented RFC9110 naming for status constants. Old constant names are preserved for backwards compatibility.

22.9.2 HTTP 狀態分類

在 3.12 版被加入.

The enum values have several properties to indicate the HTTP status category:

Property	Indicates that	詳情
is_informational	100 <= status <= 199	HTTP Semantics RFC 9110, Section 15
is_success	200 <= status <= 299	HTTP Semantics RFC 9110, Section 15
is_redirection	300 <= status <= 399	HTTP Semantics RFC 9110, Section 15
is_client_error	400 <= status <= 499	HTTP Semantics RFC 9110, Section 15
is_server_error	500 <= status <= 599	HTTP Semantics RFC 9110, Section 15

用法:

```
>>> from http import HTTPStatus
>>> HTTPStatus.OK.is_success
True
>>> HTTPStatus.OK.is_client_error
False
```

class http.**HTTPMethod**

在 3.11 版被加入.

enum.StrEnum 的子類🄵，它定義了一組 HTTP 方法以及英文描述。

用法:

```
>>> from http import HTTPMethod
>>>
>>> HTTPMethod.GET
<HTTPMethod.GET>
>>> HTTPMethod.GET == 'GET'
True
>>> HTTPMethod.GET.value
'GET'
>>> HTTPMethod.GET.description
'Retrieve the target.'
```

(繼續下一頁)

(繼續上一頁)

```
>>> list(HTTPMethod)
[<HTTPMethod.CONNECT>,
 <HTTPMethod.DELETE>,
 <HTTPMethod.GET>,
 <HTTPMethod.HEAD>,
 <HTTPMethod.OPTIONS>,
 <HTTPMethod.PATCH>,
 <HTTPMethod.POST>,
 <HTTPMethod.PUT>,
 <HTTPMethod.TRACE>]
```

22.9.3 HTTP 方法

http.HTTPStatus 當中，已支援🄵且有於 IANA 🄵🄵的狀態碼有：

方法	列舉名徵	詳情
GET	GET	HTTP Semantics **RFC 9110**, Section 9.3.1
HEAD	HEAD	HTTP Semantics **RFC 9110**, Section 9.3.2
POST	POST	HTTP Semantics **RFC 9110**, Section 9.3.3
PUT	PUT	HTTP Semantics **RFC 9110**, Section 9.3.4
DELETE	DELETE	HTTP Semantics **RFC 9110**, Section 9.3.5
CONNECT	CONNECT	HTTP Semantics **RFC 9110**, Section 9.3.6
OPTIONS	OPTIONS	HTTP Semantics **RFC 9110**, Section 9.3.7
TRACE	TRACE	HTTP Semantics **RFC 9110**, Section 9.3.8
PATCH	PATCH	HTTP/1.1 **RFC 5789**

22.10 `http.client` --- HTTP 協定用🄵端

原始碼： Lib/http/client.py

This module defines classes that implement the client side of the HTTP and HTTPS protocols. It is normally not used directly --- the module *urllib.request* uses it to handle URLs that use HTTP and HTTPS.

也參考

The Requests package is recommended for a higher-level HTTP client interface.

備🄵

HTTPS support is only available if Python was compiled with SSL support (through the *ssl* module).

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

The module provides the following classes:

class http.client.**HTTPConnection**(*host*, *port=None*, [*timeout*,]*source_address=None*, *blocksize=8192*)

An *HTTPConnection* instance represents one transaction with an HTTP server. It should be instantiated by passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional *timeout* parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional *source_address* parameter may be a tuple of a (host,

port) to use as the source address the HTTP connection is made from. The optional *blocksize* parameter sets the buffer size in bytes for sending a file-like message body.

For example, the following calls all create instances that connect to the server at the same host and port:

```
>>> h1 = http.client.HTTPConnection('www.python.org')
>>> h2 = http.client.HTTPConnection('www.python.org:80')
>>> h3 = http.client.HTTPConnection('www.python.org', 80)
>>> h4 = http.client.HTTPConnection('www.python.org', 80, timeout=10)
```

在 3.2 版的變更: 新增 *source_address*。

在 3.4 版的變更: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are no longer supported.

在 3.7 版的變更: 新增 *blocksize* 參數。

class http.client.**HTTPSConnection**(*host*, *port=None*, *, [*timeout*,]*source_address=None*, *context=None*, *blocksize=8192*)

A subclass of *HTTPConnection* that uses SSL for communication with secure servers. Default port is `443`. If *context* is specified, it must be a *ssl.SSLContext* instance describing the various SSL options.

Please read *Security considerations* for more information on best practices.

在 3.2 版的變更: 新增 *source_address*、*context* 與 *check_hostname*。

在 3.2 版的變更: This class now supports HTTPS virtual hosts if possible (that is, if *ssl.HAS_SNI* is true).

在 3.4 版的變更: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are no longer supported.

在 3.4.3 版的變更: This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the *context* parameter.

在 3.8 版的變更: This class now enables TLS 1.3 *ssl.SSLContext.post_handshake_auth* for the default *context* or when *cert_file* is passed with a custom *context*.

在 3.10 版的變更: This class now sends an ALPN extension with protocol indicator `http/1.1` when no *context* is given. Custom *context* should set ALPN protocols with *set_alpn_protocols()*.

在 3.12 版的變更: The deprecated *key_file*, *cert_file* and *check_hostname* parameters have been removed.

class http.client.**HTTPResponse**(*sock*, *debuglevel=0*, *method=None*, *url=None*)

Class whose instances are returned upon successful connection. Not instantiated directly by user.

在 3.4 版的變更: The *strict* parameter was removed. HTTP 0.9 style "Simple Responses" are no longer supported.

This module provides the following function:

http.client.**parse_headers**(*fp*)

Parse the headers from a file pointer *fp* representing a HTTP request/response. The file has to be a *BufferedIOBase* reader (i.e. not text) and must provide a valid **RFC 2822** style header.

This function returns an instance of *http.client.HTTPMessage* that holds the header fields, but no payload (the same as *HTTPResponse.msg* and *http.server.BaseHTTPRequestHandler.headers*). After returning, the file pointer *fp* is ready to read the HTTP body.

> **備🄵**
>
> *parse_headers()* does not parse the start-line of a HTTP message; it only parses the `Name: value` lines. The file has to be ready to read these field lines, so the first line should already be consumed before calling the function.

The following exceptions are raised as appropriate:

exception http.client.**HTTPException**

The base class of the other exceptions in this module. It is a subclass of *Exception*.

exception http.client.**NotConnected**

A subclass of *HTTPException*.

exception http.client.**InvalidURL**

A subclass of *HTTPException*, raised if a port is given and is either non-numeric or empty.

exception http.client.**UnknownProtocol**

A subclass of *HTTPException*.

exception http.client.**UnknownTransferEncoding**

A subclass of *HTTPException*.

exception http.client.**UnimplementedFileMode**

A subclass of *HTTPException*.

exception http.client.**IncompleteRead**

A subclass of *HTTPException*.

exception http.client.**ImproperConnectionState**

A subclass of *HTTPException*.

exception http.client.**CannotSendRequest**

A subclass of *ImproperConnectionState*.

exception http.client.**CannotSendHeader**

A subclass of *ImproperConnectionState*.

exception http.client.**ResponseNotReady**

A subclass of *ImproperConnectionState*.

exception http.client.**BadStatusLine**

A subclass of *HTTPException*. Raised if a server responds with a HTTP status code that we don't understand.

exception http.client.**LineTooLong**

A subclass of *HTTPException*. Raised if an excessively long line is received in the HTTP protocol from the server.

exception http.client.**RemoteDisconnected**

A subclass of *ConnectionResetError* and *BadStatusLine*. Raised by *HTTPConnection.getresponse()* when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

在 3.5 版被加入: Previously, *BadStatusLine*`('')` was raised.

The constants defined in this module are:

http.client.**HTTP_PORT**

The default port for the HTTP protocol (always `80`).

http.client.**HTTPS_PORT**

The default port for the HTTPS protocol (always `443`).

http.client.**responses**

This dictionary maps the HTTP 1.1 status codes to the W3C names.

Example: `http.client.responses[http.client.NOT_FOUND]` is `'Not Found'`.

See *HTTP 狀態碼* for a list of HTTP status codes that are available in this module as constants.

22.10.1 HTTPConnection 物件

HTTPConnection instances have the following methods:

HTTPConnection.**request**(*method*, *url*, *body=None*, *headers={}*, *, *encode_chunked=False*)

This will send a request to the server using the HTTP request method *method* and the request URI *url*. The provided *url* must be an absolute path to conform with **RFC 2616 §5.1.2** (unless connecting to an HTTP proxy server or using the OPTIONS or CONNECT methods).

If *body* is specified, the specified data is sent after the headers are finished. It may be a *str*, a *bytes-like object*, an open *file object*, or an iterable of *bytes*. If *body* is a string, it is encoded as ISO-8859-1, the default for HTTP. If it is a bytes-like object, the bytes are sent as is. If it is a *file object*, the contents of the file is sent; this file object should support at least the read() method. If the file object is an instance of *io.TextIOBase*, the data returned by the read() method will be encoded as ISO-8859-1, otherwise the data returned by read() is sent as is. If *body* is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The *headers* argument should be a mapping of extra HTTP headers to send with the request. A **Host header** must be provided to conform with **RFC 2616 §5.1.2** (unless connecting to an HTTP proxy server or using the OPTIONS or CONNECT methods).

If *headers* contains neither Content-Length nor Transfer-Encoding, but there is a request body, one of those header fields will be added automatically. If *body* is None, the Content-Length header is set to 0 for methods that expect a body (PUT, POST, and PATCH). If *body* is a string or a bytes-like object that is not also a *file*, the Content-Length header is set to its length. Any other type of *body* (files and iterables in general) will be chunk-encoded, and the Transfer-Encoding header will automatically be set instead of Content-Length.

The *encode_chunked* argument is only relevant if Transfer-Encoding is specified in *headers*. If *encode_chunked* is False, the HTTPConnection object assumes that all encoding is handled by the calling code. If it is True, the body will be chunk-encoded.

For example, to perform a GET request to https://docs.python.org/3/:

```
>>> import http.client
>>> host = "docs.python.org"
>>> conn = http.client.HTTPSConnection(host)
>>> conn.request("GET", "/3/", headers={"Host": host})
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200 OK
```

> **備🄵**
>
> Chunked transfer encoding has been added to the HTTP protocol version 1.1. Unless the HTTP server is known to handle HTTP 1.1, the caller must either specify the Content-Length, or must pass a *str* or bytes-like object that is not also a file as the body representation.

在 3.2 版的變更: *body* can now be an iterable.

在 3.6 版的變更: If neither Content-Length nor Transfer-Encoding are set in *headers*, file and iterable *body* objects are now chunk-encoded. The *encode_chunked* argument was added. No attempt is made to determine the Content-Length for file objects.

HTTPConnection.**getresponse**()

Should be called after a request is sent to get the response from the server. Returns an *HTTPResponse* instance.

> **備🄵**
>
> Note that you must have read the whole response before you can send a new request to the server.

在 3.5 版的變更: If a *ConnectionError* or subclass is raised, the *HTTPConnection* object will be ready to reconnect when a new request is sent.

HTTPConnection.**set_debuglevel**(*level*)

Set the debugging level. The default debug level is `0`, meaning no debugging output is printed. Any value greater than `0` will cause all currently defined debug output to be printed to stdout. The `debuglevel` is passed to any new *HTTPResponse* objects that are created.

在 3.1 版被加入.

HTTPConnection.**set_tunnel**(*host*, *port=None*, *headers=None*)

Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The *host* and *port* arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, *not* the address of the proxy server).

The *headers* argument should be a mapping of extra HTTP headers to send with the CONNECT request.

As HTTP/1.1 is used for HTTP CONNECT tunnelling request, as per the RFC, a HTTP `Host:` header must be provided, matching the authority-form of the request target provided as the destination for the CONNECT request. If a HTTP `Host:` header is not provided via the headers argument, one is generated and transmitted automatically.

For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the *HTTPSConnection* constructor, and the address of the host that we eventually want to reach to the *set_tunnel()* method:

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("localhost", 8080)
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

在 3.2 版被加入.

在 3.12 版的變更: HTTP CONNECT tunnelling requests use protocol HTTP/1.1, upgraded from protocol HTTP/1.0. `Host:` HTTP headers are mandatory for HTTP/1.1, so one will be automatically generated and transmitted if not provided in the headers argument.

HTTPConnection.**get_proxy_response_headers**()

Returns a dictionary with the headers of the response received from the proxy server to the CONNECT request.

If the CONNECT request was not sent, the method returns `None`.

在 3.12 版被加入.

HTTPConnection.**connect**()

Connect to the server specified when the object was created. By default, this is called automatically when making a request if the client does not already have a connection.

引發一個附帶引數 `self`、`host`、`port` 的稽核事件 `http.client.connect`。

HTTPConnection.**close**()

Close the connection to the server.

HTTPConnection.**blocksize**

Buffer size in bytes for sending a file-like message body.

在 3.7 版被加入.

As an alternative to using the *request()* method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.**putrequest**(*method*, *url*, *skip_host=False*, *skip_accept_encoding=False*)

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the *method* string, the *url* string, and the HTTP version (`HTTP/1.1`). To disable automatic sending of `Host:` or `Accept-Encoding:` headers (for example to accept additional content encodings), specify *skip_host* or *skip_accept_encoding* with non-False values.

HTTPConnection.**putheader**(*header*, *argument*[, ...])

Send an **RFC 822**-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.**endheaders**(*message_body=None*, *, *encode_chunked=False*)

Send a blank line to the server, signalling the end of the headers. The optional *message_body* argument can be used to pass a message body associated with the request.

If *encode_chunked* is `True`, the result of each iteration of *message_body* will be chunk-encoded as specified in **RFC 7230**, Section 3.3.1. How the data is encoded is dependent on the type of *message_body*. If *message_body* implements the buffer interface the encoding will result in a single chunk. If *message_body* is a *collections.abc.Iterable*, each iteration of *message_body* will result in a chunk. If *message_body* is a *file object*, each call to `.read()` will result in a chunk. The method automatically signals the end of the chunk-encoded data immediately after *message_body*.

> **備🄵**
>
> Due to the chunked encoding specification, empty chunks yielded by an iterator body will be ignored by the chunk-encoder. This is to avoid premature termination of the read of the request by the target server due to malformed encoding.

在 3.6 版的變更: Added chunked encoding support and the *encode_chunked* parameter.

HTTPConnection.**send**(*data*)

Send data to the server. This should be used directly only after the *endheaders()* method has been called and before *getresponse()* is called.

引發一個附帶引數 `self`、`data` 的稽核事件 `http.client.send`。

22.10.2 HTTPResponse 物件

An *HTTPResponse* instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

在 3.5 版的變更: The *io.BufferedIOBase* interface is now implemented and all of its reader operations are supported.

HTTPResponse.**read**([*amt*])

Reads and returns the response body, or up to the next *amt* bytes.

HTTPResponse.**readinto**(*b*)

Reads up to the next len(b) bytes of the response body into the buffer *b*. Returns the number of bytes read.

在 3.3 版被加入.

HTTPResponse.**getheader**(*name*, *default=None*)

Return the value of the header *name*, or *default* if there is no header matching *name*. If there is more than one header with the name *name*, return all of the values joined by ', '. If *default* is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.**getheaders**()

Return a list of (header, value) tuples.

HTTPResponse.**fileno**()

Return the `fileno` of the underlying socket.

HTTPResponse.**msg**

A *http.client.HTTPMessage* instance containing the response headers. *http.client.HTTPMessage* is a subclass of *email.message.Message*.

HTTPResponse.**version**

HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.**url**

URL of the resource retrieved, commonly used to determine if a redirect was followed.

HTTPResponse.**headers**

Headers of the response in the form of an *email.message.EmailMessage* instance.

HTTPResponse.**status**

Status code returned by server.

HTTPResponse.**reason**

Reason phrase returned by server.

HTTPResponse.**debuglevel**

A debugging hook. If *debuglevel* is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse.**closed**

Is `True` if the stream is closed.

HTTPResponse.**geturl**()

在 3.9 版之後被🄵用: Deprecated in favor of *url*.

HTTPResponse.**info**()

在 3.9 版之後被🄵用: Deprecated in favor of *headers*.

HTTPResponse.**getcode**()

在 3.9 版之後被🄵用: Deprecated in favor of *status*.

22.10.3 范例

Here is an example session that uses the `GET` method:

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while chunk := r1.read(200):
...     print(repr(chunk))
b'<!doctype html>\n<!--[if"...
...
>>> # Example of an invalid request
>>> conn = http.client.HTTPSConnection("docs.python.org")
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
```

(繼續下一頁)

(繼續上一頁)

```
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the `HEAD` method. Note that the `HEAD` method never returns any data.

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
200 OK
>>> data = res.read()
>>> print(len(data))
0
>>> data == b''
True
```

Here is an example session that uses the `POST` method:

```
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524, '@type': 'issue', '@action': 'show'})
>>> headers = {"Content-type": "application/x-www-form-urlencoded",
...            "Accept": "text/plain"}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", "", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="https://bugs.python.org/issue12524">https://bugs.python.org/
↪issue12524</a>'
>>> conn.close()
```

Client side HTTP `PUT` requests are very similar to `POST` requests. The difference lies only on the server side where HTTP servers will allow resources to be created via `PUT` requests. It should be noted that custom HTTP methods are also handled in *`urllib.request.Request`* by setting the appropriate method attribute. Here is an example session that uses the `PUT` method:

```
>>> # This creates an HTTP request
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/file
...
>>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200, OK
```

22.10.4 HTTPMessage 物件

class http.client.**HTTPMessage**(*email.message.Message*)

An *`http.client.HTTPMessage`* instance holds the headers from an HTTP response. It is implemented using the *`email.message.Message`* class.

22.11 `ftplib` --- FTP 協定用🄵端

原始碼： Lib/ftplib.py

這個模組定義了*`FTP`* 類🄴和一些相關的項目。*`FTP`* 類🄴實作了 FTP 協定的用🄴端。你可以使用它來編寫能🄴執行各種 FTP 自動作業的 Python 程式，例如鏡像 (mirror) 其他 FTP 伺服器。*`urllib.request`* 模組也使用它來處理使用 FTP 的 URL。有關 FTP（檔案傳輸協定）的更多資訊，請參🄴 **RFC 959**。

預設編碼是 UTF-8，遵循 **RFC 2640**。

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄴*WebAssembly 平台*。

這是一個使用*`ftplib`* 模組的會話範例：

```
>>> from ftplib import FTP
>>> ftp = FTP('ftp.us.debian.org')   # connect to host, default port
>>> ftp.login()                      # user anonymous, passwd anonymous@
'230 Login successful.'
>>> ftp.cwd('debian')                # change into "debian" directory
'250 Directory successfully changed.'
>>> ftp.retrlines('LIST')            # list directory contents
-rw-rw-r--    1 1176     1176         1063 Jun 15 10:18 README
...
drwxr-sr-x    5 1176     1176         4096 Dec 19  2000 pool
drwxr-sr-x    4 1176     1176         4096 Nov 17  2008 project
drwxr-xr-x    3 1176     1176         4096 Oct 10  2012 tools
'226 Directory send OK.'
>>> with open('README', 'wb') as fp:
>>>     ftp.retrbinary('RETR README', fp.write)
'226 Transfer complete.'
>>> ftp.quit()
'221 Goodbye.'
```

22.11.1 參考

FTP 物件

class ftplib.**FTP**(*host=''*, *user=''*, *passwd=''*, *acct=''*, *timeout=None*, *source_address=None*, ***, *encoding='utf-8'*)

回傳一個新的*`FTP`* 類🄴實例。

參數

- **host** (`str`) -- 要連接的主機名稱。如果有給定，`connect(host)` 會由建構函式來隱式地呼叫。
- **user** (`str`) -- The username to log in with (default: `'anonymous'`). 如果有給定，`login(host, passwd, acct)` 會由建構函式來隱式地呼叫。
- **passwd** (`str`) -- The password to use when logging in. If not given, and if *passwd* is the empty string or `"-"`, a password will be automatically generated.
- **acct** (`str`) -- Account information to be used for the `ACCT` FTP command. Few systems implement this. See RFC-959 for more details.
- **timeout** (`float` | *`None`*) -- 如*`connect()`* 的阻塞操作的超時設定，以秒🄵單位（預設：使用全域預設超時設定）。
- **source_address** (`tuple` | *`None`*) -- A 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.
- **encoding** (`str`) -- The encoding for directories and filenames (default: `'utf-8'`).

FTP 類🄵支援 `with` 陳述式，例如：

```
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
dr-xr-xr-x   9 ftp      ftp           154 May  6 10:43 .
dr-xr-xr-x   9 ftp      ftp           154 May  6 10:43 ..
dr-xr-xr-x   5 ftp      ftp          4096 May  6 10:43 CentOS
dr-xr-xr-x   3 ftp      ftp            18 Jul 10  2008 Fedora
>>>
```

在 3.2 版的變更: 新增了對 `with` 陳述式的支援。

在 3.3 版的變更: 新增 *source_address* 參數。

在 3.9 版的變更: 如果 *timeout* 參數設定🄵零，它將引發 *ValueError* 以防止建立非阻塞 socket。新增了 *encoding* 參數，預設值從 Latin-1 更改🄵 UTF-8 以遵循 **RFC 2640**。

`FTP` 的多個可用方法大致有分🄵兩個方向：一種用於處理文本檔案 (text files)，另一種用於二進位檔案 (binary files)。這些以在文本檔案的 `lines` 或二進位檔案的 `binary` 前使用的命令命名。

FTP 實例具有以下方法：

set_debuglevel(*level*)

將實例的偵錯級🄵設定🄵一個 *int*，這控制印出的偵錯訊息輸出量。

- `0`（預設值）：不🄵生偵錯輸出。
- `1`：會🄵生適量的偵錯輸出，通常是每個請求輸出一行。
- `2` 或更高的值：會🄵生最大量的偵錯輸出，以日🄵紀🄵下控制連🄵發送和接收的每個步驟。

connect(*host=''*, *port=0*, *timeout=None*, *source_address=None*)

連🄵到給定的主機 (host) 和連接埠 (port)。每個實例只應呼叫此函式一次；如果在建立 *FTP* 實例時有給定 *host* 引數，則不應呼叫它。所有其他的 `FTP` 方法只能在成功建立連🄵後使用。

參數

- **host** (`str`) -- 要連接的主機。
- **port** (`int`) -- 要連接的 TCP 連接埠（預設值：`21`，由 FTP 協定規範指定）。很少需要指定不同的連接埠號碼。
- **timeout** (`float` / *None*) -- 連🄵嘗試的超時設定，以秒🄵單位（預設：全域預設超時設定）。
- **source_address** (`tuple` / *None*) -- A 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.

引發一個附帶引數 `self`、`host`、`port` 的稽核事件 `ftplib.connect`。

在 3.3 版的變更: 新增 *source_address* 參數。

getwelcome()

回傳伺服器🄵回應初始連🄵而發送的歡迎訊息。(此訊息有時會包含與使用者相關的免責聲明或幫助資訊。)

login(*user='anonymous'*, *passwd=''*, *acct=''*)

在以連🄵的伺服器上登入。在建立連🄵後，每個實例只應呼叫此函式一次；如果在建立 *FTP* 實例時有給定 *host* 和 *user* 引數，則不應呼叫它。大多數 FTP 命令僅在用🄵端登🄵後才允許使用

參數

- **user** (`str`) -- The username to log in with (default: `'anonymous'`).

- **passwd** (str) -- The password to use when logging in. If not given, and if *passwd* is the empty string or `"-"`, a password will be automatically generated.
- **acct** (str) -- Account information to be used for the ACCT FTP command. Few systems implement this. See RFC-959 for more details.

abort()

中止正在進行的檔案傳輸。使用它🄵不是都會成功，但值得一試。

sendcmd(*cmd*)

向伺服器發送一個簡單的命令字串🄵回傳回應字串。

引發一個附帶引數 `self`、`cmd` 的稽核事件 `ftplib.sendcmd`。

voidcmd(*cmd*)

向伺服器發送一個簡單的命令字串🄵處理回應。如果收到代表成功的回應狀態碼（範圍🄵 200--299 的狀態碼），則回傳回應字串，否則引發*error_reply*。

引發一個附帶引數 `self`、`cmd` 的稽核事件 `ftplib.sendcmd`。

retrbinary(*cmd*, *callback*, *blocksize=8192*, *rest=None*)

以二進位傳輸模式 (binary transfer mode) 取得檔案。

參數

- **cmd** (str) -- 一個正確的 RETR 指令：`"RETR filename"`。
- **callback** (*callable*) -- 🄵接收到的每個資料區塊呼叫的單一參數可呼叫物件，其單一引數是以*bytes* 🄵形式的資料。
- **blocksize** (int) -- 在執行實際傳輸時所建立的低階*socket* 物件上讀取的最大分塊 (chunk) 大小。這也對應於將傳遞給 *callback* 的最大資料大小。預設🄵 8192。
- **rest** (int) -- 一個要發送到伺服器的 REST 命令。參見*transfercmd()* 方法之 *rest* 參數的文件。

retrlines(*cmd*, *callback=None*)

在初始化時以 *encoding* 參數指定的編碼來取得檔案或目🄵列表。*cmd* 要是一個正確的 RETR 命令（見*retrbinary()*）或者一個像 LIST 或 NLST 的命令（通常只是字串 `'LIST'`）。LIST 會取得檔案列表和這些檔案的相關資訊。NLST 取得檔案名稱列表。會🄵每一行以一個字串引數呼叫 *callback* 函式，其引數包含已經🄵除尾隨 CRLF 的一行。預設的 *callback* 會將各行印出到*sys.stdout*。

set_pasv(*val*)

如果 *val* 🄵真，則🄵用「被動」模式，否則禁用被動模式。被動模式預設開🄵。

storbinary(*cmd*, *fp*, *blocksize=8192*, *callback=None*, *rest=None*)

以二進位傳輸模式儲存檔案。

參數

- **cmd** (str) -- 一個正確的 STOR 指令：`"STOR filename"`。
- **fp** (*file object*) -- 一個檔案物件（以二進位模式開🄵），在大小🄵 *blocksize* 的區塊中使用其*read()* 方法讀取直到 EOF 來提供要儲存的資料。
- **blocksize** (int) -- 讀取區塊大小。預設🄵 8192。
- **callback** (*callable*) -- 🄵發送的每個資料區塊來呼叫的單一參數可呼叫物件，其單一引數是以*bytes* 🄵形式的資料。
- **rest** (int) -- 一個要發送到伺服器的 REST 命令。參見*transfercmd()* 方法之 *rest* 參數的文件。

在 3.2 版的變更: 新增 *rest* 參數。

storlines(*cmd*, *fp*, *callback=None*)

以行模式 (line mode) 儲存檔案。*cmd* 應是一個正確的 STOR 命令（參見*storbinary()*）。使用其*readline()* 方法從*檔案物件* *fp* （以二進位模式打開）讀取各行、直到 EOF，以提供要儲存的資料。*callback* 是可選的單參數可呼叫物件，於發送後以各行進行呼叫。

transfercmd(*cmd*, *rest=None*)

通過資料連🄵🄵動傳輸。如果傳輸🄵主動 (active) 模式，則發送 EPRT 或 PORT 命令和 *cmd* 指定的傳輸命令，🄵接受連🄵。如果伺服器是被動 (passive) 模式，則發送 EPSV 或 PASV 命令、連🄵、🄵🄵動傳輸命令。無論哪種方式，都是回傳連🄵的 socket。

如果有給定可選的 *rest*，一個 REST 命令會被發送到伺服器，🄵以 *rest* 作🄵引數。*rest* 通常是請求檔案的一個位元組偏移量 (byte offset)，告訴伺服器以請求的偏移量重新開始發送檔案的位元組，🄵跳過初始位元組。但是請注意，*transfercmd()* 方法將 *rest* 轉🄵🄵帶有初始化時指定的 *encoding* 參數的字串，但不會對字串的🄵容執行檢查。如果伺服器無法識🄵 REST 命令，則會引發*error_reply* 例外。如果發生這種情🄵，只需在🄵有 *rest* 引數的情🄵下呼叫*transfercmd()*。

ntransfercmd(*cmd*, *rest=None*)

類似於*transfercmd()*，但回傳一個帶有資料連🄵和資料預期大小的元組。如果無法計算預期大小，則回傳 None。*cmd* 和 *rest* 與*transfercmd()* 中的含義相同。

mlsd(*path=''*, *facts=[]*)

使用 MLSD 命令 (**RFC 3659**) 列出標準格式的目🄵。如果省略 *path* 則假定🄵作用於目前目🄵。*facts* 是表示所需資訊類型的字串列表（例如 `["type", "size", "perm"]`）。會回傳一個🄵生器物件，🄵每個在路徑中找到的檔案生成一個包含兩個元素的元組，第一個元素是檔案名稱，第二個元素是包含有關檔案名稱 facts 的字典。該字典的🄵容可能受 *facts* 引數限制，但不保證伺服器會回傳所有請求的 facts。

在 3.3 版被加入.

nlst(*argument*[, ...])

回傳由 NLST 命令回傳的檔案名稱列表。可選的 *argument* 是要列出的目🄵（預設🄵目前伺服器目🄵）。多個引數可用於將非標准選項傳遞給 NLST 命令。

> **備🄵**
>
> 如果你的伺服器支援該命令，*mlsd()* 會提供更好的 API。

dir(*argument*[, ...])

生成由 LIST 命令回傳的目🄵列表，🄵將其印出到標準輸出 (standard output)。可選的 *argument* 是要列出的目🄵（預設🄵目前伺服器目🄵）。有多個引數可用於將非標准選項傳遞給 LIST 命令。如果最後一個引數是一個函式，它被用作*retrlines()* 的 *callback* 函式；預設印出到*sys.stdout*。此方法回傳 None。

> **備🄵**
>
> 如果你的伺服器支援該命令，*mlsd()* 會提供更好的 API。

rename(*fromname*, *toname*)

將伺服器上的檔案 *fromname* 重新命名🄵 *toname*。

delete(*filename*)

從伺服器中🄵除名🄵 *filename* 的檔案。如果成功，回傳回應的文字，否則引發*error_perm* 權限錯誤或在其他錯誤發生時引發*error_reply*。

cwd(*pathname*)

設定伺服器上的目前目🄵。

mkd(*pathname*)

在伺服器上建立一個新目🄵。

pwd()

回傳伺服器上目前目🄵的路徑名。

rmd(*dirname*)

🄵除伺服器上名🄵 *dirname* 的目🄵。

size(*filename*)

請求伺服器上名🄵 *filename* 的檔案的大小。成功時，檔案的大小作🄵整數回傳，否則回傳 `None`。請注意，`SIZE` 命令不是標准化的，但被許多常見的伺服器實作支援。

quit()

向伺服器發送 `QUIT` 命令🄵關閉連🄵。這是關閉連🄵的「禮貌」方式，但如果伺服器對 `QUIT` 命令作出錯誤回應，它可能會引發例外。這意味著呼叫*`close()`* 方法使*`FTP`* 實例無法用於後續呼叫（見下文）。

close()

單方面關閉連🄵。這不應該使用於已經關閉的連🄵，例如在成功呼叫*`quit()`* 之後。呼叫後就不應該再次使用*`FTP`* 實例（在呼叫*`close()`* 或*`quit()`* 後，你不能通過發出另一個*`login()`* 方法重新打開連🄵）。

FTP_TLS 物件

class ftplib.**FTP_TLS**(*host=''*, *user=''*, *passwd=''*, *acct=''*, ***, *context=None*, *timeout=None*, *source_address=None*, *encoding='utf-8'*)

An *`FTP`* subclass which adds TLS support to FTP as described in **RFC 4217**. Connect to port 21 implicitly securing the FTP control connection before authenticating.

備🄵

The user must explicitly secure the data connection by calling the *`prot_p()`* method.

參數

- **host** (`str`) -- 要連接的主機名稱。如果有給定，`connect(host)` 會由建構函式來隱式地呼叫。
- **user** (`str`) -- The username to log in with (default: `'anonymous'`). 如果有給定，`login(host, passwd, acct)` 會由建構函式來隱式地呼叫。
- **passwd** (`str`) -- The password to use when logging in. If not given, and if *passwd* is the empty string or `"-"`, a password will be automatically generated.
- **acct** (`str`) -- Account information to be used for the `ACCT` FTP command. Few systems implement this. See RFC-959 for more details.
- **context** (*`ssl.SSLContext`*) -- An SSL context object which allows bundling SSL configuration options, certificates and private keys into a single, potentially long-lived, structure. Please read *Security considerations* for best practices.
- **timeout** (`float` | *`None`*) -- 如*`connect()`* 的阻塞操作的超時設定，以秒🄵單位（預設：使用全域預設超時設定）。
- **source_address** (`tuple` | *`None`*) -- A 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.
- **encoding** (`str`) -- The encoding for directories and filenames (default: `'utf-8'`).

在 3.2 版被加入.

在 3.3 版的變更: 新增 *source_address* 參數。

在 3.4 版的變更: 該類🄵現在支援使用*ssl.SSLContext.check_hostname* 和 *Server Name Indication* 進行主機名 (hostname) 檢查（參見*ssl.HAS_SNI*）。

在 3.9 版的變更: 如果 *timeout* 參數設定🄵零，它將引發*ValueError* 以防止建立非阻塞 socket。新增了 *encoding* 參數，預設值從 Latin-1 更改🄵 UTF-8 以遵循 **RFC 2640**。

在 3.12 版的變更: 已🄵用的 *keyfile* 和 *certfile* 參數已被移除。

這是一個使用*FTP_TLS* 類🄵的範例會話：

```
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
>>> ftps.prot_p()
'200 Data protection level set to "private"'
>>> ftps.nlst()
['6jack', 'OpenBSD', 'antilink', 'blogbench', 'bsdcam', 'clockspeed', 'djbdns-jedi',
↪'docs', 'eaccelerator-jedi', 'favicon.ico', 'francotone', 'fugu', 'ignore', 'libpuzzle
↪', 'metalog', 'minidentd', 'misc', 'mysql-udf-global-user-variables', 'php-jenkins-
↪hash', 'php-skein-hash', 'php-webdav', 'phpaudit', 'phpbench', 'pincaster', 'ping',
↪'posto', 'pub', 'public', 'public_keys', 'pure-ftpd', 'qscan', 'qtc', 'sharedance',
↪'skycache', 'sound', 'tmp', 'ucarp']
```

FTP_TLS 類🄵繼承自*FTP*，🄵另外定義了這些的方法與屬性：

ssl_version

要使用的 SSL 版本（預設🄵*ssl.PROTOCOL_SSLv23*）。

auth()

根據*ssl_version* 屬性中指定的🄵容，使用 TLS 或 SSL 設定安全控制連🄵。

在 3.4 版的變更: 該方法現在支援使用*ssl.SSLContext.check_hostname* 和 *Server Name Indication* 進行主機名檢查（參見*ssl.HAS_SNI*）。

ccc()

將控制通道恢復🄵純文本。這對於利用知道如何在不打開固定連接埠的情🄵下使用非安全 (non-secure) FTP 以處理 NAT 的防火🄵很有用。

在 3.3 版被加入.

prot_p()

設定安全資料連🄵。

prot_c()

設定明文資料 (clear text data) 連🄵。

模組變數

exception ftplib.**error_reply**

伺服器收到意外回覆時所引發的例外。

exception ftplib.**error_temp**

當收到表示暫時錯誤的錯誤碼（400--499 範圍🄵的回應狀態碼）時引發的例外。

exception ftplib.**error_perm**

當收到表示永久錯誤的錯誤碼（500--599 範圍🄵的回應狀態碼）時引發的例外。

exception ftplib.**error_proto**

當從伺服器收到不符合檔案傳輸協定回應規範的回覆時引發例外，即 1--5 範圍🄵的數字開頭。

ftplib.**all_errors**

FTP 實例方法由於 FTP 連🄵問題（相對於呼叫者的程式錯誤）而可能引發的所有例外集合（元組形式）。該集合包括上面列出的四個例外以及*OSError* 和*EOFError*。

也參考

netrc 模組
.netrc 檔案格式的剖析器。.netrc 檔案通常被 FTP 用🄵端用來在提示使用者之前載入使用者身份驗證資訊。

22.12 poplib --- POP3 協定用🄵端

原始碼： Lib/poplib.py

This module defines a class, *POP3*, which encapsulates a connection to a POP3 server and implements the protocol as defined in **RFC 1939**. The *POP3* class supports both the minimal and optional command sets from **RFC 1939**. The *POP3* class also supports the STLS command introduced in **RFC 2595** to enable encrypted communication on an already established connection.

Additionally, this module provides a class *POP3_SSL*, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the *imaplib.IMAP4* class, as IMAP servers tend to be better implemented.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

The *poplib* module provides two classes:

class poplib.**POP3**(*host*, *port=POP3_PORT*[, *timeout*])

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If *port* is omitted, the standard POP3 port (110) is used. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

引發一個附帶引數 self、host、port 的稽核事件 poplib.connect。

引發一個附帶引數 self、line 的稽核事件 poplib.putline。其中 line 🄵即將傳送給遠端的位元組。

在 3.9 版的變更: If the *timeout* parameter is set to be zero, it will raise a *ValueError* to prevent the creation of a non-blocking socket.

class poplib.**POP3_SSL**(*host*, *port=POP3_SSL_PORT*, *, *timeout=None*, *context=None*)

This is a subclass of *POP3* that connects to the server over an SSL encrypted socket. If *port* is not specified, 995, the standard POP3-over-SSL port is used. *timeout* works as in the *POP3* constructor. *context* is an optional *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read *Security considerations* for best practices.

引發一個附帶引數 self、host、port 的稽核事件 poplib.connect。

引發一個附帶引數 self、line 的稽核事件 poplib.putline。其中 line 🄵即將傳送給遠端的位元組。

在 3.2 版的變更: *context* parameter added.

在 3.4 版的變更: The class now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

在 3.9 版的變更: If the *timeout* parameter is set to be zero, it will raise a *ValueError* to prevent the creation of a non-blocking socket.

在 3.12 版的變更: The deprecated *keyfile* and *certfile* parameters have been removed.

One exception is defined as an attribute of the *poplib* module:

exception poplib.**error_proto**

Exception raised on any errors from this module (errors from *socket* module are not caught). The reason for the exception is passed to the constructor as a string.

***imaplib* 模組**
The standard Python IMAP module.

關於 Fetchmail 的常見問題
The FAQ for the **fetchmail** POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.

22.12.1 POP3 物件

All POP3 commands are represented by methods of the same name, in lowercase; most return the response text sent by the server.

POP3 實例擁有以下方法：

POP3.**set_debuglevel**(*level*)

Set the instance's debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

POP3.**getwelcome**()

Returns the greeting string sent by the POP3 server.

POP3.**capa**()

Query the server's capabilities as specified in **RFC 2449**. Returns a dictionary in the form `{'name': ['param'...]}`.

在 3.4 版被加入.

POP3.**user**(*username*)

Send user command, response should indicate that a password is required.

POP3.**pass_**(*password*)

Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until *quit()* is called.

POP3.**apop**(*user*, *secret*)

Use the more secure APOP authentication to log into the POP3 server.

POP3.**rpop**(*user*)

Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

POP3.**stat**()

Get mailbox status. The result is a tuple of 2 integers: `(message count, mailbox size)`.

POP3.**list**([*which*])

Request message list, result is in the form `(response, ['mesg_num octets', ...], octets)`. If *which* is set, it is the message to list.

POP3.**retr**(*which*)

Retrieve whole message number *which*, and set its seen flag. Result is in form `(response, ['line', ...], octets)`.

POP3.**dele**(*which*)

Flag message number *which* for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

POP3.**rset**()

Remove any deletion marks for the mailbox.

POP3.**noop**()

Do nothing. Might be used as a keep-alive.

POP3.**quit**()

Signoff: commit changes, unlock mailbox, drop connection.

POP3.**top**(*which*, *howmuch*)

Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form `(response, ['line', ...], octets)`.

The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

POP3.**uidl**(*which=None*)

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form `'response mesgnum uid`, otherwise result is list `(response, ['mesgnum uid', ...], octets)`.

POP3.**utf8**()

Try to switch to UTF-8 mode. Returns the server response if successful, raises *error_proto* if not. Specified in **RFC 6856**.

在 3.5 版被加入.

POP3.**stls**(*context=None*)

Start a TLS session on the active connection as specified in **RFC 2595**. This is only allowed before user authentication

context parameter is a *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read *Security considerations* for best practices.

This method supports hostname checking via *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

在 3.4 版被加入.

Instances of *POP3_SSL* have no additional methods. The interface of this subclass is identical to its parent.

22.12.2 POP3 范例

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.

22.13 `imaplib` --- IMAP4 協定用🄵端

原始碼： Lib/imaplib.py

This module defines three classes, *IMAP4*, *IMAP4_SSL* and *IMAP4_stream*, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in **RFC 2060**. It is backward compatible with IMAP4 (**RFC 1730**) servers, but note that the `STATUS` command is not supported in IMAP4.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

Three classes are provided by the *imaplib* module, *IMAP4* is the base class:

class imaplib.**IMAP4**(*host=''*, *port=IMAP4_PORT*, *timeout=None*)

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If *host* is not specified, `''` (the local host) is used. If *port* is omitted, the standard IMAP4 port (143) is used. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is `None`, the global default socket timeout is used.

The *IMAP4* class supports the `with` statement. When used like this, the IMAP4 `LOGOUT` command is issued automatically when the `with` statement exits. E.g.:

```
>>> from imaplib import IMAP4
>>> with IMAP4("domain.org") as M:
...     M.noop()
...
('OK', [b'Nothing Accomplished. d25if65hy903weo.87'])
```

在 3.5 版的變更: Support for the `with` statement was added.

在 3.9 版的變更: 新增 *timeout* 選用參數。

Three exceptions are defined as attributes of the *IMAP4* class:

exception IMAP4.**error**

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

exception IMAP4.**abort**

IMAP4 server errors cause this exception to be raised. This is a sub-class of *IMAP4.error*. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

exception IMAP4.**readonly**

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of *IMAP4.error*. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There's also a subclass for secure connections:

class imaplib.**IMAP4_SSL**(*host=''*, *port=IMAP4_SSL_PORT*, ***, *ssl_context=None*, *timeout=None*)

This is a subclass derived from *IMAP4* that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If *host* is not specified, `''` (the local host) is used. If *port* is omitted, the standard IMAP4-over-SSL port (993) is used. *ssl_context* is a *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read *Security considerations* for best practices.

The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is `None`, the global default socket timeout is used.

在 3.3 版的變更: 新增 *ssl_context* 參數。

在 3.4 版的變更: The class now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

在 3.9 版的變更: 新增 *timeout* 選用參數。

在 3.12 版的變更: The deprecated *keyfile* and *certfile* parameters have been removed.

The second subclass allows for connections created by a child process:

class imaplib.**IMAP4_stream**(*command*)

This is a subclass derived from *IMAP4* that connects to the `stdin/stdout` file descriptors created by passing *command* to `subprocess.Popen()`.

The following utility functions are defined:

imaplib.**Internaldate2tuple**(*datestr*)

Parse an IMAP4 `INTERNALDATE` string and return corresponding local time. The return value is a *time.struct_time* tuple or `None` if the string has wrong format.

imaplib.**Int2AP**(*num*)

Converts an integer into a bytes representation using characters from the set [`A` .. `P`].

imaplib.**ParseFlags**(*flagstr*)

Converts an IMAP4 `FLAGS` response to a tuple of individual flags.

imaplib.**Time2Internaldate**(*date_time*)

Convert *date_time* to an IMAP4 `INTERNALDATE` representation. The return value is a string in the form: `"DD-Mmm-YYYY HH:MM:SS +HHMM"` (including double-quotes). The *date_time* argument can be a number (int or float) representing seconds since epoch (as returned by *time.time()*), a 9-tuple representing local time an instance of *time.struct_time* (as returned by *time.localtime()*), an aware instance of *datetime.datetime*, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an `EXPUNGE` command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

也參考

Documents describing the protocol, sources for servers implementing it, by the University of Washington's IMAP Information Center can all be found at (**Source Code**) https://github.com/uw-imap/imap (**Not Maintained**).

22.13.1 IMAP4 物件

All IMAP4rev1 commands are represented by methods of the same name, either uppercase or lowercase.

All arguments to commands are converted to strings, except for `AUTHENTICATE`, and the last argument to `APPEND` which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn't enclosed with either parentheses or double quotes) each string is quoted. However, the *password* argument to the `LOGIN` command is always quoted. If you want to avoid having an argument string quoted (eg: the *flags* argument to `STORE`) then enclose the string in parentheses (eg: `r'(\Deleted)'`).

Most commands return a tuple: `(type, [data, ...])` where *type* is usually `'OK'` or `'NO'`, and *data* is either the text from the command response, or mandated results from the command. Each *data* is either a `bytes`, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: 'literal' value).

The *message_set* options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number (`'1'`), a range of message numbers (`'2:4'`), or a group of non-contiguous ranges separated by commas (`'1:3,6:9'`). A range can contain an asterisk to indicate an infinite upper bound (`'3:*'`).

IMAP4 實例擁有以下方法:

IMAP4.**append**(*mailbox*, *flags*, *date_time*, *message*)

Append *message* to named mailbox.

IMAP4.**authenticate**(*mechanism*, *authobject*)

Authenticate command --- requires response processing.

mechanism specifies which authentication mechanism is to be used - it should appear in the instance variable `capabilities` in the form `AUTH=mechanism`.

authobject must be a callable object:

```
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be `bytes`. It should return `bytes` *data* that will be base64 encoded and sent to the server. It should return `None` if the client abort response `*` should be sent instead.

在 3.5 版的變更: string usernames and passwords are now encoded to `utf-8` instead of being limited to ASCII.

IMAP4.**check**()

Checkpoint mailbox on server.

IMAP4.**close**()

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before `LOGOUT`.

IMAP4.**copy**(*message_set*, *new_mailbox*)

Copy *message_set* messages onto end of *new_mailbox*.

IMAP4.**create**(*mailbox*)

Create new mailbox named *mailbox*.

IMAP4.**delete**(*mailbox*)

Delete old mailbox named *mailbox*.

IMAP4.**deleteacl**(*mailbox*, *who*)

Delete the ACLs (remove any rights) set for who on mailbox.

IMAP4.**enable**(*capability*)

Enable *capability* (see **RFC 5161**). Most capabilities do not need to be enabled. Currently only the `UTF8=ACCEPT` capability is supported (see **RFC 6855**).

在 3.5 版被加入: The *`enable()`* method itself, and **RFC 6855** support.

IMAP4.**expunge**()

Permanently remove deleted items from selected mailbox. Generates an `EXPUNGE` response for each deleted message. Returned data contains a list of `EXPUNGE` message numbers in order received.

IMAP4.**fetch**(*message_set*, *message_parts*)

Fetch (parts of) messages. *message_parts* should be a string of message part names enclosed within parentheses, eg: `"(UID BODY[TEXT])"`. Returned data are tuples of message part envelope and data.

IMAP4.**getacl**(*mailbox*)

Get the `ACL`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.**getannotation**(*mailbox*, *entry*, *attribute*)

Retrieve the specified `ANNOTATION`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.**getquota**(*root*)

Get the `quota` *root*'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.**getquotaroot**(*mailbox*)

Get the list of `quota roots` for the named *mailbox*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.**idle**(*duration=None*)

Return an `Idler`: an iterable context manager implementing the IMAP4 `IDLE` command as defined in **RFC 2177**.

The returned object sends the `IDLE` command when activated by the `with` statement, produces IMAP untagged responses via the *iterator* protocol, and sends `DONE` upon context exit.

All untagged responses that arrive after sending the `IDLE` command (including any that arrive before the server acknowledges the command) will be available via iteration. Any leftover responses (those not iterated in the `with` context) can be retrieved in the usual way after `IDLE` ends, using *IMAP4.response()*.

Responses are represented as `(type, [data, ...])` tuples, as described in *IMAP4 Objects*.

The *duration* argument sets a maximum duration (in seconds) to keep idling, after which any ongoing iteration will stop. It can be an *int* or *float*, or `None` for no time limit. Callers wishing to avoid inactivity timeouts on servers that impose them should keep this at most 29 minutes (1740 seconds). Requires a socket connection; *duration* must be `None` on *IMAP4_stream* connections.

```
>>> with M.idle(duration=29 * 60) as idler:
...     for typ, data in idler:
...         print(typ, data)
...
EXISTS [b'1']
RECENT [b'1']
```

Idler.**burst**(*interval=0.1*)

Yield a burst of responses no more than *interval* seconds apart (expressed as an *int* or *float*).

This *generator* is an alternative to iterating one response at a time, intended to aid in efficient batch processing. It retrieves the next response along with any immediately available subsequent responses. (For example, a rapid series of `EXPUNGE` responses after a bulk delete.)

Requires a socket connection; does not work on *IMAP4_stream* connections.

```
>>> with M.idle() as idler:
...     # get a response and any others following by < 0.1 seconds
...     batch = list(idler.burst())
...     print(f'processing {len(batch)} responses...')
...     print(batch)
...
processing 3 responses...
[('EXPUNGE', [b'2']), ('EXPUNGE', [b'1']), ('RECENT', [b'0'])]
```

小訣竅

The `IDLE` context's maximum duration, as passed to *IMAP4.idle()*, is respected when waiting for the first response in a burst. Therefore, an expired `Idler` will cause this generator to return immediately without producing anything. Callers should consider this if using it in a loop.

備🄵

The iterator returned by *IMAP4.idle()* is usable only within a `with` statement. Before or after that context, unsolicited responses are collected internally whenever a command finishes, and can be retrieved with *IMAP4.response()*.

備🄵

The `Idler` class name and structure are internal interfaces, subject to change. Calling code can rely on its context management, iteration, and public method to remain stable, but should not subclass, instantiate, compare, or otherwise directly reference the class.

在 3.14 版被加入.

`IMAP4.`**`list`**`(`[*directory*[, *pattern*]]`)`

List mailbox names in *directory* matching *pattern*. *directory* defaults to the top-level mail folder, and *pattern* defaults to match anything. Returned data contains a list of `LIST` responses.

`IMAP4.`**`login`**`(`*user*, *password*`)`

Identify the client using a plaintext password. The *password* will be quoted.

`IMAP4.`**`login_cram_md5`**`(`*user*, *password*`)`

Force use of `CRAM-MD5` authentication when identifying the client to protect the password. Will only work if the server `CAPABILITY` response includes the phrase `AUTH=CRAM-MD5`.

在 3.14 版的變更: An *`IMAP4.error`* is raised if MD5 support is not available.

`IMAP4.`**`logout`**`()`

Shutdown connection to server. Returns server `BYE` response.

在 3.8 版的變更: The method no longer ignores silently arbitrary exceptions.

`IMAP4.`**`lsub`**`(`*directory*='""', *pattern*='*'`)`

List subscribed mailbox names in directory matching pattern. *directory* defaults to the top level directory and *pattern* defaults to match any mailbox. Returned data are tuples of message part envelope and data.

`IMAP4.`**`myrights`**`(`*mailbox*`)`

Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

`IMAP4.`**`namespace`**`()`

Returns IMAP namespaces as defined in **RFC 2342**.

`IMAP4.`**`noop`**`()`

Send `NOOP` to server.

`IMAP4.`**`open`**`(`*host*, *port*, *timeout=None*`)`

Opens socket to *port* at *host*. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is `None`, the global default socket timeout is used. Also note that if the *timeout* parameter is set to be zero, it will raise a *`ValueError`* to reject creating a non-blocking socket. This method is implicitly called by the *`IMAP4`* constructor. The connection objects established by this method will be used in the *`IMAP4.read()`*, *`IMAP4.readline()`*, *`IMAP4.send()`*, and *`IMAP4.shutdown()`* methods. You may override this method.

引發一個附帶引數 `self`、`host`、`port` 的稽核事件 `imaplib.open`。

在 3.9 版的變更: 新增 *timeout* 參數。

`IMAP4.`**`partial`**`(`*message_num*, *message_part*, *start*, *length*`)`

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

`IMAP4.`**`proxyauth`**`(`*user*`)`

Assume authentication as *user*. Allows an authorised administrator to proxy into any user's mailbox.

`IMAP4.`**`read`**`(`*size*`)`

Reads *size* bytes from the remote server. You may override this method.

`IMAP4.`**`readline`**`()`

Reads one line from the remote server. You may override this method.

IMAP4.**recent**()

Prompt server for an update. Returned data is `None` if no new messages, else value of `RECENT` response.

IMAP4.**rename**(*oldmailbox*, *newmailbox*)

Rename mailbox named *oldmailbox* to *newmailbox*.

IMAP4.**response**(*code*)

Return data for response *code* if received, or `None`. Returns the given code, instead of the usual type.

IMAP4.**search**(*charset*, *criterion*[, ...])

Search mailbox for matching messages. *charset* may be `None`, in which case no `CHARSET` will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error. *charset* must be `None` if the `UTF8=ACCEPT` capability was enabled using the *enable()* command.

範例:

```
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '"LDJ"')

# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

IMAP4.**select**(*mailbox='INBOX'*, *readonly=False*)

Select a mailbox. Returned data is the count of messages in *mailbox* (`EXISTS` response). The default *mailbox* is `'INBOX'`. If the *readonly* flag is set, modifications to the mailbox are not allowed.

IMAP4.**send**(*data*)

Sends `data` to the remote server. You may override this method.

引發一個附帶引數 `self`、`data` 的稽核事件 `imaplib.send`。

IMAP4.**setacl**(*mailbox*, *who*, *what*)

Set an `ACL` for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.**setannotation**(*mailbox*, *entry*, *attribute*[, ...])

Set `ANNOTATION`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.**setquota**(*root*, *limits*)

Set the `quota` *root*'s resource *limits*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.**shutdown**()

Close connection established in `open`. This method is implicitly called by *IMAP4.logout()*. You may override this method.

IMAP4.**socket**()

Returns socket instance used to connect to server.

IMAP4.**sort**(*sort_criteria*, *charset*, *search_criterion*[, ...])

The `sort` command is a variant of `search` with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the *search_criterion* argument(s); a parenthesized list of *sort_criteria*, and the searching *charset*. Note that unlike `search`, the searching *charset* argument is mandatory. There is also a `uid sort` command which corresponds to `sort` the way that `uid search` corresponds to `search`. The `sort` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an `IMAP4rev1` extension command.

IMAP4.**starttls**(*ssl_context=None*)

Send a STARTTLS command. The *ssl_context* argument is optional and should be a *ssl.SSLContext* object. This will enable encryption on the IMAP connection. Please read *Security considerations* for best practices.

在 3.2 版被加入.

在 3.4 版的變更: The method now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

IMAP4.**status**(*mailbox*, *names*)

Request named status conditions for *mailbox*.

IMAP4.**store**(*message_set*, *command*, *flag_list*)

Alters flag dispositions for messages in mailbox. *command* is specified by section 6.4.6 of **RFC 2060** as being one of "FLAGS", "+FLAGS", or "-FLAGS", optionally with a suffix of ".SILENT".

For example, to set the delete flag on all messages:

```
typ, data = M.search(None, 'ALL')
for num in data[0].split():
   M.store(num, '+FLAGS', '\\Deleted')
M.expunge()
```

備🄵

Creating flags containing ']' (for example: "[test]") violates **RFC 3501** (the IMAP protocol). However, imaplib has historically allowed creation of such tags, and popular IMAP servers, such as Gmail, accept and produce such flags. There are non-Python programs which also create such tags. Although it is an RFC violation and IMAP clients and servers are supposed to be strict, imaplib still continues to allow such tags to be created for backward compatibility reasons, and as of Python 3.6, handles them if they are sent from the server, since this improves real-world compatibility.

IMAP4.**subscribe**(*mailbox*)

Subscribe to new mailbox.

IMAP4.**thread**(*threading_algorithm*, *charset*, *search_criterion*[, ...])

The thread command is a variant of search with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the *search_criterion* argument(s); a *threading_algorithm*, and the searching *charset*. Note that unlike search, the searching *charset* argument is mandatory. There is also a uid thread command which corresponds to thread the way that uid search corresponds to search. The thread command first searches the mailbox for messages that match the given searching criteria using the *charset* argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

IMAP4.**uid**(*command*, *arg*[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

IMAP4.**unsubscribe**(*mailbox*)

Unsubscribe from old mailbox.

IMAP4.**unselect**()

imaplib.IMAP4.unselect() frees server's resources associated with the selected mailbox and returns the server to the authenticated state. This command performs the same actions as *imaplib.IMAP4.close()*, except that no messages are permanently removed from the currently selected mailbox.

在 3.9 版被加入.

IMAP4.**xatom**(*name*[, ...])

Allow simple extension commands notified by server in CAPABILITY response.

The following attributes are defined on instances of *IMAP4*:

IMAP4.**PROTOCOL_VERSION**

The most recent supported protocol in the CAPABILITY response from the server.

IMAP4.**debug**

Integer value to control debugging output. The initialize value is taken from the module variable Debug. Values greater than three trace each command.

IMAP4.**utf8_enabled**

Boolean value that is normally False, but is set to True if an *enable()* command is successfully issued for the UTF8=ACCEPT capability.

在 3.5 版被加入.

22.13.2 IMAP4 范例

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```
import getpass, imaplib

M = imaplib.IMAP4(host='example.org')
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print('Message %s\n%s\n' % (num, data[0][1]))
M.close()
M.logout()
```

22.14 smtplib --- SMTP 協定用🄵端

原始碼： Lib/smtplib.py

The *smtplib* module defines an SMTP client session object that can be used to send mail to any internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult **RFC 821** (Simple Mail Transfer Protocol) and **RFC 1869** (SMTP Service Extensions).

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

class smtplib.**SMTP**(*host=''*, *port=0*, *local_hostname=None*, [*timeout*,]*source_address=None*)

An *SMTP* instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional *host* and *port* parameters are given, the SMTP *connect()* method is called with those parameters during initialization. If specified, *local_hostname* is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using *socket.getfqdn()*. If the *connect()* call returns anything other than a success code, an *SMTPConnectError* is raised. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt

(if not specified, the global default timeout setting will be used). If the timeout expires, `TimeoutError` is raised. The optional *source_address* parameter allows binding to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple `(host, port)`, for the socket to bind to as its source address before connecting. If omitted (or if *host* or *port* are `''` and/or `0` respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/connect, `sendmail()`, and `SMTP.quit()` methods. An example is included below.

The `SMTP` class supports the `with` statement. When used like this, the SMTP `QUIT` command is issued automatically when the `with` statement exits. E.g.:

```
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...     smtp.noop()
...
(250, b'Ok')
>>>
```

所有指令都會引發一個附帶引數 `self`、`data` 的稽核事件 `smtplib.SMTP.send`，其中 `data` 🄵即將傳送至遠端的位元組。

在 3.3 版的變更: Support for the `with` statement was added.

在 3.3 版的變更: 新增 source_address 引數。

在 3.5 版被加入: The SMTPUTF8 extension (**RFC 6531**) is now supported.

在 3.9 版的變更: If the *timeout* parameter is set to be zero, it will raise a `ValueError` to prevent the creation of a non-blocking socket.

class smtplib.**SMTP_SSL**(*host=''*, *port=0*, *local_hostname=None*, ***, [*timeout*,]*context=None*, *source_address=None*)

An `SMTP_SSL` instance behaves exactly the same as instances of `SMTP`. `SMTP_SSL` should be used for situations where SSL is required from the beginning of the connection and using `starttls()` is not appropriate. If *host* is not specified, the local host is used. If *port* is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments *local_hostname*, *timeout* and *source_address* have the same meaning as they do in the `SMTP` class. *context*, also optional, can contain a `SSLContext` and allows configuring various aspects of the secure connection. Please read *Security considerations* for best practices.

在 3.3 版的變更: 新增 *context*。

在 3.3 版的變更: 新增 *source_address* 引數。

在 3.4 版的變更: The class now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

在 3.9 版的變更: If the *timeout* parameter is set to be zero, it will raise a `ValueError` to prevent the creation of a non-blocking socket

在 3.12 版的變更: The deprecated *keyfile* and *certfile* parameters have been removed.

class smtplib.**LMTP**(*host=''*, *port=LMTP_PORT*, *local_hostname=None*, *source_address=None*[, *timeout*])

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It's common to use Unix sockets for LMTP, so our `connect()` method must support that as well as a regular host:port server. The optional arguments *local_hostname* and *source_address* have the same meaning as they do in the `SMTP` class. To specify a Unix socket, you must use an absolute path for *host*, starting with a '/'.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don't support or require any authentication, but your mileage might vary.

在 3.9 版的變更: 新增 *timeout* 選用參數。

A nice selection of exceptions is defined as well:

exception smtplib.**SMTPException**

Subclass of *OSError* that is the base exception class for all the other exceptions provided by this module.

在 3.4 版的變更: SMTPException became subclass of *OSError*

exception smtplib.**SMTPServerDisconnected**

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the *SMTP* instance before connecting it to a server.

exception smtplib.**SMTPResponseException**

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

exception smtplib.**SMTPSenderRefused**

Sender address refused. In addition to the attributes set by on all *SMTPResponseException* exceptions, this sets 'sender' to the string that the SMTP server refused.

exception smtplib.**SMTPRecipientsRefused**

All recipient addresses refused. The errors for each recipient are accessible through the attribute `recipients`, which is a dictionary of exactly the same sort as *SMTP.sendmail()* returns.

exception smtplib.**SMTPDataError**

The SMTP server refused to accept the message data.

exception smtplib.**SMTPConnectError**

Error occurred during establishment of a connection with the server.

exception smtplib.**SMTPHeloError**

The server refused our `HELO` message.

exception smtplib.**SMTPNotSupportedError**

The command or option attempted is not supported by the server.

在 3.5 版被加入.

exception smtplib.**SMTPAuthenticationError**

SMTP authentication went wrong. Most probably the server didn't accept the username/password combination provided.

也參考

RFC 821 - Simple Mail Transfer Protocol
Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

RFC 1869 - SMTP Service Extensions
Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.

22.14.1 SMTP 物件

SMTP 實例擁有以下方法:

SMTP.**set_debuglevel**(*level*)

Set the debug output level. A value of 1 or `True` for *level* results in debug messages for connection and for all messages sent to and received from the server. A value of 2 for *level* results in these messages being timestamped.

在 3.5 版的變更: Added debuglevel 2.

SMTP.**docmd**(*cmd*, *args=''*)

Send a command *cmd* to the server. The optional argument *args* is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, *SMTPServerDisconnected* will be raised.

SMTP.**connect**(*host='localhost'*, *port=0*)

Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (`':'`) followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

引發一個附帶引數 `self`、`host`、`port` 的稽核事件 `smtplib.connect`。

SMTP.**helo**(*name=''*)

Identify yourself to the SMTP server using `HELO`. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the `helo_resp` attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the *sendmail()* when necessary.

SMTP.**ehlo**(*name=''*)

Identify yourself to an ESMTP server using `EHLO`. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by *has_extn()*. Also sets several informational attributes: the message returned by the server is stored as the `ehlo_resp` attribute, `does_esmtp` is set to `True` or `False` depending on whether the server supports ESMTP, and `esmtp_features` will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use *has_extn()* before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by *sendmail()* when necessary.

SMTP.**ehlo_or_helo_if_needed**()

This method calls *ehlo()* and/or *helo()* if there has been no previous `EHLO` or `HELO` command this session. It tries ESMTP `EHLO` first.

SMTPHeloError
The server didn't reply properly to the `HELO` greeting.

SMTP.**has_extn**(*name*)

Return *True* if *name* is in the set of SMTP service extensions returned by the server, *False* otherwise. Case is ignored.

SMTP.**verify**(*address*)

Check the validity of an address on this server using SMTP `VRFY`. Returns a tuple consisting of code 250 and a full **RFC 822** address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

> **備🄵**
>
> Many sites disable SMTP `VRFY` in order to foil spammers.

SMTP.**login**(*user*, *password*, ***, *initial_response_ok=True*)

Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous `EHLO` or `HELO` command this session, this method tries

ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

SMTPHeloError
The server didn't reply properly to the HELO greeting.

SMTPAuthenticationError
The server didn't accept the username/password combination.

SMTPNotSupportedError
The AUTH command is not supported by the server.

SMTPException
No suitable authentication method was found.

Each of the authentication methods supported by *smtplib* are tried in turn if they are advertised as supported by the server. See *auth()* for a list of supported authentication methods. *initial_response_ok* is passed through to *auth()*.

Optional keyword argument *initial_response_ok* specifies whether, for authentication methods that support it, an "initial response" as specified in **RFC 4954** can be sent along with the AUTH command, rather than requiring a challenge/response.

在 3.5 版的變更: *SMTPNotSupportedError* may be raised, and the *initial_response_ok* parameter was added.

SMTP.**auth**(*mechanism*, *authobject*, *, *initial_response_ok=True*)

Issue an SMTP AUTH command for the specified authentication *mechanism*, and handle the challenge response via *authobject*.

mechanism specifies which authentication mechanism is to be used as argument to the AUTH command; the valid values are those listed in the auth element of esmtp_features.

authobject must be a callable object taking an optional single argument:

```
data = authobject(challenge=None)
```

If optional keyword argument *initial_response_ok* is true, authobject() will be called first with no argument. It can return the **RFC 4954** "initial response" ASCII str which will be encoded and sent with the AUTH command as below. If the authobject() does not support an initial response (e.g. because it requires a challenge), it should return None when called with challenge=None. If *initial_response_ok* is false, then authobject() will not be called first with None.

If the initial response check returns None, or if *initial_response_ok* is false, authobject() will be called to process the server's challenge response; the *challenge* argument it is passed will be a bytes. It should return ASCII str *data* that will be base64 encoded and sent to the server.

The SMTP class provides authobjects for the CRAM-MD5, PLAIN, and LOGIN mechanisms; they are named SMTP.auth_cram_md5, SMTP.auth_plain, and SMTP.auth_login respectively. They all require that the user and password properties of the SMTP instance are set to appropriate values.

User code does not normally need to call auth directly, but can instead call the *login()* method, which will try each of the above mechanisms in turn, in the order listed. auth is exposed to facilitate the implementation of authentication methods not (or not yet) supported directly by *smtplib*.

在 3.5 版被加入.

SMTP.**starttls**(*, *context=None*)

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call *ehlo()* again.

If *keyfile* and *certfile* are provided, they are used to create an *ssl.SSLContext*.

Optional *context* parameter is an *ssl.SSLContext* object; This is an alternative to using a keyfile and a certfile and if specified both *keyfile* and *certfile* should be None.

If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first.

在 3.12 版的變更: The deprecated *keyfile* and *certfile* parameters have been removed.

SMTPHeloError
The server didn't reply properly to the `HELO` greeting.

SMTPNotSupportedError
The server does not support the STARTTLS extension.

RuntimeError
SSL/TLS support is not available to your Python interpreter.

在 3.3 版的變更: 新增 *context*。

在 3.4 版的變更: The method now supports hostname check with `SSLContext.check_hostname` and *Server Name Indicator* (see *HAS_SNI*).

在 3.5 版的變更: The error raised for lack of STARTTLS support is now the *SMTPNotSupportedError* subclass instead of the base *SMTPException*.

`SMTP.`**`sendmail`**(*from_addr*, *to_addrs*, *msg*, *mail_options=()*, *rcpt_options=()*)

Send mail. The required arguments are an **RFC 822** from-address string, a list of **RFC 822** to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used in `MAIL FROM` commands as *mail_options*. ESMTP options (such as `DSN` commands) that should be used with all `RCPT` commands can be passed as *rcpt_options*. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message.)

> **備🄵**
>
> The *from_addr* and *to_addrs* parameters are used to construct the message envelope used by the transport agents. `sendmail` does not modify the message headers in any way.

msg may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone `\r` and `\n` characters are converted to `\r\n` characters. A byte string is not modified.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

If `SMTPUTF8` is included in *mail_options*, and the server supports it, *from_addr* and *to_addrs* may contain non-ASCII characters.

This method may raise the following exceptions:

SMTPRecipientsRefused
All recipients were refused. Nobody got the mail. The `recipients` attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

SMTPHeloError
The server didn't reply properly to the `HELO` greeting.

SMTPSenderRefused
The server didn't accept the *from_addr*.

SMTPDataError
The server replied with an unexpected error code (other than a refusal of a recipient).

SMTPNotSupportedError
SMTPUTF8 was given in the *mail_options* but is not supported by the server.

Unless otherwise noted, the connection will be open even after an exception is raised.

在 3.2 版的變更: *msg* may be a byte string.

在 3.5 版的變更: SMTPUTF8 support added, and *SMTPNotSupportedError* may be raised if SMTPUTF8 is specified but the server does not support it.

SMTP.**send_message**(*msg*, *from_addr=None*, *to_addrs=None*, *mail_options=()*, *rcpt_options=()*)

This is a convenience method for calling *sendmail()* with the message represented by an *email.message.Message* object. The arguments have the same meaning as for *sendmail()*, except that *msg* is a Message object.

If *from_addr* is None or *to_addrs* is None, send_message fills those arguments with addresses extracted from the headers of *msg* as specified in **RFC 5322**: *from_addr* is set to the *Sender* field if it is present, and otherwise to the *From* field. *to_addrs* combines the values (if any) of the *To*, *Cc*, and *Bcc* fields from *msg*. If exactly one set of *Resent-** headers appear in the message, the regular headers are ignored and the *Resent-** headers are used instead. If the message contains more than one set of *Resent-** headers, a *ValueError* is raised, since there is no way to unambiguously detect the most recent set of *Resent-* headers.

send_message serializes *msg* using *BytesGenerator* with \r\n as the *linesep*, and calls *sendmail()* to transmit the resulting message. Regardless of the values of *from_addr* and *to_addrs*, send_message does not transmit any *Bcc* or *Resent-Bcc* headers that may appear in *msg*. If any of the addresses in *from_addr* and *to_addrs* contain non-ASCII characters and the server does not advertise SMTPUTF8 support, an *SMTPNotSupportedError* is raised. Otherwise the Message is serialized with a clone of its *policy* with the *utf8* attribute set to True, and SMTPUTF8 and BODY=8BITMIME are added to *mail_options*.

在 3.2 版被加入.

在 3.5 版被加入: Support for internationalized addresses (SMTPUTF8).

SMTP.**quit**()

Terminate the SMTP session and close the connection. Return the result of the SMTP QUIT command.

Low-level methods corresponding to the standard SMTP/ESMTP commands HELP, RSET, NOOP, MAIL, RCPT, and DATA are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.

22.14.2 SMTP 范例

This example prompts the user for addresses needed in the message envelope ('To' and 'From' addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn't do any processing of the **RFC 822** headers. In particular, the 'To' and 'From' addresses must be included in the message headers explicitly:

```
import smtplib

def prompt(title):
    return input(title).strip()

from_addr = prompt("From: ")
to_addrs  = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows):")

# Add the From: and To: headers at the start!
lines = [f"From: {from_addr}", f"To: {', '.join(to_addrs)}", ""]
while True:
    try:
        line = input()
    except EOFError:
        break
```

(繼續下一頁)

(繼續上一頁)

```
    else:
        lines.append(line)

msg = "\r\n".join(lines)
print("Message length is", len(msg))

server = smtplib.SMTP("localhost")
server.set_debuglevel(1)
server.sendmail(from_addr, to_addrs, msg)
server.quit()
```

備🄵

In general, you will want to use the *email* package's features to construct an email message, which you can then send via *send_message()*; see *email: 範例*.

22.15 uuid --- RFC 9562 定義的 UUID 物件

原始碼： Lib/uuid.py

This module provides immutable *UUID* objects (the *UUID* class) and *functions* for generating UUIDs corresponding to a specific UUID version as specified in **RFC 9562** (which supersedes **RFC 4122**), for example, *uuid1()* for UUID version 1, *uuid3()* for UUID version 3, and so on. Note that UUID version 2 is deliberately omitted as it is outside the scope of the RFC.

如果你只需要一個唯一的 ID，你應該呼叫*uuid1()* 或*uuid4()*。需要注意的是，*uuid1()* 可能會危害隱私，因🄵它會建立一個包含了電腦網路位址的 UUID。而*uuid4()* 則會建立一個隨機的 UUID。

根據底層平台的支援情🄵，*uuid1()* 可能會也可能不會回傳一個「安全的」UUID。安全的 UUID 是使用同步方法生成的，以確保不會有兩個行程取得到相同的 UUID。所有*UUID* 的實例都有一個*is_safe* 屬性，該屬性使用下面這個列舉來傳遞有關 UUID 安全性的任何資訊：

class uuid.**SafeUUID**

在 3.7 版被加入.

safe

該 UUID 是由平台以多行程安全的 (multiprocessing-safe) 方式生成的。

unsafe

該 UUID 不是以多行程安全的方式生成的。

unknown

該平台不提供 UUID 是否🄵安全生成的資訊。

class uuid.**UUID**(*hex=None*, *bytes=None*, *bytes_le=None*, *fields=None*, *int=None*, *version=None*, ***, *is_safe=SafeUUID.unknown*)

從以下其中一種引數來建立 UUID：由 32 個十六進位的數字組成的字串、以大端順序 (big-endian) 排列的 16 個位元組組成的字串作🄵 *bytes* 引數、以小端順序 (little-endian) 排列的 16 個位元組組成的字串作🄵 *bytes_le* 引數、由 6 個整數（32 位元的 *time_low*、16 位元的 *time_mid*、16 位元的 *time_hi_version*、8 位元的 *clock_seq_hi_variant*、8 位元的 *clock_seq_low*、48 位元的 *node*）組成的元組 (tuple) 作🄵 *fields* 引數，或者是單一的 128 位元整數作🄵 *int* 引數。當給定由十六進位的數字組成的字串時，大括號、連字符號和 URN 前綴都是可以選用的。例如，以下這些運算式都會🄵生相同的 UUID：

```
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes=b'\x12\x34\x56\x78'*4)
UUID(bytes_le=b'\x78\x56\x34\x12\x34\x12\x78\x56' +
              b'\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x34, 0x567812345678))
UUID(int=0x12345678123456781234567812345678)
```

必須正好給定其中一個引數 *hex*、*bytes*、*bytes_le*、*fields* 或 *int*。*version* 引數是選用的；如果給定了該引數，生成的 UUID 將根據 **RFC 9562** 設置其變體 (variant) 和版本號，覆蓋掉給定的 *hex*、*bytes*、*bytes_le*、*fields* 或 *int* 中的位元。

UUID 物件之間的比較是透過比較它們的*UUID.int* 屬性。與非 UUID 的物件進行比較會引發*TypeError*。

`str(uuid)` 會回傳一個像是 `12345678-1234-5678-1234-567812345678` 形式的字串，其中 32 個十六進位的數字代表 UUID。

UUID 實例有以下唯讀的屬性：

UUID.bytes

UUID 以 16 位元組的字串表示（包含 6 個整數欄位，按照大端位元組順序排列）。

UUID.bytes_le

UUID 以 16 位元組的字串表示（其中 *time_low*、*time_mid* 和 *time_hi_version* 按照小端位元組順序排列）。

UUID.fields

UUID 以 6 個整數欄位所組成的元組表示，也可以看作有 6 個個🄵屬性和 2 個衍生屬性：

欄位	意義
UUID.time_low	UUID 的前 32 位元。只與版本 1 有關。
UUID.time_mid	UUID 接下來的 16 位元。只與版本 1 有關。
UUID.time_hi_version	UUID 接下來的 16 位元。只與版本 1 有關。
UUID.clock_seq_hi_variant	UUID 接下來的 8 位元。只與版本 1 和 6 有關。
UUID.clock_seq_low	UUID 接下來的 8 位元。只與版本 1 和 6 有關。
UUID.node	UUID 最後的 48 位元。只與版本 1 有關。
UUID.time	The 60-bit timestamp as a count of 100-nanosecond intervals since Gregorian epoch (1582-10-15 00:00:00) for versions 1 and 6, or the 48-bit timestamp in milliseconds since Unix epoch (1970-01-01 00:00:00) for version 7.
UUID.clock_seq	14 位元的序列號。只與版本 1 和 6 有關。

UUID.**hex**
UUID 以 32 個小寫十六進位字元組成的字串表示。

UUID.**int**
UUID 以 128 位元的整數表示。

UUID.**urn**
UUID 以 **RFC 9562** 中指定的 URN 形式表示。

UUID.**variant**
UUID 的變體，🄵定 UUID 🄵部的🄵局 (layout)，是*RESERVED_NCS*、*RFC_4122*、*RESERVED_MICROSOFT* 或*RESERVED_FUTURE* 其中一個常數。

UUID.**version**
UUID 的版本號（1 到 8，只有當變體是*RFC_4122* 時才有意義）。

在 3.14 版的變更: 新增了 UUID 版本 6、7 和 8。

UUID.**is_safe**
SafeUUID 的列舉，表示平台是否以多行程安全的方式🄵生 UUID。

在 3.7 版被加入.

uuid 模組定義了以下函式:

uuid.**getnode**()
取得 48 位元正整數形式的硬體位址。第一次執行時，有可能會🄵動一個獨立的程式，這也許會相當耗時。如果所有取得硬體位址的嘗試都失敗，我們會根據 **RFC 4122** 中的建議，使用一個 48 位元的隨機數，其中群播位元 (multicast bit)（第一個八位元組的最低有效位）設置🄵 1。「硬體位址」指的是網路介面 (network interface) 的 MAC 位址。在具有多個網路介面的機器上，將優先選擇通用管理 (universally administered) 的 MAC 位址（即第一個八位元組的第二個最低有效位是 未設置的），而不是本地管理 (locally administered) 的 MAC 位址，除此之外不保證任何選擇的順序。

在 3.7 版的變更: 通用管理的 MAC 位址優於本地管理的 MAC 位址，因🄵前者保證是全球唯一的，而後者不是。

uuid.**uuid1**(*node=None*, *clock_seq=None*)
Generate a UUID from a host ID, sequence number, and the current time according to **RFC 9562, §5.1**.

When *node* is not specified, *getnode()* is used to obtain the hardware address as a 48-bit positive integer. When a sequence number *clock_seq* is not specified, a pseudo-random 14-bit positive integer is generated.

If *node* or *clock_seq* exceed their expected bit count, only their least significant bits are kept.

uuid.**uuid3**(*namespace*, *name*)
根據 **RFC 9562, §5.3**，基於命名空間識🄵碼 (namespace identifier)（一個 UUID）和名稱（一個*bytes* 物件或使用 UTF-8 編碼的字串）的 MD5 hash 來生成 UUID。

uuid.**uuid4**()
Generate a random UUID in a cryptographically-secure method according to **RFC 9562, §5.4**.

uuid.**uuid5**(*namespace*, *name*)
根據 **RFC 9562, §5.5**，基於命名空間識🄵碼（一個 UUID）和名稱（一個*bytes* 物件或使用 UTF-8 編碼的字串）的 SHA-1 hash 來生成 UUID。

uuid.**uuid6**(*node=None*, *clock_seq=None*)
Generate a UUID from a sequence number and the current time according to **RFC 9562, §5.6**.

This is an alternative to *uuid1()* to improve database locality.

When *node* is not specified, *getnode()* is used to obtain the hardware address as a 48-bit positive integer. When a sequence number *clock_seq* is not specified, a pseudo-random 14-bit positive integer is generated.

If *node* or *clock_seq* exceed their expected bit count, only their least significant bits are kept.

在 3.14 版被加入.

uuid.**uuid7**()

Generate a time-based UUID according to **RFC 9562, §5.7**.

For portability across platforms lacking sub-millisecond precision, UUIDs produced by this function embed a 48-bit timestamp and use a 42-bit counter to guarantee monotonicity within a millisecond.

在 3.14 版被加入.

uuid.**uuid8**(*a=None*, *b=None*, *c=None*)

Generate a pseudo-random UUID according to **RFC 9562, §5.8**.

When specified, the parameters *a*, *b* and *c* are expected to be positive integers of 48, 12 and 62 bits respectively. If they exceed their expected bit count, only their least significant bits are kept; non-specified arguments are substituted for a pseudo-random integer of appropriate size.

By default, *a*, *b* and *c* are not generated by a cryptographically secure pseudo-random number generator (CSPRNG). Use *uuid4()* when a UUID needs to be used in a security-sensitive context.

在 3.14 版被加入.

uuid 模組🄵*uuid3()* 或*uuid5()* 定義了以下的命名空間識🄵碼。

uuid.**NAMESPACE_DNS**

當指定這個命名空間時，*name* 字串是一個完整網域名稱 (fully qualified domain name)。

uuid.**NAMESPACE_URL**

當指定這個命名空間時，*name* 字串是一個 URL。

uuid.**NAMESPACE_OID**

當指定這個命名空間時，*name* 字串是一個 ISO OID。

uuid.**NAMESPACE_X500**

當指定這個命名空間時，*name* 字串是以 DER 或文字輸出格式表示的 X.500 DN。

uuid 模組🄵*variant* 屬性的可能值定義了以下常數：

uuid.**RESERVED_NCS**

保留供 NCS 相容性使用。

uuid.**RFC_4122**

Specifies the UUID layout given in **RFC 4122**. This constant is kept for backward compatibility even though **RFC 4122** has been superseded by **RFC 9562**.

uuid.**RESERVED_MICROSOFT**

保留供 Microsoft 相容性使用。

uuid.**RESERVED_FUTURE**

保留供未來定義使用。

uuid 模組定義了特殊的 Nil 和 Max UUID 值：

uuid.**NIL**

A special form of UUID that is specified to have all 128 bits set to zero according to **RFC 9562, §5.9**.

在 3.14 版被加入.

uuid.**MAX**

A special form of UUID that is specified to have all 128 bits set to one according to **RFC 9562, §5.10**.

在 3.14 版被加入.

也參考

RFC 9562 - 通用唯一辨識碼 (UUID, Universally Unique IDentifier) 的 URN 命名空間
這個規範定義了 UUID 的統一資源名稱 (Uniform Resource Name) 命名空間、UUID 的🄵部格式和生成 UUID 的方法。

22.15.1 命令列的用法

在 3.12 版被加入.

uuid 模組可以在命令列下作🄵🄵本來執行。

```
python -m uuid [-h] [-u {uuid1,uuid3,uuid4,uuid5,uuid6,uuid7,uuid8}] [-n NAMESPACE] [-N NAME]
```

可以接受以下選項:

-h, --help
顯示幫助訊息🄴退出。

-u <uuid>

--uuid <uuid>
指定要用來生成 UUID 的函式名稱。預設使用*uuid4()*。

在 3.14 版的變更: Allow generating UUID versions 6, 7 and 8.

-n <namespace>

--namespace <namespace>
該命名空間是一個 `UUID` 或 `@ns`, 其中 `ns` 是指知名預定義 UUID 的命名空間名稱, 例如 `@dns`、`@url`、`@oid` 和 `@x500`。只有*uuid3()* / *uuid5()* 函式會需要。

-N <name>

--name <name>
用於生成 uuid 的名稱。只有*uuid3()* / *uuid5()* 函式會需要。

-C <num>

--count <num>
生成 *num* 個新 UUID。

在 3.14 版被加入.

22.15.2 范例

以下是一些*uuid* 模組的典型使用範例:

```
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID and a name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID and a name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')
```

(繼續下一頁)

(繼續上一頁)

```
>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r\x0e\x0f'

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
UUID('00010203-0405-0607-0809-0a0b0c0d0e0f')

>>> # get the Nil UUID
>>> uuid.NIL
UUID('00000000-0000-0000-0000-000000000000')

>>> # get the Max UUID
>>> uuid.MAX
UUID('ffffffff-ffff-ffff-ffff-ffffffffffff')

>>> # same as UUIDv1 but with fields reordered to improve DB locality
>>> uuid.uuid6()
UUID('1f0799c0-98b9-62db-92c6-a0d365b91053')

>>> # get UUIDv7 creation (local) time as a timestamp in milliseconds
>>> u = uuid.uuid7()
>>> u.time
1743936859822

>>> # get UUIDv7 creation (local) time as a datetime object
>>> import datetime as dt
>>> dt.datetime.fromtimestamp(u.time / 1000)
datetime.datetime(...)

>>> # make a UUID with custom blocks
>>> uuid.uuid8(0x12345678, 0x9abcdef0, 0x11223344)
UUID('00001234-5678-8ef0-8000-000011223344')
```

22.15.3 命令列的范例

以下是一些*uuid*命令列介面的典型使用範例：

```
# 生成一個隨機的 UUID - 預設使用 uuid4()
$ python -m uuid

# 使用 uuid1() 生成一組 UUID
$ python -m uuid -u uuid1

# 使用 uuid5 生成一組 UUID
$ python -m uuid -u uuid5 -n @url -N example.com

# 生成 42 個隨機 UUID
$ python -m uuid -C 42
```

22.16 `socketserver` --- 用於網路伺服器的框架

原始碼： Lib/socketserver.py

The *socketserver* module simplifies the task of writing network servers.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

There are four basic concrete server classes:

class socketserver.**TCPServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*)

This uses the internet TCP protocol, which provides for continuous streams of data between the client and server. If *bind_and_activate* is true, the constructor automatically attempts to invoke *server_bind()* and *server_activate()*. The other parameters are passed to the *BaseServer* base class.

class socketserver.**UDPServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*)

This uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The parameters are the same as for *TCPServer*.

class socketserver.**UnixStreamServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*)

class socketserver.**UnixDatagramServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*)

These more infrequently used classes are similar to the TCP and UDP classes, but use Unix domain sockets; they're not available on non-Unix platforms. The parameters are the same as for *TCPServer*.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the *ForkingMixIn* and *ThreadingMixIn* mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the *BaseRequestHandler* class and overriding its *handle()* method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server's address and the request handler class. It is recommended to use the server in a `with` statement. Then call the *handle_request()* or *serve_forever()* method of the server object to process one or many requests. Finally, call *server_close()* to close the socket (unless you used a `with` statement).

When inheriting from *ThreadingMixIn* for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The *ThreadingMixIn* class defines an attribute *daemon_threads*, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is *False*, meaning that Python will not exit until all threads created by *ThreadingMixIn* have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.

22.16.1 Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+
| BaseServer |
+------------+
      |
      v
+-----------+        +------------------+
| TCPServer |------->| UnixStreamServer |
+-----------+        +------------------+
      |
```

(繼續下一頁)

(繼續上一頁)

```
      v
+-----------+         +--------------------+
| UDPServer |-------->| UnixDatagramServer |
+-----------+         +--------------------+
```

Note that *UnixDatagramServer* derives from *UDPServer*, not from *UnixStreamServer* --- the only difference between an IP and a Unix server is the address family.

class socketserver.**ForkingMixIn**

class socketserver.**ThreadingMixIn**

Forking and threading versions of each type of server can be created using these mix-in classes. For instance, *ThreadingUDPServer* is created as follows:

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer):
    pass
```

The mix-in class comes first, since it overrides a method defined in *UDPServer*. Setting the various attributes also changes the behavior of the underlying server mechanism.

ForkingMixIn and the Forking classes mentioned below are only available on POSIX platforms that support *fork()*.

block_on_close

ForkingMixIn.server_close waits until all child processes complete, except if *block_on_close* attribute is `False`.

ThreadingMixIn.server_close waits until all non-daemon threads complete, except if *block_on_close* attribute is `False`.

max_children

Specify how many child processes will exist to handle requests at a time for *ForkingMixIn*. If the limit is reached, new requests will wait until one child process has finished.

daemon_threads

For *ThreadingMixIn* use daemonic threads by setting *ThreadingMixIn.daemon_threads* to `True` to not wait until threads complete.

在 3.7 版的變更: *ForkingMixIn.server_close* and *ThreadingMixIn.server_close* now waits until all child processes and non-daemonic threads complete. Add a new *ForkingMixIn.block_on_close* class attribute to opt-in for the pre-3.7 behaviour.

class socketserver.**ForkingTCPServer**

class socketserver.**ForkingUDPServer**

class socketserver.**ThreadingTCPServer**

class socketserver.**ThreadingUDPServer**

class socketserver.**ForkingUnixStreamServer**

class socketserver.**ForkingUnixDatagramServer**

class socketserver.**ThreadingUnixStreamServer**

class socketserver.**ThreadingUnixDatagramServer**

These classes are pre-defined using the mix-in classes.

在 3.12 版被加入: The `ForkingUnixStreamServer` and `ForkingUnixDatagramServer` classes were added.

To implement a service, you must derive a class from *BaseRequestHandler* and redefine its *handle()* method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses *StreamRequestHandler* or *DatagramRequestHandler*.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process

would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service "deaf" while one request is being handled -- which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class *handle()* method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor *fork()* (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use *selectors* to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used).

22.16.2 Server Objects

class socketserver.**BaseServer**(*server_address*, *RequestHandlerClass*)

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses. The two parameters are stored in the respective *server_address* and *RequestHandlerClass* attributes.

fileno()

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to *selectors*, to allow monitoring multiple servers in the same process.

handle_request()

Process a single request. This function calls the following methods in order: *get_request()*, *verify_request()*, and *process_request()*. If the user-provided *handle()* method of the handler class raises an exception, the server's *handle_error()* method will be called. If no request is received within *timeout* seconds, *handle_timeout()* will be called and *handle_request()* will return.

serve_forever(*poll_interval=0.5*)

Handle requests until an explicit *shutdown()* request. Poll for shutdown every *poll_interval* seconds. Ignores the *timeout* attribute. It also calls *service_actions()*, which may be used by a subclass or mixin to provide actions specific to a given service. For example, the *ForkingMixIn* class uses *service_actions()* to clean up zombie child processes.

在 3.3 版的變更: Added `service_actions` call to the `serve_forever` method.

service_actions()

This is called in the *serve_forever()* loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

在 3.3 版被加入.

shutdown()

Tell the *serve_forever()* loop to stop and wait until it does. *shutdown()* must be called while *serve_forever()* is running in a different thread otherwise it will deadlock.

server_close()

Clean up the server. May be overridden.

address_family

The family of protocols to which the server's socket belongs. Common examples are *socket.AF_INET*, *socket.AF_INET6*, and *socket.AF_UNIX*. Subclass the TCP or UDP server classes in this module with class attribute `address_family = AF_INET6` set if you want IPv6 server classes.

RequestHandlerClass

The user-provided request handler class; an instance of this class is created for each request.

server_address

The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the *socket* module for details. For internet protocols, this is a tuple containing a string giving the address, and an integer port number: `('127.0.0.1', 80)`, for example.

socket

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

allow_reuse_address

Whether the server will allow the reuse of an address. This defaults to *False*, and can be set in subclasses to change the policy.

request_queue_size

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to *request_queue_size* requests. Once the queue is full, further requests from clients will get a "Connection denied" error. The default value is usually 5, but this can be overridden by subclasses.

socket_type

The type of socket used by the server; *socket.SOCK_STREAM* and *socket.SOCK_DGRAM* are two common values.

timeout

Timeout duration, measured in seconds, or *None* if no timeout is desired. If *handle_request()* receives no incoming requests within the timeout period, the *handle_timeout()* method is called.

There are various server methods that can be overridden by subclasses of base server classes like *TCPServer*; these methods aren't useful to external users of the server object.

finish_request(*request*, *client_address*)

Actually processes the request by instantiating *RequestHandlerClass* and calling its *handle()* method.

get_request()

Must accept a request from the socket, and return a 2-tuple containing the *new* socket object to be used to communicate with the client, and the client's address.

handle_error(*request*, *client_address*)

This function is called if the *handle()* method of a *RequestHandlerClass* instance raises an exception. The default action is to print the traceback to standard error and continue handling further requests.

在 3.6 版的變更: Now only called for exceptions derived from the *Exception* class.

handle_timeout()

This function is called when the *timeout* attribute has been set to a value other than *None* and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

process_request(*request*, *client_address*)

Calls *finish_request()* to create an instance of the *RequestHandlerClass*. If desired, this function can create a new process or thread to handle the request; the *ForkingMixIn* and *ThreadingMixIn* classes do this.

server_activate()

Called by the server's constructor to activate the server. The default behavior for a TCP server just invokes *listen()* on the server's socket. May be overridden.

server_bind()

Called by the server's constructor to bind the socket to the desired address. May be overridden.

verify_request(*request*, *client_address*)

Must return a Boolean value; if the value is `True`, the request will be processed, and if it's `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`.

在 3.6 版的變更: Support for the *context manager* protocol was added. Exiting the context manager is equivalent to calling `server_close()`.

22.16.3 Request Handler Objects

class socketserver.**BaseRequestHandler**

This is the superclass of all request handler objects. It defines the interface, given below. A concrete request handler subclass must define a new `handle()` method, and can override any of the other methods. A new instance of the subclass is created for each request.

setup()

Called before the `handle()` method to perform any initialization actions required. The default implementation does nothing.

handle()

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as `request`; the client address as `client_address`; and the server instance as `server`, in case it needs access to per-server information.

The type of `request` is different for datagram or stream services. For stream services, `request` is a socket object; for datagram services, `request` is a pair of string and socket.

finish()

Called after the `handle()` method to perform any clean-up actions required. The default implementation does nothing. If `setup()` raises an exception, this function will not be called.

request

The *new* `socket.socket` object to be used to communicate with the client.

client_address

Client address returned by `BaseServer.get_request()`.

server

`BaseServer` object used for handling the request.

class socketserver.**StreamRequestHandler**

class socketserver.**DatagramRequestHandler**

These `BaseRequestHandler` subclasses override the `setup()` and `finish()` methods, and provide `rfile` and `wfile` attributes.

rfile

A file object from which receives the request is read. Support the `io.BufferedIOBase` readable interface.

wfile

A file object to which the reply is written. Support the `io.BufferedIOBase` writable interface

在 3.6 版的變更: `wfile` also supports the `io.BufferedIOBase` writable interface.

22.16.4 范例

socketserver.TCPServer 范例

This is the server side:

```
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    """
    The request handler class for our server.

    It is instantiated once per connection to the server, and must
    override the handle() method to implement communication to the
    client.
    """

    def handle(self):
        # self.request is the TCP socket connected to the client
        pieces = [b'']
        total = 0
        while b'\n' not in pieces[-1] and total < 10_000:
            pieces.append(self.request.recv(2000))
            total += len(pieces[-1])
        self.data = b''.join(pieces)
        print(f"Received from {self.client_address[0]}:")
        print(self.data.decode("utf-8"))
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())
        # after we return, the socket will be closed.

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    with socketserver.TCPServer((HOST, PORT), MyTCPHandler) as server:
        # Activate the server; this will keep running until you
        # interrupt the program with Ctrl-C
        server.serve_forever()
```

An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```
class MyTCPHandler(socketserver.StreamRequestHandler):

    def handle(self):
        # self.rfile is a file-like object created by the handler.
        # We can now use e.g. readline() instead of raw recv() calls.
        # We limit ourselves to 10000 bytes to avoid abuse by the sender.
        self.data = self.rfile.readline(10000).rstrip()
        print(f"{self.client_address[0]} wrote:")
        print(self.data.decode("utf-8"))
        # Likewise, self.wfile is a file-like object used to write back
        # to the client
        self.wfile.write(self.data.upper())
```

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the first handler had to use a `recv()` loop to accumulate data until a newline itself. If it had just used a single `recv()` without the loop it would just have returned what has been received so far from the client. TCP is stream based: data arrives in the order it was sent, but there no correlation between client `send()` or `sendall()` calls and the number of `recv()` calls on the server required to receive it.

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
```

(繼續下一頁)

(繼續上一頁)

```
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as sock:
    # Connect to server and send data
    sock.connect((HOST, PORT))
    sock.sendall(bytes(data, "utf-8"))
    sock.sendall(b"\n")

    # Receive data from the server and shut down
    received = str(sock.recv(1024), "utf-8")

print("Sent:     ", data)
print("Received:", received)
```

The output of the example should look something like this:

Server:

```
$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'
```

Client:

```
$ python TCPClient.py hello world with TCP
Sent:     hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent:     python is nice
Received: PYTHON IS NICE
```

`socketserver.UDPServer` 范例

This is the server side:

```
import socketserver

class MyUDPHandler(socketserver.BaseRequestHandler):
    """
    This class works similar to the TCP handler class, except that
    self.request consists of a pair of data and client socket, and since
    there is no connection the client address must be given explicitly
    when sending data back via sendto().
    """

    def handle(self):
        data = self.request[0].strip()
        socket = self.request[1]
        print(f"{self.client_address[0]} wrote:")
        print(data)
        socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    with socketserver.UDPServer((HOST, PORT), MyUDPHandler) as server:
        server.serve_forever()
```

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has no connections.
# Instead, data is directly sent to the recipient via sendto().
sock.sendto(bytes(data + "\n", "utf-8"), (HOST, PORT))
received = str(sock.recv(1024), "utf-8")

print("Sent:     ", data)
print("Received:", received)
```

The output of the example should look exactly like for the TCP server example.

Asynchronous Mixins

To build asynchronous handlers, use the *ThreadingMixIn* and *ForkingMixIn* classes.

An example for the *ThreadingMixIn* class:

```
import socket
import threading
import socketserver

class ThreadedTCPRequestHandler(socketserver.BaseRequestHandler):

    def handle(self):
        data = str(self.request.recv(1024), 'ascii')
        cur_thread = threading.current_thread()
        response = bytes("{}: {}".format(cur_thread.name, data), 'ascii')
        self.request.sendall(response)

class ThreadedTCPServer(socketserver.ThreadingMixIn, socketserver.TCPServer):
    pass

def client(ip, port, message):
    with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as sock:
        sock.connect((ip, port))
        sock.sendall(bytes(message, 'ascii'))
        response = str(sock.recv(1024), 'ascii')
        print("Received: {}".format(response))

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    with server:
        ip, port = server.server_address

        # Start a thread with the server -- that thread will then start one
        # more thread for each request
        server_thread = threading.Thread(target=server.serve_forever)
        # Exit the server thread when the main thread terminates
        server_thread.daemon = True
        server_thread.start()
        print("Server loop running in thread:", server_thread.name)
```

(繼續下一頁)

(繼續上一頁)

```
        client(ip, port, "Hello World 1")
        client(ip, port, "Hello World 2")
        client(ip, port, "Hello World 3")

        server.shutdown()
```

The output of the example should look something like this:

```
$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3
```

The *ForkingMixIn* class is used in the same way, except that the server will spawn a new process for each request. Available only on POSIX platforms that support *fork()*.

22.17 http.server —HTTP 伺服器

原始碼： Lib/http/server.py

此模組定義了用於實作 HTTP 伺服器的類🄴。

> **⚠ 警告**
>
> *http.server* is not recommended for production. It only implements *basic security checks*.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄴*WebAssembly 平台*。

One class, *HTTPServer*, is a *socketserver.TCPServer* subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```
def run(server_class=HTTPServer, handler_class=BaseHTTPRequestHandler):
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

class http.server.**HTTPServer**(*server_address*, *RequestHandlerClass*)

This class builds on the *TCPServer* class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler's `server` instance variable.

class http.server.**ThreadingHTTPServer**(*server_address*, *RequestHandlerClass*)

This class is identical to HTTPServer but uses threads to handle requests by using the *ThreadingMixIn*. This is useful to handle web browsers pre-opening sockets, on which *HTTPServer* would wait indefinitely.

在 3.7 版被加入.

class http.server.**HTTPSServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*, ***, *certfile*, *keyfile=None*, *password=None*, *alpn_protocols=None*)

Subclass of *HTTPServer* with a wrapped socket using the *ssl* module. If the *ssl* module is not available, instantiating a `HTTPSServer` object fails with a *RuntimeError*.

The *certfile* argument is the path to the SSL certificate chain file, and the *keyfile* is the path to file containing the private key.

A *password* can be specified for files protected and wrapped with PKCS#8, but beware that this could possibly expose hardcoded passwords in clear.

> **也參考**
>
> See `ssl.SSLContext.load_cert_chain()` for additional information on the accepted values for *certfile*, *keyfile* and *password*.

When specified, the *alpn_protocols* argument must be a sequence of strings specifying the "Application-Layer Protocol Negotiation" (ALPN) protocols supported by the server. ALPN allows the server and the client to negotiate the application protocol during the TLS handshake.

By default, it is set to `["http/1.1"]`, meaning the server supports HTTP/1.1.

在 3.14 版被加入.

class http.server.**ThreadingHTTPSServer**(*server_address*, *RequestHandlerClass*, *bind_and_activate=True*, ***, *certfile*, *keyfile=None*, *password=None*, *alpn_protocols=None*)

This class is identical to `HTTPSServer` but uses threads to handle requests by inheriting from `ThreadingMixIn`. This is analogous to `ThreadingHTTPServer` only using `HTTPSServer`.

在 3.14 版被加入.

The `HTTPServer`, `ThreadingHTTPServer`, `HTTPSServer` and `ThreadingHTTPSServer` must be given a *RequestHandlerClass* on instantiation, of which this module provides three different variants:

class http.server.**BaseHTTPRequestHandler**(*request*, *client_address*, *server*)

This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). `BaseHTTPRequestHandler` provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method `SPAM`, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

`BaseHTTPRequestHandler` 有以下實例變數:

client_address

Contains a tuple of the form `(host, port)` referring to the client's address.

server

Contains the server instance.

close_connection

Boolean that should be set before `handle_one_request()` returns, indicating if another request may be expected, or if the connection should be shut down.

requestline

Contains the string representation of the HTTP request line. The terminating CRLF is stripped. This attribute should be set by `handle_one_request()`. If no valid request line was processed, it should be set to the empty string.

command

Contains the command (request type). For example, `'GET'`.

path

Contains the request path. If query component of the URL is present, then `path` includes the query. Using the terminology of **RFC 3986**, `path` here includes `hier-part` and the `query`.

request_version

Contains the version string from the request. For example, `'HTTP/1.0'`.

headers

Holds an instance of the class specified by the *MessageClass* class variable. This instance parses and manages the headers in the HTTP request. The *parse_headers()* function from *http.client* is used to parse the headers and it requires that the HTTP request provide a valid **RFC 2822** style header.

rfile

An *io.BufferedIOBase* input stream, ready to read from the start of the optional input data.

wfile

Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream in order to achieve successful interoperation with HTTP clients.

在 3.6 版的變更: This is an *io.BufferedIOBase* stream.

BaseHTTPRequestHandler 擁有以下屬性:

server_version

Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, `'BaseHTTP/0.2'`.

sys_version

Contains the Python system version, in a form usable by the *version_string* method and the *server_version* class variable. For example, `'Python/1.4'`.

error_message_format

Specifies a format string that should be used by *send_error()* method for building an error response to the client. The string is filled by default with variables from *responses* based on the status code that passed to *send_error()*.

error_content_type

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is `'text/html'`.

protocol_version

Specifies the HTTP version to which the server is conformant. It is sent in responses to let the client know the server's communication capabilities for future requests. If set to `'HTTP/1.1'`, the server will permit HTTP persistent connections; however, your server *must* then include an accurate `Content-Length` header (using *send_header()*) in all of its responses to clients. For backwards compatibility, the setting defaults to `'HTTP/1.0'`.

MessageClass

Specifies an *email.message.Message*-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to *http.client.HTTPMessage*.

responses

This attribute contains a mapping of error code integers to two-element tuples containing a short and long message. For example, `{code: (shortmessage, longmessage)}`. The *shortmessage* is usually used as the *message* key in an error response, and *longmessage* as the *explain* key. It is used by *send_response_only()* and *send_error()* methods.

BaseHTTPRequestHandler 實例擁有以下方法:

handle()

Calls *handle_one_request()* once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate `do_*()` methods.

handle_one_request()

This method will parse and dispatch the request to the appropriate `do_*()` method. You should never need to override it.

handle_expect_100()

When an HTTP/1.1 conformant server receives an `Expect: 100-continue` request header it responds back with a `100 Continue` followed by `200 OK` headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can choose to send `417 Expectation Failed` as a response header and `return False`.

在 3.2 版被加入.

send_error(*code*, *message=None*, *explain=None*)

Sends and logs a complete error reply to the client. The numeric *code* specifies the HTTP error code, with *message* as an optional, short, human readable description of the error. The *explain* argument can be used to provide more detailed information about the error; it will be formatted using the *error_message_format* attribute and emitted, after a complete set of headers, as the response body. The *responses* attribute holds the default values for *message* and *explain* that will be used if no value is provided; for unknown codes the default value for both is the string `???`. The body will be empty if the method is HEAD or the response code is one of the following: `1xx`, `204 No Content`, `205 Reset Content`, `304 Not Modified`.

在 3.4 版的變更: The error response includes a Content-Length header. Added the *explain* argument.

send_response(*code*, *message=None*)

Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the internal buffer, followed by *Server* and *Date* headers. The values for these two headers are picked up from the *version_string()* and *date_time_string()* methods, respectively. If the server does not intend to send any other headers using the *send_header()* method, then *send_response()* should be followed by an *end_headers()* call.

在 3.3 版的變更: Headers are stored to an internal buffer and *end_headers()* needs to be called explicitly.

send_header(*keyword*, *value*)

Adds the HTTP header to an internal buffer which will be written to the output stream when either *end_headers()* or *flush_headers()* is invoked. *keyword* should specify the header keyword, with *value* specifying its value. Note that, after the send_header calls are done, *end_headers()* MUST BE called in order to complete the operation.

在 3.2 版的變更: Headers are stored in an internal buffer.

send_response_only(*code*, *message=None*)

Sends the response header only, used for the purposes when `100 Continue` response is sent by the server to the client. The headers not buffered and sent directly the output stream.If the *message* is not specified, the HTTP message corresponding the response *code* is sent.

在 3.2 版被加入.

end_headers()

Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls *flush_headers()*.

在 3.2 版的變更: The buffered headers are written to the output stream.

flush_headers()

Finally send the headers to the output stream and flush the internal headers buffer.

在 3.3 版被加入.

log_request(*code='-'*, *size='-'*)

Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

log_error(...)

Logs an error when a request cannot be fulfilled. By default, it passes the message to *log_message()*, so it takes the same arguments (*format* and additional values).

log_message(*format*, ...)

Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The *format* argument is a standard printf-style format string, where the additional arguments to *log_message()* are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

version_string()

Returns the server software's version string. This is a combination of the *server_version* and *sys_version* attributes.

date_time_string(*timestamp=None*)

Returns the date and time given by *timestamp* (which must be `None` or in the format returned by *time.time()*), formatted for a message header. If *timestamp* is omitted, it uses the current date and time.

The result looks like `'Sun, 06 Nov 1994 08:49:37 GMT'`.

log_date_time_string()

Returns the current date and time, formatted for logging.

address_string()

Returns the client address.

在 3.3 版的變更: Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

class http.server.**SimpleHTTPRequestHandler**(*request*, *client_address*, *server*, *directory=None*)

This class serves files from the directory *directory* and below, or the current directory if *directory* is not provided, directly mapping the directory structure to HTTP requests.

在 3.7 版的變更: 新增 *directory* 參數。

在 3.9 版的變更: The *directory* parameter accepts a *path-like object*.

A lot of the work, such as parsing the request, is done by the base class *BaseHTTPRequestHandler*. This class implements the *do_GET()* and *do_HEAD()* functions.

The following are defined as class-level attributes of *SimpleHTTPRequestHandler*:

server_version

This will be `"SimpleHTTP/" + __version__`, where `__version__` is defined at the module level.

extensions_map

A dictionary mapping suffixes into MIME types, contains custom overrides for the default system mappings. The mapping is used case-insensitively, and so should contain only lower-cased keys.

在 3.9 版的變更: This dictionary is no longer filled with the default system mappings, but only contains overrides.

SimpleHTTPRequestHandler 類🄵定義了以下方法:

do_HEAD()

This method serves the `'HEAD'` request type: it sends the headers it would send for the equivalent `GET` request. See the *do_GET()* method for a more complete explanation of the possible headers.

do_GET()

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named `index.html` or `index.htm` (in that order). If found, the file's contents are returned; otherwise a directory listing is

generated by calling the `list_directory()` method. This method uses *os.listdir()* to scan the directory, and returns a `404` error response if the *listdir()* fails.

If the request was mapped to a file, it is opened. Any *OSError* exception in opening the requested file is mapped to a `404`, `'File not found'` error. If there was an `'If-Modified-Since'` header in the request, and the file was not modified after this time, a `304`, `'Not Modified'` response is sent. Otherwise, the content type is guessed by calling the `guess_type()` method, which in turn uses the *extensions_map* variable, and the file contents are returned.

A `'Content-type:'` header with the guessed content type is output, followed by a `'Content-Length:'` header with the file's size and a `'Last-Modified:'` header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output.

For example usage, see the implementation of the `test` function in Lib/http/server.py.

在 3.7 版的變更: Support of the `'If-Modified-Since'` header.

The *SimpleHTTPRequestHandler* class can be used in the following manner in order to create a very basic web-server serving files relative to the current directory:

```
import http.server
import socketserver

PORT = 8000

Handler = http.server.SimpleHTTPRequestHandler

with socketserver.TCPServer(("", PORT), Handler) as httpd:
    print("serving at port", PORT)
    httpd.serve_forever()
```

SimpleHTTPRequestHandler can also be subclassed to enhance behavior, such as using different index file names by overriding the class attribute `index_pages`.

class `http.server.`**CGIHTTPRequestHandler**(*request*, *client_address*, *server*)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in *SimpleHTTPRequestHandler*.

> **備🄵**
>
> CGI scripts run by the *CGIHTTPRequestHandler* class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used --- the other common server configuration is to treat special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

CGIHTTPRequestHandler 類🄵定義了以下資料成員:

cgi_directories

This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

CGIHTTPRequestHandler 類🄵定義了以下方法:

do_POST()

This method serves the `'POST'` request type, only allowed for CGI scripts. Error 501, "Can only POST to CGI scripts", is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

Deprecated since version 3.13, will be removed in version 3.15: *CGIHTTPRequestHandler* is being removed in 3.15. CGI has not been considered a good way to do things for well over a decade. This code has been unmaintained for a while now and sees very little practical use. Retaining it could lead to further *security considerations*.

22.17.1 命令列介面

http.server can also be invoked directly using the `-m` switch of the interpreter. The following example illustrates how to serve files relative to the current directory:

```
python -m http.server [OPTIONS] [port]
```

可接受以下選項:

port

The server listens to port 8000 by default. The default can be overridden by passing the desired port number as an argument:

```
python -m http.server 9000
```

-b, --bind <address>

Specifies a specific address to which it should bind. Both IPv4 and IPv6 addresses are supported. By default, the server binds itself to all interfaces. For example, the following command causes the server to bind to localhost only:

```
python -m http.server --bind 127.0.0.1
```

在 3.4 版被加入.

在 3.8 版的變更: 於 `--bind` 選項中支援 IPv6。

-d, --directory <dir>

Specifies a directory to which it should serve the files. By default, the server uses the current directory. For example, the following command uses a specific directory:

```
python -m http.server --directory /tmp/
```

在 3.7 版被加入.

-p, --protocol <version>

Specifies the HTTP version to which the server is conformant. By default, the server is conformant to HTTP/1.0. For example, the following command runs an HTTP/1.1 conformant server:

```
python -m http.server --protocol HTTP/1.1
```

在 3.11 版被加入.

--cgi

CGIHTTPRequestHandler can be enabled in the command line by passing the `--cgi` option:

```
python -m http.server --cgi
```

Deprecated since version 3.13, will be removed in version 3.15: *http.server* command line `--cgi` support is being removed because *CGIHTTPRequestHandler* is being removed.

> **警告**
>
> *CGIHTTPRequestHandler* and the `--cgi` command-line option are not intended for use by untrusted clients and may be vulnerable to exploitation. Always use within a secure environment.

--tls-cert

Specifies a TLS certificate chain for HTTPS connections:

```
python -m http.server --tls-cert fullchain.pem
```

在 3.14 版被加入.

--tls-key

Specifies a private key file for HTTPS connections.

This option requires `--tls-cert` to be specified.

在 3.14 版被加入.

--tls-password-file

Specifies the password file for password-protected private keys:

```
python -m http.server \
       --tls-cert cert.pem \
       --tls-key key.pem \
       --tls-password-file password.txt
```

This option requires *--tls-cert*‘ to be specified.

在 3.14 版被加入.

22.17.2 安全性注意事項

SimpleHTTPRequestHandler will follow symbolic links when handling requests, this makes it possible for files outside of the specified directory to be served.

Earlier versions of Python did not scrub control characters from the log messages emitted to stderr from `python -m http.server` or the default *BaseHTTPRequestHandler* `.log_message` implementation. This could allow remote clients connecting to your server to send nefarious control codes to your terminal.

在 3.12 版的變更: Control characters are scrubbed in stderr logs.

22.18 `http.cookies` --- HTTP 狀態管理

原始碼： Lib/http/cookies.py

---

http.cookies 模組定義了 cookie 概念的抽象化的類🄵，cookie 是一種 HTTP 狀態管理機制。它支援簡單的純字串 cookie，也提供了將任何可序列化的資料型🄵作🄵 cookie 值的抽象化。

此模組原先嚴格遵循了 **RFC 2109** 和 **RFC 2068** 規範所描述的剖析規則。自從發現 MSIE 3.0x 🄵不遵循這些規範所描述的字元規則，許多目前的🄵覽器和伺服器也在處理 cookie 時放寬了剖析規則。因此，此模組現在使用的剖析規則比之前的更🄵寬松。

字元集*string.ascii_letters*、*string.digits* 和 `!#$%&'*+-.^_`|~` 表示此模組在 cookie 名稱 (*key*) 中允許的合法字元集合。

在 3.3 版的變更: 允許':' 作🄵有效的 cookie 名稱字元。

備🄵

當遇到無效的 cookie 時，會引發*CookieError*，因此如果你的 cookie 資料來自🄵覽器，在剖析時你應該總是🄵無效資料作准備🄵捕捉*CookieError*。

exception http.cookies.**CookieError**

因🄵不符合 **RFC 2109** 而引發的例外：不正確的屬性、不正確的 *Set-Cookie* 標頭等。

class http.cookies.**BaseCookie**([*input*])

這個類🄵是一個類似字典的物件，其中的鍵是字串，而值則是*Morsel* 實例。請注意，當設定鍵的值時，值會先被轉🄵🄵一個包含該鍵和值的*Morsel*。

如果有給定 *input*，它會被傳遞給*load()* 方法。

class http.cookies.**SimpleCookie**([*input*])

這個類🄵繼承自*BaseCookie* 🄵覆寫了*value_decode()* 和*value_encode()*。SimpleCookie 支援字串作🄵 cookie 值。當設定值時，SimpleCookie 會呼叫🄵建的*str()* 來將值轉🄵🄵字串。從 HTTP 接收的值會保持🄵字串。

也參考

***http.cookiejar* 模組**
用於網路用🄵端的 HTTP cookie 處理。*http.cookiejar* 和*http.cookies* 模組互不相依。

RFC 2109 - HTTP 狀態管理機制
這是此模組實作的狀態管理規範。

22.18.1 Cookie 物件

BaseCookie.**value_decode**(*val*)

從字串表示回傳 (real_value, coded_value) 的元組。real_value 可以是任何型🄵。此方法在*BaseCookie* 中不做解碼 --- 它存在以便可以被覆寫。

BaseCookie.**value_encode**(*val*)

回傳一個元組 (real_value, coded_value)。*val* 可以是任何型🄵，但 coded_value 總是會被轉🄵🄵字串。此方法在*BaseCookie* 中不做編碼 --- 它存在以便可以被覆寫。

一般來🄵，*value_encode()* 和*value_decode()* 應該在 *value_decode* 的範圍🄵是互逆的 (inverse)。

BaseCookie.**output**(*attrs=None*, *header='Set-Cookie:'*, *sep='\r\n'*)

回傳一個適合作🄵 HTTP 標頭來傳送的字串表示。*attrs* 和 *header* 會傳送給每個*Morsel* 的*output()* 方法。*sep* 用來連接標頭，預設🄵 '\r\n' (CRLF) 的組合。

BaseCookie.**js_output**(*attrs=None*)

回傳一個可嵌入的 JavaScript 片段，如果在支援 JavaScript 的🄵覽器上執行，它的行🄵會與 HTTP 標頭被傳送的情🄵相同。

attrs 的意義與*output()* 🄵的相同。

BaseCookie.**load**(*rawdata*)

如果 *rawdata* 是字串，會將其作🄵 HTTP_COOKIE 剖析，🄵將在其中找到的值當作*Morsel* 新增。如果它是一個字典，則等同於：

```
for k, v in rawdata.items():
    cookie[k] = v
```

22.18.2 Morsel 物件

class http.cookies.**Morsel**

抽象化一個鍵 / 值對，它有一些 **RFC 2109** 屬性。

Morsel 是一種類似字典的物件，其鍵的集合是固定的 --- 有效的 **RFC 2109** 屬性，它們是：

expires
path
comment
domain
max-age
secure
version
httponly
samesite
partitioned

屬性*httponly* 指定 cookie 僅在 HTTP 請求中傳輸，而不可通過 JavaScript 存取。這是🄵了🄵輕某些形式的跨網站🄵本攻擊。

samesite 屬性控制🄵覽器要在何時將 cookie 與跨網站請求一起傳送，這有助於🄵輕 CSRF 攻擊。有效值🄵"Strict"（僅在同站請求時傳送）、"Lax"（同站請求和頂層導航時傳送）和"None"（同站請求和跨站請求時傳送）。使用"None" 時，必須同時設定"secure" 屬性，這是現代🄵覽器的要求。

The attribute *partitioned* indicates to user agents that these cross-site cookies *should* only be available in the same top-level context that the cookie was first set in. For this to be accepted by the user agent, you **must** also set `Secure`.

In addition, it is recommended to use the `__Host` prefix when setting partitioned cookies to make them bound to the hostname and not the registrable domain. Read CHIPS (Cookies Having Independent Partitioned State) for full details and examples.

鍵不區分大小寫，其預設值🄵 `''`。

在 3.5 版的變更: `__eq__()` 現在會考慮*key* 和*value*。

在 3.7 版的變更: 屬性*key*、*value* 和*coded_value* 是唯讀的。請使用*set()* 來設定它們。

在 3.8 版的變更: 新增對*samesite* 屬性的支援。

在 3.14 版的變更: 新增對*partitioned* 屬性的支援。

Morsel.**value**

cookie 的值。

Morsel.**coded_value**

cookie 的編碼值 --- 這是應該被傳送的值。

Morsel.**key**

cookie 的名稱。

Morsel.**set**(*key*, *value*, *coded_value*)

設定 *key*、*value* 和 *coded_value* 屬性。

Morsel.**isReservedKey**(*K*)

K 是否🄵*Morsel* 的鍵集合中的成員。

Morsel.**output**(*attrs=None*, *header='Set-Cookie:'*)

回傳適合作🄵 HTTP 標頭傳送的 Morsel 的字串表示。預設會包含所有屬性，除非有給定 *attrs*，在此情🄵下，它應該是一個要使用的屬性的串列。預設的 *header* 是 `"Set-Cookie:"`。

Morsel.**js_output**(*attrs=None*)

回傳一個可嵌入的 JavaScript 片段，如果在支援 JavaScript 的🄴覽器上執行，它的行🄴會與 HTTP 標頭被傳送的情🄴相同。

attrs 的意義與*output()* 🄵的相同。

Morsel.**OutputString**(*attrs=None*)

回傳表示 Morsel 的字串，不包含周圍任何的 HTTP 或 JavaScript。

attrs 的意義與*output()* 🄵的相同。

Morsel.**update**(*values*)

更新 Morsel 字典中的值🄵 *values* 字典中的值。如果 *values* 字典中的任何鍵不是有效的 **RFC 2109** 屬性則引發錯誤。

在 3.5 版的變更: 對於無效的鍵會引發錯誤。

Morsel.**copy**(*value*)

回傳 Morsel 物件的淺層🄵🄵。

在 3.5 版的變更: 回傳 Morsel 物件而不是字典。

Morsel.**setdefault**(*key*, *value=None*)

如果鍵不是一個有效的 **RFC 2109** 屬性會引發錯誤，否則行🄴與*dict.setdefault()* 相同。

22.18.3 范例

以下範例示範如何使用*http.cookies* 模組。

```
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C) # 🄵生 HTTP 標頭
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output()) # 同上
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger") # 從字串 (HTTP 標頭) 載入
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
>>> C.load('keebler="E=everybody; L=\\"Loves\\"; fudge=\\012;";')
>>> print(C)
Set-Cookie: keebler="E=everybody; L=\"Loves\"; fudge=\012;"
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print(C)
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C["twix"] = "none for you"
>>> C["twix"].value
```

(繼續下一頁)

(繼續上一頁)

```
'none for you'
>>> C = cookies.SimpleCookie()
>>> C["number"] = 7 # 等同於 C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
>>> C["string"].value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
```

22.19 `http.cookiejar` --- HTTP 用🄵端的 Cookie 處理

原始碼： Lib/http/cookiejar.py

---

http.cookiejar 模組定義了自動處理 HTTP cookie 的類🄵。當需要存取小量資料——*cookies*——的網站時會非常有用。這些資料會依據網頁伺服器的 HTTP 回應來設置於用🄵端機器，🄵在之後的請求中被回傳到伺服器。

一般的 Netscape cookie 協定和 **RFC 2965** 定義的 cookie 協定都會被處理。RFC 2965 的處理預設是關閉的。**RFC 2109** cookie 會被剖析🄵 Netscape cookie，然後根據有生效的「策略」來被看作🄵 Netscape 或 RFC 2965 cookie。*http.cookiejar* 會嘗試遵循實際上的 Netscape cookie 協定（與原始的 Netscape 規格中的協定有很大的不同），包括 RFC 2965 所引進的 `max-age` 和 `port` cookie 屬性。

> **備🄵**
>
> 在 *Set-Cookie* 和 *Set-Cookie2* 標頭中出現的各種命名參數（例如 `domain` 和 `expires`）通常被稱🄵 *attributes*。🄵了與 Python 的屬性分🄵開，這個模組的🄵明檔案改用 *cookie-attribute* 來稱呼。

模組定義了以下例外：

exception http.cookiejar.**LoadError**

當從檔案載入 cookies 失敗時，*FileCookieJar* 的實例會引發這個例外。*LoadError* 是*OSError* 的子類🄵。

在 3.3 版的變更: *LoadError* 以前是*IOError* 的子型🄵，現在是*OSError* 的🄵名。

這個模組提供了以下類🄵：

class http.cookiejar.**CookieJar**(*policy=None*)

policy 是實作了*CookiePolicy* 介面的一個物件。

CookieJar 類🄵會儲存 HTTP cookies。它會從 HTTP 請求中抽取出 cookies，🄵在 HTTP 回應中將它們回傳。*CookieJar* 實例會在必要時自動使包含的 cookies 過期。它的子類🄵也負責從檔案或資料庫中儲存和🄵取 cookies。

class http.cookiejar.**FileCookieJar**(*filename=None*, *delayload=None*, *policy=None*)

policy 是實作了*CookiePolicy* 介面的一個物件。至於其他引數，請參🄵對應屬性的🄵明文件。

一個可以從磁碟上的檔案載入 Cookie，也可以儲存 Cookie 到磁碟上檔案的*CookieJar*。在*load()* 或*revert()* 方法被呼叫之前，Cookie 🄵**不會**從指定的檔案載入。這個類🄵的子類🄵有記載於*FileCookieJar 子類🄵及與網頁🄵覽器的合作* 章節。

這個類🄵不應該直接初始化 - 請使用下面的子類🄵代替。

在 3.8 版的變更: filename 參數支援傳入一個*path-like object*。

class http.cookiejar.**CookiePolicy**

此類🄴負責🄴定是否應從伺服器接受 / 回傳每個 cookie。

class http.cookiejar.**DefaultCookiePolicy**(*blocked_domains=None*, *allowed_domains=None*, *netscape=True*, *rfc2965=False*, *rfc2109_as_netscape=None*, *hide_cookie2=False*, *strict_domain=False*, *strict_rfc2965_unverifiable=True*, *strict_ns_unverifiable=False*, *strict_ns_domain=DefaultCookiePolicy.DomainLiberal*, *strict_ns_set_initial_dollar=False*, *strict_ns_set_path=False*, *secure_protocols=('https', 'wss')*)

建構函式引數只能以關鍵字引數的形式傳送。*blocked_domains* 是我們從不接受 cookies 或回傳 cookies 的網域名稱序列。*allowed_domains* 如果不是*None*，這是我們接受🄴回傳 cookies 的唯一網域名稱序列。*secure_protocols* 是可以加入安全 cookies 的通訊協定序列。預設情🄴下，*https* 和 *wss*（安全 websocket）會被視🄴安全通訊協定。所有其他引數請參🄴*CookiePolicy* 及*DefaultCookiePolicy* 物件的🄴明文件。

DefaultCookiePolicy 實作了 Netscape 和 **RFC 2965** cookies 的標准接受/拒🄴規則。預設情🄴下，**RFC 2109** cookies（即在 *Set-Cookie* 標頭中接收到的版本 cookie-attribute 🄵 1 的 cookies）會根據 RFC 2965 規則處理。但是，如果 RFC 2965 處理被關閉，或者*rfc2109_as_netscape* 是 `True`，RFC 2109 cookie 會被*CookieJar* 實例「降級」🄵 Netscape cookie，方法是將*Cookie* 實例的 `version` 屬性設🄵 0。*DefaultCookiePolicy* 也提供了一些參數來允許對策略進行一些微調。

class http.cookiejar.**Cookie**

這個類🄴代表 Netscape、**RFC 2109** 和 **RFC 2965** cookies。我們不希望*http.cookiejar* 的使用者建立自己的*Cookie* 實例。如有必要，請在*CookieJar* 實例上呼叫 `make_cookies()`。

也參考

***urllib.request* 模組**
URL 打開時會自動處理 cookie。

***http.cookies* 模組**
HTTP cookie 類🄵，主要用於伺服器端程式碼。*http.cookiejar* 和*http.cookies* 模組不互相依賴。

https://curl.se/rfc/cookie_spec.html
原始 Netscape cookie 協定的規範。雖然這仍是主流協定，但所有主要🄵覽器（以及*http.cookiejar*）實作的「Netscape cookie 協定」與 `cookie_spec.html` 中實作的協定只有一點相似之處。

RFC 2109 - HTTP 狀態管理機制
被 **RFC 2965** 所取代，會使用 *Set-Cookie* 設定 version=1。

RFC 2965 - HTTP 狀態管理機制
有錯誤修正的 Netscape 通訊協定。使用 *Set-Cookie2* 取代 *Set-Cookie*。未被廣泛使用。

https://kristol.org/cookie/errata.html
未完成的 **RFC 2965** 勘誤表。

RFC 2964 - HTTP 狀態管理使用方法

22.19.1 CookieJar 與 FileCookieJar 物件

CookieJar 物件支援*iterator* 協定來遍歷包含的*Cookie* 物件。

CookieJar 擁有以下方法：

CookieJar.**add_cookie_header**(*request*)

將正確的 *Cookie* 標頭加入 *request*。

如果策略允許（即*CookieJar* 的*CookiePolicy* 實例的 rfc2965 和 hide_cookie2 屬性分🄵🄵 true 和 false），*Cookie2* 標頭也會在適當的時候加入。

如*urllib.request* 文件所述，*request* 物件（通常是*urllib.request.Request* 的實例）必須支援 get_full_url()、has_header()、get_header()、header_items()、add_unredirected_header() 方法與 host、type、unverifiable、origin_req_host 屬性。

在 3.3 版的變更: *request* 物件需要 origin_req_host 屬性。已移除對已廢🄵方法 get_origin_req_host() 的依賴。

CookieJar.**extract_cookies**(*response*, *request*)

在策略允許的情🄵下，從 HTTP *response* 抽取出 cookies 🄵儲存到*CookieJar* 中。

CookieJar 會在 *response* 引數中尋找允許的 *Set-Cookie* 和 *Set-Cookie2* 標頭，🄵視情🄵儲存 cookies（需經*CookiePolicy.set_ok()* 方法的檢測）。

response 物件（通常是呼叫*urllib.request.urlopen()* 的結果或類似的東西）應該支援 info() 方法，它會回傳一個*email.message.Message* 的實例。

如*urllib.request* 的檔案所🄵，*request* 物件（通常是*urllib.request.Request* 的實例）必須支援 get_full_url() 方法以及 host、unverifiable 和 origin_req_host 等屬性，該請求被用於設置 cookie-attributes 的預設值🄵檢查 cookie 是否允許被設置。

在 3.3 版的變更: *request* 物件需要 origin_req_host 屬性。已移除對已廢🄵方法 get_origin_req_host() 的依賴。

CookieJar.**set_policy**(*policy*)

設定要使用的*CookiePolicy* 實例。

CookieJar.**make_cookies**(*response*, *request*)

回傳從 *response* 物件抽取出的*Cookie* 物件序列。

有關 *response* 和 *request* 引數所需的介面，請參🄵*extract_cookies()* 的🄵明檔案。

CookieJar.**set_cookie_if_ok**(*cookie*, *request*)

如果策略允許這🄵做，設定*Cookie*。

CookieJar.**set_cookie**(*cookie*)

設定一個*Cookie*，不經過策略檢查。

CookieJar.**clear**(*[domain[, path[, name]]]*)

清除一些 cookies。

如果不帶引數地叫用，則清除所有 cookies。如果給定單一引數，則只移除屬於該 *domain* 的 cookies。如果給定兩個引數，則會移除屬於指定 *domain* 和 URL *path* 的 cookie。如果給定三個引數，則會移除指定 *domain*、*path* 和 *name* 的 cookie。

如果🄵有符合的 cookie 存在，則引發*KeyError*。

CookieJar.**clear_session_cookies**()

🄵除所有 session cookies。

🄵除所有包含有 true discard 屬性的 cookie (通常是因🄵它們🄵有 *max-age* 或 *expires* cookie 屬性，或有明確的 *discard* cookie 屬性)。對於互動式🄵覽器，工作階段的結束通常對應於關閉🄵覽器視窗。

請注意 save() 方法無論如何都不會儲存 session cookies，除非你透過傳入 true *ignore_discard* 引數來要求。

FileCookieJar 實例有下列附加方法：

FileCookieJar.**save**(*filename=None*, *ignore_discard=False*, *ignore_expires=False*)

將 cookies 儲存到檔案中。

這個基底類🄵會🄵生*NotImplementedError*。子類🄵可以不實作此方法。

filename 是儲存 cookies 的檔案名稱。如果 *filename* 未指定，則會使用 `self.filename`（其預設值是傳給建構函式的值（如果有））；如果 `self.filename` 是*None*，則會🄵生*ValueError*。

ignore_discard: 即使設定🄵舍🄵的 cookies 也會儲存。*ignore_expires*: 保存過期的 cookie

如果檔案已經存在，則會被覆寫，因此會抹除其中包含的所有 cookies。儲存的 cookies 可以稍後使用*load()* 或*revert()* 方法還原。

`FileCookieJar.`**`load`**(*filename=None*, *ignore_discard=False*, *ignore_expires=False*)

從檔案中載入 cookies。

舊的 cookies 會被保留，除非被新載入的 cookies 覆蓋。

引數與*save()* 相同。

被命名的檔案必須是類🄵所能正確剖析的格式，否則會🄵生*LoadError*。此外，*OSError* 可能會被引發，例如檔案不存在時。

在 3.3 版的變更: 以前會引發*IOError*，現在它是*OSError* 的🄵名。

`FileCookieJar.`**`revert`**(*filename=None*, *ignore_discard=False*, *ignore_expires=False*)

清除所有 cookies，🄵從儲存的檔案重新載入 cookies。

revert() 可以🄵生與*load()* 相同的例外。如果失敗，物件的狀態不會被改變。

FileCookieJar 實例擁有以下公開屬性:

`FileCookieJar.`**`filename`**

保存 cookie 的預設檔案的檔案名稱。此屬性可以被指定。

`FileCookieJar.`**`delayload`**

若🄵 true，則從硬盤惰性地載入 cookies。此屬性不應被指定。這只是一個提示，因🄵這只會影響效能，不會影響行🄵 (除非磁碟上的 cookies 正在改變)。一個*CookieJar* 物件可以忽略它。🄵有一個包含在標準函式庫中的*FileCookieJar* 類🄵會惰性地載入 cookies。

22.19.2 FileCookieJar 子類🄵及與網頁🄵覽器的合作

以下*CookieJar* 子類🄵提供用於讀取和寫入。

`class` `http.cookiejar.`**`MozillaCookieJar`**(*filename=None*, *delayload=None*, *policy=None*)

一個能🄵以 Mozilla `cookies.txt` 檔案格式（該格式也被 curl 和 Lynx 以及 Netscape 🄵覽器所使用）從磁碟載入和儲存 cookie 的*FileCookieJar*。

> **備🄵**
>
> 這會遺失關於 **RFC 2965** cookie 的訊息，以及較新或非標準 cookie 屬性（例如 `port`）的訊息。

> **警告**
>
> 如果 Cookie 遺失或損壞會造成不便，請在儲存之前先備份 Cookie（有些微妙的情🄵可能會導致檔案在載入/儲存往返過程中發生輕微變化）。

另外請注意，在 Mozilla 執行時儲存的 cookies 會被 Mozilla 🄵除。

`class` `http.cookiejar.`**`LWPCookieJar`**(*filename=None*, *delayload=None*, *policy=None*)

一個*FileCookieJar* 可以從 libwww-perl 函式庫的 *Set-Cookie3* 檔案格式載入 cookies 🄵儲存 cookies 到磁碟。如果你想要將 cookie 儲存在人類可讀的檔案中，這是很方便的。

在 3.8 版的變更: filename 參數支援傳入一個*path-like object*。

22.19.3 CookiePolicy 物件

實作*CookiePolicy* 介面的物件有以下方法：

CookiePolicy.**set_ok**(*cookie*, *request*)

回傳值表示的是否接受伺服器 cookie 的布林值。

cookie 是一個*Cookie* 實例。*request* 是一個實作了*CookieJar.extract_cookies()* 文件所定義的介面的物件。

CookiePolicy.**return_ok**(*cookie*, *request*)

回傳布林值，表示 cookie 是否應回傳伺服器。

cookie 是一個*Cookie* 實例。*request* 是一個實作了*CookieJar.add_cookie_header()* 文件所定義的介面的物件。

CookiePolicy.**domain_return_ok**(*domain*, *request*)

在給定 cookie 網域如果不應回傳 cookie，則回傳 `False`。

此方法🄵一種最佳化。它消除了檢查每個具有特定網域的 cookie 的需要（這可能需要讀取許多檔案）。從*domain_return_ok()* 和*path_return_ok()* 回傳 true 會把所有的工作留給*return_ok()*。

如果*domain_return_ok()* 對 cookie 網域回傳 true，*path_return_ok()* 就會被用來呼叫 cookie 路徑。否則*path_return_ok()* 和*return_ok()* 永遠不會被呼叫。如果*path_return_ok()* 回傳 true，則會呼叫*return_ok()* 附帶的*Cookie* 物件本身以進行全面檢查。否則，*return_ok()* 將永遠不會被呼叫。

請注意，*domain_return_ok()* 是針對每個 *cookie* 網域來呼叫的，而不只是針對 *request* 網域。例如，如果請求網域是 `"www.example.com"`，這個函式可能會同時被 `".example.com"` 和 `"www.example.com"` 呼叫。同樣的道理也適用於*path_return_ok()*。

request 引數與*return_ok()* 的🄵明文件相同。

CookiePolicy.**path_return_ok**(*path*, *request*)

給定 cookie 路徑如不應該回傳 cookie，則回傳 `False` 。

關於*domain_return_ok()* 請見文件。

除了實作上述方法外，*CookiePolicy* 介面的實作也必須提供下列屬性，指出應該使用哪些通訊協定，以及如何使用。所有這些屬性都可以被指定。

CookiePolicy.**netscape**

實作 Netscape 協定。

CookiePolicy.**rfc2965**

實作 **RFC 2965** 協定。

CookiePolicy.**hide_cookie2**

不要在請求中加入 *Cookie2* 標頭（這個標頭的存在向伺服器表明我們能🄵正確剖析 **RFC 2965** cookie）。

以*DefaultCookiePolicy* 🄵子類🄵定義*CookiePolicy* 類🄵，🄵覆寫其中的一些或全部方法是最有用的。*CookiePolicy* 本身可以用做’無策略’，允許設定和接收任何和所有的 cookies (這不太可能有用)。

22.19.4 DefaultCookiePolicy 物件

執行接受和回傳 cookie 的標准規則。

同時支援 **RFC 2965** 和 Netscape cookies。RFC 2965 的處理預設🄵關閉。

提供你自己的策略的最簡單方法是覆寫此類🄵，🄵在你覆寫的實作中呼叫其方法，然後再加入你自己的額外檢查：

```
import http.cookiejar
class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

除了實作*CookiePolicy* 介面所需的功能外，這個類🄵還允許你阻止或允許網域名稱設定和接收 cookies。還有調整嚴格度的控制選項，可讓你稍微收緊相對寬松的 Netscape 通訊協定（代價是阻擋一些良性 cookies）。

提供網域阻止清單和允許清單（預設都關閉）。只有不在阻止清單中和在允許清單中（如果允許清單是有效的）的網域才參與 cookie 設定和回傳。使用 *blocked_domains* 構造函式引數，以及 `blocked_domains()` 和 `set_blocked_domains()` 方法（以及 *allowed_domains* 的相應引數和方法）。如果你設定了允許清單，你可以透過設定🄵*None* 來再次關閉它。

封鎖或允許清單中不以點開頭的網域必須與 cookie 網域相等才能匹配。例如，`"example.com"` 會與封鎖清單項目 `"example.com"` 匹配，但 `"www.example.com"` 則不會。以點開頭的網域也會與更特定的網域相匹配。例如，`"www.example.com"` 和 `"www.coyote.example.com"` 都匹配 `".example.com"`（但 `"example.com"` 本身不匹配）。IP 位址是例外，它們必須完全匹配。例如，如果 blocked_domains 包含 `"192.168.1.2"` 和 `".168.1.2"`，則 192.168.1.2 會被封鎖，但 193.168.1.2 則不會。

DefaultCookiePolicy 實作了下列附加方法：

`DefaultCookiePolicy.`**`blocked_domains`**`()`
: 回傳被阻止網域的序列（以元組形式）。

`DefaultCookiePolicy.`**`set_blocked_domains`**`(`*blocked_domains*`)`
: 設定阻止網域的順序。

`DefaultCookiePolicy.`**`is_blocked`**`(`*domain*`)`
: 如果 *domain* 在設定或接收 cookies 的阻止列表上，則回傳 `True`。

`DefaultCookiePolicy.`**`allowed_domains`**`()`
: 回傳*None*，或允許網域的序列（以元組形式）。

`DefaultCookiePolicy.`**`set_allowed_domains`**`(`*allowed_domains*`)`
: 設定允許網域的序列，或*None*。

`DefaultCookiePolicy.`**`is_not_allowed`**`(`*domain*`)`
: 如果 *domain* 不在設定或接收 cookies 的允許清單上，則回傳 `True`。

DefaultCookiePolicy 實例有以下屬性，這些屬性都是由同名的建構函式引數初始化，而且都可以被指定。

`DefaultCookiePolicy.`**`rfc2109_as_netscape`**
: 如果🄵 true，請求*CookieJar* 實例透過設定*Cookie* 實例的版本屬性🄵 0，將 **RFC 2109** cookies (即在 *Set-Cookie* 標頭中收到的、版本 cookie 屬性🄵 1 的 cookies) 降級🄵 Netscape cookies。預設值是*None*，在這種情🄵下，如果且僅如果 **RFC 2965** 處理被關閉，RFC 2109 cookies 才會被降級。因此，RFC 2109 cookie 在預設情🄵下被降級。

一般的調整嚴格度的控制選項：

`DefaultCookiePolicy.`**`strict_domain`**
: 不允許網站設定具有國家代碼頂層域名的兩層域名，如 `.co.uk`、`.gov.uk`、`.co.nz` 等。這遠遠不🄵完美，也不能保證一定有效！

RFC 2965 通訊協定調整嚴格度的控制選項：

`DefaultCookiePolicy.`**`strict_rfc2965_unverifiable`**
: 遵循針對不可驗證事務（transaction）的 **RFC 2965** 規則（不可驗證事務通常是由重定向或請求發🄵在其它網站的圖片導致的）。如果該屬性🄵假值，則永遠不會基於可驗證性而阻止 cookie

Netscape 通訊協定調整嚴格度的控制選項:

DefaultCookiePolicy.**strict_ns_unverifiable**

即便是對 Netscape cookie 也要應用 **RFC 2965** 規則。

DefaultCookiePolicy.**strict_ns_domain**

指明針對 Netscape cookie 的網域匹配規則的嚴格程度。可接受的值見下文。

DefaultCookiePolicy.**strict_ns_set_initial_dollar**

忽略 Set-Cookie: 標頭中名稱以 `'$'` 開頭的 cookies。

DefaultCookiePolicy.**strict_ns_set_path**

不允許設置路徑與請求 URL 路徑不匹配的 cookie。

strict_ns_domain 是一系列旗標。它的值由將旗標按位元或組成（例如，DomainStrictNoDots|DomainStrictNonDomain 表示兩個旗標都被設定）。

DefaultCookiePolicy.**DomainStrictNoDots**

設定 cookie 時，「host 前綴」不得包含點（例如，www.foo.bar.com 不能🄵 .bar.com 設定 cookie，因🄵 www.foo 包含一個點）。

DefaultCookiePolicy.**DomainStrictNonDomain**

未明確指定 domain cookie-attribute 的 Cookie 只能回傳給與設定 Cookie 的網域相同的網域（例如，spam.example.com 將不會回傳來自 example.com 但🄵有 domain cookie-attribute 的 Cookie）。

DefaultCookiePolicy.**DomainRFC2965Match**

設定 cookie 時，需要完整的 **RFC 2965** 網域匹配。

🄵了方便起見，以下屬性是上述旗標最有用的組合:

DefaultCookiePolicy.**DomainLiberal**

等於 0（即關閉上述所有 Netscape 網域嚴格度旗標）。

DefaultCookiePolicy.**DomainStrict**

等價於 DomainStrictNoDots|DomainStrictNonDomain。

22.19.5 Cookie 物件

Cookie 實例的 Python 屬性大致對應於各種 cookie 標準中指定的標準 cookie 屬性。這個對應關🄵不是一一對應的，因🄵有🄵雜的規則來指定預設值，因🄵 max-age 和 expires cookie 屬性包含相等的訊息，也因🄵 **RFC 2109** cookie 可能會被*http.cookiejar* 從版本 1「降級」到版本 0 (Netscape) cookie。

除了在*CookiePolicy* 方法中的罕見情🄵外，不應該對這些屬性進行指定。這個類🄵不會🄵制執行🄵部一致性，所以如果你這🄵做，你應該要知道你在做什🄵。

Cookie.**version**

整數或*None*。Netscape cookie 的*version* 🄵 0。**RFC 2965** 和 **RFC 2109** cookie 的 version cookie 屬性🄵 1。但是，請注意*http.cookiejar* 可能會將 RFC 2109 cookie 「降級」🄵 Netscape cookie，在這種情🄵下*version* 🄵 0。

Cookie.**name**

Cookie 名稱（字串）。

Cookie.**value**

Cookie 值（字串），或*None*。

Cookie.**port**

代表一個連接埠或一組連接埠的字串 (例如「80」，或「880,8080」)，或*None*。

Cookie.**domain**

Cookie 網域（字串）。

Cookie.**path**
Cookie 路徑（字串，例如 '/acme/rocket_launchers'）。

Cookie.**secure**
如果 cookie 只能透過安全連🄵回傳，則🄵 True。

Cookie.**expires**
自 epoch 起計算的整數到期時間，以秒🄵單位，或*None*。另請參🄵*is_expired()* 方法。

Cookie.**discard**
如果這是 session cookie，即🄵 True。

Cookie.**comment**
來自伺服器解釋此 cookie 功能的字串🄵解，或*None*。

Cookie.**comment_url**
鏈接到來自伺服器的解釋此 cookie 功能的🄵釋的 URL，或者🄵*None*。

Cookie.**rfc2109**
True 如果這個 cookie 是以 **RFC 2109** cookie 的形式收到的 (即這個 cookie 是在 *Set-Cookie* 標頭中收到的，而且在那個標頭中的 Version cookie-attribute 的值是 1)。提供這個屬性的原因是*http.cookiejar* 可能會將 RFC 2109 cookie 「降級」🄵 Netscape cookie，在這種情🄵下*version* 的值是 0。

Cookie.**port_specified**
如果伺服器顯式地指定了一個連接埠或一組連接埠（在 *Set-Cookie* / *Set-Cookie2* 標頭中)。

Cookie.**domain_specified**
如果伺服器明確指定網域，則🄵 True。

Cookie.**domain_initial_dot**
如果伺服器明確指定的網域以點 ('.') 開頭，則🄵 True。

Cookies 可能具有額外的非標准 cookie 屬性。你可以使用下列方法存取這些屬性:

Cookie.**has_nonstandard_attr**(*name*)
如果 cookie 具有指定的 cookie 屬性，則回傳 True 。

Cookie.**get_nonstandard_attr**(*name*, *default=None*)
如果 cookie 具有指定的 cookie 屬性，則回傳其值。否則，回傳 *default*。

Cookie.**set_nonstandard_attr**(*name*, *value*)
設定指定 cookie 屬性的值。

Cookie 類🄵也定義了以下方法:

Cookie.**is_expired**(*now=None*)
如果 cookie 已經超過伺服器要求的過期時間，則回傳 True 。如果給定了 *now* （以自紀元起的秒數🄵單位)，則會回傳 cookie 是否已在指定時間過期。

22.19.6 范例

第一個範例展示了*http.cookiejar*: 最常見的用法:

```
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

本範例🄵明如何使用你的 Netscape、Mozilla 或 Lynx cookies 打開 URL (假設 Unix/Netscape 會慣用 cookies 檔案的位置):

```
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".netscape", "cookies.txt"))
opener = urllib.request.build_opener(urllib.request.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

下一個範例🄵明*DefaultCookiePolicy* 的使用。開🄵 **RFC 2965** cookies，在設定和回傳 Netscape cookies 時對網域更嚴格，🄵阻止某些網域設定 cookies 或讓其回傳：

```
import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStrict,
    blocked_domains=["ads.net", ".ads.net"])
cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

22.20 `xmlrpc` --- XMLRPC 伺服器與用🄵模組

XML-RPC 是一種遠端程序呼叫 (Remote Procedure Call) 方法，它使用通過 HTTP 傳輸（transport）的 XML 來做傳遞。有了它，用🄵端可以在遠端伺服器上呼叫帶有參數的方法（伺服器以 URI 命名）🄵取得結構化的資料。

`xmlrpc` 是一個集合了 XML-RPC 伺服器與用🄵端模組實作的套件。這些模組是：

- *xmlrpc.client*
- *xmlrpc.server*

22.21 `xmlrpc.client` --- XML-RPC 用🄵端存取

原始碼： Lib/xmlrpc/client.py

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP(S) as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

> **⚠ 警告**
>
> The *xmlrpc.client* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data, see *XML 安全性*.

在 3.5 版的變更: For HTTPS URIs, *xmlrpc.client* now performs all the necessary certificate and hostname checks by default.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

class xmlrpc.client.**ServerProxy**(*uri*, *transport=None*, *encoding=None*, *verbose=False*, *allow_none=False*, *use_datetime=False*, *use_builtin_types=False*, ***, *headers=()*, *context=None*)

A *ServerProxy* instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal `SafeTransport`

instance for https: URLs and an internal HTTP `Transport` instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag.

The following parameters govern the use of the returned proxy instance. If *allow_none* is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a *TypeError*. This is a commonly used extension to the XML-RPC specification, but isn't supported by all clients and servers; see http://ontosys.com/xml-rpc/extensions.php for a description. The *use_builtin_types* flag can be used to cause date/time values to be presented as *datetime.datetime* objects and binary data to be presented as *bytes* objects; this flag is false by default. *datetime.datetime*, *bytes* and *bytearray* objects may be passed to calls. The *headers* parameter is an optional sequence of HTTP headers to send with each request, expressed as a sequence of 2-tuples representing the header name and value. (e.g. `[('Header-Name', 'value')]`). If an HTTPS URL is provided, *context* may be *ssl.SSLContext* and configures the SSL settings of the underlying HTTPS connection. The obsolete *use_datetime* flag is similar to *use_builtin_types* but it applies only to date/time values.

在 3.3 版的變更: 新增 *use_builtin_types* 旗標。

在 3.8 版的變更: 新增 *headers* 參數。

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: `http://user:pass@host:port/path`. The `user:pass` portion will be base64-encoded as an HTTP 'Authorization' header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

XML-RPC type	Python type
`boolean`	*bool*
`int`、`i1`、`i2`、`i4`、`i8` 或 `biginteger`	*int* in range from -2147483648 to 2147483647. Values get the `<int>` tag.
`double` 或 `float`	*float*. Values get the `<double>` tag.
`string`	*str*
`array`	*list* or *tuple* containing conformable elements. Arrays are returned as *lists*.
`struct`	*dict*. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their `__dict__` attribute is transmitted.
`dateTime.iso8601`	*DateTime* or *datetime.datetime*. Returned type depends on values of *use_builtin_types* and *use_datetime* flags.
`base64`	*Binary*, *bytes* or *bytearray*. Returned type depends on the value of the *use_builtin_types* flag.
`nil`	The `None` constant. Passing is allowed only if *allow_none* is true.
`bigdecimal`	*decimal.Decimal*. Returned type only.

This is the full set of data types supported by XML-RPC. Method calls may also raise a special *Fault* instance, used to signal XML-RPC server errors, or *ProtocolError* used to signal an error in the HTTP/HTTPS transport layer. Both *Fault* and *ProtocolError* derive from a base class called `Error`. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return);

failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use *bytes* or *bytearray* classes or the *Binary* wrapper class described below.

`Server` is retained as an alias for *ServerProxy* for backwards compatibility. New code should use *ServerProxy*.

在 3.5 版的變更: 加入 *context* 引數。

在 3.6 版的變更: Added support of type tags with prefixes (e.g. `ex:nil`). Added support of unmarshalling additional types used by Apache XML-RPC implementation for numerics: `i1`, `i2`, `i8`, `biginteger`, `float` and `bigdecimal`. See https://ws.apache.org/xmlrpc/types.html for a description.

XML-RPC HOWTO
A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

XML-RPC Introspection
Describes the XML-RPC protocol extension for introspection.

XML-RPC Specification
The official specification.

22.21.1 ServerProxy 物件

A *ServerProxy* instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a *Fault* or *ProtocolError* object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved `system` attribute:

`ServerProxy.system.`**`listMethods`**`()`

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

`ServerProxy.system.`**`methodSignature`**`(`*name*`)`

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply "string, array". If it expects three integers and returns a string, its signature is "string, int, int, int".

If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

`ServerProxy.system.`**`methodHelp`**`(`*name*`)`

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

在 3.5 版的變更: Instances of *ServerProxy* support the *context manager* protocol for closing the underlying transport.

A working example follows. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

def is_even(n):
    return n % 2 == 0

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

with xmlrpc.client.ServerProxy("http://localhost:8000/") as proxy:
    print("3 is even: %s" % str(proxy.is_even(3)))
    print("100 is even: %s" % str(proxy.is_even(100)))
```

22.21.2 日期時間物件

class xmlrpc.client.**DateTime**

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a *datetime.datetime* instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(*string*)

Accept a string as the instance's new time value.

encode(*out*)

Write the XML-RPC encoding of this *DateTime* item to the *out* stream object.

It also supports certain of Python's built-in operators through `rich comparison` and `__repr__()` methods.

A working example follows. The server code:

```
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client
import datetime

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/")

today = proxy.today()
# 將 ISO8601 字串轉🄴成 datetime 物件
converted = datetime.datetime.strptime(today.value, "%Y%m%dT%H:%M:%S")
print("Today: %s" % converted.strftime("%d.%m.%Y, %H:%M"))
```

22.21.3 Binary Objects

class xmlrpc.client.**Binary**

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a *Binary* object is provided by an attribute:

data

The binary data encapsulated by the *Binary* instance. The data is provided as a *bytes* object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(*bytes*)

Accept a base64 *bytes* object and decode it as the instance's new data.

encode(*out*)

Write the XML-RPC base 64 encoding of this binary item to the *out* stream object.

The encoded data will have newlines every 76 characters as per **RFC 2045 section 6.8**, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python's built-in operators through `__eq__()` and `__ne__()` methods.

Example usage of the binary objects. We're going to transfer an image over XMLRPC:

```
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')

server.serve_forever()
```

The client gets the image and saves it to a file:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/")
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
```

22.21.4 Fault Objects

class xmlrpc.client.**Fault**

A *Fault* object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

faultCode

An int indicating the fault type.

faultString

A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a *Fault* by returning a complex type object. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a
# complex number
def add(x, y):
    return x+y+0j

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(add, 'add')

server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/")
try:
    proxy.add(2, 5)
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
```

22.21.5 ProtocolError 物件

class xmlrpc.client.**ProtocolError**

A *ProtocolError* object describes a protocol error in the underlying transport layer (such as a 404 'not found' error if the server named by the URI does not exist). It has the following attributes:

url

The URI or URL that triggered the error.

errcode

The error code.

errmsg

The error message or diagnostic string.

headers

A dict containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we're going to intentionally cause a *ProtocolError* by providing an invalid URI:

```
import xmlrpc.client

# create a ServerProxy with a URI that doesn't respond to XMLRPC requests
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
    print("URL: %s" % err.url)
    print("HTTP/HTTPS headers: %s" % err.headers)
    print("Error code: %d" % err.errcode)
    print("Error message: %s" % err.errmsg)
```

22.21.6 MultiCall 物件

The *MultiCall* object provides a way to encapsulate multiple calls to a remote server into a single request[1].

class xmlrpc.client.**MultiCall**(*server*)

Create an object used to boxcar method calls. *server* is the eventual target of the call. Calls can be made to the result object, but they will immediately return `None`, and only store the call name and parameters in the *MultiCall* object. Calling the object itself causes all stored calls to be transmitted as a single `system.multicall` request. The result of this call is a *generator*; iterating over this generator yields the individual results.

A usage example of this class follows. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y

def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_multicall_functions()
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/")
multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```

22.21.7 便捷的函式

xmlrpc.client.**dumps**(*params*, *methodname=None*, *methodresponse=None*, *encoding=None*, *allow_none=False*)

Convert *params* into an XML-RPC request. or into a response if *methodresponse* is true. *params* can be either a tuple of arguments or an instance of the *Fault* exception class. If *methodresponse* is true, only a single value can be returned, meaning that *params* must be of length 1. *encoding*, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python's *None* value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for *allow_none*.

[1] This approach has been first presented in a discussion on xmlrpc.com.

xmlrpc.client.**loads**(*data*, *use_datetime=False*, *use_builtin_types=False*)

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. *params* is a tuple of argument; *methodname* is a string, or `None` if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a *Fault* exception. The *use_builtin_types* flag can be used to cause date/time values to be presented as *datetime.datetime* objects and binary data to be presented as *bytes* objects; this flag is false by default.

The obsolete *use_datetime* flag is similar to *use_builtin_types* but it applies only to date/time values.

在 3.3 版的變更: 新增 *use_builtin_types* 旗標。

22.21.8 Example of Client Usage

```
# simple test program (from the XML-RPC specification)
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000") # local server
with ServerProxy("http://betty.userland.com") as proxy:

    print(proxy)

    try:
        print(proxy.examples.getStateName(41))
    except Error as v:
        print("ERROR", v)
```

To access an XML-RPC server through a HTTP proxy, you need to define a custom transport. The following example shows how:

```
import http.client
import xmlrpc.client

class ProxiedTransport(xmlrpc.client.Transport):

    def set_proxy(self, host, port=None, headers=None):
        self.proxy = host, port
        self.proxy_headers = headers

    def make_connection(self, host):
        connection = http.client.HTTPConnection(*self.proxy)
        connection.set_tunnel(host, headers=self.proxy_headers)
        self._connection = host, connection
        return connection

transport = ProxiedTransport()
transport.set_proxy('proxy-server', 8080)
server = xmlrpc.client.ServerProxy('http://betty.userland.com', transport=transport)
print(server.examples.getStateName(41))
```

22.21.9 Example of Client and Server Usage

See *SimpleXMLRPCServer 範例*.

22.22 `xmlrpc.server` --- 基本 XML-RPC 伺服器

原始碼： Lib/xmlrpc/server.py

The *xmlrpc.server* module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using *SimpleXMLRPCServer*, or embedded in a CGI environment, using *CGIXMLRPCRequestHandler*.

> **⚠ 警告**
>
> The *xmlrpc.server* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data, see *XML 安全性*.

可用性: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參🄵*WebAssembly 平台*。

class xmlrpc.server.**SimpleXMLRPCServer**(*addr*, *requestHandler=SimpleXMLRPCRequestHandler*, *logRequests=True*, *allow_none=False*, *encoding=None*, *bind_and_activate=True*, *use_builtin_types=False*)

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The *requestHandler* parameter should be a factory for request handler instances; it defaults to *SimpleXMLRPCRequestHandler*. The *addr* and *requestHandler* parameters are passed to the *socketserver.TCPServer* constructor. If *logRequests* is true (the default), requests will be logged; setting this parameter to false will turn off logging. The *allow_none* and *encoding* parameters are passed on to *xmlrpc.client* and control the XML-RPC responses that will be returned from the server. The *bind_and_activate* parameter controls whether `server_bind()` and `server_activate()` are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the *allow_reuse_address* class variable before the address is bound. The *use_builtin_types* parameter is passed to the *loads()* function and controls which types are processed when date/times values or binary data are received; it defaults to false.

在 3.3 版的變更: The *use_builtin_types* flag was added.

class xmlrpc.server.**CGIXMLRPCRequestHandler**(*allow_none=False*, *encoding=None*, *use_builtin_types=False*)

Create a new instance to handle XML-RPC requests in a CGI environment. The *allow_none* and *encoding* parameters are passed on to *xmlrpc.client* and control the XML-RPC responses that will be returned from the server. The *use_builtin_types* parameter is passed to the *loads()* function and controls which types are processed when date/times values or binary data are received; it defaults to false.

在 3.3 版的變更: The *use_builtin_types* flag was added.

class xmlrpc.server.**SimpleXMLRPCRequestHandler**

Create a new request handler instance. This request handler supports `POST` requests and modifies logging so that the *logRequests* parameter to the *SimpleXMLRPCServer* constructor parameter is honored.

22.22.1 SimpleXMLRPCServer 物件

The *SimpleXMLRPCServer* class is based on *socketserver.TCPServer* and provides a means of creating simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.**register_function**(*function=None*, *name=None*)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise `function.__name__` will be used. *name* is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, *name* can only be given as a keyword argument to register *function* under *name*. If no *name* is given, `function.__name__` will be used.

在 3.7 版的變更: *register_function()* 也可被當作裝飾器使用。

SimpleXMLRPCServer.**register_instance**(*instance*, *allow_dotted_names=False*)

Register an object which is used to expose method names which have not been registered using *register_function()*. If *instance* contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request. Its API is `def _dispatch(self, method, params)` (note that *params* does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as `func(*params)`, expanding the parameter list. The return value from

`_dispatch()` is returned to the client as the result. If *instance* does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method.

If the optional *allow_dotted_names* argument is true and the instance does not have a `_dispatch()` method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

> **⚠ 警告**
>
> Enabling the *allow_dotted_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

`SimpleXMLRPCServer.`**`register_introspection_functions`**`()`

Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

`SimpleXMLRPCServer.`**`register_multicall_functions`**`()`

Registers the XML-RPC multicall function system.multicall.

`SimpleXMLRPCRequestHandler.`**`rpc_paths`**

An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 "no such page" HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

SimpleXMLRPCServer 范例

Server code:

```
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
with SimpleXMLRPCServer(('localhost', 8000),
                        requestHandler=RequestHandler) as server:
    server.register_introspection_functions()

    # Register pow() function; this will use the value of
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name
    def adder_function(x, y):
        return x + y
    server.register_function(adder_function, 'add')

    # Register an instance; all the methods of the instance are
    # published as XML-RPC methods (in this case, just 'mul').
    class MyFuncs:
        def mul(self, x, y):
            return x * y

    server.register_instance(MyFuncs())

    # Run the server's main loop
    server.serve_forever()
```

The following client code will call the methods made available by the preceding server:

```
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2,3))  # Returns 2**3 = 8
print(s.add(2,3))  # Returns 5
print(s.mul(5,2))  # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())
```

`register_function()` can also be used as a decorator. The previous server example can register functions in a decorator way:

```
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

with SimpleXMLRPCServer(('localhost', 8000),
                        requestHandler=RequestHandler) as server:
    server.register_introspection_functions()

    # Register pow() function; this will use the value of
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name, using
    # register_function as a decorator. *name* can only be given
    # as a keyword argument.
    @server.register_function(name='add')
    def adder_function(x, y):
        return x + y

    # Register a function under function.__name__.
    @server.register_function
    def mul(x, y):
        return x * y

    server.serve_forever()
```

The following example included in the `Lib/xmlrpc/server.py` module shows a server allowing dotted names and registering a multicall function.

⚠ 警告

Enabling the *allow_dotted_names* option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this example only within a secure, closed network.

```
import datetime

class ExampleService:
    def getData(self):
        return '42'

    class currentTime:
        @staticmethod
        def getCurrentTime():
```

(繼續下一頁)

(繼續上一頁)

```
            return datetime.datetime.now()

with SimpleXMLRPCServer(("localhost", 8000)) as server:
    server.register_function(pow)
    server.register_function(lambda x,y: x+y, 'add')
    server.register_instance(ExampleService(), allow_dotted_names=True)
    server.register_multicall_functions()
    print('Serving XML-RPC on localhost port 8000')
    try:
        server.serve_forever()
    except KeyboardInterrupt:
        print("\nKeyboard interrupt received, exiting.")
        sys.exit(0)
```

This ExampleService demo can be invoked from the command line:

```
python -m xmlrpc.server
```

The client that interacts with the above server is included in `Lib/xmlrpc/client.py`:

```
server = ServerProxy("http://localhost:8000")

try:
    print(server.currentTime.getCurrentTime())
except Error as v:
    print("ERROR", v)

multi = MultiCall(server)
multi.getData()
multi.pow(2,9)
multi.add(1,2)
try:
    for response in multi():
        print(response)
except Error as v:
    print("ERROR", v)
```

This client which interacts with the demo XMLRPC server can be invoked as:

```
python -m xmlrpc.client
```

22.22.2 CGIXMLRPCRequestHandler

The *CGIXMLRPCRequestHandler* class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.**register_function**(*function=None*, *name=None*)

Register a function that can respond to XML-RPC requests. If *name* is given, it will be the method name associated with *function*, otherwise `function.__name__` will be used. *name* is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, *name* can only be given as a keyword argument to register *function* under *name*. If no *name* is given, `function.__name__` will be used.

在 3.7 版的變更: *register_function()* 也可被當作裝飾器使用。

CGIXMLRPCRequestHandler.**register_instance**(*instance*)

Register an object which is used to expose method names which have not been registered using *register_function()*. If instance contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for

individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.**register_introspection_functions**()

Register the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

CGIXMLRPCRequestHandler.**register_multicall_functions**()

Register the XML-RPC multicall function `system.multicall`.

CGIXMLRPCRequestHandler.**handle_request**(*request_text=None*)

Handle an XML-RPC request. If *request_text* is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

範例:

```
class MyFuncs:
    def mul(self, x, y):
        return x * y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```

22.22.3 Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using *DocXMLRPCServer*, or embedded in a CGI environment, using *DocCGIXMLRPCRequestHandler*.

class xmlrpc.server.**DocXMLRPCServer**(*addr*, *requestHandler=DocXMLRPCRequestHandler*, *logRequests=True*, *allow_none=False*, *encoding=None*, *bind_and_activate=True*, *use_builtin_types=True*)

Create a new server instance. All parameters have the same meaning as for *SimpleXMLRPCServer*; *requestHandler* defaults to *DocXMLRPCRequestHandler*.

在 3.3 版的變更: The *use_builtin_types* flag was added.

class xmlrpc.server.**DocCGIXMLRPCRequestHandler**

Create a new instance to handle XML-RPC requests in a CGI environment.

class xmlrpc.server.**DocXMLRPCRequestHandler**

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the *logRequests* parameter to the *DocXMLRPCServer* constructor parameter is honored.

22.22.4 DocXMLRPCServer 物件

The *DocXMLRPCServer* class is derived from *SimpleXMLRPCServer* and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.**set_server_title**(*server_title*)

Set the title used in the generated HTML documentation. This title will be used inside the HTML "title" element.

DocXMLRPCServer.**set_server_name**(*server_name*)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a "h1" element.

DocXMLRPCServer.**set_server_documentation**(*server_documentation*)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

22.22.5 DocCGIXMLRPCRequestHandler

The *DocCGIXMLRPCRequestHandler* class is derived from *CGIXMLRPCRequestHandler* and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocCGIXMLRPCRequestHandler.**set_server_title**(*server_title*)

Set the title used in the generated HTML documentation. This title will be used inside the HTML "title" element.

DocCGIXMLRPCRequestHandler.**set_server_name**(*server_name*)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a "h1" element.

DocCGIXMLRPCRequestHandler.**set_server_documentation**(*server_documentation*)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.

22.23 ipaddress --- IPv4/IPv6 操作函式庫

原始碼： Lib/ipaddress.py

---

ipaddress provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference—for an overview and introduction, see ipaddress-howto.

在 3.3 版被加入.

22.23.1 Convenience factory functions

The *ipaddress* module provides factory functions to conveniently create IP addresses, networks and interfaces:

ipaddress.**ip_address**(*address*)

Return an *IPv4Address* or *IPv6Address* object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than `2**32` will be considered to be IPv4 by default. A *ValueError* is raised if *address* does not represent a valid IPv4 or IPv6 address.

```
>>> ipaddress.ip_address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

ipaddress.**ip_network**(*address*, *strict=True*)

Return an *IPv4Network* or *IPv6Network* object depending on the IP address passed as argument. *address* is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than `2**32` will be considered to be IPv4 by default. *strict* is passed to *IPv4Network* or *IPv6Network*

constructor. A *ValueError* is raised if *address* does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

ipaddress.**ip_interface**(*address*)

Return an *IPv4Interface* or *IPv6Interface* object depending on the IP address passed as argument. *address* is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than `2**32` will be considered to be IPv4 by default. A *ValueError* is raised if *address* does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don't know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.

22.23.2 IP Addresses

Address objects

The *IPv4Address* and *IPv6Address* objects share a lot of common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by *IPv4Address* objects, in order to make it easier to write code that handles both IP versions correctly. Address objects are *hashable*, so they can be used as keys in dictionaries.

class ipaddress.**IPv4Address**(*address*)

Construct an IPv4 address. An *AddressValueError* is raised if *address* is not a valid IPv4 address.

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0--255, separated by dots (e.g. `192.168.0.1`). Each integer represents an octet (byte) in the address. Leading zeroes are not tolerated to prevent confusion with octal notation.
2. An integer that fits into 32 bits.
3. An integer packed into a *bytes* object of length 4 (most significant octet first).

```
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\xC0\xA8\x00\x01')
IPv4Address('192.168.0.1')
```

在 3.8 版的變更: Leading zeros are tolerated, even in ambiguous cases that look like octal notation.

在 3.9.5 版的變更: Leading zeros are no longer tolerated and are treated as an error. IPv4 address strings are now parsed as strict as glibc *inet_pton()*.

version

The appropriate version number: `4` for IPv4, `6` for IPv6.

在 3.14 版的變更: Made available on the class.

max_prefixlen

The total number of bits in the address representation for this version: `32` for IPv4, `128` for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

在 3.14 版的變更: Made available on the class.

compressed

exploded

The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

packed

The binary representation of this address - a *bytes* object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

reverse_pointer

The name of the reverse DNS PTR record for the IP address, e.g.:

```
>>> ipaddress.ip_address("127.0.0.1").reverse_pointer
'1.0.0.127.in-addr.arpa'
>>> ipaddress.ip_address("2001:db8::1").reverse_pointer
'1.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.8.b.d.0.1.0.0.2.ip6.arpa'
```

This is the name that could be used for performing a PTR lookup, not the resolved hostname itself.

在 3.5 版被加入.

is_multicast

`True` if the address is reserved for multicast use. See **RFC 3171** (for IPv4) or **RFC 2373** (for IPv6).

is_private

`True` if the address is defined as not globally reachable by iana-ipv4-special-registry (for IPv4) or iana-ipv6-special-registry (for IPv6) with the following exceptions:

- `is_private` is `False` for the shared address space (`100.64.0.0/10`)
- For IPv4-mapped IPv6-addresses the `is_private` value is determined by the semantics of the underlying IPv4 addresses and the following condition holds (see *`IPv6Address.ipv4_mapped`*):

  ```
  address.is_private == address.ipv4_mapped.is_private
  ```

`is_private` has value opposite to *`is_global`*, except for the shared address space (`100.64.0.0/10` range) where they are both `False`.

在 3.13 版的變更: Fixed some false positives and false negatives.

- `192.0.0.0/24` is considered private with the exception of `192.0.0.9/32` and `192.0.0.10/32` (previously: only the `192.0.0.0/29` sub-range was considered private).
- `64:ff9b:1::/48` is considered private.
- `2002::/16` is considered private.
- There are exceptions within `2001::/23` (otherwise considered private): `2001:1::1/128`, `2001:1::2/128`, `2001:3::/32`, `2001:4:112::/48`, `2001:20::/28`, `2001:30::/28`. The exceptions are not considered private.

is_global

`True` if the address is defined as globally reachable by iana-ipv4-special-registry (for IPv4) or iana-ipv6-special-registry (for IPv6) with the following exception:

For IPv4-mapped IPv6-addresses the `is_private` value is determined by the semantics of the underlying IPv4 addresses and the following condition holds (see *`IPv6Address.ipv4_mapped`*):

```
address.is_global == address.ipv4_mapped.is_global
```

`is_global` has value opposite to *`is_private`*, except for the shared address space (`100.64.0.0/10` range) where they are both `False`.

在 3.4 版被加入.

在 3.13 版的變更: Fixed some false positives and false negatives, see *`is_private`* for details.

is_unspecified

`True` if the address is unspecified. See **RFC 5735** (for IPv4) or **RFC 2373** (for IPv6).

is_reserved

`True` if the address is noted as reserved by the IETF. For IPv4, this is only `240.0.0.0/4`, the `Reserved` address block. For IPv6, this is all addresses allocated as `Reserved by IETF` for future use.

> **備🄵**
>
> For IPv4, `is_reserved` is not related to the address block value of the `Reserved-by-Protocol` column in iana-ipv4-special-registry.

> **警示**
>
> For IPv6, `fec0::/10` a former Site-Local scoped address prefix is currently excluded from that list (see *`is_site_local`* & **RFC 3879**).

is_loopback

`True` if this is a loopback address. See **RFC 3330** (for IPv4) or **RFC 2373** (for IPv6).

is_link_local

`True` if the address is reserved for link-local usage. See **RFC 3927**.

ipv6_mapped

`IPv4Address` object representing the IPv4-mapped IPv6 address. See **RFC 4291**.

在 3.13 版被加入.

`IPv4Address.`**`__format__`**(*fmt*)

Returns a string representation of the IP address, controlled by an explicit format string. *fmt* can be one of the following: `'s'`, the default option, equivalent to *`str()`*, `'b'` for a zero-padded binary string, `'X'` or `'x'` for an uppercase or lowercase hexadecimal representation, or `'n'`, which is equivalent to `'b'` for IPv4 addresses and `'x'` for IPv6. For binary and hexadecimal representations, the form specifier `'#'` and the grouping option `'_'` are available. `__format__` is used by `format`, `str.format` and f-strings.

```
>>> format(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> '{:#b}'.format(ipaddress.IPv4Address('192.168.0.1'))
'0b11000000101010000000000000000001'
>>> f'{ipaddress.IPv6Address("2001:db8::1000"):s}'
'2001:db8::1000'
>>> format(ipaddress.IPv6Address('2001:db8::1000'), '_X')
'2001_0DB8_0000_0000_0000_0000_0000_1000'
>>> '{:#_n}'.format(ipaddress.IPv6Address('2001:db8::1000'))
'0x2001_0db8_0000_0000_0000_0000_0000_1000'
```

在 3.9 版被加入.

class `ipaddress.`**`IPv6Address`**(*address*)

Construct an IPv6 address. An *`AddressValueError`* is raised if *address* is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an *exploded* (longhand) notation. The string can also be *compressed* (shorthand notation) by various means. See **RFC 4291** for details. For example, `"0000:0000:0000:0000:0000:0abc:0007:0def"` can be compressed to `"::abc:7:def"`.

   Optionally, the string may also have a scope zone ID, expressed with a suffix `%scope_id`. If present, the scope ID must be non-empty, and may not contain `%`. See **RFC 4007** for details. For example, `fe80::1234%1` might identify address `fe80::1234` on the first link of the node.

2. An integer that fits into 128 bits.

3. An integer packed into a *bytes* object of length 16, big-endian.

```
>>> ipaddress.IPv6Address('2001:db8::1000')
IPv6Address('2001:db8::1000')
>>> ipaddress.IPv6Address('ff02::5678%1')
IPv6Address('ff02::5678%1')
```

compressed

The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by `str(addr)` for IPv6 addresses.

exploded

The long form of the address representation, with all leading zeroes and groups consisting entirely of zeroes included.

For the following attributes and methods, see the corresponding documentation of the *IPv4Address* class:

packed

reverse_pointer

version

max_prefixlen

is_multicast

is_private

is_global

在 3.4 版被加入.

is_unspecified

is_reserved

is_loopback

is_link_local

is_site_local

`True` if the address is reserved for site-local usage. Note that the site-local address space has been deprecated by **RFC 3879**. Use *is_private* to test if this address is in the space of unique local addresses as defined by **RFC 4193**.

ipv4_mapped

For addresses that appear to be IPv4 mapped addresses (starting with `::FFFF/96`), this property will report the embedded IPv4 address. For any other address, this property will be `None`.

scope_id

For scoped addresses as defined by **RFC 4007**, this property identifies the particular zone of the address's scope that the address belongs to, as a string. When no scope zone is specified, this property will be `None`.

sixtofour

For addresses that appear to be 6to4 addresses (starting with `2002::/16`) as defined by **RFC 3056**, this property will report the embedded IPv4 address. For any other address, this property will be `None`.

teredo

For addresses that appear to be Teredo addresses (starting with `2001::/32`) as defined by **RFC 4380**, this property will report the embedded `(server, client)` IP address pair. For any other address, this property will be `None`.

`IPv6Address.__format__`(*fmt*)

Refer to the corresponding method documentation in *IPv4Address*.

在 3.9 版被加入.

Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is handled using the *str()* and *int()* builtin functions:

```
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
>>> str(ipaddress.IPv6Address('::1'))
'::1'
>>> int(ipaddress.IPv6Address('::1'))
1
```

Note that IPv6 scoped addresses are converted to integers without scope zone ID.

運算子

Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

比較運算子

Address objects can be compared with the usual set of comparison operators. Same IPv6 addresses with different scope zone IDs are not equal. Some examples:

```
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
>>> IPv6Address('fe80::1234') == IPv6Address('fe80::1234%1')
False
>>> IPv6Address('fe80::1234%1') != IPv6Address('fe80::1234%2')
True
```

算術運算子

Integers can be added to or subtracted from address objects. Some examples:

```
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32) is not permitted as an IPv4 address
```

22.23.3 IP Network definitions

The *IPv4Network* and *IPv6Network* objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a *mask* and a *network address*, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask `255.255.255.0` and the network address `192.168.1.0` consists of IP addresses in the inclusive range `192.168.1.0` to `192.168.1.255`.

Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A *prefix* `/<nbits>` is a notation that denotes how many high-order bits are set in the network mask. A *net mask* is an IP address with some number of high-order bits set. Thus the prefix `/24` is equivalent to the net mask `255.255.255.0` in IPv4, or `ffff:ff00::` in IPv6. In addition, a *host mask* is the logical inverse of a *net mask*, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to `/24` in IPv4 is `0.0.0.255`.

Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement additional attributes. All of these are common between *IPv4Network* and *IPv6Network*, so to avoid duplication they are only documented for *IPv4Network*. Network objects are *hashable*, so they can be used as keys in dictionaries.

class ipaddress.**IPv4Network**(*address*, *strict=True*)

Construct an IPv4 network definition. *address* can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (`/`). The IP address is the network address, and the mask can be either a single number, which means it's a *prefix*, or a string representation of an IPv4 address. If it's the latter, the mask is interpreted as a *net mask* if it starts with a non-zero field, or as a *host mask* if it starts with a zero field, with the single exception of an all-zero mask which is treated as a *net mask*. If no mask is provided, it's considered to be `/32`.

   For example, the following *address* specifications are equivalent: `192.168.1.0/24`, `192.168.1.0/255.255.255.0` and `192.168.1.0/0.0.0.255`.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being *address* and the mask being `/32`.

3. An integer packed into a *bytes* object of length 4, big-endian. The interpretation is similar to an integer *address*.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 32-bits integer, a 4-bytes packed integer, or an existing *IPv4Address* object; and the netmask is either an integer representing the prefix length (e.g. `24`) or a string representing the prefix mask (e.g. `255.255.255.0`).

An *AddressValueError* is raised if *address* is not a valid IPv4 address. A *NetmaskValueError* is raised if the mask is not valid for an IPv4 address.

If *strict* is `True` and host bits are set in the supplied address, then *ValueError* is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Unless stated otherwise, all network methods accepting other network/address objects will raise *TypeError* if the argument's IP version is incompatible to `self`.

在 3.5 版的變更: Added the two-tuple form for the *address* constructor parameter.

version

max_prefixlen

Refer to the corresponding attribute documentation in *IPv4Address*.

is_multicast

is_private

is_unspecified

is_reserved

is_loopback

is_link_local

These attributes are true for the network as a whole if they are true for both the network address and the broadcast address.

network_address

The network address for the network. The network address and the prefix length together uniquely define a network.

broadcast_address

The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

hostmask

The host mask, as an *IPv4Address* object.

netmask

The net mask, as an *IPv4Address* object.

with_prefixlen

compressed

exploded

A string representation of the network, with the mask in prefix notation.

`with_prefixlen` and `compressed` are always the same as `str(network)`. `exploded` uses the exploded form the network address.

with_netmask

A string representation of the network, with the mask in net mask notation.

with_hostmask

A string representation of the network, with the mask in host mask notation.

num_addresses

The total number of addresses in the network.

prefixlen

Length of the network prefix, in bits.

hosts()

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address. For networks with a mask length of 31, the network address and network broadcast address are also included in the result. Networks with a mask of 32 will return a list containing the single host address.

```
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2.2'),
 IPv4Address('192.0.2.3'), IPv4Address('192.0.2.4'),
 IPv4Address('192.0.2.5'), IPv4Address('192.0.2.6')]
>>> list(ip_network('192.0.2.0/31').hosts())
[IPv4Address('192.0.2.0'), IPv4Address('192.0.2.1')]
>>> list(ip_network('192.0.2.1/32').hosts())
[IPv4Address('192.0.2.1')]
```

overlaps(*other*)

`True` if this network is partly or wholly contained in *other* or *other* is wholly contained in this network.

address_exclude(*network*)

Computes the network definitions resulting from removing the given *network* from this one. Returns an iterator of network objects. Raises *`ValueError`* if *network* is not completely contained in this network.

```
>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.0.2.4/30'),
 IPv4Network('192.0.2.2/31'), IPv4Network('192.0.2.0/32')]
```

subnets(*prefixlen_diff=1*, *new_prefix=None*)

The subnets that join to make the current network definition, depending on the argument values. *prefixlen_diff* is the amount our prefix length should be increased by. *new_prefix* is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of *prefixlen_diff* and *new_prefix* must be set. Returns an iterator of network objects.

```
>>> list(ip_network('192.0.2.0/24').subnets())
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=2))
[IPv4Network('192.0.2.0/26'), IPv4Network('192.0.2.64/26'),
 IPv4Network('192.0.2.128/26'), IPv4Network('192.0.2.192/26')]
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix=26))
[IPv4Network('192.0.2.0/26'), IPv4Network('192.0.2.64/26'),
 IPv4Network('192.0.2.128/26'), IPv4Network('192.0.2.192/26')]
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix=23))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    raise ValueError('new prefix must be longer')
ValueError: new prefix must be longer
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix=25))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
```

supernet(*prefixlen_diff=1*, *new_prefix=None*)

The supernet containing this network definition, depending on the argument values. *prefixlen_diff* is the amount our prefix length should be decreased by. *new_prefix* is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of *prefixlen_diff* and *new_prefix* must be set. Returns a single network object.

```
>>> ip_network('192.0.2.0/24').supernet()
IPv4Network('192.0.2.0/23')
>>> ip_network('192.0.2.0/24').supernet(prefixlen_diff=2)
IPv4Network('192.0.0.0/22')
>>> ip_network('192.0.2.0/24').supernet(new_prefix=20)
IPv4Network('192.0.0.0/20')
```

subnet_of(*other*)

Return `True` if this network is a subnet of *other*.

```
>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> b.subnet_of(a)
True
```

在 3.7 版被加入.

supernet_of(*other*)

Return `True` if this network is a supernet of *other*.

```
>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> a.supernet_of(b)
True
```

在 3.7 版被加入.

compare_networks(*other*)

Compare this network to *other*. In this comparison only the network addresses are considered; host bits aren't. Returns either `-1`, `0` or `1`.

```
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.2/32'))
-1
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.0/32'))
1
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32'))
0
```

在 3.7 版之後被🄵用: It uses the same ordering and comparison algorithm as "<", "==", and ">"

class ipaddress.**IPv6Network**(*address*, *strict=True*)

Construct an IPv6 network definition. *address* can be one of the following:

1. A string consisting of an IP address and an optional prefix length, separated by a slash (`/`). The IP address is the network address, and the prefix length must be a single number, the *prefix*. If no prefix length is provided, it's considered to be `/128`.

   Note that currently expanded netmasks are not supported. That means `2001:db00::0/24` is a valid argument while `2001:db00::0/ffff:ff00::` is not.

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being *address* and the mask being `/128`.

3. An integer packed into a *bytes* object of length 16, big-endian. The interpretation is similar to an integer *address*.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 128-bits integer, a 16-bytes packed integer, or an existing *IPv6Address* object; and the netmask is an integer representing the prefix length.

An *AddressValueError* is raised if *address* is not a valid IPv6 address. A *NetmaskValueError* is raised if the mask is not valid for an IPv6 address.

If *strict* is `True` and host bits are set in the supplied address, then *ValueError* is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

在 3.5 版的變更: Added the two-tuple form for the *address* constructor parameter.

version

max_prefixlen

hosts()

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the Subnet-Router anycast address. For networks with a mask length of 127, the Subnet-Router anycast address is also included in the result. Networks with a mask of 128 will return a list containing the single host address.

supernet(*prefixlen_diff=1*, *new_prefix=None*)

subnet_of(*other*)

supernet_of(*other*)

compare_networks(*other*)

Refer to the corresponding attribute documentation in *IPv4Network*.

is_site_local

This attribute is true for the network as a whole if it is true for both the network address and the broadcast address.

運算子

Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

Logical operators

Network objects can be compared with the usual set of logical operators. Network objects are ordered first by network address, then by net mask.

🄵代

Network objects can be iterated to list all the addresses belonging to the network. For iteration, *all* hosts are returned, including unusable hosts (for usable hosts, use the `hosts()` method). An example:

```
>>> for addr in IPv4Network('192.0.2.0/28'):
...     addr
...
IPv4Address('192.0.2.0')
IPv4Address('192.0.2.1')
IPv4Address('192.0.2.2')
IPv4Address('192.0.2.3')
IPv4Address('192.0.2.4')
IPv4Address('192.0.2.5')
IPv4Address('192.0.2.6')
IPv4Address('192.0.2.7')
IPv4Address('192.0.2.8')
IPv4Address('192.0.2.9')
IPv4Address('192.0.2.10')
IPv4Address('192.0.2.11')
IPv4Address('192.0.2.12')
IPv4Address('192.0.2.13')
IPv4Address('192.0.2.14')
IPv4Address('192.0.2.15')
```

Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/28')
True
>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/28')
False
```

22.23.4 Interface objects

Interface objects are *hashable*, so they can be used as keys in dictionaries.

class ipaddress.**IPv4Interface**(*address*)

Construct an IPv4 interface. The meaning of *address* is as in the constructor of `IPv4Network`, except that arbitrary host addresses are always accepted.

`IPv4Interface` is a subclass of `IPv4Address`, so it inherits all the attributes from that class. In addition, the following attributes are available:

ip

The address (`IPv4Address`) without network information.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.ip
IPv4Address('192.0.2.5')
```

network

The network (*IPv4Network*) this interface belongs to.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.network
IPv4Network('192.0.2.0/24')
```

with_prefixlen

A string representation of the interface with the mask in prefix notation.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_prefixlen
'192.0.2.5/24'
```

with_netmask

A string representation of the interface with the network as a net mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'
```

with_hostmask

A string representation of the interface with the network as a host mask.

```
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'
```

class ipaddress.**IPv6Interface**(*address*)

Construct an IPv6 interface. The meaning of *address* is as in the constructor of *IPv6Network*, except that arbitrary host addresses are always accepted.

IPv6Interface is a subclass of *IPv6Address*, so it inherits all the attributes from that class. In addition, the following attributes are available:

ip

network

with_prefixlen

with_netmask

with_hostmask

Refer to the corresponding attribute documentation in *IPv4Interface*.

運算子

Interface objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

Logical operators

Interface objects can be compared with the usual set of logical operators.

For equality comparison (== and !=), both the IP address and network must be the same for the objects to be equal. An interface will not compare equal to any address or network object.

For ordering (<, >, etc) the rules are different. Interface and address objects with the same IP version can be compared, and the address objects will always sort before the interface objects. Two interface objects are first compared by their networks and, if those are the same, then by their IP addresses.

22.23.5 Other Module Level Functions

The module also provides the following module level functions:

ipaddress.**v4_int_to_packed**(*address*)

Represent an address as 4 packed bytes in network (big-endian) order. *address* is an integer representation of an IPv4 IP address. A *ValueError* is raised if the integer is negative or too large to be an IPv4 IP address.

```
>>> ipaddress.ip_address(3221225985)
IPv4Address('192.0.2.1')
>>> ipaddress.v4_int_to_packed(3221225985)
b'\xc0\x00\x02\x01'
```

ipaddress.**v6_int_to_packed**(*address*)

Represent an address as 16 packed bytes in network (big-endian) order. *address* is an integer representation of an IPv6 IP address. A *ValueError* is raised if the integer is negative or too large to be an IPv6 IP address.

ipaddress.**summarize_address_range**(*first*, *last*)

Return an iterator of the summarized network range given the first and last IP addresses. *first* is the first *IPv4Address* or *IPv6Address* in the range and *last* is the last *IPv4Address* or *IPv6Address* in the range. A *TypeError* is raised if *first* or *last* are not IP addresses or are not of the same version. A *ValueError* is raised if *last* is not greater than *first* or if *first* address version is not 4 or 6.

```
>>> [ipaddr for ipaddr in ipaddress.summarize_address_range(
...    ipaddress.IPv4Address('192.0.2.0'),
...    ipaddress.IPv4Address('192.0.2.130'))]
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/31'), IPv4Network('192.0.2.130/32
↪')]
```

ipaddress.**collapse_addresses**(*addresses*)

Return an iterator of the collapsed *IPv4Network* or *IPv6Network* objects. *addresses* is an *iterable* of *IPv4Network* or *IPv6Network* objects. A *TypeError* is raised if *addresses* contains mixed version objects.

```
>>> [ipaddr for ipaddr in
... ipaddress.collapse_addresses([ipaddress.IPv4Network('192.0.2.0/25'),
... ipaddress.IPv4Network('192.0.2.128/25')])]
[IPv4Network('192.0.2.0/24')]
```

ipaddress.**get_mixed_type_key**(*obj*)

Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they're fundamentally different, so the expression:

```
IPv4Address('192.0.2.0') <= IPv4Network('192.0.2.0/24')
```

doesn't make sense. There are some times however, where you may wish to have *ipaddress* sort these anyway. If you need to do this, you can use this function as the *key* argument to *sorted()*.

obj is either a network or address object.

22.23.6 Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

exception ipaddress.**AddressValueError**(*ValueError*)

Any value error related to the address.

exception ipaddress.**NetmaskValueError**(*ValueError*)

Any value error related to the net mask.

CHAPTER 23

多媒體服務

此章節所描述的模組 (module) 實作了多種在多媒體服務中相當有用的演算法和介面，🄵可在安裝時🄵定是否要使用它們。以下🄵綜述：

23.1 wave --- 讀寫 WAV 檔案

原始碼： Lib/wave.py

---

wave 模組🄵波形音訊檔案格式「WAVE」（或稱「WAV」）提供了便捷的介面。僅支援未壓縮的 PCM 編碼波形檔。

在 3.12 版的變更: 增加了標頭 WAVE_FORMAT_EXTENSIBLE 的支援，要求的擴展格式🄵KSDATAFORMAT_SUBTYPE_PCM。

wave 模組定義了以下的函式和例外：

wave.**open**(*file*, *mode=None*)

如果 *file* 是一個字串，會打開對應名稱的檔案，否則會以類檔案物件處理。*mode* 可以是：

'rb'
唯讀模式。

'wb'
唯寫模式。

請注意，不支援同時讀寫 WAV 檔案。

mode 設定🄵 'rb' 時，會回傳一個*Wave_read* 物件，*mode* 設定🄵 'wb' 時，則回傳一個*Wave_write* 物件。如果省略 *mode*，🄵且將類檔案 (file-like) 物件作🄵 *file* 參數傳遞，則 file.mode 會是 *mode* 的預設值。

如果你傳遞一個類檔案物件，當呼叫其 close() 方法時，wave 物件不會自動關閉該物件；關閉檔案物件的責任會在呼叫者上。

open() 函式可以在 with 陳述式中使用。當 with 區塊完成時，會呼叫*Wave_read.close()* 或是*Wave_write.close()* 方法。

在 3.4 版的變更: 增加對不可搜尋 (unseekable) 檔案的支援。

exception wave.**Error**

當不符合 WAV 格式或無法操作時會引發錯誤。

23.1.1 Wave_read 物件

class wave.**Wave_read**

讀取一個 WAV 檔案。

由*open()* 回傳的 Wave_read 物件具有以下方法：

close()

關閉*wave* 開🄵的串流🄵使該實例無法使用。當物件回收時自動呼叫。

getnchannels()

回傳音訊聲道的數量（單聲道🄵 `1`，立體聲🄵 `2`）。

getsampwidth()

回傳以位元組表示的取樣寬度 (sample width)。

getframerate()

回傳取樣率。

getnframes()

回傳音訊幀數。

getcomptype()

回傳壓縮類型（僅支援 `'NONE'` 類型）。

getcompname()

getcomptype() 的人類可讀的版本。通常使用 `'not compressed'` 代替 `'NONE'`。

getparams()

回傳一個*namedtuple()* `(nchannels, sampwidth, framerate, nframes, comptype, compname)`，等同於 `get*()` 方法的輸出。

readframes(*n*)

讀取🄵回傳以*bytes* 物件表示的最多 *n* 個音訊幀。

rewind()

重置檔案指標至音訊流的開頭。

以下兩個方法是🄵了與舊的 `aifc` 模組保持相容性，🄵不執行任何操作。

getmarkers()

回傳 `None`。

Deprecated since version 3.13, will be removed in version 3.15: 該方法是🄵了保持與 `aifc` 模組相容性而留存，此模組已於 Python 3.13 中🄵除。

getmark(*id*)

引發錯誤。

Deprecated since version 3.13, will be removed in version 3.15: 該方法是🄵了保持與 `aifc` 模組相容性而留存，此模組已於 Python 3.13 中🄵除。

以下兩個方法所定義的「位置」，在它們之間是相容的，但其他情🄵下則取🄵於具體實作方式。

setpos(*pos*)

將檔案指標設定🄵指定的位置。

tell()

回傳目前的檔案指標位置。

23.1.2 Wave_write 物件

class wave.**Wave_write**

寫入一個 WAV 檔案。

Wave_write 物件，由*open()* 回傳。

對於可搜尋 (seekable) 的輸出串流，wave 標頭將自動更新，以反映實際寫入的幀數。對於不可搜尋的串流，當寫入第一個幀資料時，*nframes* 的值必須是准確的。要取得准確的 *nframes* 值，可以通過呼叫*setnframes()* 或*setparams()* 方法，🄵在呼叫*close()* 之前設定將寫入的幀數量，然後使用*writeframesraw()* 方法寫入幀資料；或者通過呼叫*writeframes()* 方法一次性寫入所有的幀資料。在後一種情🄵下，*writeframes()* 方法將計算資料中的幀數量，🄵在寫入幀資料之前相應地設定 *nframes* 的值。

在 3.4 版的變更: 增加對不可搜尋 (unseekable) 檔案的支援。

Wave_write 物件具有以下方法：

close()

確保 *nframes* 正確，如果該檔案是由*wave* 開🄵的，則關閉該檔案。此方法在物件回收時被呼叫。如果輸出串流不可搜尋且 *nframes* 不符合實際寫入的幀數，則會引發例外。

setnchannels(*n*)

設定音訊的通道數量。

setsampwidth(*n*)

設定取樣寬度🄵 *n* 個位元組。

setframerate(*n*)

設定取樣頻率🄵 *n*。

在 3.2 版的變更: 此方法的非整數輸入會被將四舍五入到最接近的整數。

setnframes(*n*)

設定幀數🄵 *n*。如果實際寫入的幀數不同，則稍後將進行更改（如果輸出串流不可搜尋，則此嘗試將引發錯誤）。

setcomptype(*type*, *name*)

設定壓縮類型和描述。目前只支援壓縮類型🄵 NONE，表示無壓縮。

setparams(*tuple*)

這個 *tuple* 應該是 (nchannels, sampwidth, framerate, nframes, comptype, compname)，值需要是符合 set*() 方法的參數。設定所有參數。

tell()

回傳檔案中的指標位置，其指標位置含意與*Wave_read.tell()* 和*Wave_read.setpos()* 是一致的。

writeframesraw(*data*)

寫入音訊幀，不修正 *nframes*。

在 3.4 版的變更: 現在可接受任何*bytes-like object*。

writeframes(*data*)

寫入音訊幀🄵確保 *nframes* 正確。如果輸出串流不可搜尋，🄵且在寫入 *data* 後已寫入的總幀數與先前設定的 *nframes* 值不符，則會引發錯誤。

在 3.4 版的變更: 現在可接受任何*bytes-like object*。

注意在呼叫*writeframes()* 或*writeframesraw()* 之後設置任何參數都是無效的，任何嘗試這樣做的操作都會引發*wave.Error*。

23.2 `colorsys` --- 🄵色系統間的轉🄵

原始碼： Lib/colorsys.py

`colorsys` 模組 (module) 定義了電腦顯示器所用的 RGB （紅🄵藍）色彩空間與三種其他色彩座標系統：YIQ、HLS (色相、亮度、飽和度) 和 HSV (色相、飽和度、明度) 所表示的🄵色值之間的雙向轉🄵。所有這些色彩空間的座標都使用浮點數值 (floating-point) 來表示。在 YIQ 空間中，Y 座標值🄵 0 和 1 之間，而 I 和 Q 座標均可以🄵正數或負數。在所有其他空間中，座標值均🄵 0 和 1 之間。

也參考

有關色彩空間的更多資訊請見 https://poynton.ca/ColorFAQ.html 和 https://www.cambridgeincolour.com/tutorials/color-spaces.htm。

`colorsys` 模組定義了以下函式：

`colorsys.`**`rgb_to_yiq`**(*r*, *g*, *b*)
: 將🄵色自 RGB 座標轉🄵至 YIQ 座標。

`colorsys.`**`yiq_to_rgb`**(*y*, *i*, *q*)
: 將🄵色自 YIQ 座標轉🄵至 RGB 座標。

`colorsys.`**`rgb_to_hls`**(*r*, *g*, *b*)
: 將🄵色自 RGB 座標轉🄵至 HLS 座標。

`colorsys.`**`hls_to_rgb`**(*h*, *l*, *s*)
: 將🄵色自 HLS 座標轉🄵至 RGB 座標。

`colorsys.`**`rgb_to_hsv`**(*r*, *g*, *b*)
: 將🄵色自 RGB 座標轉🄵至 HSV 座標。

`colorsys.`**`hsv_to_rgb`**(*h*, *s*, *v*)
: 將🄵色自 HSV 座標轉🄵至 RGB 座標。

範例：

```
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```

CHAPTER 24

國際化

本章所描述的模組透過提供用於程式訊息中語言的選擇機制或是調整輸出以符合當地慣例，來幫助你編寫不依賴語言和地區設定的軟體

本章節所描述的模組列表🄵:

24.1 gettext --- 多語言國際化服務

原始碼： Lib/gettext.py

The *gettext* module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU **gettext** message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.

24.1.1 GNU gettext API

The *gettext* module defines the following API, which is very similar to the GNU **gettext** API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

gettext.**bindtextdomain**(*domain*, *localedir=None*)

Bind the *domain* to the locale directory *localedir*. More concretely, *gettext* will look for binary `.mo` files for the given domain using the path (on Unix): *localedir*`/`*language*`/LC_MESSAGES/`*domain*`.mo`, where *language* is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If *localedir* is omitted or `None`, then the current binding for *domain* is returned.[1]

[1] The default locale directory is system dependent; for example, on Red Hat Linux it is `/usr/share/locale`, but on Solaris it is `/usr/lib/locale`. The `gettext` module does not try to support these system dependent defaults; instead its default is *sys.base_prefix*`/share/locale` (see *sys.base_prefix*). For this reason, it is always best to call *bindtextdomain()* with an explicit absolute path at the start of your application.

gettext.**textdomain**(*domain=None*)

Change or query the current global domain. If *domain* is `None`, then the current global domain is returned, otherwise the global domain is set to *domain*, which is returned.

gettext.**gettext**(*message*)

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as `_()` in the local namespace (see examples below).

gettext.**dgettext**(*domain*, *message*)

Like *gettext()*, but look the message up in the specified *domain*.

gettext.**ngettext**(*singular*, *plural*, *n*)

Like *gettext()*, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in `.po` files and the formulas for a variety of languages.

gettext.**dngettext**(*domain*, *singular*, *plural*, *n*)

Like *ngettext()*, but look the message up in the specified *domain*.

gettext.**pgettext**(*context*, *message*)

gettext.**dpgettext**(*domain*, *context*, *message*)

gettext.**npgettext**(*context*, *singular*, *plural*, *n*)

gettext.**dnpgettext**(*domain*, *context*, *singular*, *plural*, *n*)

Similar to the corresponding functions without the `p` in the prefix (that is, *gettext()*, *dgettext()*, *ngettext()*, *dngettext()*), but the translation is restricted to the given message *context*.

在 3.8 版被加入.

Note that GNU **gettext** also defines a `dcgettext()` method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:

```
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my/language/directory')
gettext.textdomain('myapplication')
_ = gettext.gettext
# ...
print(_('This is a translatable string.'))
```

24.1.2 Class-based API

The class-based API of the *gettext* module gives you more flexibility and greater convenience than the GNU **gettext** API. It is the recommended way of localizing your Python applications and modules. `gettext` defines a *GNUTranslations* class which implements the parsing of GNU `.mo` format files, and has methods for returning strings. Instances of this class can also install themselves in the built-in namespace as the function `_()`.

gettext.**find**(*domain*, *localedir=None*, *languages=None*, *all=False*)

This function implements the standard `.mo` file search algorithm. It takes a *domain*, identical to what *textdomain()* takes. Optional *localedir* is as in *bindtextdomain()*. Optional *languages* is a list of strings, where each string is a language code.

If *localedir* is not given, then the default system locale directory is used.[2] If *languages* is not given, then the following environment variables are searched: `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG`. The first one returning a non-empty value is used for the *languages* variable. The environment variables should contain a

[2] 請見上方*bindtextdomain()* 之🄵解。

colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

localedir/*language*/LC_MESSAGES/*domain*.mo

The first such file name that exists is returned by *find()*. If no such file is found, then None is returned. If *all* is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

gettext.**translation**(*domain*, *localedir=None*, *languages=None*, *class_=None*, *fallback=False*)

Return a *Translations instance based on the *domain*, *localedir*, and *languages*, which are first passed to *find()* to get a list of the associated .mo file paths. Instances with identical .mo file names are cached. The actual class instantiated is *class_* if provided, otherwise *GNUTranslations*. The class's constructor must take a single *file object* argument.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, *copy.copy()* is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no .mo file is found, this function raises *OSError* if *fallback* is false (which is the default), and returns a *NullTranslations* instance if *fallback* is true.

在 3.3 版的變更: *IOError* 曾經被引發，現在它是一個*OSError* 的🄵名。

在 3.11 版的變更: *codeset* 參數被移除。

gettext.**install**(*domain*, *localedir=None*, *, *names=None*)

This installs the function _() in Python's builtins namespace, based on *domain* and *localedir* which are passed to the function *translation()*.

For the *names* parameter, please see the description of the translation object's *install()* method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the _() function, like this:

```
print(_('This string will be translated.'))
```

For convenience, you want the _() function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

在 3.11 版的變更: *names* is now a keyword-only parameter.

The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is *NullTranslations*; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of NullTranslations:

class gettext.**NullTranslations**(*fp=None*)

Takes an optional *file object* *fp*, which is ignored by the base class. Initializes "protected" instance variables *_info* and *_charset* which are set by derived classes, as well as *_fallback*, which is set through *add_fallback()*. It then calls self._parse(fp) if *fp* is not None.

_parse(*fp*)

No-op in the base class, this method takes file object *fp*, and reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

add_fallback(*fallback*)

Add *fallback* as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

gettext(*message*)

If a fallback has been set, forward `gettext()` to the fallback. Otherwise, return *message*. Overridden in derived classes.

ngettext(*singular*, *plural*, *n*)

If a fallback has been set, forward `ngettext()` to the fallback. Otherwise, return *singular* if *n* is 1; return *plural* otherwise. Overridden in derived classes.

pgettext(*context*, *message*)

If a fallback has been set, forward *pgettext()* to the fallback. Otherwise, return the translated message. Overridden in derived classes.

在 3.8 版被加入.

npgettext(*context*, *singular*, *plural*, *n*)

If a fallback has been set, forward *npgettext()* to the fallback. Otherwise, return the translated message. Overridden in derived classes.

在 3.8 版被加入.

info()

Return a dictionary containing the metadata found in the message catalog file.

charset()

Return the encoding of the message catalog file.

install(*names=None*)

This method installs *gettext()* into the built-in namespace, binding it to _.

If the *names* parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to `_()`. Supported names are `'gettext'`, `'ngettext'`, `'pgettext'`, and `'npgettext'`.

Note that this is only one way, albeit the most convenient way, to make the `_()` function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install `_()`. Instead, they should use this code to make `_()` available to their module:

```
import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
```

This puts `_()` only in the module's global namespace and so only affects calls within this module.

在 3.8 版的變更: 新增 `'pgettext'` 與 `'npgettext'`。

The `GNUTranslations` class

The `gettext` module provides one additional class derived from *NullTranslations*: *GNUTranslations*. This class overrides `_parse()` to enable reading GNU **gettext** format `.mo` files in both big-endian and little-endian format.

GNUTranslations parses optional metadata out of the translation catalog. It is convention with GNU **gettext** to include metadata as the translation for the empty string. This metadata is in **RFC 822**-style `key: value` pairs, and should contain the `Project-Id-Version` key. If the key `Content-Type` is found, then the `charset` property is used to initialize the "protected" `_charset` instance variable, defaulting to `None` if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII is assumed.

Since message ids are read as Unicode strings too, all `*gettext()` methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the "protected" `_info` instance variable.

If the `.mo` file's magic number is invalid, the major version number is unexpected, or if other problems occur while reading the file, instantiating a *GNUTranslations* class can raise *OSError*.

class gettext.**GNUTranslations**

The following methods are overridden from the base class implementation:

gettext(*message*)

Look up the *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id, and a fallback has been set, the look up is forwarded to the fallback's *gettext()* method. Otherwise, the *message* id is returned.

ngettext(*singular*, *plural*, *n*)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's *ngettext()* method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

以下是個範例:

```
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ngettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

pgettext(*context*, *message*)

Look up the *context* and *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id and *context*, and a fallback has been set, the look up is forwarded to the fallback's *pgettext()* method. Otherwise, the *message* id is returned.

在 3.8 版被加入.

npgettext(*context*, *singular*, *plural*, *n*)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use.

If the message id for *context* is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's *npgettext()* method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

在 3.8 版被加入.

Solaris message catalog support

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

The Catalog constructor

GNOME uses a version of the *gettext* module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print(_('hello world'))
```

For compatibility with this older module, the function `Catalog()` is an alias for the *translation()* function described above.

One difference between this module and Henstridge's: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.

24.1.3 Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language-specific translations of the message catalogs
4. use the *gettext* module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_('...')` --- that is, a call to the function `_`. For example:

```
filename = 'mylog.txt'
message = _('writing a log message')
with open(filename, 'w') as fp:
    fp.write(message)
```

In this example, the string `'writing a log message'` is marked as a candidate for translation, while the strings `'mylog.txt'` and `'w'` are not.

There are a few tools to extract the strings meant for translation. The original GNU **gettext** only supported C or C++ source code but its extended version **xgettext** scans code written in a number of languages, including Python, to find strings marked as translatable. Babel is a Python internationalization library that includes a `pybabel` script to extract and compile message catalogs. François Pinard's program called **xpot** does a similar job and is available as part of his po-utils package.

(Python also includes pure-Python versions of these programs, called **pygettext.py** and **msgfmt.py**; some Python distributions will install them for you. **pygettext.py** is similar to **xgettext**, but only understands Python source code and cannot handle other programming languages such as C or C++. **pygettext.py** supports a command-line interface similar to **xgettext**; for details on its use, run `pygettext.py --help`. **msgfmt.py** is binary compatible with GNU **msgfmt**. With these two programs, you may not need the GNU **gettext** package to internationalize your Python applications.)

xgettext, **pygettext**, and similar tools generate `.po` files that are message catalogs. They are structured human-readable files that contain every marked string in the source code, along with a placeholder for the translated versions of these strings.

Copies of these `.po` files are then handed over to the individual human translators who write translations for every supported natural language. They send back the completed language-specific versions as a `<language-name>.po` file that's compiled into a machine-readable `.mo` binary catalog file using the **msgfmt** program. The `.mo` files are used by the *gettext* module for the actual translation processing at run-time.

How you use the *gettext* module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.

Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU **gettext** API but instead the class-based API.

Let's say your module is called "spam" and the module's various natural language translation `.mo` files reside in `/usr/share/locale` in GNU **gettext** format. Here's what you would put at the top of your module:

```
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.gettext
```

Localizing your application

If you are localizing your application, you can install the `_()` function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use `_('...')` without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```
import gettext
gettext.install('myapplication')
```

If you need to set the locale directory, you can pass it into the *install()* function:

```
import gettext
gettext.install('myapplication', '/usr/share/locale')
```

Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```
import gettext

lang1 = gettext.translation('myapplication', languages=['en'])
lang2 = gettext.translation('myapplication', languages=['fr'])
lang3 = gettext.translation('myapplication', languages=['de'])

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:

```
animals = ['mollusk',
           'albatross',
           'rat',
           'penguin',
           'python', ]
# ...
for a in animals:
    print(a)
```

Here, you want to mark the strings in the `animals` list as being translatable, but you don't actually want to translate them until they are printed.

Here is one way you can handle this situation:

```
def _(message): return message

animals = [_('mollusk'),
           _('albatross'),
           _('rat'),
           _('penguin'),
           _('python'), ]

del _

# ...
for a in animals:
    print(_(a))
```

This works because the dummy definition of `_()` simply returns the string unchanged. And this dummy definition will temporarily override any definition of `_()` in the built-in namespace (until the `del` command). Take care, though if you have a previous definition of `_()` in the local namespace.

Note that the second use of `_()` will not identify "a" as being translatable to the **gettext** program, because the parameter is not a string literal.

Another way to handle this is with the following example:

```
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function `N_()`, which won't conflict with any definition of `_()`. However, you will need to teach your message extraction program to look for translatable strings marked with `N_()`. **xgettext**, **pygettext**, `pybabel extract`, and **xpot** all support this through the use of the `-k` command-line switch. The choice of `N_()` here is totally arbitrary; it could have just as easily been `MarkThisStringForTranslation()`.

24.1.4 致謝

F解

24.2 locale --- 國際化服務

原始碼： Lib/locale.py

The *locale* module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The *locale* module is implemented on top of the _locale module, which in turn uses an ANSI C locale implementation if available.

The *locale* module defines the following exception and functions:

exception locale.**Error**

Exception raised when the locale passed to *setlocale()* is not recognized.

locale.**setlocale**(*category*, *locale=None*)

If *locale* is given and not None, *setlocale()* modifies the locale setting for the *category*. The available categories are listed in the data description below. *locale* may be a *string*, or a pair, language code and encoding. An empty string specifies the user's default settings. If the modification of the locale fails, the exception *Error* is raised. If successful, the new locale setting is returned.

If *locale* is a pair, it is converted to a locale name using the locale aliasing engine. The language code has the same format as a *locale name*, but without encoding and @-modifier. The language code and encoding can be None.

If *locale* is omitted or None, the current setting for *category* is returned.

setlocale() is not thread-safe on most systems. Applications typically start with a call of

```
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user's default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

locale.**localeconv**()

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

分類	Key	含義
LC_NUMERIC	'decimal_point'	Decimal point character.
	'grouping'	Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. If the sequence is terminated with *CHAR_MAX*, no further grouping is performed. If the sequence terminates with a 0, the last group size is repeatedly used.
	'thousands_sep'	Character used between groups.
LC_MONETARY	'int_curr_symbol'	International currency symbol.
	'currency_symbol'	Local currency symbol.
	'p_cs_precedes/n_cs_precedes'	Whether the currency symbol precedes the value (for positive resp. negative values).
	'p_sep_by_space/n_sep_by_space'	Whether the currency symbol is separated from the value by a space (for positive resp. negative values).
	'mon_decimal_point'	Decimal point used for monetary values.
	'frac_digits'	Number of fractional digits used in local formatting of monetary values.
	'int_frac_digits'	Number of fractional digits used in international formatting of monetary values.
	'mon_thousands_sep'	Group separator used for monetary values.
	'mon_grouping'	Equivalent to 'grouping', used for monetary values.
	'positive_sign'	Symbol used to annotate a positive monetary value.
	'negative_sign'	Symbol used to annotate a negative monetary value.
	'p_sign_posn/n_sign_posn'	The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to *CHAR_MAX* to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

Value	Explanation
0	Currency and value are surrounded by parentheses.
1	The sign should precede the value and currency symbol.
2	The sign should follow the value and currency symbol.
3	The sign should immediately precede the value.
4	The sign should immediately follow the value.
CHAR_MAX	Nothing is specified in this locale.

The function temporarily sets the LC_CTYPE locale to the LC_NUMERIC locale or the LC_MONETARY locale if locales are different and numeric or monetary strings are non-ASCII. This temporary change affects other threads.

在 3.7 版的變更: The function now temporarily sets the LC_CTYPE locale to the LC_NUMERIC locale in some cases.

locale.**nl_langinfo**(*option*)

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The *nl_langinfo()* function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

locale.**CODESET**

Get a string with the name of the character encoding used in the selected locale.

locale.**D_T_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent date and time in a locale-specific way.

locale.**D_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent a date in a locale-specific way.

locale.**T_FMT**

Get a string that can be used as a format string for *time.strftime()* to represent a time in a locale-specific way.

locale.**T_FMT_AMPM**

Get a format string for *time.strftime()* to represent time in the am/pm format.

locale.**DAY_1**

locale.**DAY_2**

locale.**DAY_3**

locale.**DAY_4**

locale.**DAY_5**

locale.**DAY_6**

locale.**DAY_7**

Get the name of the n-th day of the week.

> **備🄵**
>
> This follows the US convention of *DAY_1* being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

locale.**ABDAY_1**

locale.**ABDAY_2**

locale.**ABDAY_3**

locale.**ABDAY_4**

locale.**ABDAY_5**

locale.**ABDAY_6**

locale.**ABDAY_7**

Get the abbreviated name of the n-th day of the week.

locale.**MON_1**

locale.**MON_2**

locale.**MON_3**

locale.**MON_4**

locale.**MON_5**

locale.**MON_6**

locale.**MON_7**
locale.**MON_8**
locale.**MON_9**
locale.**MON_10**
locale.**MON_11**
locale.**MON_12**
Get the name of the n-th month.

locale.**ABMON_1**
locale.**ABMON_2**
locale.**ABMON_3**
locale.**ABMON_4**
locale.**ABMON_5**
locale.**ABMON_6**
locale.**ABMON_7**
locale.**ABMON_8**
locale.**ABMON_9**
locale.**ABMON_10**
locale.**ABMON_11**
locale.**ABMON_12**
Get the abbreviated name of the n-th month.

locale.**RADIXCHAR**
Get the radix character (decimal dot, decimal comma, etc.).

locale.**THOUSEP**
Get the separator character for thousands (groups of three digits).

locale.**YESEXPR**
Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

locale.**NOEXPR**
Get a regular expression that can be used with the `regex(3)` function to recognize a negative response to a yes/no question.

> **備🄵**
>
> The regular expressions for *YESEXPR* and *NOEXPR* use syntax suitable for the `regex` function from the C library, which might differ from the syntax used in *re*.

locale.**CRNCYSTR**
Get the currency symbol, preceded by "-" if the symbol should appear before the value, "+" if the symbol should appear after the value, or "." if the symbol should replace the radix character.

locale.**ERA**
Get a string which describes how years are counted and displayed for each era in a locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor's reign.

Normally it should not be necessary to use this value directly. Specifying the `E` modifier in their format strings causes the *time.strftime()* function to use this information. The format of the returned string is specified in *The Open Group Base Specifications Issue 8*, paragraph 7.3.5.2 LC_TIME C-Language Access.

locale.**ERA_D_T_FMT**

Get a format string for *time.strftime()* to represent date and time in a locale-specific era-based way.

locale.**ERA_D_FMT**

Get a format string for *time.strftime()* to represent a date in a locale-specific era-based way.

locale.**ERA_T_FMT**

Get a format string for *time.strftime()* to represent a time in a locale-specific era-based way.

locale.**ALT_DIGITS**

Get a string consisting of up to 100 semicolon-separated symbols used to represent the values 0 to 99 in a locale-specific way. In most locales this is an empty string.

The function temporarily sets the `LC_CTYPE` locale to the locale of the category that determines the requested value (`LC_TIME`, `LC_NUMERIC`, `LC_MONETARY` or `LC_MESSAGES`) if locales are different and the resulting string is non-ASCII. This temporary change affects other threads.

在 3.14 版的變更: The function now temporarily sets the `LC_CTYPE` locale in some cases.

locale.**getdefaultlocale**([*envvars*])

Tries to determine the default locale settings and returns them as a tuple of the form `(language code, encoding)`.

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable `'C'` locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the `LANG` variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the `LANG` variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. *envvars* defaults to the search path used in GNU gettext; it must always contain the variable name `'LANG'`. The GNU gettext search path contains `'LC_ALL'`, `'LC_CTYPE'`, `'LANG'` and `'LANGUAGE'`, in that order.

The language code has the same format as a *locale name*, but without encoding and `@`-modifier. The language code and encoding may be `None` if their values cannot be determined. The "C" locale is represented as `(None, None)`.

Deprecated since version 3.11, will be removed in version 3.15.

locale.**getlocale**(*category=LC_CTYPE*)

Returns the current setting for the given locale category as a tuple containing the language code and encoding. *category* may be one of the `LC_*` values except *LC_ALL*. It defaults to *LC_CTYPE*.

The language code has the same format as a *locale name*, but without encoding and `@`-modifier. The language code and encoding may be `None` if their values cannot be determined. The "C" locale is represented as `(None, None)`.

locale.**getpreferredencoding**(*do_setlocale=True*)

Return the *locale encoding* used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke *setlocale()* to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, *do_setlocale* should be set to `False`.

On Android or if the *Python UTF-8 Mode* is enabled, always return `'utf-8'`, the *locale encoding* and the *do_setlocale* argument are ignored.

The Python preinitialization configures the LC_CTYPE locale. See also the *filesystem encoding and error handler*.

在 3.7 版的變更: The function now always returns `"utf-8"` on Android or if the *Python UTF-8 Mode* is enabled.

locale.**getencoding**()

Get the current *locale encoding*:

- On Android and VxWorks, return `"utf-8"`.
- On Unix, return the encoding of the current *LC_CTYPE* locale. Return `"utf-8"` if `nl_langinfo(CODESET)` returns an empty string: for example, if the current LC_CTYPE locale is not supported.
- On Windows, return the ANSI code page.

The Python preinitialization configures the LC_CTYPE locale. See also the *filesystem encoding and error handler*.

This function is similar to *getpreferredencoding(False)* except this function ignores the *Python UTF-8 Mode*.

在 3.11 版被加入.

locale.**normalize**(*localename*)

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with *setlocale()*. If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like *setlocale()*.

locale.**strcoll**(*string1*, *string2*)

Compares two strings according to the current *LC_COLLATE* setting. As any other compare function, returns a negative, or a positive value, or `0`, depending on whether *string1* collates before or after *string2* or is equal to it.

locale.**strxfrm**(*string*)

Transforms a string to one that can be used in locale-aware comparisons. For example, `strxfrm(s1) < strxfrm(s2)` is equivalent to `strcoll(s1, s2) < 0`. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

locale.**format_string**(*format*, *val*, *grouping=False*, *monetary=False*)

Formats a number *val* according to the current *LC_NUMERIC* setting. The format follows the conventions of the `%` operator. For floating-point values, the decimal point is modified if appropriate. If *grouping* is `True`, also takes the grouping into account.

If *monetary* is true, the conversion uses monetary thousands separator and grouping strings.

Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

在 3.7 版的變更: The *monetary* keyword parameter was added.

locale.**currency**(*val*, *symbol=True*, *grouping=False*, *international=False*)

Formats a number *val* according to the current *LC_MONETARY* settings.

The returned string includes the currency symbol if *symbol* is true, which is the default. If *grouping* is `True` (which is not the default), grouping is done with the value. If *international* is `True` (which is not the default), the international currency symbol is used.

> **備🄵**
>
> This function will not work with the 'C' locale, so you have to set a locale via *setlocale()* first.

locale.**str**(*float*)

Formats a floating-point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

locale.**delocalize**(*string*)

Converts a string into a normalized number string, following the *LC_NUMERIC* settings.

在 3.5 版被加入.

locale.**localize**(*string*, *grouping=False*, *monetary=False*)

Converts a normalized number string into a formatted string following the *LC_NUMERIC* settings.

在 3.10 版被加入.

locale.**atof**(*string*, *func=float*)

Converts a string to a number, following the *LC_NUMERIC* settings, by calling *func* on the result of calling *delocalize()* on *string*.

locale.**atoi**(*string*)

Converts a string to an integer, following the *LC_NUMERIC* conventions.

locale.**LC_CTYPE**

Locale category for the character type functions. Most importantly, this category defines the text encoding, i.e. how bytes are interpreted as Unicode codepoints. See **PEP 538** and **PEP 540** for how this variable might be automatically coerced to `C.UTF-8` to avoid issues created by invalid settings in containers or incompatible settings passed over remote SSH connections.

Python doesn't internally use locale-dependent character transformation functions from `ctype.h`. Instead, an internal `pyctype.h` provides locale-independent equivalents like `Py_TOLOWER`.

locale.**LC_COLLATE**

Locale category for sorting strings. The functions *strcoll()* and *strxfrm()* of the *locale* module are affected.

locale.**LC_TIME**

Locale category for the formatting of time. The function *time.strftime()* follows these conventions.

locale.**LC_MONETARY**

Locale category for formatting of monetary values. The available options are available from the *localeconv()* function.

locale.**LC_MESSAGES**

Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by *os.strerror()* might be affected by this category.

This value may not be available on operating systems not conforming to the POSIX standard, most notably Windows.

locale.**LC_NUMERIC**

Locale category for formatting numbers. The functions *format_string()*, *atoi()*, *atof()* and *str()* of the *locale* module are affected by that category. All other numeric formatting operations are not affected.

locale.**LC_ALL**

Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale.**CHAR_MAX**

This is a symbolic constant used for different values returned by *localeconv()*.

範例:

```
>>> import locale
>>> loc = locale.getlocale()  # get current locale
# use German locale; name might vary with platform
```

(繼續下一頁)

(繼續上一頁)

```
>>> locale.setlocale(locale.LC_ALL, 'de_DE')
>>> locale.strcoll('f\xe4n', 'foo')  # compare a string containing an umlaut
>>> locale.setlocale(locale.LC_ALL, '')    # use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, 'C')   # use default (C) locale
>>> locale.setlocale(locale.LC_ALL, loc)   # restore saved locale
```

24.2.1 Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementations are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the `C` locale, no matter what the user's preferred locale is. There is one exception: the *LC_CTYPE* category is changed at startup to set the current locale encoding to the user's preferred locale encoding. The program must explicitly say that it wants the user's preferred locale settings for other categories by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call *setlocale()* in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with *time.strftime()*), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-`C` locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: *atof()*, *atoi()*, *format_string()*, *str()*.

There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.

24.2.2 Locale names

The format of the locale name is platform dependent, and the set of supported locales can depend on the system configuration.

On Posix platforms, it usually has the format[1]:

```
language ["_" territory] ["." charset] ["@" modifier]
```

where *language* is a two- or three-letter language code from ISO 639, *territory* is a two-letter country or region code from ISO 3166, *charset* is a locale encoding, and *modifier* is a script name, a language subtag, a sort order identifier, or other locale modifier (for example, "latin", "valencia", "stroke" and "euro").

On Windows, several formats are supported.[2][3] A subset of IETF BCP 47 tags:

```
language ["-" script] ["-" territory] ["." charset]
language ["-" script] "-" territory "-" modifier
```

where *language* and *territory* have the same meaning as in Posix, *script* is a four-letter script code from ISO 15924, and *modifier* is a language subtag, a sort order identifier or custom modifier (for example, "valencia", "stroke" or "x-python"). Both hyphen (`'-'`) and underscore (`'_'`) separators are supported. Only UTF-8 encoding is allowed for BCP 47 tags.

Windows also supports locale names in the format:

[1] IEEE Std 1003.1-2024; 8.2 Internationalization Variables
[2] UCRT Locale names, Languages, and Country/Region strings
[3] Locale Names

```
language ["_" territory] ["." charset]
```

where *language* and *territory* are full names, such as ”English” and ”United States”, and *charset* is either a code page number (for example, ”1252”) or UTF-8. Only the underscore separator is supported in this format.

The ”C” locale is supported on all platforms.

24.2.3 For extension writers and programs that embed Python

Extension modules should never call *setlocale()*, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is `C`).

When Python code uses the *locale* module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.

24.2.4 Access to message catalogs

`locale.`**`gettext`**(*msg*)

`locale.`**`dgettext`**(*domain*, *msg*)

`locale.`**`dcgettext`**(*domain*, *msg*, *category*)

`locale.`**`textdomain`**(*domain*)

`locale.`**`bindtextdomain`**(*domain*, *dir*)

`locale.`**`bind_textdomain_codeset`**(*domain*, *codeset*)

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions *gettext()*, *dgettext()*, *dcgettext()*, *textdomain()*, *bindtextdomain()*, and *bind_textdomain_codeset()*. These are similar to the same functions in the *gettext* module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use *gettext* instead. A known exception to this rule are applications that link with additional C libraries which internally invoke C functions `gettext` or `dcgettext`. For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.

CHAPTER 25

以 Tk 打造圖形使用者介面 (Graphical User Interfaces)

Tk/Tcl 長期以來一直是 Python 不可或缺的一部分。它提供了一個🄵大且獨立於平台的視窗工具包，可供使用*tkinter* 套件及其擴充套件*tkinter.ttk* 模組的 Python 開發者使用。

tkinter 套件是 Tcl/Tk 之上的一個輕薄物件導向層。要使用*tkinter*，你不需要編寫 Tcl 程式，但會需要查🄵 Tk 文件和部份 Tcl 文件。*tkinter* 是一組將 Tk 小工具 (widget) 實作🄵 Python 類🄵的包裝器。

tkinter 的主要優點是速度快，而且通常與 Python 捆綁 (bundle) 在一起。🄵管其標准文件不是很完整，但還是有些不錯的材料，包括：參考資料、教學、書籍等。*tkinter* 曾因其過時的外觀而🄵所皆知，但這在 Tk 8.5 中得到了極大的改進。此外，還有許多其他你可能會感興趣的 GUI 函式庫。Python wiki 列出了幾個替代的 GUI 框架和工具。

25.1 `tkinter` --- Tcl/Tk 的 Python 介面

原始碼： Lib/tkinter/__init__.py

tkinter 套件（「Tk 介面」）是 Tcl/Tk GUI 工具集的標准 Python 介面。Tk 和*tkinter* 在大多數 Unix 平台（包含 macOS）以及 Windows 系統上都可以使用。

從命令列執行 `python -m tkinter` 應該會開🄵一個展示簡單 Tk 介面的視窗，讓你知道*tkinter* 已正確安裝在你的系統上，🄵且也會顯示已安裝的 Tcl/Tk 版本，這樣你就可以🄵讀該版本專屬的 Tcl/Tk 文件。

Tkinter 支援一系列的 Tcl/Tk 版本，這些版本可以是有或🄵有執行緒支援的建構版本。官方的 Python 二進位發行版捆綁了有執行緒支援的 Tcl/Tk 8.6。關於支援版本的更多資訊，請參🄵*_tkinter* 模組的原始碼。

Tkinter 🄵非一個輕薄的包裝器，而是加入了相當多自身的邏輯，使其體驗更具 Python 風格（pythonic）。本文件將著重於這些新增和變更，對於未變更的細節，則會引導讀者參🄵官方的 Tcl/Tk 文件。

備🄵

Tcl/Tk 8.5（2007）引入了一套現代化的主題式使用者介面元件，以及一個用以操作它們的新 API。新舊 API 目前都還能使用。你在網路上找到的大多數文件仍使用舊版 API，而且可能已經嚴重過時。

也參考

25.1.1 架構

Tcl/Tk □非單一函式庫，而是由幾個不同的模組所組成，每個模組都有獨立的功能和官方文件。Python 的二進位發行版也隨附了一個附加模組。

Tcl
Tcl 是一個動態直譯的程式語言，就像 Python 一樣。雖然它可以作□通用程式語言獨立使用，但它最常被嵌入到 C 應用程式中，作□□本引擎或 Tk 工具集的介面。Tcl 函式庫有一個 C 介面，可用於建立和管理一個或多個 Tcl 直譯器的實例，在這些實例中執行 Tcl 指令和□本，□新增以 Tcl 或 C 實作的自訂指令。每個直譯器都有一個事件□列，□有設施可以向其傳送事件□加以處理。與 Python 不同，Tcl 的執行模型是圍繞著協同多工（cooperative multitasking）設計的，而 Tkinter 則彌合了這種差□（詳情請參□*Threading model*）。

Tk
Tk 是一個以 C 實作的 Tcl 套件，它新增了自訂指令來建立和操作 GUI 元件。每個 `Tk` 物件都嵌入了自己載入 Tk 的 Tcl 直譯器實例。Tk 的元件非常可自訂，但代價是外觀較□過時。Tk 使用 Tcl 的事件□列來□生和處理 GUI 事件。

Ttk
主題式 Tk（Ttk）是較新的一族 Tk 元件，相較於許多傳統的 Tk 元件，它在不同平台上提供了更好的外觀。從 Tk 8.5 版開始，Ttk 作□ Tk 的一部分發行。Python 的□結（bindings）則在一個獨立的模組 `tkinter.ttk` 中提供。

在□部，Tk 和 Ttk 使用底層作業系統的設施，即 Unix/X11 上的 Xlib、macOS 上的 Cocoa、Windows 上的 GDI。

當你的 Python 應用程式使用 Tkinter 中的類□（例如，建立一個元件）時，`tkinter` 模組會先組合一個 Tcl/Tk 指令字串。它將該 Tcl 指令字串傳遞給一個□部的 `_tkinter` 二進位模組，後者再呼叫 Tcl 直譯器來對其進行計算。Tcl 直譯器接著會呼叫 Tk 和/或 Ttk 套件，而這些套件又會再呼叫 Xlib、Cocoa 或 GDI。

25.1.2 Tkinter 模組

對 Tkinter 的支援分散在數個模組中。大多數應用程式將需要主要的*tkinter*模組，以及*tkinter.ttk*模組，後者提供了現代主題式元件集和 API：

```
from tkinter import *
from tkinter import ttk
```

class tkinter.**Tk**(*screenName=None*, *baseName=None*, *className='Tk'*, *useTk=True*, *sync=False*, *use=None*)

建構一個頂層 Tk 元件，它通常是應用程式的主視窗，🄵🄵此元件初始化一個 Tcl 直譯器。每個實例都有其自己關聯的 Tcl 直譯器。

*Tk*類🄵通常使用所有預設值來實例化。然而，目前可辨識下列關鍵字引數：

screenName
當給定（作🄵字串）時，設定 DISPLAY 環境變數。（僅限 X11）

baseName
設定檔的名稱。預設情🄵下，*baseName* 是從程式名稱（`sys.argv[0]`）衍生而來。

className
元件類🄵的名稱。用作設定檔，也用作呼叫 Tcl 時的名稱（*interp* 中的 *argv0*）。

useTk
若🄵 True，則初始化 Tk 子系統。*tkinter.Tcl()* 函式會將此設定🄵 False。

sync
若🄵 True，則同步執行所有 X 伺服器指令，以便立即回報錯誤。可用於偵錯。（僅限 X11）

use
指定要嵌入應用程式的視窗 *id*，而不是將其建立🄵獨立的頂層視窗。*id* 必須以與頂層元件的 -use 選項值相同的方式指定（也就是🄵，其形式類似 `winfo_id()` 回傳的形式）。

請注意，在某些平台上，只有當 *id* 指向一個已🄵用 -container 選項的 Tk 框架或頂層視窗時，此功能才能正常運作。

Tk 會讀取名🄵 *.className*.tcl 和 *.baseName*.tcl 的設定檔，🄵在 Tcl 直譯器中進行直譯，🄵對 *.className*.py 和 *.baseName*.py 的🄵容呼叫*exec()*。設定檔的路徑是 HOME 環境變數，如果未定義，則是*os.curdir*。

tk
透過實例化*Tk* 建立的 Tk 應用程式物件。這提供了對 Tcl 直譯器的存取。每個附加到同一個*Tk*實例的元件，其*tk* 屬性都具有相同的值。

master
包含此元件的元件物件。對於*Tk*，*master* 是*None*，因🄵它是主視窗。*master* 和 *parent* 這兩個術語很相似，有時會作🄵引數名稱互🄵使用；然而，呼叫 `winfo_parent()` 會回傳元件名稱的字串，而*master* 則回傳物件。*parent*/*child* 反映了樹狀關🄵，而 *master*/*slave* 反映了容器結構。

children
此元件的直接子代，形式🄵一個*dict*，其中鍵🄵子元件的名稱，值🄵子實例物件。

tkinter.**Tcl**(*screenName=None*, *baseName=None*, *className='Tk'*, *useTk=False*)

Tcl() 函式是一個工廠函式，它建立的物件與*Tk* 類🄵建立的物件非常相似，只是它不會初始化 Tk 子系統。這在驅動 Tcl 直譯器時最🄵有用，尤其是在不希望建立額外頂層視窗的環境中，或者在無法建立的環境中（例如🄵有 X 伺服器的 Unix/Linux 系統）。由*Tcl()* 物件建立的物件可以透過呼叫其 `loadtk()` 方法來建立一個頂層視窗（🄵初始化 Tk 子系統）。

提供 Tk 支援的模組包括：

tkinter
主要的 Tkinter 模組。

tkinter.colorchooser
讓使用者選擇🄵色的對話方塊。

tkinter.commondialog
此處列出的其他模組中定義的對話方塊的基底類🄵。

tkinter.filedialog
讓使用者指定要開🄵或儲存的檔案的通用對話方塊。

tkinter.font
協助處理字型的工具程式。

tkinter.messagebox
存取標准的 Tk 對話方塊。

tkinter.scrolledtext
🄵建垂直🄵軸的文字元件。

tkinter.simpledialog
基本的對話方塊和便利函式。

tkinter.ttk
在 Tk 8.5 中引入的主題式元件集，🄵主*tkinter* 模組中的許多傳統元件提供了現代化的替代方案。

額外模組：

_tkinter
一個包含 Tcl/Tk 低階介面的二進位模組。它由主*tkinter* 模組自動引入，應用程式開發者不應直接使用它。它通常是一個共享函式庫（或 DLL），但在某些情🄵下可能會與 Python 直譯器🄵態連結。

idlelib
Python 的整合開發與學習環境（IDLE）。基於*tkinter*。

tkinter.constants
在將各種參數傳遞給 Tkinter 呼叫時，可用於替代字串的符號常數。由主*tkinter* 模組自動引入。

tkinter.dnd
（實驗性）對*tkinter* 的拖放支援。當它被 Tk DND 取代時，將會被🄵用。

turtle
在 Tk 視窗中的海龜繪圖。

25.1.3 Tkinter 應急指南

本節🄵非旨在成🄵 Tk 或 Tkinter 的詳盡教學。🄵此，請參🄵前面提到的外部資源之一。相反地，本節提供了一個快速導覽，介紹 Tkinter 應用程式的外觀、識🄵基礎的 Tk 概念，🄵解釋 Tkinter 包裝器的結構。

本節的其余部分將幫助你識🄵在 Tkinter 應用程式中所需的類🄵、方法和選項，以及在哪🄵可以找到關於它們的更詳細文件，包括在官方的 Tcl/Tk 參考手🄵中。

一個 Hello World 程式

我們將從一個 Tkinter 的"Hello World" 應用程式開始。這不是我們能寫出的最小程式，但足以🄵明一些你需要知道的關鍵概念。

```
from tkinter import *
from tkinter import ttk
root = Tk()
frm = ttk.Frame(root, padding=10)
frm.grid()
ttk.Label(frm, text="Hello World!").grid(column=0, row=0)
ttk.Button(frm, text="Quit", command=root.destroy).grid(column=1, row=0)
root.mainloop()
```

在引入之後，下一行建立了一個 `Tk` 類🄵的實例，它會初始化 Tk 🄵建立其關聯的 Tcl 直譯器。它還會建立一個頂層視窗，稱🄵根視窗，作🄵應用程式的主視窗。

接下來的一行建立了一個框架元件，在本例中，它將包含我們接下來要建立的一個標🄵和一個按鈕。該框架被放置在根視窗🄵。

下一行建立了一個包含🄵態文字字串的標🄵元件。`grid()` 方法用於指定標🄵在其包含的框架元件中的相對🄵局（位置），類似於 HTML 中表格的運作方式。

然後建立一個按鈕元件，🄵放置在標🄵的右側。當按下時，它將呼叫根視窗的 `destroy()` 方法。

最後，`mainloop()` 方法將所有🄵容顯示在螢幕上，🄵回應使用者輸入，直到程式終止。

重要的 Tk 概念

即使是這個簡單的程式也🄵明了以下關鍵的 Tk 概念：

元件（widgets）
: 一個 Tkinter 使用者介面是由個🄵的元件所組成。每個元件都表示🄵一個 Python 物件，從 `ttk.Frame`、`ttk.Label` 和 `ttk.Button` 等類🄵實例化而來。

元件階層（widget hierarchy）
: 元件被安排在一個階層中。標🄵和按鈕被包含在一個框架🄵，而框架又被包含在根視窗🄵。在建立每個子元件時，其父元件會作🄵第一個引數傳遞給元件的建構函式。

設定選項（configuration options）
: 元件具有設定選項，可以修改其外觀和行🄵，例如在標🄵或按鈕中顯示的文字。不同類🄵的元件會有不同的選項集。

🄵局管理（geometry management）
: 元件在建立時不會自動新增到使用者介面中。像 `grid` 這樣的🄵局管理器（geometry manager）會控制它們在使用者介面中的放置位置。

事件🄵圈（event loop）
: Tkinter 只有在主動執行事件🄵圈時，才會對使用者輸入、程式的變更，甚至螢幕刷新做出反應。如果你的程式🄵有執行事件🄵圈，你的使用者介面將不會更新。

了解 Tkinter 如何包裝 Tcl/Tk

當你的應用程式使用 Tkinter 的類🄵和方法時，Tkinter 🄵部正在組合代表 Tcl/Tk 指令的字串，🄵在附加到你應用程式 `Tk` 實例的 Tcl 直譯器中執行這些指令。

無論是試圖🄵覽參考文件、尋找正確的方法或選項、改寫一些現有程式碼，還是偵錯你的 Tkinter 應用程式，在某些時候，了解那些底層 Tcl/Tk 指令的樣貌會很有幫助。

🄵了🄵明，以下是上面 Tkinter 🄵本主要部分的 Tcl/Tk 對等程式碼。

```
ttk::frame .frm -padding 10
grid .frm
grid [ttk::label .frm.lbl -text "Hello World!"] -column 0 -row 0
grid [ttk::button .frm.btn -text "Quit" -command "destroy ."] -column 1 -row 0
```

Tcl 的語法類似於許多 shell 語言，第一個字是要執行的指令，後面跟著該指令的引數，以空格分隔。在不深入太多細節的情🄴下，請注意以下幾點：

- 用於建立元件的指令（如 `ttk::frame`）對應於 Tkinter 中的元件類🄵。
- Tcl 元件選項（如 `-text`）對應於 Tkinter 中的關鍵字引數。
- 在 Tcl 中，元件是透過路徑名稱（如 `.frm.btn`）來參照，而 Tkinter 不使用名稱，而是使用物件參照。
- 元件在元件階層中的位置被編碼在其（階層式）路徑名稱中，該路徑名稱使用 `.`（點）作🄵路徑分隔符。根視窗的路徑名稱就是 `.`（點）。在 Tkinter 中，階層不是由路徑名稱定義的，而是在建立每個子元件時指定父元件來定義的。
- 在 Tcl 中實作🄵獨立指令的操作（如 `grid` 或 `destroy`），在 Tkinter 中則表示🄵元件物件上的方法。正如你稍後會看到的，在其他時候，Tcl 使用的看起來像是對元件物件的方法呼叫，這更接近 Tkinter 中的用法。

我該如何... ? 哪個選項可以... ?

如果你不確定如何在 Tkinter 中做某件事，𠀀且無法立即在你正在使用的教學或參考文件中找到它，這𠀀有一些可能有幫助的策略。

首先，請記住，個𠀀元件的運作細節可能會因 Tkinter 和 Tcl/Tk 的不同版本而𠀀。如果你正在搜尋文件，請確保它對應於你系統上安裝的 Python 和 Tcl/Tk 版本。

在搜尋如何使用 API 時，知道你正在使用的類𠀀、選項或方法的確切名稱會很有幫助。自省（Introspection），無論是在互動式 Python shell 中還是使用*print()*，都可以幫助你識𠀀所需𠀀容。

要找出任何元件上有哪些可用的設定選項，請呼叫其 `configure()` 方法，該方法會回傳一個字典，其中包含有關每個物件的各種資訊，包括其預設值和目前值。使用 `keys()` 僅取得每個選項的名稱。

```
btn = ttk.Button(frm, ...)
print(btn.configure().keys())
```

由於大多數元件有許多共通的設定選項，找出特定於某個元件類𠀀的選項會很有用。將選項串列與像框架這樣較簡單的元件的選項串列進行比較，是做到這一點的一種方法。

```
print(set(btn.configure().keys()) - set(frm.configure().keys()))
```

同樣地，你可以使用標準的*dir()*函式來尋找元件物件可用的方法。如果你試一下，你會看到有超過 200 個常見的元件方法，所以再次𠀀調，識𠀀特定於某個元件類𠀀的方法是很有幫助的。

```
print(dir(btn))
print(set(dir(btn)) - set(dir(frm)))
```

𠀀覽 Tcl/Tk 參考手𠀀

如前所述，官方的 Tk 指令 參考手𠀀（man pages）通常是對元件上特定操作作用的最准確描述。即使你知道所需選項或方法的名稱，你可能仍有幾個地方需要查看。

雖然 Tkinter 中的所有操作都實作𠀀對元件物件的方法呼叫，但你已經看到許多 Tcl/Tk 操作顯示𠀀指令，這些指令將元件路徑名稱作𠀀其第一個參數，後面跟著可選的參數，例如：

```
destroy .
grid .frm.btn -column 0 -row 0
```

然而，其他的看起來更像是對元件物件呼叫的方法（事實上，當你在 Tcl/Tk 中建立一個元件時，它會建立一個以元件路徑名稱𠀀名的 Tcl 指令，該指令的第一個參數是要呼叫的方法名稱）。

```
.frm.btn invoke
.frm.lbl configure -text "Goodbye"
```

在官方的 Tcl/Tk 參考文件中，你會在特定元件的 man page 上找到大多數看起來像方法呼叫的操作（例如，你可以在 ttk::button man page 上找到 `invoke()` 方法），而將元件作𠀀參數的函式通常有自己的 man page（例如 grid）。

你可以在 options 或 ttk::widget man page 中找到許多常見的選項和方法，而其他的則在特定元件類𠀀的 man page 中找到。

你還會發現許多 Tkinter 方法有𠀀合名稱，例如 `winfo_x()`、`winfo_height()`、`winfo_viewable()`。你可以在 winfo man page 中找到所有這些文件的𠀀明。

備𠀀

有點令人困惑的是，所有 Tkinter 元件上還有一些方法，它們實際上𠀀不是對該元件進行操作，而是在全域範圍𠀀操作，獨立於任何元件。例如存取剪貼簿或系統鈴聲的方法。（它們恰好被實作𠀀所有 Tkinter 元件都繼承的基底 `Widget` 類𠀀中的方法）。

25.1.4 執行緒模型

Python 和 Tcl/Tk 有非常不同的執行緒模型，*tkinter* 試圖彌合這種差F。如果你使用執行緒，你可能需要意識到這一點。

一個 Python 直譯器可能有多個與之關聯的執行緒。在 Tcl 中，可以建立多個執行緒，但每個執行緒都有一個獨立的 Tcl 直譯器實例與之關聯。執行緒也可以建立多個直譯器實例，但每個直譯器實例只能由建立它的那個執行緒使用。

由*tkinter* 建立的每個 `Tk` 物件都包含一個 Tcl 直譯器。它還會追F是哪個執行緒建立了該直譯器。可以從任何 Python 執行緒呼叫*tkinter*。在F部，如果呼叫來自建立 `Tk` 物件的執行緒以外的執行緒，則會將一個事件發F到直譯器的事件F列中，執行後，結果會回傳給呼叫的 Python 執行緒。

Tcl/Tk 應用程式通常是事件驅動的，這意味著在初始化之後，直譯器會執行一個事件F圈（即 `Tk.mainloop()`）F回應事件。因F它是單執行緒的，事件處理常式必須快速回應，否則它們會阻塞其他事件的處理。F避免這種情F，任何長時間執行的計算都不應在事件處理常式中執行，而是使用計時器將其分解成更小的部分，或在另一個執行緒中執行。這與許多 GUI 工具集不同，在那些工具集中，GUI 在一個與所有應用程式碼（包括事件處理常式）完全分離的執行緒中執行。

如果 Tcl 直譯器F有在執行事件F圈和處理事件，那F從執行 Tcl 直譯器的執行緒以外的執行緒發出的任何*tkinter* 呼叫都將失敗。

存在一些特殊情F：

- Tcl/Tk 函式庫可以被建構成不具備執行緒感知能力。在這種情F下，*tkinter* 會從原始的 Python 執行緒呼叫該函式庫，即使這與建立 Tcl 直譯器的執行緒不同。一個全域鎖確保一次只發生一個呼叫。
- 雖然*tkinter* 允許你建立多個 `Tk` 物件的實例（每個都有自己的直譯器），但屬於同一個執行緒的所有直譯器共享一個共同的事件F列，這很快就會變得混亂。在實務上，不要一次建立多個 `Tk` 的實例。否則，最好在不同的執行緒中建立它們，F確保你正在執行一個具備執行緒感知能力的 Tcl/Tk 建構版本。
- 阻塞事件處理常式F不是防止 Tcl 直譯器重新進入事件F圈的唯一方法。甚至可以執行多個巢狀的事件F圈或完全放F事件F圈。如果你在事件或執行緒方面做任何F雜的操作，請注意這些可能性。
- 目前有少數幾個*tkinter* 函式只有在從建立 Tcl 直譯器的執行緒中呼叫時才能正常運作。

25.1.5 實用參考

設定選項

選項控制著諸如元件的F色和邊框寬度等。選項可以透過三種方式設定：

在物件建立時，使用關鍵字引數

```
fred = Button(self, fg="red", bg="blue")
```

在物件建立後，將選項名稱視F字典索引

```
fred["fg"] = "red"
fred["bg"] = "blue"
```

在物件建立後，使用 config() 方法更新多個屬性

```
fred.config(fg="red", bg="blue")
```

有關給定選項及其行F的完整解釋，請參F相關元件的 Tk man pages。

請注意，man pages F每個元件列出了「標準選項」和「元件特定選項」。前者是許多元件共有的選項串列，後者是該特定元件特有的選項。標準選項記F在 *options(3)* man page 中。

本文件中未對標準選項和元件特定選項進行區分。某些選項不適用於某些類型的元件。給定元件是否回應特定選項取F於該元件的類F；按鈕有 `command` 選項，標F則F有。

給定元件支援的選項列在該元件的 man page 中，或者可以在 runtime 透過不帶引數呼叫 `config()` 方法，或對該元件呼叫 `keys()` 方法來查詢。這些呼叫的回傳值是一個字典，其鍵是選項名稱的字串（例如 `'relief'`），其值是 5-tuples。

某些選項，如 `bg`，是具有長名稱的常見選項的同義詞（`bg` 是"background" 的簡寫）。將簡寫選項的名稱傳遞給 `config()` 方法將回傳一個 2-tuple，而不是 5-tuple。回傳的 2-tuple 將包含同義詞的名稱和「真實」選項（例如 `('bg', 'background')`）。

索引	含義	範例
0	選項名稱	`'relief'`
1	用於資料庫查詢的選項名稱	`'relief'`
2	用於資料庫查詢的選項類🄵	`'Relief'`
3	預設值	`'raised'`
4	目前值	`'groove'`

範例：

```
>>> print(fred.config())
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

當然，印出的字典將包含所有可用的選項及其值。這僅作🄵一個範例。

Packer 🄵局管理器

packer 是 Tk 的🄵局管理（geometry manager）機制之一。🄵局管理器（geometry manager）用於指定元件在其容器（它們共同的 *master*）🄵的相對位置。與較🄵繁瑣的 *placer*（較不常用，我們在此不予介紹）相比，packer 🄵用定性的關🄵規範——上方、左方、填滿等——🄵🄵你計算出確切的放置座標。

任何 *master* 元件的大小由其🄵部的「slave 元件」的大小🄵定。packer 用於控制 slave 元件在被 packed 的 master 🄵部出現的位置。你可以將元件 pack 到框架中，再將框架 pack 到其他框架中，以達到你想要的🄵局。此外，一旦 packed，🄵局會動態調整以適應設定的增量變更。

請注意，元件在透過🄵局管理器（geometry manager）指定其🄵局（geometry）之前是不會出現的。一個常見的早期錯誤是忽略了🄵局（geometry）指定，然後在元件被建立但🄵有任何東西出現時感到驚訝。一個元件只有在例如 packer 的 `pack()` 方法被應用於其上之後才會出現。

pack() 方法可以與關鍵字選項/值對一起呼叫，以控制元件在其容器中出現的位置，以及當主應用程式視窗調整大小時它的行🄵方式。以下是一些範例：

```
fred.pack()                     # 預設🄵 side = "top"
fred.pack(side="left")
fred.pack(expand=1)
```

Packer 選項

有關 packer 及其可接受選項的更詳盡資訊，請參🄵 man pages 和 John Ousterhout 書中的第 183 頁。

anchor
: 錨點類型。表示 packer 將每個 slave 放置在其區域中的位置。

expand
: 布林值，`0` 或 `1`。

fill
: 合法值：`'x'`、`'y'`、`'both'`、`'none'`。

ipadx 和 ipady
: 一個距離——指定 slave 元件每側的🄵部填充。

padx 和 pady
: 一個距離——指定 slave 元件每側的外部填充。

side
合法值🄵：`'left'`、`'right'`、`'top'`、`'bottom'`。

耦合元件變數

某些元件（如文字輸入元件）的當前值設定可以透過使用特殊選項直接連接到應用程式變數。這些選項是 `variable`、`textvariable`、`onvalue`、`offvalue` 和 `value`。這種連接是雙向的：如果變數因任何原因發生變化，與之連接的元件將會更新以反映新值。

不幸的是，在*tkinter* 的目前實作中，無法透過 `variable` 或 `textvariable` 選項將任意的 Python 變數傳遞給元件。唯一適用此功能的變數類型是從*tkinter* 中定義的一個名🄵 Variable 的類🄵繼承的子類🄵變數。

已經定義了許多有用的 Variable 子類🄵：`StringVar`、`IntVar`、`DoubleVar` 和 `BooleanVar`。要讀取此類變數的目前值，請對其呼叫 `get()` 方法，要更改其值，則呼叫 `set()` 方法。如果你遵循此協定，元件將始終追🄵變數的值，無需你進一步干預。

舉例來🄵：

```
import tkinter as tk

class App(tk.Frame):
    def __init__(self, master):
        super().__init__(master)
        self.pack()

        self.entrythingy = tk.Entry()
        self.entrythingy.pack()

        # 建立應用程式變數。
        self.contents = tk.StringVar()
        # 將其設定🄵某個值。
        self.contents.set("this is a variable")
        # 告訴 entry 元件監視此變數。
        self.entrythingy["textvariable"] = self.contents

        # 🄵使用者按下 return 鍵定義一個回呼。
        # 它會印出變數的目前值。
        self.entrythingy.bind('<Key-Return>',
                              self.print_contents)

    def print_contents(self, event):
        print("Hi. The current entry content is:",
              self.contents.get())

root = tk.Tk()
myapp = App(root)
myapp.mainloop()
```

視窗管理器

在 Tk 中，有一個工具指令 `wm`，用於與視窗管理器互動。`wm` 指令的選項允許你控制標題、位置、圖示點陣圖等。在*tkinter* 中，這些指令已實作🄵 `Wm` 類🄵上的方法。頂層元件是 `Wm` 類🄵的子類🄵，因此可以直接呼叫 `Wm` 方法。

要取得包含給定元件的頂層視窗，你通常可以直接參照該元件的 master。當然，如果該元件被 packed 在一個框架🄵，master 將不代表一個頂層視窗。要取得包含任意元件的頂層視窗，你可以呼叫 `_root()` 方法。此方法以底🄵開頭，表示此函式是實作的一部分，而不是 Tk 功能的介面。

以下是一些常見用法範例：

```
import tkinter as tk
```

(繼續下一頁)

(繼續上一頁)

```
class App(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

# 建立應用程式
myapp = App()

#
# 以下是對視窗管理器類🄵的方法呼叫
#
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# 🄵動程式
myapp.mainloop()
```

Tk 選項資料型🄵

anchor
合法值🄵羅盤方位點：`"n"`、`"ne"`、`"e"`、`"se"`、`"s"`、`"sw"`、`"w"`、`"nw"`，以及 `"center"`。

bitmap
有八個🄵建的、命名的點陣圖：`'error'`、`'gray25'`、`'gray50'`、`'hourglass'`、`'info'`、`'questhead'`、`'question'`、`'warning'`。要指定一個 X 點陣圖檔名，請給出檔案的完整路徑，🄵在前面加上一個 `@`，例如 `"@/usr/contrib/bitmap/gumby.bit"`。

boolean
你可以傳遞整數 0 或 1，或字串 `"yes"` 或 `"no"`。

callback
這是任何不帶引數的 Python 函式。例如：

```
def print_it():
    print("hi there")
fred["command"] = print_it
```

color
🄵色可以以 rgb.txt 檔案中的 X 🄵色名稱給出，或以表示 RGB 值的字串給出，範圍可以是 4 位元：`"#RGB"`、8 位元：`"#RRGGBB"`、12 位元：`"#RRRGGGBBB"` 或 16 位元：`"#RRRRGGGGBBBB"`，其中 R、G、B 在此代表任何合法的十六進位數字。詳情請參🄵 Ousterhout 書中的第 160 頁。

cursor
可以使用 `cursorfont.h` 中的標準 X 游標名稱，無需 `XC_` 前綴。例如，要取得手形游標（`XC_hand2`），請使用字串 `"hand2"`。你也可以指定自己的點陣圖和遮罩檔案。請參🄵 Ousterhout 書中的第 179 頁。

distance
螢幕距離可以以像素或🄵對距離指定。像素以數字給出，🄵對距離以字串給出，尾隨字元表示單位：`c` 代表公分，`i` 代表英寸，`m` 代表毫米，`p` 代表印刷的點。例如，3.5 英寸表示🄵 `"3.5i"`。

font
Tk 使用串列字型名稱格式，例如 `{courier 10 bold}`。帶有正數的字型大小以點🄵單位；帶有負數的大小以像素🄵單位。

geometry
這是一個 `widthxheight` 形式的字串，其中 width 和 height 對於大多數元件是以像素🄵單位（對於顯示文字的元件則以字元🄵單位）。例如：`fred["geometry"] = "200x100"`。

justify
合法值🄵字串：`"left"`、`"center"`、`"right"` 和 `"fill"`。

region
這是一個由四個以空格分隔的元素組成的字串，每個元素都是一個合法的距離（見上文）。例如：

`"2 3 4 5"`、`"3i 2i 4.5i 2i"` 和 `"3c 2c 4c 10.43c"` 都是合法的區域。

relief
🄵定元件的邊框樣式。合法值🄵：`"raised"`、`"sunken"`、`"flat"`、`"groove"` 和 `"ridge"`。

scrollcommand
這幾乎總是某個🄵軸元件的 `set()` 方法，但也可以是任何接受單一引數的元件方法。

wrap
必須是以下之一：`"none"`、`"char"` 或 `"word"`。

🄵結與事件

來自元件指令的 bind 方法允許你監視某些事件，🄵在該事件類型發生時觸發一個回呼函式。bind 方法的形式是：

```
def bind(self, sequence, func, add=''):
```

其中：

sequence
是一個表示目標事件類型的字串。（詳情請參🄵 *bind(3tk)* man page，以及 John Ousterhout 的書 *Tcl and the Tk Toolkit (2nd edition)* 的第 201 頁）。

func
是一個 Python 函式，接受一個引數，在事件發生時被呼叫。一個 Event 實例將作🄵引數傳遞。（以這種方式部署的函式通常稱🄵回呼。）

add
是可選的，可以是 `''` 或 `'+'`。傳遞一個空字串表示此🄵結將取代與此事件關聯的任何其他🄵結。傳遞一個 `'+'` 意味著此函式將被新增到🄵結到此事件類型的函式串列中。

舉例來🄵：

```
def turn_red(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turn_red)
```

請注意在 `turn_red()` 回呼中如何存取事件的 widget 欄位。此欄位包含捕獲 X 事件的元件。下表列出了你可以存取的其他事件欄位，以及它們在 Tk 中的表示方式，這在參🄵 Tk man pages 時可能很有用。

Tk	Tkinter 事件欄位	Tk	Tkinter 事件欄位
%f	focus	%A	char
%h	height	%E	send_event
%k	keycode	%K	keysym
%s	state	%N	keysym_num
%t	time	%T	type
%w	width	%W	widget
%x	x	%X	x_root
%y	y	%Y	y_root

index 參數

許多元件需要傳遞"index" 參數。這些參數用於指向 Text 元件中的特定位置、Entry 元件中的特定字元，或 Menu 元件中的特定選單項目。

Entry 元件索引（index、view index 等）
Entry 元件具有參照所顯示文字中字元位置的選項。你可以使用這些 *tkinter* 函式來存取文字元件中的這些特殊點：

Text 元件索引
Text 元件的索引表示法非常豐富，在 Tk man pages 中有最好的描述。

選單索引（menu.invoke()、menu.entryconfig() 等）

選單的某些選項和方法會操作特定的選單項目。每當選項或參數需要選單索引時，你可以傳入：

- 一個整數，它參照元件中項目的數字位置，從頂部開始計數，從 0 開始；
- 字串 `"active"`，它參照目前在游標下的選單位置；
- 字串 `"last"`，它參照最後一個選單項目；
- 一個以 `@` 🄵前綴的整數，如 `@6`，其中該整數被解釋🄵選單座標系統中的 y 像素座標；
- 字串 `"none"`，表示完全🄵有選單項目，最常用於 menu.activate() 以停用所有項目，最後，
- 一個文字字串，它會與從選單頂部掃描到底部的選單項目標🄴進行模式匹配。請注意，此索引類型在所有其他類型之後考慮，這意味著標🄵🄵 `last`、`active` 或 `none` 的選單項目的匹配可能會被解釋🄵上述的字面值。

圖片

可以透過 `tkinter.Image` 的相應子類🄵來建立不同格式的圖片：

- `BitmapImage` 用於 XBM 格式的圖片。
- `PhotoImage` 用於 PGM、PPM、GIF 和 PNG 格式的圖片。後者從 Tk 8.6 開始支援。

任一類型的圖片都是透過 `file` 或 `data` 選項建立的（也有其他選項可用）。

在 3.13 版的變更: 新增了 `PhotoImage` 方法 `copy_replace()`，用於將一個區域從一個圖片🄵🄵到另一個圖片，可能帶有像素縮放和/或子🄵樣。將 *from_coords* 參數新增到 `PhotoImage` 方法 `copy()`、`zoom()` 和 `subsample()`。將 *zoom* 和 *subsample* 參數新增到 `PhotoImage` 方法 `copy()`。

然後，圖片物件可以在任何支援 `image` 選項的元件（例如標🄴、按鈕、選單）中使用。在這些情🄵下，Tk 將不會保留對圖片的參照。當對圖片物件的最後一個 Python 參照被🄵除時，圖片資料也會被🄴除，Tk 將在使用該圖片的任何地方顯示一個空框。

也參考

Pillow 套件新增了對 BMP、JPEG、TIFF 和 WebP 等格式的支援。

25.1.6 檔案處理常式

Tk 允許你🄵🄵和取消🄵🄵一個回呼函式，當檔案描述器上可以進行 I/O 時，該函式將從 Tk 主🄵圈中被呼叫。每個檔案描述器只能🄵🄵一個處理常式。範例程式碼：

```
import tkinter
widget = tkinter.Tk()
mask = tkinter.READABLE | tkinter.WRITABLE
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

此功能在 Windows 上不可用。

由於你不知道有多少位元組可供讀取，你可能不想使用 *BufferedIOBase* 或 *TextIOBase* 的 *read()* 或 *readline()* 方法，因🄴這些方法會堅持讀取預定義數量的位元組。對於 sockets（通訊端），*recv()* 或 *recvfrom()* 方法可以正常運作；對於其他檔案，請使用原始讀取或 `os.read(file.fileno(), maxbytecount)`。

`Widget.tk.`**`createfilehandler`**(*file*, *mask*, *func*)

🄵🄵檔案處理常式回呼函式 *func*。*file* 引數可以是一個具有 *fileno()* 方法的物件（例如檔案或 socket（通訊端）物件），或是一個整數檔案描述器。*mask* 引數是下面三個常數中任意一個的 OR 組合。回呼函式被呼叫的方式如下：

```
callback(file, mask)
```

Widget.tk.**deletefilehandler**(*file*)

取消🄵🄵檔案處理常式。

_tkinter.**READABLE**

_tkinter.**WRITABLE**

_tkinter.**EXCEPTION**

用於 *mask* 引數的常數。

25.2 tkinter.colorchooser --- 🄵色選擇對話框

原始碼： Lib/tkinter/colorchooser.py

---

tkinter.colorchooser 模組提供類🄵*Chooser* 當作與原生🄵色選擇器對話框的介面。Chooser 實作了一個🄵色選擇的互動視窗。類🄵 Chooser 繼承了類🄵*Dialog*。

class tkinter.colorchooser.**Chooser**(*master=None*, ***options*)

tkinter.colorchooser.**askcolor**(*color=None*, ***options*)

建立一個🄵色選擇對話框。一旦呼叫這個方法便會顯示視窗，等待使用者做出選擇後，回傳選擇的🄵色（或者是 None）給呼叫者。

也參考

***tkinter.commondialog* 模組**
Tkinter 標准對話框模組

25.3 tkinter.font --- Tkinter 字型包裝器

原始碼： Lib/tkinter/font.py

---

tkinter.font 模組提供類🄵*Font*，可以建立及使用已命名的字型。

不同的字重 (font weights) 以及傾斜 (slant) 是：

tkinter.font.**NORMAL**

tkinter.font.**BOLD**

tkinter.font.**ITALIC**

tkinter.font.**ROMAN**

class tkinter.font.**Font**(*root=None*, *font=None*, *name=None*, *exists=False*, ***options*)

類🄵*Font* 代表一個已命名字型。*Font* 實例會被賦予一個的名字，也可以特指他們的字型家族 (font family)、字級 (size)、以及外觀設定。已命名字型是 Tk 建立及辨識字型🄵單一物件的方式，而不是每次出現時特指字型的屬性。

引數：

font - 字型指定符號元組 (family, size, options)
name - 獨特字型名稱
exists - 如果存在的話，指向現有的已命名字型

額外的關鍵字選項（若已指定 *font* 則會忽略）：

family - 字型家族，例如：Courier、Times
size - 字級
如果 *size* 是正數則會直譯成以點 (point) 𝔽單位的字級。
如果 *size* 是負數則會變成𝔽對值
以像素 (pixel) 𝔽單位的字級。
weight - 𝔽調字型，例如：NORMAL（標准體）、BOLD（粗體）
slant - 例如：ROMAN（正體）、ITALIC（斜體）
underline - 字型加上底𝔽（0 - 無底𝔽、1 - 加上底𝔽）
overstrike - 字型加上𝔽除𝔽（0 - 無𝔽除𝔽、1 - 加上𝔽除𝔽）

actual(*option=None*, *displayof=None*)
回傳字型的屬性。

cget(*option*)
取得字型的其中一個屬性。

config(***options*)
修改字體的多個屬性。

copy()
回傳目前字體的新實例。

measure(*text*, *displayof=None*)
回傳目前字型被格式化時，在特定顯示區域中文字所用的空間。若顯示區域𝔽有被指定，則會假定主程式視窗𝔽顯示區域。

metrics(**options*, ***kw*)
回傳字型特定的資料。其選項包含：

***ascent* - 基准𝔽以及最高點的距離**
在字型中的一個字母可以𝔽用的空間

***descent* - 基准𝔽以及最低點的距離**
在字型中的一個字母可以𝔽用的空間

***linespace* - 最小所需的垂直間距**
在字型中的任兩個字母之間，確保跨行時不會有垂直重𝔽。

fixed - 若字型𝔽等寬 (fixed-width) 的則𝔽 1，否則𝔽 0

tkinter.font.**families**(*root=None*, *displayof=None*)
回傳不同的字型家族。

tkinter.font.**names**(*root=None*)
回傳已定義字型的名字。

tkinter.font.**nametofont**(*name*, *root=None*)
回傳一個*Font*，代表一個 tk 已命名字型。

在 3.10 版的變更: 新增 *root* 參數。

25.4 Tkinter 對話框

25.4.1 tkinter.simpledialog --- 標準 Tkinter 輸入對話框

原始碼： Lib/tkinter/simpledialog.py

The *tkinter.simpledialog* module contains convenience classes and functions for creating simple modal dialogs to get a value from the user.

tkinter.simpledialog.**askfloat**(*title*, *prompt*, ***kw*)

tkinter.simpledialog.**askinteger**(*title*, *prompt*, ***kw*)

tkinter.simpledialog.**askstring**(*title*, *prompt*, ***kw*)

The above three functions provide dialogs that prompt the user to enter a value of the desired type.

class tkinter.simpledialog.**Dialog**(*parent*, *title=None*)

The base class for custom dialogs.

body(*master*)

Override to construct the dialog's interface and return the widget that should have initial focus.

buttonbox()

Default behaviour adds OK and Cancel buttons. Override for custom button layouts.

25.4.2 tkinter.filedialog --- File selection dialogs

原始碼： Lib/tkinter/filedialog.py

The *tkinter.filedialog* module provides classes and factory functions for creating file/directory selection windows.

Native Load/Save Dialogs

The following classes and functions provide file dialog windows that combine a native look-and-feel with configuration options to customize behaviour. The following keyword arguments are applicable to the classes and functions listed below:

parent - the window to place the dialog on top of

title - the title of the window

initialdir - the directory that the dialog starts in

initialfile - the file selected upon opening of the dialog

filetypes - a sequence of (label, pattern) tuples, '*' wildcard is allowed

defaultextension - default extension to append to file (save dialogs)

multiple - when true, selection of multiple items is allowed

Static factory functions

The below functions when called create a modal, native look-and-feel dialog, wait for the user's selection, then return the selected value(s) or `None` to the caller.

tkinter.filedialog.**askopenfile**(*mode='r'*, ***options*)

tkinter.filedialog.**askopenfiles**(*mode='r'*, ***options*)

The above two functions create an *Open* dialog and return the opened file object(s) in read-only mode.

tkinter.filedialog.**asksaveasfile**(*mode='w'*, ***options*)

Create a *SaveAs* dialog and return a file object opened in write-only mode.

tkinter.filedialog.**askopenfilename**(***options*)

tkinter.filedialog.**askopenfilenames**(***options*)

The above two functions create an *Open* dialog and return the selected filename(s) that correspond to existing file(s).

tkinter.filedialog.**asksaveasfilename**(***options*)

Create a *SaveAs* dialog and return the selected filename.

tkinter.filedialog.**askdirectory**(***options*)

Prompt user to select a directory.

Additional keyword option:

mustexist - determines if selection must be an existing directory.

class tkinter.filedialog.**Open**(*master=None*, ***options*)

class tkinter.filedialog.**SaveAs**(*master=None*, ***options*)

The above two classes provide native dialog windows for saving and loading files.

Convenience classes

The below classes are used for creating file/directory windows from scratch. These do not emulate the native look-and-feel of the platform.

class tkinter.filedialog.**Directory**(*master=None*, ***options*)

Create a dialog prompting the user to select a directory.

備🄵

The *FileDialog* class should be subclassed for custom event handling and behaviour.

class tkinter.filedialog.**FileDialog**(*master*, *title=None*)

Create a basic file selection dialog.

cancel_command(*event=None*)

Trigger the termination of the dialog window.

dirs_double_event(*event*)

Event handler for double-click event on directory.

dirs_select_event(*event*)

Event handler for click event on directory.

files_double_event(*event*)

Event handler for double-click event on file.

files_select_event(*event*)

Event handler for single-click event on file.

filter_command(*event=None*)

Filter the files by directory.

get_filter()

Retrieve the file filter currently in use.

get_selection()

Retrieve the currently selected item.

go(*dir_or_file=os.curdir*, *pattern='*'*, *default=''*, *key=None*)

Render dialog and start event loop.

ok_event(*event*)

Exit dialog returning current selection.

quit(*how=None*)

Exit dialog returning filename, if any.

set_filter(*dir*, *pat*)

Set the file filter.

set_selection(*file*)

Update the current file selection to *file*.

class tkinter.filedialog.**LoadFileDialog**(*master*, *title=None*)

A subclass of FileDialog that creates a dialog window for selecting an existing file.

ok_command()

Test that a file is provided and that the selection indicates an already existing file.

class tkinter.filedialog.**SaveFileDialog**(*master*, *title=None*)

A subclass of FileDialog that creates a dialog window for selecting a destination file.

ok_command()

Test whether or not the selection points to a valid file that is not a directory. Confirmation is required if an already existing file is selected.

25.4.3 tkinter.commondialog --- Dialog window templates

原始碼： Lib/tkinter/commondialog.py

The *tkinter.commondialog* module provides the *Dialog* class that is the base class for dialogs defined in other supporting modules.

class tkinter.commondialog.**Dialog**(*master=None*, ***options*)

show(***options*)

Render the Dialog window.

25.5 tkinter.messagebox --- Tkinter 訊息提示

原始碼： Lib/tkinter/messagebox.py

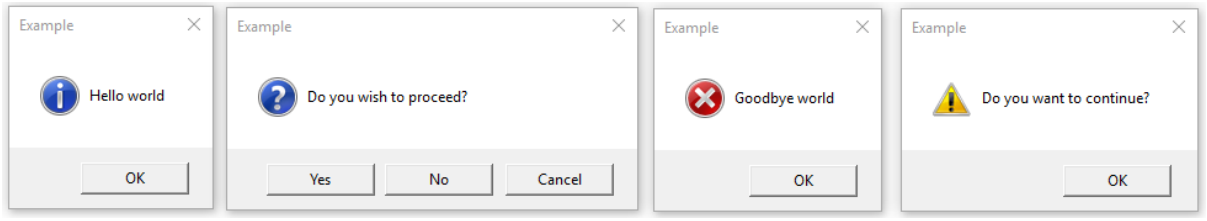
---

tkinter.messagebox 模組提供了模板基底類🄴以及各種常用配置的便捷方法。訊息框 (message box) 是互動視窗 (modal)，會基於使用者的選擇回傳（`True`、`False`、`None`、*OK*、*CANCEL*、*YES*、*NO*）的子集。常見的訊息框樣式 (style) 和版面配置 (layout) 包括但不限於：

class tkinter.messagebox.**Message**(*master=None*, ***options*)

建立一個訊息視窗，其中包含應用程式指定的訊息、一個圖示和一組按鈕。訊息視窗中的每個按鈕都有唯一的符號名稱作🄴識🄴（請參考 *type* 選項）。

支援以下選項：



command
指定當使用者關閉對話框 (dialog) 時要呼叫的函式。使用者按一下以關閉對話框的按鈕的名稱作🄵引數傳遞。此選項僅適用於 macOS。

default
給出此訊息視窗的預設按鈕的符號名稱（*OK*、*CANCEL* 等）。如果未指定此選項，則對話框中的第一個按鈕將成🄵預設按鈕。

detail
透過 *message* 選項指定將輔助訊息給主訊息。訊息詳細資訊將顯示在主要訊息下方，🄵且在作業系統支援的情🄵下，將以比主要訊息更不🄵調的字體顯示。

icon
指定要顯示的圖示。如果未指定此選項，則會顯示 *INFO* 圖示。

message
指定要在此訊息框中顯示的訊息。預設值🄵空字串。

parent
使指定視窗成🄵訊息框的邏輯父視窗 (logical parent window)。訊息框顯示在其父視窗的頂部。

title
指定顯示🄵訊息框標題的字串。此選項在 macOS 上被忽略，其平台指南禁止在此類對話方塊上使用標題。

type
安排一組需顯示的預先定義的按鈕組合。

show(***options*)
顯示訊息視窗🄵等待使用者選擇其中一個按鈕。然後回傳所選按鈕的符號名稱。關鍵字引數可以覆寫建構函式中指定的選項。

資訊訊息框

tkinter.messagebox.**showinfo**(*title=None*, *message=None*, ***options*)
建立🄵顯示具有指定標題和訊息的資訊訊息框。

警告訊息框

tkinter.messagebox.**showwarning**(*title=None*, *message=None*, ***options*)
建立🄵顯示具有指定標題和訊息的警告訊息框。

tkinter.messagebox.**showerror**(*title=None*, *message=None*, ***options*)
建立🄵顯示具有指定標題和訊息的錯誤訊息框。

問題留言框

tkinter.messagebox.**askquestion**(*title=None*, *message=None*, ***, *type=YESNO*, ***options*)
問一個問題。預設顯示按鈕 *YES* 和 *NO*。回傳所選按鈕的符號名稱。

tkinter.messagebox.**askokcancel**(*title=None*, *message=None*, ***options*)
詢問操作是否應該繼續。顯示按鈕 *OK* 和 *CANCEL*。如果答案正確則傳回 `True`，否則回傳 `False`。

tkinter.messagebox.**askretrycancel**(*title=None*, *message=None*, ***options*)
詢問是否應重試操作。顯示按鈕 *RETRY* 和 *CANCEL*。如果答案🄵是，則回傳 `True`，否則回傳 `False`。

tkinter.messagebox.**askyesno**(*title=None*, *message=None*, ***options*)

問一個問題。顯示按鈕*YES*和*NO*。如果答案🄵是，則回傳 `True`，否則回傳 `False`。

tkinter.messagebox.**askyesnocancel**(*title=None*, *message=None*, ***options*)

問一個問題。顯示按鈕*YES*、*NO*和*CANCEL*。如果答案🄵是，則回傳 `True`；如果取消則回傳 `None`，否則回傳 `False`。

按鈕的符號名稱：

tkinter.messagebox.**ABORT = 'abort'**

tkinter.messagebox.**RETRY = 'retry'**

tkinter.messagebox.**IGNORE = 'ignore'**

tkinter.messagebox.**OK = 'ok'**

tkinter.messagebox.**CANCEL = 'cancel'**

tkinter.messagebox.**YES = 'yes'**

tkinter.messagebox.**NO = 'no'**

預先定義的按鈕組合：

tkinter.messagebox.**ABORTRETRYIGNORE = 'abortretryignore'**

顯示三個按鈕，其符號名稱🄵*ABORT*、*RETRY*和*IGNORE*。

tkinter.messagebox.**OK = 'ok'**

顯示一個按鈕，其符號名稱🄵*OK*。

tkinter.messagebox.**OKCANCEL = 'okcancel'**

顯示兩個按鈕，其符號名稱🄵*OK*和*CANCEL*。

tkinter.messagebox.**RETRYCANCEL = 'retrycancel'**

顯示兩個按鈕，其符號名稱🄵*RETRY*和*CANCEL*。

tkinter.messagebox.**YESNO = 'yesno'**

顯示兩個按鈕，其符號名稱🄵*YES*和*NO*。

tkinter.messagebox.**YESNOCANCEL = 'yesnocancel'**

顯示三個按鈕，其符號名稱🄵*YES*、*NO*和*CANCEL*。

圖示圖像：

tkinter.messagebox.**ERROR = 'error'**

tkinter.messagebox.**INFO = 'info'**

tkinter.messagebox.**QUESTION = 'question'**

tkinter.messagebox.**WARNING = 'warning'**

25.6 `tkinter.scrolledtext` --- 🄵動文字小工具

原始碼： Lib/tkinter/scrolledtext.py

The *tkinter.scrolledtext* module provides a class of the same name which implements a basic text widget which has a vertical scroll bar configured to do the ”right thing.” Using the *ScrolledText* class is a lot easier than setting up a text widget and scroll bar directly.

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the *`ScrolledText`* widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

class `tkinter.scrolledtext.`**ScrolledText**(*master=None*, ***kw*)

frame

The frame which surrounds the text and scroll bar widgets.

vbar

The scroll bar widget.

25.7 `tkinter.dnd` --- 拖放支援

原始碼： Lib/tkinter/dnd.py

備🄵

這是一個實驗性的功能，🄵將在被 Tk DND 取代時🄵用。

`tkinter.dnd` 模組🄵單一應用程式🄵、同一個視窗🄵或視窗之間的物件提供拖放支援。要讓一個物件可以被拖動，你必須🄵它建立一個事件🄵結來🄵動拖放過程。你通常會將一個 ButtonPress 事件🄵結到你所寫的回呼函式（請參🄵🄵*結與事件*）。該函式應該呼叫*`dnd_start()`*，其中'source' 是要被拖動的物件，而'event' 是觸發呼叫的事件（你的回呼函式的引數）。

目標物件的選擇過程如下：

1. 由上而下搜尋滑鼠下方的區域以尋找目標元件（widget）
   - 目標元件應該要有一個可呼叫的 *dnd_accept* 屬性（attribute）
   - 如果 *dnd_accept* 不存在或回傳 `None`，搜尋會移至父元件
   - 如果找不到目標元件，則目標物件🄵 `None`
2. 呼叫 *<old_target>.dnd_leave(source, event)*
3. 呼叫 *<new_target>.dnd_enter(source, event)*
4. 呼叫 *<target>.dnd_commit(source, event)* 以通知放下動作
5. 呼叫 *<source>.dnd_end(target, event)* 以表示拖放結束

class `tkinter.dnd.`**DndHandler**(*source*, *event*)

DndHandler 類🄵處理拖放事件，它會追🄵事件元件的根上的 Motion 和 ButtonRelease 事件。

cancel(*event=None*)

取消拖放過程。

finish(*event*, *commit=0*)

執行拖放結束函式。

on_motion(*event*)

在拖動過程中檢查滑鼠下方的區域以尋找目標物件。

on_release(*event*)

當釋放模式被觸發時，發出拖動結束的訊號。

tkinter.dnd.**dnd_start**(*source*, *event*)

用於拖放過程的工廠函式。

🄵結與事件

25.8 tkinter.ttk --- Tk 主題化小工具

原始碼： Lib/tkinter/ttk.py

The *tkinter.ttk* module provides access to the Tk themed widget set, introduced in Tk 8.5. It provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for *tkinter.ttk* is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

也參考

Tk Widget Styling Support
A document introducing theming support for Tk

25.8.1 使用 Ttk

To start using Ttk, import its module:

```
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```
from tkinter import *
from tkinter.ttk import *
```

That code causes several *tkinter.ttk* widgets (`Button`, `Checkbutton`, `Entry`, `Frame`, `Label`, `LabelFrame`, `Menubutton`, `PanedWindow`, `Radiobutton`, `Scale` and `Scrollbar`) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as "fg", "bg" and others related to widget styling are no longer present in Ttk widgets. Instead, use the `ttk.Style` class for improved styling effects.

也參考

Converting existing applications to use Tile widgets
A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.

25.8.2 Ttk Widgets

Ttk comes with 18 widgets, twelve of which already existed in tkinter: `Button`, `Checkbutton`, `Entry`, `Frame`, `Label`, `LabelFrame`, `Menubutton`, `PanedWindow`, `Radiobutton`, `Scale`, `Scrollbar`, and *Spinbox*. The other six are new: *Combobox*, *Notebook*, *Progressbar*, `Separator`, `Sizegrip` and *Treeview*. And all them are subclasses of *Widget*.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about *TtkStyling*, see the `Style` class documentation.

25.8.3 Widget

`ttk.Widget` defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

標準選項

All the `ttk` Widgets accept the following options:

選項	描述
class	Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This option is read-only, and may only be specified when the window is created.
cursor	Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.
takefocus	Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.
style	May be used to specify a custom widget style.

Scrollable Widget Options

The following options are supported by widgets that are controlled by a scrollbar.

選項	描述
xscrollcommand	Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method `Scrollbar.set()` of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.
yscrollcommand	Used to communicate with vertical scrollbars. For some more information, see above.

Label Options

The following options are supported by labels, buttons and other button-like widgets.

選項	描述
text	Specifies a text string to be displayed inside the widget.
textvariable	Specifies a name whose value will be used in place of the text option resource.
underline	If set, specifies the index (0-based) of a character to underline in the text string. The underline character is used for mnemonic activation.
image	Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list if a sequence of statespec/value pairs as defined by *Style.map()*, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.
compound	Specifies how to display the image relative to the text, in the case both text and images options are present. Valid values are: • text: display text only • image: display image only • top, bottom, left, right: display image above, below, left of, or right of the text, respectively. • none: the default. display the image if present, otherwise the text.
width	If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.

相容性選項

選項	描述
state	May be set to ”normal” or ”disabled” to control the ”disabled” state bit. This is a write-only option: setting it changes the widget state, but the *Widget.state()* method does not affect this option.

Widget States

The widget state is a bitmap of independent state flags.

旗標	描述
active	The mouse cursor is over the widget and pressing a mouse button will cause some action to occur
disabled	Widget is disabled under program control
focus	Widget has keyboard focus
pressed	Widget is being pressed
selected	”On”, ”true”, or ”current” for things like Checkbuttons and radiobuttons
background	Windows and Mac have a notion of an ”active” or foreground window. The *background* state is set for widgets in a background window, and cleared for those in the foreground window
readonly	Widget should not allow user modification
alternate	A widget-specific alternate display format
invalid	The widget’s value is invalid

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

ttk.Widget

Besides the methods described below, the `ttk.Widget` supports the methods `tkinter.Widget.cget()` and `tkinter.Widget.configure()`.

class tkinter.ttk.**Widget**

identify(*x*, *y*)

Returns the name of the element at position *x* *y*, or the empty string if the point does not lie within any element.

x and *y* are pixel coordinates relative to the widget.

instate(*statespec*, *callback=None*, **args*, ***kw*)

Test the widget's state. If a callback is not specified, returns `True` if the widget state matches *statespec* and `False` otherwise. If callback is specified then it is called with args if widget state matches *statespec*.

state(*statespec=None*)

Modify or inquire widget state. If *statespec* is specified, sets the widget state according to it and return a new *statespec* indicating which flags were changed. If *statespec* is not specified, returns the currently enabled state flags.

statespec will usually be a list or a tuple.

25.8.4 Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from *`Widget`*: `Widget.cget()`, `Widget.configure()`, *`Widget.identify()`*, *`Widget.instate()`* and *`Widget.state()`*, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.insert()`, `Entry.selection()`, `Entry.xview()`, it has some other methods, described at `ttk.Combobox`.

選項

This widget accepts the following specific options:

選項	描述
exportselection	Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).
justify	Specifies how the text is aligned within the widget. One of ”left”, ”center”, or ”right”.
height	Specifies the height of the pop-down listbox, in rows.
postcommand	A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.
state	One of ”normal”, ”readonly”, or ”disabled”. In the ”readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the ”normal” state, the text field is directly editable. In the ”disabled” state, no interaction is possible.
textvariable	Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See `tkinter.StringVar`.
values	Specifies the list of values to display in the drop-down listbox.
width	Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget's font.

Virtual events

The combobox widgets generates a **«ComboboxSelected»** virtual event when the user selects an element from the list of values.

ttk.Combobox

class tkinter.ttk.**Combobox**

current(*newindex=None*)

If *newindex* is specified, sets the combobox value to the element position *newindex*. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

get()

Returns the current value of the combobox.

set(*value*)

Sets the value of the combobox to *value*.

25.8.5 Spinbox

The `ttk.Spinbox` widget is a `ttk.Entry` enhanced with increment and decrement arrows. It can be used for numbers or lists of string values. This widget is a subclass of `Entry`.

Besides the methods inherited from *`Widget`*: `Widget.cget()`, `Widget.configure()`, *`Widget.identify()`*, *`Widget.instate()`* and *`Widget.state()`*, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.insert()`, `Entry.xview()`, it has some other methods, described at `ttk.Spinbox`.

選項

This widget accepts the following specific options:

選項	描述
from	Float value. If set, this is the minimum value to which the decrement button will decrement. Must be spelled as `from_` when used as an argument, since `from` is a Python keyword.
to	Float value. If set, this is the maximum value to which the increment button will increment.
increment	Float value. Specifies the amount which the increment/decrement buttons change the value. Defaults to 1.0.
values	Sequence of string or float values. If specified, the increment/decrement buttons will cycle through the items in this sequence rather than incrementing or decrementing numbers.
wrap	Boolean value. If `True`, increment and decrement buttons will cycle from the `to` value to the `from` value or the `from` value to the `to` value, respectively.
format	String value. This specifies the format of numbers set by the increment/decrement buttons. It must be in the form "%W.Pf", where W is the padded width of the value, P is the precision, and '%' and 'f' are literal.
command	Python callable. Will be called with no arguments whenever either of the increment or decrement buttons are pressed.

Virtual events

The spinbox widget generates an **«Increment»** virtual event when the user presses <Up>, and a **«Decrement»** virtual event when the user presses <Down>.

ttk.Spinbox

class tkinter.ttk.**Spinbox**

get()

Returns the current value of the spinbox.

set(*value*)

Sets the value of the spinbox to *value*.

25.8.6 Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently displayed window.

選項

This widget accepts the following specific options:

選項	描述
height	If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.
padding	Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.
width	If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.

Tab Options

There are also specific options for tabs:

選項	描述
state	Either ”normal”, ”disabled” or ”hidden”. If ”disabled”, then the tab is not selectable. If ”hidden”, then the tab is not shown.
sticky	Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters ”n”, ”s”, ”e” or ”w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the `grid()` geometry manager.
padding	Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.
text	Specifies a text to be displayed in the tab.
image	Specifies an image to display in the tab. See the option image described in *`Widget`*.
compound	Specifies how to display the image relative to the text, in the case both options text and image are present. See *Label Options* for legal values.
underline	Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if *`Notebook.enable_traversal()`* is called.

Tab Identifiers

The tab_id present in several methods of `ttk.Notebook` may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form ”@x,y”, which identifies the tab
- The literal string ”current”, which identifies the currently selected tab
- The literal string ”end”, which returns the number of tabs (only valid for *`Notebook.index()`*)

🄵擬事件

This widget generates a **«NotebookTabChanged»** virtual event after a new tab is selected.

ttk.Notebook

class tkinter.ttk.**Notebook**

add(*child*, ***kw*)

Adds a new tab to the notebook.

If window is currently managed by the notebook but hidden, it is restored to its previous position.

可用的選項清單請見*Tab Options*。

forget(*tab_id*)

Removes the tab specified by *tab_id*, unmaps and unmanages the associated window.

hide(*tab_id*)

Hides the tab specified by *tab_id*.

The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the `add()` command.

identify(*x*, *y*)

Returns the name of the tab element at position *x*, *y*, or the empty string if none.

index(*tab_id*)

Returns the numeric index of the tab specified by *tab_id*, or the total number of tabs if *tab_id* is the string ”end”.

insert(*pos*, *child*, ***kw*)

Inserts a pane at the specified position.

pos is either the string ”end”, an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

可用的選項清單請見*Tab Options*。

select(*tab_id=None*)

Selects the specified *tab_id*.

The associated child window will be displayed, and the previously selected window (if different) is unmapped. If *tab_id* is omitted, returns the widget name of the currently selected pane.

tab(*tab_id*, *option=None*, ***kw*)

Query or modify the options of the specific *tab_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

tabs()

Returns a list of windows managed by the notebook.

enable_traversal()

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- `Control-Tab`: selects the tab following the currently selected one.
- `Shift-Control-Tab`: selects the tab preceding the currently selected one.
- `Alt-K`: where *K* is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.

25.8.7 Progressbar

The `ttk.Progressbar` widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

選項

This widget accepts the following specific options:

選項	描述
orient	One of ”horizontal” or ”vertical”. Specifies the orientation of the progress bar.
length	Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).
mode	”determinate” 與”indeterminate” 其中之一
maximum	A number specifying the maximum value. Defaults to 100.
value	The current value of the progress bar. In ”determinate” mode, this represents the amount of work completed. In ”indeterminate” mode, it is interpreted as modulo *maximum*; that is, the progress bar completes one ”cycle” when its value increases by *maximum*.
variable	A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.
phase	Read-only option. The widget periodically increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

ttk.Progressbar

class tkinter.ttk.**Progressbar**

start(*interval=None*)

Begin autoincrement mode: schedules a recurring timer event that calls *Progressbar.step()* every *interval* milliseconds. If omitted, *interval* defaults to 50 milliseconds.

step(*amount=None*)

Increments the progress bar's value by *amount*.

amount defaults to 1.0 if omitted.

stop()

Stop autoincrement mode: cancels any recurring timer event initiated by *Progressbar.start()* for this progress bar.

25.8.8 Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

選項

This widget accepts the following specific option:

選項	描述
orient	One of ”horizontal” or ”vertical”. Specifies the orientation of the separator.

25.8.9 Sizegrip

The `ttk.Sizegrip` widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from `ttk.Widget`.

Platform-specific notes

- On macOS, toplevel windows automatically include a built-in size grip by default. Adding a `Sizegrip` is harmless, since the built-in grip will just mask the widget.

Bugs

- If the containing toplevel's position was specified relative to the right or bottom of the screen (e.g. ....), the `Sizegrip` widget will not resize the window.
- This widget supports only "southeast" resizing.

25.8.10 Treeview

The `ttk.Treeview` widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See *Column Identifiers*.

Each item is identified by a unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in *Scrollable Widget Options* and the methods *`Treeview.xview()`* and *`Treeview.yview()`*.

選項

This widget accepts the following specific options:

選項	描述
columns	A list of column identifiers, specifying the number of columns and their names.
displaycolumns	A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string ”#all”.
height	Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.
padding	Specifies the internal padding for the widget. The padding is a list of up to four length specifications.
selectmode	Controls how the built-in class bindings manage the selection. One of ”extended”, ”browse” or ”none”. If set to ”extended” (the default), multiple items may be selected. If ”browse”, only a single item will be selected at a time. If ”none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.
show	A list containing zero or more of the following values, specifying which elements of the tree to display. • tree: display tree labels in column #0. • headings: display the heading row. The default is ”tree headings”, i.e., show all elements. **Note**: Column #0 always refers to the tree column, even if show=”tree” is not specified.

Item Options

The following item options may be specified for items in the insert and item widget commands.

選項	描述
text	The textual label to display for the item.
image	A Tk Image, displayed to the left of the label.
values	The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.
open	`True`/`False` value indicating whether the item’s children should be displayed or hidden.
tags	A list of tags associated with this item.

Tag Options

The following options may be specified on tags:

選項	描述
foreground	Specifies the text foreground color.
background	Specifies the cell or item background color.
font	Specifies the font to use when drawing text.
image	Specifies the item image, in case the item’s image option is empty.

Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer n, specifying the nth data column.
- A string of the form #n, where n is an integer, specifying the nth display column.

🄵解:

- Item's option values may be displayed in a different order than the order in which they are stored.
- Column #0 always refers to the tree column, even if show="tree" is not specified.

A data column number is an index into an item's option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column #0. If option displaycolumns is not set, then data column n is displayed in column #n+1. Again, **column #0 always refers to the tree column**.

🄵擬事件

The Treeview widget generates the following virtual events.

事件	描述
«TreeviewSelect»	Generated whenever the selection changes.
«TreeviewOpen»	Generated just before settings the focus item to open=True.
«TreeviewClose»	Generated just after setting the focus item to open=False.

The *Treeview.focus()* and *Treeview.selection()* methods can be used to determine the affected item or items.

ttk.Treeview

class tkinter.ttk.**Treeview**

bbox(*item*, *column=None*)

Returns the bounding box (relative to the treeview widget's window) of the specified *item* in the form (x, y, width, height).

If *column* is specified, returns the bounding box of that cell. If the *item* is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

get_children(*item=None*)

Returns the list of children belonging to *item*.

If *item* is not specified, returns root children.

set_children(*item*, **newchildren*)

Replaces *item*'s child with *newchildren*.

Children present in *item* that are not present in *newchildren* are detached from the tree. No items in *newchildren* may be an ancestor of *item*. Note that not specifying *newchildren* results in detaching *item*'s children.

column(*column*, *option=None*, ***kw*)

Query or modify the options for the specified *column*.

If *kw* is not given, returns a dict of the column option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

有效的選項/值🄵:

id
回傳欄位名稱。這是唯讀選項。

***anchor*: One of the standard Tk anchor values.**
Specifies how the text in this column should be aligned with respect to the cell.

***minwidth*: width**
The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

***stretch*: `True/False`**
Specifies whether the column's width should be adjusted when the widget is resized.

***width*: width**
The width of the column in pixels.

To configure the tree column, call this with column = "#0"

`delete`(**items*)

Delete all specified *items* and all their descendants.

The root item may not be deleted.

`detach`(**items*)

Unlinks all of the specified *items* from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

`exists`(*item*)

Returns `True` if the specified *item* is present in the tree.

`focus`(*item=None*)

If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or '' if there is none.

`heading`(*column*, *option=None*, ***kw*)

Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

有效的選項/值🄵:

***text*: text**
The text to display in the column heading.

***image*: imageName**
Specifies an image to display to the right of the column heading.

***anchor*: anchor**
Specifies how the heading text should be aligned. One of the standard Tk anchor values.

***command*: callback**
A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = "#0".

`identify`(*component*, *x*, *y*)

Returns a description of the specified *component* under the point given by *x* and *y*, or the empty string if no such *component* is present at that position.

`identify_row`(*y*)

Returns the item ID of the item at position *y*.

`identify_column`(*x*)

Returns the data column identifier of the cell at position *x*.

The tree column has ID #0.

`identify_region`(*x*, *y*)

Returns one of:

region	meaning
heading	Tree heading area.
separator	Space between two columns headings.
tree	The tree area.
cell	A data cell.

Availability: Tk 8.6.

identify_element(*x*, *y*)

Returns the element at position *x*, *y*.

Availability: Tk 8.6.

index(*item*)

Returns the integer index of *item* within its parent's list of children.

insert(*parent*, *index*, *iid=None*, ***kw*)

Creates a new item and returns the item identifier of the newly created item.

parent is the item ID of the parent item, or the empty string to create a new top-level item. *index* is an integer, or the value "end", specifying where in the list of parent's children to insert the new item. If *index* is less than or equal to zero, the new node is inserted at the beginning; if *index* is greater than or equal to the current number of children, it is inserted at the end. If *iid* is specified, it is used as the item identifier; *iid* must not already exist in the tree. Otherwise, a new unique identifier is generated.

可用的選項清單請見*Item Options*。

item(*item*, *option=None*, ***kw*)

Query or modify the options for the specified *item*.

If no options are given, a dict with options/values for the item is returned. If *option* is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by *kw*.

move(*item*, *parent*, *index*)

Moves *item* to position *index* in *parent*'s list of children.

It is illegal to move an item under one of its descendants. If *index* is less than or equal to zero, *item* is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If *item* was detached it is reattached.

next(*item*)

Returns the identifier of *item*'s next sibling, or '' if *item* is the last child of its parent.

parent(*item*)

Returns the ID of the parent of *item*, or '' if *item* is at the top level of the hierarchy.

prev(*item*)

Returns the identifier of *item*'s previous sibling, or '' if *item* is the first child of its parent.

reattach(*item*, *parent*, *index*)

一個`Treeview.move()`的🄵名。

see(*item*)

確保 *item* 是可見的。

Sets all of *item*'s ancestors open option to `True`, and scrolls the widget if necessary so that *item* is within the visible portion of the tree.

selection()

Returns a tuple of selected items.

在 3.8 版的變更: `selection()` no longer takes arguments. For changing the selection state use the following selection methods.

selection_set(**items*)

items becomes the new selection.

在 3.6 版的變更: *items* can be passed as separate arguments, not just as a single tuple.

selection_add(**items*)

將 *items* 加入選擇。

在 3.6 版的變更: *items* can be passed as separate arguments, not just as a single tuple.

selection_remove(**items*)

從選擇中移除 *items*。

在 3.6 版的變更: *items* can be passed as separate arguments, not just as a single tuple.

selection_toggle(**items*)

Toggle the selection state of each item in *items*.

在 3.6 版的變更: *items* can be passed as separate arguments, not just as a single tuple.

set(*item*, *column=None*, *value=None*)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With three arguments, sets the value of given *column* in given *item* to the specified *value*.

tag_bind(*tagname*, *sequence=None*, *callback=None*)

Bind a callback for the given event *sequence* to the tag *tagname*. When an event is delivered to an item, the callbacks for each of the item's tags option are called.

tag_configure(*tagname*, *option=None*, ***kw*)

Query or modify the options for the specified *tagname*.

If *kw* is not given, returns a dict of the option settings for *tagname*. If *option* is specified, returns the value for that *option* for the specified *tagname*. Otherwise, sets the options to the corresponding values for the given *tagname*.

tag_has(*tagname*, *item=None*)

If *item* is specified, returns 1 or 0 depending on whether the specified *item* has the given *tagname*. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

xview(**args*)

Query or modify horizontal position of the treeview.

yview(**args*)

Query or modify vertical position of the treeview.

25.8.11 Ttk Styling

Each widget in `ttk` is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class name of a widget, use the method `Misc.winfo_class()` (somewidget.winfo_class()).

This document explains how the theme engine works

class tkinter.ttk.**Style**

This class is used to manipulate the style database.

configure(*style*, *query_opt=None*, ***kw*)

Query or set the default value of the specified option(s) in *style*.

Each key in *kw* is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color:

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

ttk.Style().configure("TButton", padding=6, relief="flat",
   background="#ccc")

btn = ttk.Button(text="Sample")
btn.pack()

root.mainloop()
```

map(*style*, *query_opt=None*, ***kw*)

Query or sets dynamic values of the specified option(s) in *style*.

Each key in *kw* is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```
import tkinter
from tkinter import ttk

root = tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active', 'blue')],
    background=[('pressed', '!disabled', 'black'), ('active', 'white')]
    )

colored_btn = ttk.Button(text="Test", style="C.TButton").pack()

root.mainloop()
```

Note that the order of the (states, value) sequences for an option does matter, if the order is changed to `[('active', 'blue'), ('pressed', 'red')]` in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

lookup(*style*, *option*, *state=None*, *default=None*)

Returns the value specified for *option* in *style*.

If *state* is specified, it is expected to be a sequence of one or more states. If the *default* argument is set, it is used as a fallback value in case no specification for option is found.

To check what font a Button uses by default:

```
from tkinter import ttk

print(ttk.Style().lookup("TButton", "font"))
```

layout(*style*, *layoutspec=None*)

Define the widget layout for given *style*. If *layoutspec* is omitted, return the layout specification for given style.

layoutspec, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in *Layouts*.

To understand the format, see the following example (it is not intended to do anything useful):

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.layout("TMenubutton", [
   ("Menubutton.background", None),
   ("Menubutton.button", {"children":
       [("Menubutton.focus", {"children":
           [("Menubutton.padding", {"children":
               [("Menubutton.label", {"side": "left", "expand": 1})]
           })]
       })]
   }),
])

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
```

element_create(*elementname*, *etype*, **args*, ***kw*)

Create a new element in the current theme, of the given *etype* which is expected to be either ”image”, ”from” or ”vsapi”. The latter is only available in Tk 8.6 on Windows.

If ”image” is used, *args* should contain the default image name followed by statespec/value pairs (this is the imagespec), and *kw* may have the following options:

border=padding
: padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

height=height
: Specifies a minimum height for the element. If less than zero, the base image’s height is used as a default.

padding=padding
: Specifies the element’s interior padding. Defaults to border’s value if not specified.

sticky=spec
: Specifies how the image is placed within the final parcel. spec contains zero or more characters ”n”, ”s”, ”w”, or ”e”.

width=width
: Specifies a minimum width for the element. If less than zero, the base image’s width is used as a default.

範例：

```
img1 = tkinter.PhotoImage(master=root, file='button.png')
img1 = tkinter.PhotoImage(master=root, file='button-pressed.png')
img1 = tkinter.PhotoImage(master=root, file='button-active.png')
style = ttk.Style(root)
style.element_create('Button.button', 'image',
                     img1, ('pressed', img2), ('active', img3),
                     border=(2, 4), sticky='we')
```

If ”from” is used as the value of *etype*, `element_create()` will clone an existing element. *args* is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. *kw* is discarded.

範例：

```
style = ttk.Style(root)
style.element_create('plain.background', 'from', 'default')
```

If ”vsapi” is used as the value of *etype*, `element_create()` will create a new element in the current theme whose visual appearance is drawn using the Microsoft Visual Styles API which is responsible for the themed styles on Windows XP and Vista. *args* is expected to contain the Visual Styles class and part as given in the Microsoft documentation followed by an optional sequence of tuples of ttk states and the corresponding Visual Styles API state value. *kw* may have the following options:

padding=padding
: Specify the element's interior padding. *padding* is a list of up to four integers specifying the left, top, right and bottom padding quantities respectively. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left. In other words, a list of three numbers specify the left, vertical, and right padding; a list of two numbers specify the horizontal and the vertical padding; a single number specifies the same padding all the way around the widget. This option may not be mixed with any other options.

margins=padding
: Specifies the elements exterior padding. *padding* is a list of up to four integers specifying the left, top, right and bottom padding quantities respectively. This option may not be mixed with any other options.

width=width
: Specifies the width for the element. If this option is set then the Visual Styles API will not be queried for the recommended size or the part. If this option is set then *height* should also be set. The *width* and *height* options cannot be mixed with the *padding* or *margins* options.

height=height
: Specifies the height of the element. See the comments for *width*.

範例：

```
style = ttk.Style(root)
style.element_create('pin', 'vsapi', 'EXPLORERBAR', 3, [
                     ('pressed', '!selected', 3),
                     ('active', '!selected', 2),
                     ('pressed', 'selected', 6),
                     ('active', 'selected', 5),
                     ('selected', 4),
                     ('', 1)])
style.layout('Explorer.Pin',
             [('Explorer.Pin.pin', {'sticky': 'news'})])
pin = ttk.Checkbutton(style='Explorer.Pin')
pin.pack(expand=True, fill='both')
```

在 3.13 版的變更: Added support of the ”vsapi” element factory.

element_names()
: Returns the list of elements defined in the current theme.

element_options(*elementname*)
: Returns the list of *elementname*'s options.

theme_create(*themename*, *parent=None*, *settings=None*)
: Create a new theme.

  It is an error if *themename* already exists. If *parent* is specified, the new theme will inherit styles, elements and layouts from the parent theme. If *settings* are present they are expected to have the same syntax used for `theme_settings()`.

theme_settings(*themename*, *settings*)

Temporarily sets the current theme to *themename*, apply specified *settings* and then restore the previous theme.

Each key in *settings* is a style and each value may contain the keys 'configure', 'map', 'layout' and 'element create' and they are expected to have the same format as specified by the methods *Style.configure()*, *Style.map()*, *Style.layout()* and *Style.element_create()* respectively.

As an example, let's change the Combobox for the default theme a bit:

```
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
   "TCombobox": {
       "configure": {"padding": 5},
       "map": {
           "background": [("active", "green2"),
                          ("!disabled", "green4")],
           "fieldbackground": [("!disabled", "green3")],
           "foreground": [("focus", "OliveDrab1"),
                          ("!disabled", "OliveDrab2")]
       }
   }
})

combo = ttk.Combobox().pack()

root.mainloop()
```

theme_names()

回傳所有已知的主題。

theme_use(*themename=None*)

If *themename* is not given, returns the theme in use. Otherwise, sets the current theme to *themename*, refreshes all widgets and emits a «ThemeChanged» event.

Layouts

A layout can be just `None`, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel.

有效的選項/值🄴:

***side*: whichside**

Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

***sticky*: nswe**

Specifies where the element is placed inside its allocated parcel.

***unit*: 0 或 1**

If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of *Widget.identify()* et al. It's used for things like scrollbar thumbs with grips.

***children*: [sublayout...]**

Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a *Layout*.

25.9 IDLE --- Python 編輯器與 shell

原始碼： Lib/idlelib/

IDLE 是 Python 的整合開發與學習環境 (Integrated Development and Learning Environment)。

IDLE 具有以下功能：

- 跨平台：在 Windows、Unix 和 macOS 上的運作大致相同
- Python shell window（互動式直譯器）提供有色彩的程式碼輸入、輸出和錯誤訊息
- 多視窗文字編輯器，具有多次復原、Python 語法上色、智慧縮排、呼叫提示、自動完成等功能
- 能在任何視窗中搜尋、編輯器視窗中取代文字，以及搜尋多個檔案 (grep)
- 具有持久性斷點、能🄵逐步執行和檢視全域和區域命名空間的除錯器
- 設定、🄵覽器和其他對話框

25.9.1 目🄵

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. On Windows and Linux, each has its own top menu. Each menu documented below indicates which window type it is associated with.

Output windows, such as used for Edit => Find in Files, are a subtype of editor window. They currently have the same top menu but a different default title and context menu.

On macOS, there is one application menu. It dynamically changes according to the window currently selected. It has an IDLE menu, and some entries described below are moved around to conform to Apple guidelines.

File menu (Shell and Editor)

新增檔案
Create a new file editing window.

Open...
Open an existing file with an Open dialog.

Open Module...
Open an existing module (searches sys.path).

Recent Files
Open a list of recent files. Click one to open it.

Module Browser
Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

Path Browser
Show sys.path directories, modules, functions, classes and methods in a tree structure.

Save
Save the current window to the associated file, if there is one. Windows that have been changed since being opened or last saved have a * before and after the window title. If there is no associated file, do Save As instead.

Save As...
Save the current window with a Save As dialog. The file saved becomes the new associated file for the window. (If your file namager is set to hide extensions, the current extension will be omitted in the file name box. If the new filename has no '.', '.py' and '.txt' will be added for Python and text files, except that on macOS Aqua,'.py' is added for all files.)

Save Copy As...
Save the current window to different file without changing the associated file. (See Save As note above about filename extensions.)

Print Window
Print the current window to the default printer.

Close Window
Close the current window (if an unsaved editor, ask to save; if an unsaved Shell, ask to quit execution). Calling `exit()` or `close()` in the Shell window also closes Shell. If this is the only window, also exit IDLE.

離開 IDLE
Close all windows and quit IDLE (ask to save unsaved edit windows).

Edit menu (Shell and Editor)

Undo
Undo the last change to the current window. A maximum of 1000 changes may be undone.

Redo
Redo the last undone change to the current window.

Select All（選擇全部）
Select the entire contents of the current window.

Cut（剪下）
Copy selection into the system-wide clipboard; then delete the selection.

Copy（🄵🄵）
Copy selection into the system-wide clipboard.

Paste（貼上）
Insert contents of the system-wide clipboard into the current window.

The clipboard functions are also available in context menus.

Find...
Open a search dialog with many options

Find Again
Repeat the last search, if there is one.

Find Selection
Search for the currently selected string, if there is one.

Find in Files...
Open a file search dialog. Put results in a new output window.

Replace...
Open a search-and-replace dialog.

Go to Line
Move the cursor to the beginning of the line requested and make that line visible. A request past the end of the file goes to the end. Clear any selection and update the line and column status.

Show Completions
Open a scrollable list allowing selection of existing names. See *Completions* in the Editing and navigation section below.

Expand Word
Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

Show Call Tip
After an unclosed parenthesis for a function, open a small window with function parameter hints. See *Calltips* in the Editing and navigation section below.

Show Surrounding Parens
Highlight the surrounding parenthesis.

Format menu (Editor window only)

Format Paragraph
Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

Indent Region
Shift selected lines right by the indent width (default 4 spaces).

Dedent Region
Shift selected lines left by the indent width (default 4 spaces).

Comment Out Region
Insert ## in front of selected lines.

Uncomment Region
Remove leading # or ## from selected lines.

Tabify Region
Turn *leading* stretches of spaces into tabs. (Note: We recommend using 4 space blocks to indent Python code.)

Untabify Region
Turn *all* tabs into the correct number of spaces.

Toggle Tabs
Open a dialog to switch between indenting with spaces and tabs.

New Indent Width
Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

Strip Trailing Chitespace
Remove trailing space and other whitespace characters after the last non-whitespace character of a line by applying str.rstrip to each line, including lines within multiline strings. Except for Shell windows, remove extra newlines at the end of the file.

Run menu (Editor window only)

Run Module
Do *Check Module*. If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of `print` or `write`. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with `python -i file` at a command line.

Run... Customized
Same as *Run Module*, but run the module with customized settings. *Command Line Arguments* extend `sys.argv` as if passed on a command line. The module can be run in the Shell without restarting.

Check Module
Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

Python Shell
Open or wake up the Python Shell window.

Shell menu (Shell window only)

View Last Restart
Scroll the shell window to the last Shell restart.

Restart Shell
Restart the shell to clean the environment and reset display and exception handling.

Previous History
Cycle through earlier commands in history which match the current entry.

Next History
Cycle through later commands in history which match the current entry.

Interrupt Execution
Stop a running program.

Debug menu (Shell window only)

Go to File/Line
Look on the current line. with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also available in the context menu of the Shell window and Output windows.

Debugger (toggle)
When activated, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

Stack Viewer
Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

Auto-open Stack Viewer
Toggle automatically opening the stack viewer on an unhandled exception.

Options menu (Shell and Editor)

Configure IDLE
Open a configuration dialog and change preferences for the following: fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions. On macOS, open the configuration dialog by selecting Preferences in the application menu. For more details, see *Setting preferences* under Help and preferences.

Most configuration options apply to all windows or all future windows. The option items below only apply to the active window.

Show/Hide Code Context (Editor Window only)
Open a pane at the top of the edit window which shows the block context of the code which has scrolled above the top of the window. See *Code Context* in the Editing and Navigation section below.

Show/Hide Line Numbers (Editor Window only)
Open a column to the left of the edit window which shows the number of each line of text. The default is off, which may be changed in the preferences (see *Setting preferences*).

Zoom/Restore Height
Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog. The maximum height for a screen is determined by momentarily maximizing a window the first time one is zoomed on the screen. Changing screen settings may invalidate the saved height. This toggle has no effect when a window is maximized.

Window menu (Shell and Editor)

Lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

Help menu (Shell and Editor)

關於 IDLE
Display version, copyright, license, credits, and more.

IDLE Help
Display this IDLE document, detailing the menu options, basic editing and navigation, and other tips.

Python Docs
Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

Turtle Demo
Run the turtledemo module with example Python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE dialog under the General tab. See the *Help sources* subsection below for more on Help menu choices.

Context menus

Open a context menu by right-clicking in a window (Control-click on macOS). Context menus have the standard clipboard functions also on the Edit menu.

Cut（剪下）
Copy selection into the system-wide clipboard; then delete the selection.

Copy（🄵🄵）
Copy selection into the system-wide clipboard.

Paste（貼上）
Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user's `.idlerc` directory.

Set Breakpoint
Set a breakpoint on the current line.

Clear Breakpoint
Clear the breakpoint on that line.

Shell and Output windows also have the following.

Go to file/line
Same as in Debug menu.

The Shell window also has an output squeezing facility explained in the *Python Shell window* subsection below.

Squeeze
If the cursor is over an output line, squeeze all the output between the code above and the prompt below down to a 'Squeezed text' label.

25.9.2 Editing and Navigation

Editor windows

IDLE may open editor windows when it starts, depending on settings and how you start IDLE. Thereafter, use the File menu. There can be only one open editor window for a given file.

The title bar contains the name of the file, the full path, and the version of Python and IDLE running the window. The status bar contains the line number ('Ln') and column number ('Col'). Line numbers start with 1; column numbers with 0.

IDLE assumes that files with a known .py* extension contain Python code and that other files do not. Run Python code with the Run menu.

Key bindings

The IDLE insertion cursor is a thin vertical bar between character positions. When characters are entered, the insertion cursor and everything to its right moves right one character and the new character is entered in the new space.

Several non-character keys move the cursor and possibly delete characters. Deletion does not puts text on the clipboard, but IDLE has an undo list. Wherever this doc discusses keys, 'C' refers to the `Control` key on Windows and Unix and the `Command` key on macOS. (And all such discussions assume that the keys have not been re-bound to something else.)

- Arrow keys move the cursor one character or line.

- C-LeftArrow and C-RightArrow moves left or right one word.
- Home and End go to the beginning or end of the line.
- Page Up and Page Down go up or down one screen.
- C-Home and C-End go to beginning or end of the file.
- Backspace and Del (or C-d) delete the previous or next character.
- C-Backspace and C-Del delete one word left or right.
- C-k deletes ('kills') everything to the right.

Standard keybindings (like C-c to copy and C-v to paste) may work. Keybindings are selected in the Configure IDLE dialog.

Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, Backspace deletes up to 4 spaces if they are there. Tab inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently, tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands on the *Format menu*.

Search and Replace

Any selection becomes a search target. However, only selections within a line work because searches are only performed within lines with the terminal newline removed. If [x] Regular expression is checked, the target is interpreted according to the Python re module.

Completions

Completions are supplied, when requested and available, for module names, attributes of classes or functions, or filenames. Each request method displays a completion box with existing names. (See tab completions below for an exception.) For any box, change the name being completed and the item highlighted in the box by typing and deleting characters; by hitting Up, Down, PageUp, PageDown, Home, and End keys; and by a single click within the box. Close the box with Escape, Enter, and double Tab keys or clicks outside the box. A double click within the box selects and closes.

One way to open a box is to type a key character and wait for a predefined interval. This defaults to 2 seconds; customize it in the settings dialog. (To prevent auto popups, set the delay to a large number of milliseconds, such as 100000000.) For imported module names or class or function attributes, type '.'. For filenames in the root directory, type *os.sep* or *os.altsep* immediately after an opening quote. (On Windows, one can specify a drive first.) Move into subdirectories by typing a directory name and a separator.

Instead of waiting, or after a box is closed, open a completion box immediately with Show Completions on the Edit menu. The default hot key is C-space. If one types a prefix for the desired name before opening the box, the first match or near miss is made visible. The result is the same as if one enters a prefix after the box is displayed. Show Completions after a quote completes filenames in the current directory instead of a root directory.

Hitting Tab after a prefix usually has the same effect as Show Completions. (With no prefix, it indents.) However, if there is only one match to the prefix, that match is immediately added to the editor text without opening a box.

Invoking 'Show Completions', or hitting Tab after a prefix, outside of a string and without a preceding '.' opens a box with keywords, builtin names, and available module-level names.

When editing code in an editor (as oppose to Shell), increase the available module-level names by running your code and not restarting the Shell thereafter. This is especially useful after adding imports at the top of a file. This also increases possible attribute completions.

Completion boxes initially exclude names beginning with '_' or, for modules, not included in '__all__'. The hidden names can be accessed by typing '_' after '.', either before or after the box is opened.

Calltips

A calltip is shown automatically when one types `(` after the name of an *accessible* function. A function name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or `)` is typed. Whenever the cursor is in the argument part of a definition, select Edit and "Show Call Tip" on the menu or enter its shortcut to display a calltip.

The calltip consists of the function's signature and docstring up to the latter's first blank line or the fifth non-blank line. (Some builtin functions lack an accessible signature.) A '/' or '*' in the signature indicates that the preceding or following arguments are passed by position or name (keyword) only. Details are subject to change.

In Shell, the accessible functions depends on what modules have been imported into the user process, including those imported by Idle itself, and which definitions have been run, all since the last restart.

For example, restart the Shell and enter `itertools.count(`. A calltip appears because Idle imports itertools into the user process for its own use. (This could change.) Enter `turtle.write(` and nothing appears. Idle does not itself import turtle. The menu entry and shortcut also do nothing. Enter `import turtle`. Thereafter, `turtle.write(` will display a calltip.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing import statements, after adding function definitions, or after opening an existing file.

Code Context

Within an editor window containing Python code, code context can be toggled in order to show or hide a pane at the top of the window. When shown, this pane freezes the opening lines for block code, such as those beginning with `class`, `def`, or `if` keywords, that would have otherwise scrolled out of view. The size of the pane will be expanded and contracted as needed to show the all current levels of context, up to the maximum number of lines defined in the Configure IDLE dialog (which defaults to 15). If there are no current context lines and the feature is toggled on, a single blank line will display. Clicking on a line in the context pane will move that line to the top of the editor.

The text and background colors for the context pane can be configured under the Highlights tab in the Configure IDLE dialog.

Shell window

In IDLE's Shell, enter, edit, and recall complete statements. (Most consoles and terminals only work with a single physical line at a time).

Submit a single-line statement for execution by hitting `Return` with the cursor anywhere on the line. If a line is extended with Backslash (`\`), the cursor must be on the last physical line. Submit a multi-line compound statement by entering a blank line after the statement.

When one pastes code into Shell, it is not compiled and possibly executed until one hits `Return`, as specified above. One may edit pasted code first. If one pastes more than one statement into Shell, the result will be a *SyntaxError* when multiple statements are compiled as if they were one.

Lines containing `RESTART` mean that the user execution process has been re-started. This occurs when the user execution process has crashed, when one requests a restart on the Shell menu, or when one runs code in an editor window.

The editing features described in previous subsections work when entering code interactively. IDLE's Shell window also responds to the following:

- `C-c` attempts to interrupt statement execution (but may fail).
- `C-d` closes Shell if typed at a `>>>` prompt.
- `Alt-p` and `Alt-n` (`C-p` and `C-n` on macOS) retrieve to the current prompt the previous or next previously entered statement that matches anything already typed.
- `Return` while the cursor is on any previous statement appends the latter to anything already typed at the prompt.

Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, builtin class and function names, names following `class` and `def`, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

IDLE also highlights the soft keywords `match`, `case`, and _ in pattern-matching statements. However, this highlighting is not perfect and will be incorrect in some rare cases, including some _-s in `case` patterns.

Text coloring is done in the background, so uncolorized text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.

25.9.3 Startup and Code Execution

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables `IDLESTARTUP` or `PYTHONSTARTUP`. IDLE first checks for `IDLESTARTUP`; if `IDLESTARTUP` is present the file referenced is run. If `IDLESTARTUP` is not present, IDLE checks for `PYTHONSTARTUP`. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, `Tk` also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user's home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE's Python shell.

命令列用法

IDLE can be invoked from the command line with various options. The general syntax is:

```
python -m idlelib [options] [file ...]
```

The following options are available:

-c <command>
: Run the specified Python command in the shell window. For example, pass `-c "print('Hello, World!')"`. On Windows, the outer quotes must be double quotes as shown.

-d
: Enable the debugger and open the shell window.

-e
: Open an editor window.

-h
: Print a help message with legal combinations of options and exit.

-i
: Open a shell window.

-r <file>
: Run the specified file in the shell window.

-s
: Run the startup file (as defined by the environment variables `IDLESTARTUP` or `PYTHONSTARTUP`) before opening the shell window.

-t <title>
: Set the title of the shell window.

-
: Read and execute standard input in the shell window. This option must be the last one before any arguments.

If arguments are provided:

- If `-`, `-c`, or `-r` is used, all arguments are placed in `sys.argv[1:]`, and `sys.argv[0]` is set to `''`, `'-c'`, or `'-r'` respectively. No editor window is opened, even if that is the default set in the *Options* dialog.
- Otherwise, arguments are treated as files to be opened for editing, and `sys.argv` reflects the arguments passed to IDLE itself.

Startup failure

IDLE uses a socket to communicate between the IDLE GUI process and the user code execution process. A connection must be established whenever the Shell starts or restarts. (The latter is indicated by a divider line that says 'RESTART'). If the user process fails to connect to the GUI process, it usually displays a `Tk` error box with a 'cannot connect' message that directs the user here. It then exits.

One specific connection failure on Unix systems results from misconfigured masquerading rules somewhere in a system's network setup. When IDLE is started from a terminal, one will see a message starting with `** Invalid host:`. The valid value is `127.0.0.1 (idlelib.rpc.LOCALHOST)`. One can diagnose with `tcpconnect -irv 127.0.0.1 6543` in one terminal window and `tcplisten <same args>` in another.

A common cause of failure is a user-written file with the same name as a standard library module, such as *random.py* and *tkinter.py*. When such a file is located in the same directory as a file that is about to be run, IDLE cannot import the stdlib file. The current fix is to rename the user file.

Though less common than in the past, an antivirus or firewall program may stop the connection. If the program cannot be taught to allow the connection, then it must be turned off for IDLE to work. It is safe to allow this internal connection because no data is visible on external ports. A similar problem is a network mis-configuration that blocks connections.

Python installation issues occasionally stop IDLE: multiple versions can clash, or a single installation might need admin access. If one undo the clash, or cannot or does not want to run as admin, it might be easiest to completely remove Python and start over.

A zombie pythonw.exe process could be a problem. On Windows, use Task Manager to check for one and stop it if there is. Sometimes a restart initiated by a program crash or Keyboard Interrupt (control-C) may fail to connect. Dismissing the error box or using Restart Shell on the Shell menu may fix a temporary problem.

When IDLE first starts, it attempts to read user configuration files in `~/.idlerc/` (~ is one's home directory). If there is a problem, an error message should be displayed. Leaving aside random disk glitches, this can be prevented by never editing the files by hand. Instead, use the configuration dialog, under Options. Once there is an error in a user configuration file, the best solution may be to delete it and start over with the settings dialog.

If IDLE quits with no message, and it was not started from a console, try starting it from a console or terminal (`python -m idlelib`) and see if this results in an error message.

On Unix-based systems with tcl/tk older than `8.6.11` (see `About IDLE`) certain characters of certain fonts can cause a tk failure with a message to the terminal. This can happen either if one starts IDLE to edit a file with such a character or later when entering such a character. If one cannot upgrade tcl/tk, then re-configure IDLE to use a font that works better.

Running user code

With rare exceptions, the result of executing Python code with IDLE is intended to be the same as executing the same code by the default method, directly with Python in a text-mode system console or terminal window. However, the different interface and operation occasionally affect visible results. For instance, `sys.modules` starts with more entries, and `threading.active_count()` returns 2 instead of 1.

By default, IDLE runs user code in a separate OS process rather than in the user interface process that runs the shell and editor. In the execution process, it replaces `sys.stdin`, `sys.stdout`, and `sys.stderr` with objects that get input from and send output to the Shell window. The original values stored in `sys.__stdin__`, `sys.__stdout__`, and `sys.__stderr__` are not touched, but may be `None`.

Sending print output from one process to a text widget in another is slower than printing to a system terminal in the same process. This has the most effect when printing multiple arguments, as the string for each argument, each separator, the newline are sent separately. For development, this is usually not a problem, but if one wants to print

faster in IDLE, format and join together everything one wants displayed together and then print a single string. Both format strings and *str.join()* can help combine fields and lines.

IDLE's standard stream replacements are not inherited by subprocesses created in the execution process, whether directly by user code or by modules such as multiprocessing. If such subprocess use `input` from sys.stdin or `print` or `write` to sys.stdout or sys.stderr, IDLE should be started in a command line window. (On Windows, use `python` or `py` rather than `pythonw` or `pyw`.) The secondary subprocess will then be attached to that window for input and output.

If `sys` is reset by user code, such as with `importlib.reload(sys)`, IDLE's changes are lost and input from the keyboard and output to the screen will not work correctly.

When Shell has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard and screen will not work. These include system-specific functions that determine whether a key has been pressed and if so, which.

The IDLE code running in the execution process adds frames to the call stack that would not be there otherwise. IDLE wraps `sys.getrecursionlimit` and `sys.setrecursionlimit` to reduce the effect of the additional stack frames.

When user code raises SystemExit either directly or by calling sys.exit, IDLE returns to a Shell prompt instead of exiting.

User output in Shell

When a program outputs text, the result is determined by the corresponding output device. When IDLE executes user code, `sys.stdout` and `sys.stderr` are connected to the display area of IDLE's Shell. Some of its features are inherited from the underlying Tk Text widget. Others are programmed additions. Where it matters, Shell is designed for development rather than production runs.

For instance, Shell never throws away output. A program that sends unlimited output to Shell will eventually fill memory, resulting in a memory error. In contrast, some system text windows only keep the last n lines of output. A Windows console, for instance, keeps a user-settable 1 to 9999 lines, with 300 the default.

A Tk Text widget, and hence IDLE's Shell, displays characters (codepoints) in the BMP (Basic Multilingual Plane) subset of Unicode. Which characters are displayed with a proper glyph and which with a replacement box depends on the operating system and installed fonts. Tab characters cause the following text to begin after the next tab stop. (They occur every 8 'characters'). Newline characters cause following text to appear on a new line. Other control characters are ignored or displayed as a space, box, or something else, depending on the operating system and font. (Moving the text cursor through such output with arrow keys may exhibit some surprising spacing behavior.)

```
>>> s = 'a\tb\a<\x02><\r>\bc\nd'  # Enter 22 chars.
>>> len(s)
14
>>> s  # Display repr(s)
'a\tb\x07<\x02><\r>\x08c\nd'
>>> print(s, end='')  # Display s as is.
# Result varies by OS and font.  Try it.
```

The `repr` function is used for interactive echo of expression values. It returns an altered version of the input string in which control codes, some BMP codepoints, and all non-BMP codepoints are replaced with escape codes. As demonstrated above, it allows one to identify the characters in a string, regardless of how they are displayed.

Normal and error output are generally kept separate (on separate lines) from code input and each other. They each get different highlight colors.

For SyntaxError tracebacks, the normal '^' marking where the error was detected is replaced by coloring the text with an error highlight. When code run from a file causes other exceptions, one may right click on a traceback line to jump to the corresponding line in an IDLE editor. The file will be opened if necessary.

Shell has a special facility for squeezing output lines down to a 'Squeezed text' label. This is done automatically for output over N lines (N = 50 by default). N can be changed in the PyShell section of the General page of the Settings dialog. Output with fewer lines can be squeezed by right clicking on the output. This can be useful lines long enough to slow down scrolling.

Squeezed output is expanded in place by double-clicking the label. It can also be sent to the clipboard or a separate view window by right-clicking the label.

Developing tkinter applications

IDLE is intentionally different from standard Python in order to facilitate development of tkinter programs. Enter `import tkinter as tk; root = tk.Tk()` in standard Python and nothing appears. Enter the same in IDLE and a tk window appears. In standard Python, one must also enter `root.update()` to see the window. IDLE does the equivalent in the background, about 20 times a second, which is about every 50 milliseconds. Next enter `b = tk.Button(root, text='button'); b.pack()`. Again, nothing visibly changes in standard Python until one enters `root.update()`.

Most tkinter programs run `root.mainloop()`, which usually does not return until the tk app is destroyed. If the program is run with `python -i` or from an IDLE editor, a `>>>` shell prompt does not appear until `mainloop()` returns, at which time there is nothing left to interact with.

When running a tkinter program from an IDLE editor, one can comment out the mainloop call. One then gets a shell prompt immediately and can interact with the live application. One just has to remember to re-enable the mainloop call when running in standard Python.

Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the -n command line switch.

If IDLE is started with the -n command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must reload() the affected modules and re-import any specific items (e.g. from foo import baz) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

在 3.4 版之後被🄴用.

25.9.4 Help and Preferences

Help sources

Help menu entry ”IDLE Help” displays a formatted html version of the IDLE chapter of the Library Reference. The result, in a read-only tkinter text window, is close to what one sees in a web browser. Navigate through the text with a mousewheel, the scrollbar, or up and down arrow keys held down. Or click the TOC (Table of Contents) button and select a section header in the opened box.

Help menu entry ”Python Docs” opens the extensive sources of help, including tutorials, available at `docs.python.org/x.y`, where ’x.y’ is the currently running Python version. If your system has an off-line copy of the docs (this may be an installation option), that will be opened instead.

Selected URLs can be added or removed from the help menu at any time using the General tab of the Configure IDLE dialog.

設定偏好

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Non-default user settings are saved in a `.idlerc` directory in the user’s home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in `.idlerc`.

On the Font tab, see the text sample for the effect of font face and size on multiple characters in multiple languages. Edit the sample to add other characters of personal interest. Use the sample to select monospaced fonts. If particular

characters have problems in Shell or an editor, add them to the top of the sample and try changing first size and then font.

On the Highlights and Keys tab, select a built-in or custom color theme and key set. To use a newer built-in color theme or key set with older IDLEs, save it as a new custom theme or key set and it well be accessible to older IDLEs.

macOS 上的 IDLE

Under System Preferences: Dock, one can set "Prefer tabs when opening documents" to "Always". This setting is not compatible with the tk/tkinter GUI framework used by IDLE, and it breaks a few IDLE features.

Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with the Extensions tab of the preferences dialog. See the beginning of config-extensions.def in the idlelib directory for further information. The only current default extension is zzdummy, an example also used for testing.

25.9.5 idlelib --- implementation of IDLE application

原始碼： Lib/idlelib/

The Lib/idlelib package implements the IDLE application. See the rest of this page for how to use IDLE.

The files in idlelib are described in idlelib/README.txt. Access it either in idlelib or click Help => About IDLE on the IDLE menu. This file also maps IDLE menu items to the code that implements the item. Except for files listed under 'Startup', the idlelib code is 'private' in sense that feature changes can be backported (see **PEP 434**).

25.10 `turtle` --- 龜圖學 (Turtle graphics)

原始碼： Lib/turtle.py

25.10.1 介紹

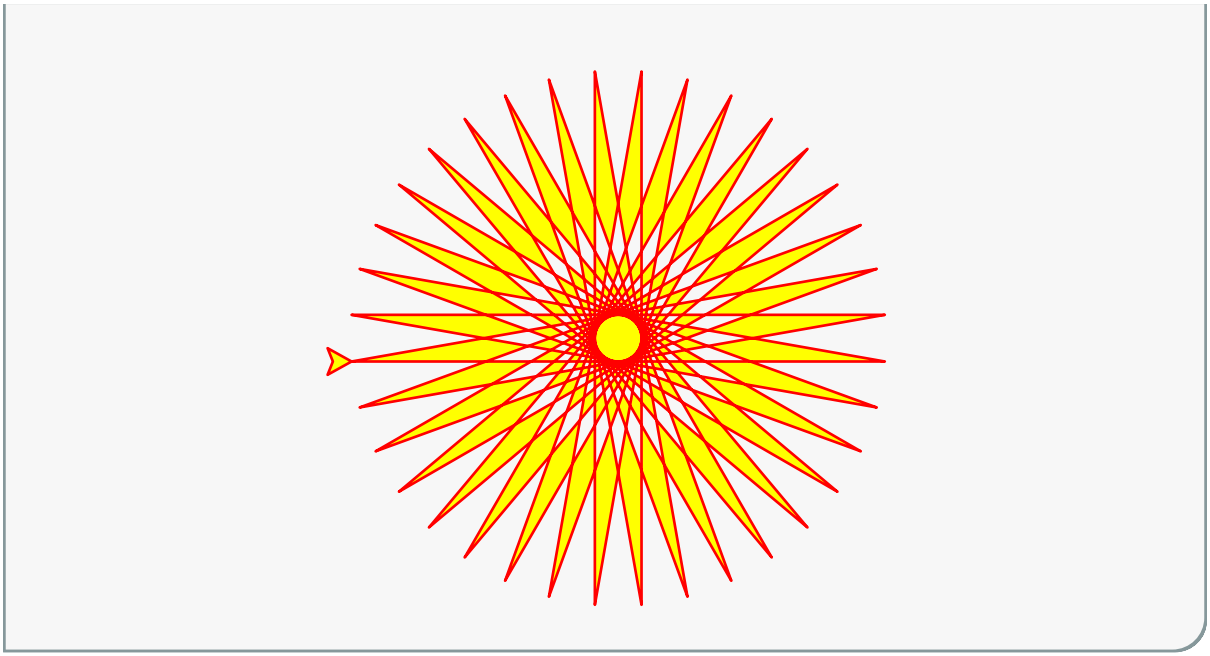
龜圖學是由 Wally Feurzeig，Seymour Papert 與 Cynthia Solomon 於 1967 年開發的，一個 以 Logo 程式語言撰寫的廣受歡迎的幾何繪圖工具。

25.10.2 Get started

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an `import turtle`, give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.right(25)`, and it rotates in-place 25 degrees clockwise.

Turtle star

龜可以使用重🄵簡單動作之程式來畫出🄵雜的形狀。



In Python, turtle graphics provides a representation of a physical ”turtle” (a little robot with a pen) that draws on a sheet of paper on the floor.

It's an effective and well-proven way for learners to encounter programming concepts and interaction with software, as it provides instant, visible feedback. It also provides convenient access to graphical output in general.

Turtle drawing was originally created as an educational tool, to be used by teachers in the classroom. For the programmer who needs to produce some graphical output it can be a way to do that without the overhead of introducing more complex or external libraries into their work.

25.10.3 教學

New users should start here. In this tutorial we'll explore some of the basics of turtle drawing.

🄵動一個烏龜環境

在 Python shell 中，引入 `turtle` 模組中所有物件：

```
from turtle import *
```

If you run into a `No module named '_tkinter'` error, you'll have to install the *Tk interface package* on your system.

基本繪圖

Send the turtle forward 100 steps:

```
forward(100)
```

You should see (most likely, in a new window on your display) a line drawn by the turtle, heading East. Change the direction of the turtle, so that it turns 120 degrees left (anti-clockwise):

```
left(120)
```

Let's continue by drawing a triangle:

```
forward(100)
left(120)
forward(100)
```

Notice how the turtle, represented by an arrow, points in different directions as you steer it.

Experiment with those commands, and also with `backward()` and `right()`.

Pen control

Try changing the color - for example, `color('blue')` - and width of the line - for example, `width(3)` - and then drawing again.

You can also move the turtle around without drawing, by lifting up the pen: `up()` before moving. To start drawing again, use `down()`.

The turtle's position

Send your turtle back to its starting-point (useful if it has disappeared off-screen):

```
home()
```

The home position is at the center of the turtle's screen. If you ever need to know them, get the turtle's x-y coordinates with:

```
pos()
```

Home is at `(0, 0)`.

And after a while, it will probably help to clear the window so we can start anew:

```
clearscreen()
```

Making algorithmic patterns

Using loops, it's possible to build up geometric patterns:

```
for steps in range(100):
    for c in ('blue', 'red', 'green'):
        color(c)
        forward(steps)
        right(30)
```

- which of course, are limited only by the imagination!

Let's draw the star shape at the top of this page. We want red lines, filled in with yellow:

```
color('red')
fillcolor('yellow')
```

Just as `up()` and `down()` determine whether lines will be drawn, filling can be turned on and off:

```
begin_fill()
```

Next we'll create a loop:

```
while True:
    forward(200)
    left(170)
    if abs(pos()) < 1:
        break
```

`abs(pos()) < 1` is a good way to know when the turtle is back at its home position.

Finally, complete the filling:

```
end_fill()
```

(Note that filling only actually takes place when you give the `end_fill()` command.)

25.10.4 How to...

This section covers some typical turtle use-cases and approaches.

Get started as quickly as possible

One of the joys of turtle graphics is the immediate, visual feedback that's available from simple commands - it's an excellent way to introduce children to programming ideas, with a minimum of overhead (not just children, of course).

The turtle module makes this possible by exposing all its basic functionality as functions, available with `from turtle import *`. The *turtle graphics tutorial* covers this approach.

It's worth noting that many of the turtle commands also have even more terse equivalents, such as `fd()` for *`forward()`*. These are especially useful when working with learners for whom typing is not a skill.

> You'll need to have the *`Tk interface package`* installed on your system for turtle graphics to work. Be warned that this is not always straightforward, so check this in advance if you're planning to use turtle graphics with a learner.

Automatically begin and end filling

Starting with Python 3.14, you can use the *`fill()` context manager* instead of *`begin_fill()`* and *`end_fill()`* to automatically begin and end fill. Here is an example:

```
with fill():
    for i in range(4):
        forward(100)
        right(90)

forward(200)
```

The code above is equivalent to:

```
begin_fill()
for i in range(4):
    forward(100)
    right(90)
end_fill()

forward(200)
```

Use the `turtle` module namespace

Using `from turtle import *` is convenient - but be warned that it imports a rather large collection of objects, and if you're doing anything but turtle graphics you run the risk of a name conflict (this becomes even more an issue if you're using turtle graphics in a script where other modules might be imported).

The solution is to use `import turtle` - `fd()` becomes `turtle.fd()`, `width()` becomes `turtle.width()` and so on. (If typing "turtle" over and over again becomes tedious, use for example `import turtle as t` instead.)

Use turtle graphics in a script

It's recommended to use the `turtle` module namespace as described immediately above, for example:

```
import turtle as t
from random import random

```

(繼續下一頁)

(繼續上一頁)

```
for i in range(100):
    steps = int(random() * 100)
    angle = int(random() * 360)
    t.right(angle)
    t.fd(steps)
```

Another step is also required though - as soon as the script ends, Python will also close the turtle's window. Add:

```
t.mainloop()
```

to the end of the script. The script will now wait to be dismissed and will not exit until it is terminated, for example by closing the turtle graphics window.

Use object-oriented turtle graphics

也參考

Explanation of the object-oriented interface

Other than for very basic introductory purposes, or for trying things out as quickly as possible, it's more usual and much more powerful to use the object-oriented approach to turtle graphics. For example, this allows multiple turtles on screen at once.

In this approach, the various turtle commands are methods of objects (mostly of `Turtle` objects). You *can* use the object-oriented approach in the shell, but it would be more typical in a Python script.

The example above then becomes:

```
from turtle import Turtle
from random import random

t = Turtle()
for i in range(100):
    steps = int(random() * 100)
    angle = int(random() * 360)
    t.right(angle)
    t.fd(steps)

t.screen.mainloop()
```

Note the last line. `t.screen` is an instance of the *`Screen`* that a Turtle instance exists on; it's created automatically along with the turtle.

The turtle's screen can be customised, for example:

```
t.screen.title('Object-oriented turtle demo')
t.screen.bgcolor("orange")
```

25.10.5 Turtle graphics reference

備🄵

In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument *self* which is omitted here.

25.10.6 Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called `turtle`.

Turtle motion

`turtle.`**`forward`**`(`*distance*`)`
`turtle.`**`fd`**`(`*distance*`)`

參數
`distance` -- a number (integer or float)

Move the turtle forward by the specified *distance*, in the direction the turtle is headed.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00,0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00,0.00)
```

`turtle.`**`back`**`(`*distance*`)`
`turtle.`**`bk`**`(`*distance*`)`
`turtle.`**`backward`**`(`*distance*`)`

參數
`distance` -- a number

Move the turtle backward by *distance*, opposite to the direction the turtle is headed. Do not change the turtle's heading.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
```

turtle.**right**(*angle*)

turtle.**rt**(*angle*)

參數

angle -- a number (integer or float)

Turn turtle right by *angle* units. (Units are by default degrees, but can be set via the *degrees()* and *radians()* functions.) Angle orientation depends on the turtle mode, see *mode()*.

```
>>> turtle.heading()
22.0
>>> turtle.right(45)
>>> turtle.heading()
337.0
```

turtle.**left**(*angle*)

turtle.**lt**(*angle*)

參數

angle -- a number (integer or float)

Turn turtle left by *angle* units. (Units are by default degrees, but can be set via the *degrees()* and *radians()* functions.) Angle orientation depends on the turtle mode, see *mode()*.

```
>>> turtle.heading()
22.0
>>> turtle.left(45)
>>> turtle.heading()
67.0
```

turtle.**goto**(*x*, *y=None*)

turtle.**setpos**(*x*, *y=None*)

turtle.**setposition**(*x*, *y=None*)

參數

- **x** -- a number or a pair/vector of numbers
- **y** -- a number or `None`

If *y* is `None`, *x* must be a pair of coordinates or a *Vec2D* (e.g. as returned by *pos()*).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```
>>> tp = turtle.pos()
>>> tp
(0.00,0.00)
>>> turtle.setpos(60,30)
>>> turtle.pos()
(60.00,30.00)
>>> turtle.setpos((20,80))
>>> turtle.pos()
(20.00,80.00)
>>> turtle.setpos(tp)
```

(繼續下一頁)

(繼續上一頁)

```
>>> turtle.pos()
(0.00,0.00)
```

turtle.**teleport**(*x*, *y=None*, *, *fill_gap=False*)

參數

- **x** -- a number or None
- **y** -- a number or None
- **fill_gap** -- a boolean

Move turtle to an absolute position. Unlike goto(x, y), a line will not be drawn. The turtle's orientation does not change. If currently filling, the polygon(s) teleported from will be filled after leaving, and filling will begin again after teleporting. This can be disabled with fill_gap=True, which makes the imaginary line traveled during teleporting act as a fill barrier like in goto(x, y).

```
>>> tp = turtle.pos()
>>> tp
(0.00,0.00)
>>> turtle.teleport(60)
>>> turtle.pos()
(60.00,0.00)
>>> turtle.teleport(y=10)
>>> turtle.pos()
(60.00,10.00)
>>> turtle.teleport(20, 30)
>>> turtle.pos()
(20.00,30.00)
```

在 3.12 版被加入.

turtle.**setx**(*x*)

參數

x -- a number (integer or float)

Set the turtle's first coordinate to *x*, leave second coordinate unchanged.

```
>>> turtle.position()
(0.00,240.00)
>>> turtle.setx(10)
>>> turtle.position()
(10.00,240.00)
```

turtle.**sety**(*y*)

參數

y -- a number (integer or float)

Set the turtle's second coordinate to *y*, leave first coordinate unchanged.

```
>>> turtle.position()
(0.00,40.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00,-10.00)
```

turtle.**setheading**(*to_angle*)

turtle.**seth**(*to_angle*)

參數

to_angle -- a number (integer or float)

Set the orientation of the turtle to *to_angle*. Here are some common directions in degrees:

standard mode	logo mode
0 - east	0 - north
90 - north	90 - east
180 - west	180 - south
270 - south	270 - west

```
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```

turtle.**home**()

Move turtle to the origin -- coordinates (0,0) -- and set its heading to its start-orientation (which depends on the mode, see *mode()*).

```
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00,-10.00)
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.**circle**(*radius*, *extent=None*, *steps=None*)

參數

- **radius** -- a number
- **extent** -- a number (or None)
- **steps** -- an integer (or None)

Draw a circle with given *radius*. The center is *radius* units left of the turtle; *extent* -- an angle -- determines which part of the circle is drawn. If *extent* is not given, draw the entire circle. If *extent* is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if *radius* is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of *extent*.

As the circle is approximated by an inscribed regular polygon, *steps* determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(50)
>>> turtle.position()
(-0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(120, 180)  # draw a semicircle
>>> turtle.position()
(0.00,240.00)
>>> turtle.heading()
180.0
```

turtle.**dot**(*size=None*, **color*)

參數

- **size** -- an integer >= 1 (if given)
- **color** -- a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize+4 and 2*pensize is used.

```
>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle.fd(50)
>>> turtle.position()
(100.00,-0.00)
>>> turtle.heading()
0.0
```

turtle.**stamp**()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling `clearstamp(stamp_id)`.

```
>>> turtle.color("blue")
>>> stamp_id = turtle.stamp()
>>> turtle.fd(50)
```

turtle.**clearstamp**(*stampid*)

參數

stampid -- an integer, must be return value of previous *stamp()* call

Delete stamp with given *stampid*.

```
>>> turtle.position()
(150.00,-0.00)
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.position()
(200.00,-0.00)
>>> turtle.clearstamp(astamp)
>>> turtle.position()
(200.00,-0.00)
```

turtle.**clearstamps**(*n=None*)

參數

n -- an integer (or `None`)

Delete all or first/last *n* of turtle's stamps. If *n* is `None`, delete all stamps, if $n > 0$ delete first *n* stamps, else if $n < 0$ delete last *n* stamps.

```
>>> for i in range(8):
...     unused_stamp_id = turtle.stamp()
...     turtle.fd(30)
>>> turtle.clearstamps(2)
>>> turtle.clearstamps(-2)
>>> turtle.clearstamps()
```

turtle.**undo**()

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```
>>> for i in range(4):
...     turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...     turtle.undo()
```

turtle.**speed**(*speed=None*)

參數

speed -- an integer in the range 0..10 or a speedstring (see below)

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- "fastest": 0
- "fast": 10
- "normal": 6
- "slow": 3
- "slowest": 1

Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention: *speed* = 0 means that *no* animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

Tell Turtle's state

turtle.**position**()

turtle.**pos**()

Return the turtle's current location (x,y) (as a *Vec2D* vector).

```
>>> turtle.pos()
(440.00,-0.00)
```

turtle.**towards**(*x*, *y=None*)

參數

- **x** -- a number or a pair/vector of numbers or a turtle instance
- **y** -- a number if *x* is a number, else None

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - "standard"/"world" or "logo".

```
>>> turtle.goto(10, 10)
>>> turtle.towards(0,0)
225.0
```

turtle.**xcor**()

Return the turtle's x coordinate.

```
>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28,76.60)
>>> print(round(turtle.xcor(), 5))
64.27876
```

turtle.**ycor**()

Return the turtle's y coordinate.

```
>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.pos())
(50.00,86.60)
>>> print(round(turtle.ycor(), 5))
86.60254
```

turtle.**heading**()

Return the turtle's current heading (value depends on the turtle mode, see *mode()*).

```
>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
67.0
```

turtle.**distance**(*x*, *y=None*)

參數

- **x** -- a number or a pair/vector of numbers or a turtle instance
- **y** -- a number if *x* is a number, else None

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```
>>> turtle.home()
>>> turtle.distance(30,40)
50.0
>>> turtle.distance((30,40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

Settings for measurement

turtle.**degrees**(*fullcircle=360.0*)

參數

fullcircle -- a number

Set angle measurement units, i.e. set number of "degrees" for a full circle. Default value is 360 degrees.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
```

(繼續下一頁)

(繼續上一頁)

```
90.0

>>> # Change angle measurement unit to grad (also known as gon,
>>> # grade, or gradian and equals 1/100-th of the right angle.)
>>> turtle.degrees(400.0)
>>> turtle.heading()
100.0
>>> turtle.degrees(360)
>>> turtle.heading()
90.0
```

turtle.**radians**()

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
>>> turtle.radians()
>>> turtle.heading()
1.5707963267948966
```

Pen control

Drawing state

turtle.**pendown**()

turtle.**pd**()

turtle.**down**()

Pull the pen down -- drawing when moving.

turtle.**penup**()

turtle.**pu**()

turtle.**up**()

Pull the pen up -- no drawing when moving.

turtle.**pensize**(*width=None*)

turtle.**width**(*width=None*)

參數

width -- a positive number

Set the line thickness to *width* or return it. If resizemode is set to ”auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```
>>> turtle.pensize()
1
>>> turtle.pensize(10)   # from here on lines of width 10 are drawn
```

turtle.**pen**(*pen=None*, ***pendict*)

參數

- **pen** -- a dictionary with some or all of the below listed keys
- **pendict** -- one or more keyword-arguments with the below listed keys as keywords

Return or set the pen’s attributes in a ”pen-dictionary” with the following key/value pairs:

- ”shown”: True/False
- ”pendown”: True/False

- ”pencolor”: color-string or color-tuple
- ”fillcolor”: color-string or color-tuple
- ”pensize”: positive number
- ”speed”: number in range 0..10
- ”resizemode”: ”auto” or ”user” or ”noresize”
- ”stretchfactor”: (positive number, positive number)
- ”outline”: positive number
- ”tilt”: number

This dictionary can be used as argument for a subsequent call to *pen()* to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```
>>> turtle.pen(fillcolor="black", pencolor="red", pensize=10)
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencolor', 'red'),
 ('pendown', True), ('pensize', 10), ('resizemode', 'noresize'),
 ('shearfactor', 0.0), ('shown', True), ('speed', 9),
 ('stretchfactor', (1.0, 1.0)), ('tilt', 0.0)]
>>> penstate=turtle.pen()
>>> turtle.color("yellow", "")
>>> turtle.penup()
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', ''), ('outline', 1), ('pencolor', 'yellow')]
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', 'green'), ('outline', 1), ('pencolor', 'red')]
```

turtle.**isdown**()

Return `True` if pen is down, `False` if it’s up.

```
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```

Color control

turtle.**pencolor**(**args*)

Return or set the pencolor.

Four input formats are allowed:

pencolor()
Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

pencolor(colorstring)
Set pencolor to *colorstring*, which is a Tk color specification string, such as `"red"`, `"yellow"`, or `"#33cc8c"`.

pencolor((r, g, b))
Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see *colormode()*).

pencolor(r, g, b)
Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
>>> turtle.pencolor('#32c18f')
>>> turtle.pencolor()
(50.0, 193.0, 143.0)
```

turtle.**fillcolor**(**args*)
Return or set the fillcolor.

Four input formats are allowed:

fillcolor()
Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

fillcolor(colorstring)
Set fillcolor to *colorstring*, which is a Tk color specification string, such as `"red"`, `"yellow"`, or `"#33cc8c"`.

fillcolor((r, g, b))
Set fillcolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see *colormode()*).

fillcolor(r, g, b)
Set fillcolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

```
>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> turtle.pencolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor((50, 193, 143))  # 🄵整數而非浮點數
>>> turtle.fillcolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor('#ffffff')
>>> turtle.fillcolor()
(255.0, 255.0, 255.0)
```

turtle.**color**(**args*)
Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()
Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by *pencolor()* and *fillcolor()*.

color(colorstring), color((r,g,b)), color(r,g,b)
Inputs as in *pencolor()*, set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))
Equivalent to `pencolor(colorstring1)` and `fillcolor(colorstring2)` and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

```
>>> turtle.color("red", "green")
>>> turtle.color()
('red', 'green')
>>> color("#285078", "#a0c8f0")
>>> color()
((40.0, 80.0, 120.0), (160.0, 200.0, 240.0))
```

See also: Screen method *colormode()*.

Filling

`turtle.`**filling**`()`
Return fillstate (`True` if filling, `False` else).

```
>>> turtle.begin_fill()
>>> if turtle.filling():
...     turtle.pensize(5)
... else:
...     turtle.pensize(3)
```

`turtle.`**fill**`()`
Fill the shape drawn in the `with turtle.fill():` block.

```
>>> turtle.color("black", "red")
>>> with turtle.fill():
...     turtle.circle(80)
```

Using `fill()` is equivalent to adding the *begin_fill()* before the fill-block and *end_fill()* after the fill-block:

```
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

在 3.14 版被加入.

`turtle.`**begin_fill**`()`
To be called just before drawing a shape to be filled.

`turtle.`**end_fill**`()`
Fill the shape drawn after the last call to *begin_fill()*.

Whether or not overlap regions for self-intersecting polygons or multiple shapes are filled depends on the operating system graphics, type of overlap, and number of overlaps. For example, the Turtle star above may be either all yellow or have some white regions.

```
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

More drawing control

turtle.**reset**()

Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.

```
>>> turtle.goto(0,-22)
>>> turtle.left(100)
>>> turtle.position()
(0.00,-22.00)
>>> turtle.heading()
100.0
>>> turtle.reset()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.**clear**()

Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.**write**(*arg*, *move=False*, *align='left'*, *font=('Arial', 8, 'normal')*)

參數

- **arg** -- object to be written to the TurtleScreen
- **move** -- True/False
- **align** -- one of the strings "left", "center" or right"
- **font** -- a triple (fontname, fontsize, fonttype)

Write text - the string representation of *arg* - at the current turtle position according to *align* ("left", "center" or "right") and with the given font. If *move* is true, the pen is moved to the bottom-right corner of the text. By default, *move* is `False`.

```
>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
```

Turtle state

Visibility

turtle.**hideturtle**()

turtle.**ht**()

Make the turtle invisible. It's a good idea to do this while you're in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```
>>> turtle.hideturtle()
```

turtle.**showturtle**()

turtle.**st**()

Make the turtle visible.

```
>>> turtle.showturtle()
```

turtle.**isvisible**()

Return `True` if the Turtle is shown, `False` if it's hidden.

```
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

Appearance

turtle.**shape**(*name=None*)

參數

name -- a string which is a valid shapename

Set turtle shape to shape with given *name* or, if name is not given, return name of current shape. Shape with *name* must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: "arrow", "turtle", "circle", "square", "triangle", "classic". To learn about how to deal with shapes see Screen method *register_shape()*.

```
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.**resizemode**(*rmode=None*)

參數

rmode -- one of the strings "auto", "user", "noresize"

Set resizemode to one of the values: "auto", "user", "noresize". If *rmode* is not given, return current resizemode. Different resizemodes have the following effects:

- "auto": adapts the appearance of the turtle corresponding to the value of pensize.
- "user": adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by *shapesize()*.
- "noresize": no adaption of the turtle's appearance takes place.

`resizemode("user")` is called by *shapesize()* when used with arguments.

```
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
>>> turtle.resizemode()
'auto'
```

turtle.**shapesize**(*stretch_wid=None*, *stretch_len=None*, *outline=None*)

turtle.**turtlesize**(*stretch_wid=None*, *stretch_len=None*, *outline=None*)

參數

- **stretch_wid** -- positive number
- **stretch_len** -- positive number
- **outline** -- positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set resizemode to "user". If and only if resizemode is set to "user", the turtle will be displayed stretched according to its stretchfactors: *stretch_wid* is stretchfactor perpendicular to its orientation, *stretch_len* is stretchfactor in direction of its orientation, *outline* determines the width of the shape's outline.

```
>>> turtle.shapesize()
(1.0, 1.0, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

turtle.**shearfactor**(*shear=None*)

參數

shear -- number (optional)

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of the shear angle. Do *not* change the turtle's heading (direction of movement). If shear is not given: return the current shearfactor, i. e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()
0.5
```

turtle.**tilt**(*angle*)

參數

angle -- a number

Rotate the turtleshape by *angle* from its current tilt-angle, but do *not* change the turtle's heading (direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.**tiltangle**(*angle=None*)

參數

angle -- a number (optional)

Set or return the current tilt-angle. If angle is given, rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do *not* change the turtle's heading (direction of movement). If angle is not given: return the current tilt-angle, i. e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0
```

turtle.**shapetransform**(*t11=None*, *t12=None*, *t21=None*, *t22=None*)

參數

- **t11** -- a number (optional)
- **t12** -- a number (optional)
- **t21** -- a number (optional)
- **t12** -- a number (optional)

Set or return the current transformation matrix of the turtle shape.

If none of the matrix elements are given, return the transformation matrix as a tuple of 4 elements. Otherwise set the given elements and transform the turtleshape according to the matrix consisting of first row t11, t12 and second row t21, t22. The determinant t11 * t22 - t12 * t21 must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4,2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform()
(4.0, -1.0, -0.0, 2.0)
```

turtle.**get_shapepoly**()

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

Using events

turtle.**onclick**(*fun*, *btn=1*, *add=None*)

參數

- **fun** -- a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** -- number of the mouse-button, defaults to 1 (left mouse button)
- **add** -- `True` or `False` -- if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is `None`, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```
>>> def turn(x, y):
...     left(180)
...
>>> onclick(turn)  # Now clicking into the turtle will turn it.
>>> onclick(None)  # event-binding will be removed
```

turtle.**onrelease**(*fun*, *btn=1*, *add=None*)

參數

- **fun** -- a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** -- number of the mouse-button, defaults to 1 (left mouse button)

- **add** -- `True` or `False` -- if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is `None`, existing bindings are removed.

```
>>> class MyTurtle(Turtle):
...     def glow(self,x,y):
...         self.fillcolor("red")
...     def unglow(self,x,y):
...         self.fillcolor("")
...
>>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)      # clicking on turtle turns fillcolor red,
>>> turtle.onrelease(turtle.unglow) # releasing turns it to transparent.
```

`turtle.`**`ondrag`**(*fun*, *btn=1*, *add=None*)

參數

- **fun** -- a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** -- number of the mouse-button, defaults to 1 (left mouse button)
- **add** -- `True` or `False` -- if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is `None`, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

Special Turtle methods

`turtle.`**`poly`**()

Record the vertices of a polygon drawn in the `with turtle.poly():` block. The first and last vertices will be connected.

```
>>> with turtle.poly():
...     turtle.forward(100)
...     turtle.right(60)
...     turtle.forward(100)
```

在 3.14 版被加入.

`turtle.`**`begin_poly`**()

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

`turtle.`**`end_poly`**()

Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

`turtle.`**`get_poly`**()

Return the last recorded polygon.

```
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
```

(繼續下一頁)

(繼續上一頁)

```
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

turtle.**clone**()

Create and return a clone of the turtle with same position, heading and turtle properties.

```
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle.**getturtle**()

turtle.**getpen**()

Return the Turtle object itself. Only reasonable use: as a function to return the ”anonymous turtle”:

```
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```

turtle.**getscreen**()

Return the *TurtleScreen* object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

turtle.**setundobuffer**(*size*)

參數

size -- 一個整數或 None

Set or disable undobuffer. If *size* is an integer, an empty undobuffer of given size is installed. *size* gives the maximum number of turtle actions that can be undone by the *undo()* method/function. If *size* is None, the undobuffer is disabled.

```
>>> turtle.setundobuffer(42)
```

turtle.**undobufferentries**()

Return number of entries in the undobuffer.

```
>>> while undobufferentries():
...     undo()
```

Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class *Shape* explicitly as described below:

1. Create an empty Shape object of type ”compound”.
2. Add as many components to this object as desired, using the *addcomponent()* method.

   舉例來🄵:

```
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
```

3. Now add the Shape to the Screen's shapelist and use it:

```
>>> register_shape("myshape", s)
>>> shape("myshape")
```

備🄵

The *Shape* class is used internally by the *register_shape()* method in different ways. The application programmer has to deal with the Shape class *only* when using compound shapes like shown above!

25.10.7 Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

Window control

`turtle.`**`bgcolor`**(**args*)

參數

`args` -- a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```
>>> screen.bgcolor("orange")
>>> screen.bgcolor()
'orange'
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()
(128.0, 0.0, 128.0)
```

`turtle.`**`bgpic`**(*picname=None*)

參數

`picname` -- a string, name of an image file (PNG, GIF, PGM, and PPM) or `"nopic"`, or `None`

Set background image or return name of current backgroundimage. If *picname* is a filename, set the corresponding image as background. If *picname* is `"nopic"`, delete background image, if present. If *picname* is `None`, return the filename of the current backgroundimage.

```
>>> screen.bgpic()
'nopic'
>>> screen.bgpic("landscape.gif")
>>> screen.bgpic()
"landscape.gif"
```

`turtle.`**`clear`**()

備🄵

This TurtleScreen method is available as a global function only under the name `clearscreen`. The global function `clear` is a different one derived from the Turtle method `clear`.

turtle.**clearscreen**()

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

turtle.**reset**()

> **備🄵**
>
> This TurtleScreen method is available as a global function only under the name `resetscreen`. The global function `reset` is another one derived from the Turtle method `reset`.

turtle.**resetscreen**()

Reset all Turtles on the Screen to their initial state.

turtle.**screensize**(*canvwidth=None*, *canvheight=None*, *bg=None*)

參數

- **canvwidth** -- positive integer, new width of canvas in pixels
- **canvheight** -- positive integer, new height of canvas in pixels
- **bg** -- colorstring or color-tuple, new background color

If no arguments are given, return current (canvaswidth, canvasheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000,1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle ;-)

turtle.**setworldcoordinates**(*llx*, *lly*, *urx*, *ury*)

參數

- **llx** -- a number, x-coordinate of lower left corner of canvas
- **lly** -- a number, y-coordinate of lower left corner of canvas
- **urx** -- a number, x-coordinate of upper right corner of canvas
- **ury** -- a number, y-coordinate of upper right corner of canvas

Set up user-defined coordinate system and switch to mode ”world” if necessary. This performs a `screen.reset()`. If mode ”world” is already active, all drawings are redrawn according to the new coordinates.

ATTENTION: in user-defined coordinate systems angles may appear distorted.

```
>>> screen.reset()
>>> screen.setworldcoordinates(-50,-7.5,50,7.5)
>>> for _ in range(72):
...     left(10)
...
>>> for _ in range(8):
...     left(45); fd(2)   # a regular octagon
```

Animation control

turtle.**no_animation**()

Temporarily disable turtle animation. The code written inside the `no_animation` block will not be animated; once the code block is exited, the drawing will appear.

```
>>> with screen.no_animation():
...     for dist in range(2, 400, 2):
...         fd(dist)
...         rt(90)
```

在 3.14 版被加入.

turtle.**delay**(*delay=None*)

參數

delay -- positive integer

Set or return the drawing *delay* in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

turtle.**tracer**(*n=None*, *delay=None*)

參數

- **n** -- nonnegative integer
- **delay** -- nonnegative integer

Turn turtle animation on/off and set delay for update drawings. If *n* is given, only each n-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value of n. Second argument sets delay value (see *delay()*).

```
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...     fd(dist)
...     rt(90)
...     dist += 2
```

turtle.**update**()

Perform a TurtleScreen update. To be used when tracer is turned off.

另請參🄵 RawTurtle/Turtle 的*speed()* 方法。

Using screen events

turtle.**listen**(*xdummy=None*, *ydummy=None*)

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass *listen()* to the onclick method.

turtle.**onkey**(*fun*, *key*)

turtle.**onkeyrelease**(*fun*, *key*)

參數

- **fun** -- a function with no arguments or `None`

- **key** -- a string: key (e.g. ”a”) or key-symbol (e.g. ”space”)

Bind *fun* to key-release event of key. If *fun* is `None`, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method *listen()*.)

```
>>> def f():
...     fd(50)
...     lt(60)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

`turtle.`**onkeypress**(*fun*, *key=None*)

參數

- **fun** -- a function with no arguments or `None`
- **key** -- a string: key (e.g. ”a”) or key-symbol (e.g. ”space”)

Bind *fun* to key-press event of key if key is given, or to any key-press-event if no key is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method *listen()*.)

```
>>> def f():
...     fd(50)
...
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

`turtle.`**onclick**(*fun*, *btn=1*, *add=None*)

`turtle.`**onscreenclick**(*fun*, *btn=1*, *add=None*)

參數

- **fun** -- a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **btn** -- number of the mouse-button, defaults to 1 (left mouse button)
- **add** -- `True` or `False` -- if `True`, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this screen. If *fun* is `None`, existing bindings are removed.

Example for a TurtleScreen instance named `screen` and a Turtle instance named `turtle`:

```
>>> screen.onclick(turtle.goto) # Subsequently clicking into the TurtleScreen will
>>>                             # make the turtle move to the clicked point.
>>> screen.onclick(None)        # remove event binding again
```

備🄵

This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

`turtle.`**ontimer**(*fun*, *t=0*)

參數

- **fun** -- a function with no arguments
- **t** -- a number >= 0

Install a timer that calls *fun* after *t* milliseconds.

```
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...         screen.ontimer(f, 250)
>>> f()   ### makes the turtle march around
>>> running = False
```

turtle.**mainloop**()

turtle.**done**()

Starts event loop - calling Tkinter's mainloop function. Must be the last statement in a turtle graphics program. Must *not* be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```
>>> screen.mainloop()
```

Input methods

turtle.**textinput**(*title*, *prompt*)

參數

- **title** -- string（字串）
- **prompt** -- string（字串）

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, prompt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return `None`.

```
>>> screen.textinput("NIM", "Name of first player:")
```

turtle.**numinput**(*title*, *prompt*, *default=None*, *minval=None*, *maxval=None*)

參數

- **title** -- string（字串）
- **prompt** -- string（字串）
- **default** -- number (optional)
- **minval** -- number (optional)
- **maxval** -- number (optional)

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value for input, maxval: maximum value for input. The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return `None`.

```
>>> screen.numinput("Poker", "Your stakes:", 1000, minval=10, maxval=10000)
```

Settings and special methods

turtle.**mode**(*mode=None*)

參數

mode -- one of the strings "standard", "logo" or "world"

Set turtle mode ("standard", "logo" or "world") and perform reset. If mode is not given, current mode is returned.

Mode ”standard” is compatible with old *turtle*. Mode ”logo” is compatible with most Logo turtle graphics. Mode ”world” uses user-defined ”world coordinates”. **Attention**: in this mode angles appear distorted if `x/y` unit-ratio doesn't equal 1.

Mode	Initial turtle heading	positive angles
”standard”	to the right (east)	counterclockwise
”logo”	upward (north)	clockwise

```
>>> mode("logo")   # resets turtle heading to north
>>> mode()
'logo'
```

`turtle.`**`colormode`**(*cmode=None*)

參數

`cmode` -- one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently *r*, *g*, *b* values of color triples have to be in the range 0..*cmode*.

```
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
     ...
TurtleGraphicsError: bad color sequence: (240, 160, 80)
>>> screen.colormode()
1.0
>>> screen.colormode(255)
>>> screen.colormode()
255
>>> turtle.pencolor(240,160,80)
```

`turtle.`**`getcanvas`**()

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas object ...>
```

`turtle.`**`getshapes`**()

Return a list of names of all currently available turtle shapes.

```
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

`turtle.`**`register_shape`**(*name*, *shape=None*)

`turtle.`**`addshape`**(*name*, *shape=None*)

There are four different ways to call this function:

(1) *name* is the name of an image file (PNG, GIF, PGM, and PPM) and *shape* is `None`: Install the corresponding image shape.

```
>>> screen.register_shape("turtle.gif")
```

> **備🄵**
>
> Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

(2) *name* is an arbitrary string and *shape* is the name of an image file (PNG, GIF, PGM, and PPM): Install the corresponding image shape.

```
>>> screen.register_shape("turtle", "turtle.gif")
```

> **備🄵**
>
> Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

(3) *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```
>>> screen.register_shape("triangle", ((5,-3), (0,5), (-5,-3)))
```

(4) *name* is an arbitrary string and *shape* is a (compound) `Shape` object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen's shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

在 3.14 版的變更: Added support for PNG, PGM, and PPM image formats. Both a shape name and an image file name can be specified.

`turtle.`**`turtles`**`()`

Return the list of turtles on the screen.

```
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

`turtle.`**`window_height`**`()`

Return the height of the turtle window.

```
>>> screen.window_height()
480
```

`turtle.`**`window_width`**`()`

Return the width of the turtle window.

```
>>> screen.window_width()
640
```

Methods specific to Screen, not inherited from TurtleScreen

`turtle.`**`bye`**`()`

Shut the turtlegraphics window.

`turtle.`**`exitonclick`**`()`

Bind `bye()` method to mouse clicks on the Screen.

If the value "using_IDLE" in the configuration dictionary is `False` (default value), also enter mainloop. Remark: If IDLE with the `-n` switch (no subprocess) is used, this value should be set to `True` in `turtle.cfg`. In this case IDLE's own mainloop is active also for the client script.

`turtle.`**`save`**`(`*filename*, *overwrite=False*`)`

Save the current turtle drawing (and turtles) as a PostScript file.

參數

- **`filename`** -- the path of the saved PostScript file

- **overwrite** -- if `False` and there already exists a file with the given filename, then the function will raise a `FileExistsError`. If it is `True`, the file will be overwritten.

```
>>> screen.save("my_drawing.ps")
>>> screen.save("my_drawing.ps", overwrite=True)
```

在 3.14 版被加入.

`turtle.`**`setup`**(*width=_CFG['width']*, *height=_CFG['height']*, *startx=_CFG['leftright']*, *starty=_CFG['topbottom']*)

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

參數

- **width** -- if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- **height** -- if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
- **startx** -- if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if `None`, center window horizontally
- **starty** -- if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if `None`, center window vertically

```
>>> screen.setup (width=200, height=200, startx=0, starty=0)
>>>              # sets window to 200x200 pixels, in upper left of screen
>>> screen.setup(width=.75, height=0.5, startx=None, starty=None)
>>>              # sets window to 75% of screen by 50% of screen and centers
```

`turtle.`**`title`**(*titlestring*)

參數

titlestring -- a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```
>>> screen.title("Welcome to the turtle zoo!")
```

25.10.8 Public classes

class `turtle.`**`RawTurtle`**(*canvas*)

class `turtle.`**`RawPen`**(*canvas*)

參數

canvas -- a `tkinter.Canvas`, a *ScrolledCanvas* or a *TurtleScreen*

Create a turtle. The turtle has all methods described above as "methods of Turtle/RawTurtle".

class `turtle.`**`Turtle`**

Subclass of RawTurtle, has the same interface but draws on a default *Screen* object created automatically when needed for the first time.

class `turtle.`**`TurtleScreen`**(*cv*)

參數

cv -- 一個 `tkinter.Canvas`

Provides screen oriented methods like *bgcolor()* etc. that are described above.

class `turtle.`**`Screen`**

Subclass of TurtleScreen, with *four methods added*.

class turtle.**ScrolledCanvas**(*master*)

參數

master -- some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.

class turtle.**Shape**(*type_*, *data*)

參數

type_ -- one of the strings ”polygon”, ”image”, ”compound”

Data structure modeling shapes. The pair `(type_, data)` must follow this specification:

*type_*	*data*
”polygon”	a polygon-tuple, i.e. a tuple of pairs of coordinates
”image”	an image (in this form only used internally!)
”compound”	`None` (a compound shape has to be constructed using the *`addcomponent()`* method)

addcomponent(*poly*, *fill*, *outline=None*)

參數

- **poly** -- a polygon, i.e. a tuple of pairs of numbers
- **fill** -- a color the *poly* will be filled with
- **outline** -- a color for the poly's outline (if given)

例如：

```
>>> poly = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

請見*Compound shapes*。

class turtle.**Vec2D**(*x*, *y*)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics programs too. Derived from tuple, so a vector is a tuple!

Provides (for *a*, *b* vectors, *k* number):

- `a + b` 向量加法
- `a - b` 向量🄵法
- `a * b` 🄵積
- `k * a` and `a * k` multiplication with scalar
- `abs(a)` a 的🄵對值
- `a.rotate(angle)` 旋轉

25.10.9 解釋

A turtle object draws on a screen object, and there a number of key classes in the turtle object-oriented interface that can be used to create them and relate them to each other.

A *`Turtle`* instance will automatically create a *`Screen`* instance if one is not already present.

`Turtle` is a subclass of *`RawTurtle`*, which *doesn't* automatically create a drawing surface - a *canvas* will need to be provided or created for it. The *canvas* can be a `tkinter.Canvas`, *`ScrolledCanvas`* or *`TurtleScreen`*.

TurtleScreen is the basic drawing surface for a turtle. *Screen* is a subclass of TurtleScreen, and includes *some additional methods* for managing its appearance (including size and title) and behaviour. TurtleScreen's constructor needs a tkinter.Canvas or a *ScrolledCanvas* as an argument.

The functional interface for turtle graphics uses the various methods of Turtle and TurtleScreen/Screen. Behind the scenes, a screen object is automatically created whenever a function derived from a Screen method is called. Similarly, a turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen, the object-oriented interface must be used.

25.10.10 Help and configuration

How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.
- Calling *help()* on methods or functions displays the docstrings:

```
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers
    in the range 0..colormode or a 3-tuple of such numbers.

    >>> screen.bgcolor("orange")
    >>> screen.bgcolor()
    "orange"
    >>> screen.bgcolor(0.5,0,0.5)
    >>> screen.bgcolor()
    "#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up

    No argument

    >>> turtle.penup()
```

- The docstrings of the functions which are derived from methods have a modified form:

```
>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers
    in the range 0..colormode or a 3-tuple of such numbers.
```

(繼續下一頁)

(繼續上一頁)

```
    Example::

      >>> bgcolor("orange")
      >>> bgcolor()
      "orange"
      >>> bgcolor(0.5,0,0.5)
      >>> bgcolor()
      "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up

    No argument

    Example:
    >>> penup()
```

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

`turtle.`**`write_docstringdict`**(*filename='turtle_docstringdict'*)

參數
`filename` -- a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script *`filename`*`.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use *`turtle`* with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.

At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following `turtle.cfg`:

```
width = 0.5
height = 0.75
```

(繼續下一頁)

(繼續上一頁)

```
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
title = Python Turtle Graphics
using_IDLE = False
```

Short explanation of selected entries:

- The first four lines correspond to the arguments of the *Screen.setup* method.
- Line 5 and 6 correspond to the arguments of the method *Screen.screensize*.
- *shape* can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fill color (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as *turtle*).
- The entries *exampleturtle* and *examplescreen* define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- *using_IDLE*: Set this to `True` if you regularly work with IDLE and its `-n` switch (”no subprocess”). This will prevent *exitonclick()* to enter the mainloop.

There can be a `turtle.cfg` file in the directory where *turtle* is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `Lib/turtledemo` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos (preferably not from within the demo-viewer).

25.10.11 `turtledemo` --- Demo scripts

The *turtledemo* package includes a set of demo scripts. These scripts can be run and viewed using the supplied demo viewer as follows:

```
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```
python -m turtledemo.bytedesign
```

The *turtledemo* package directory contains:

- A demo viewer `__main__.py` which can be used to view the sourcecode of the scripts and run them at the same time.
- Multiple scripts demonstrating different features of the *turtle* module. Examples can be accessed via the Examples menu. They can also be run standalone.

- A `turtle.cfg` file which serves as an example of how to write and use such files.

The demo scripts are:

Name	描述	Features
bytedesign	complex classical turtle graphics pattern	*`tracer()`*, delay, *`update()`*
chaos	graphs Verhulst dynamics, shows that computer's computations can generate results sometimes against the common sense expectations	world coordinates
clock	analog clock showing time of your computer	turtles as clock's hands, ontimer
colormixer	experiment with r, g, b	*`ondrag()`*
forest	3 breadth-first trees	randomization
fractalcurves	Hilbert & Koch curves	recursion
lindenmayer	ethnomathematics (indian kolams)	L-System
minimal_hanoi	Towers of Hanoi	Rectangular Turtles as Hanoi discs (shape, shapesize)
nim	play the classical nim game with three heaps of sticks against the computer.	turtles as nimsticks, event driven (mouse, keyboard)
paint	super minimalistic drawing program	*`onclick()`*
peace	elementary	turtle: appearance and animation
penrose	aperiodic tiling with kites and darts	*`stamp()`*
planet_and_moon	simulation of gravitational system	compound shapes, *`Vec2D`*
rosette	a pattern from the wikipedia article on turtle graphics	*`clone()`*, *`undo()`*
round_dance	dancing turtles rotating pairwise in opposite direction	compound shapes, clone shapesize, tilt, get_shapepoly, update
sorting_animate	visual demonstration of different sorting methods	simple alignment, randomization
tree	a (graphical) breadth first tree (using generators)	*`clone()`*
two_canvases	simple design	turtles on two canvases
yinyang	another elementary example	*`circle()`*

Have fun!

25.10.12 Changes since Python 2.6

- The methods *`Turtle.tracer`*, *`Turtle.window_width`* and *`Turtle.window_height`* have been eliminated. Methods with these names and functionality are now available only as methods of *`Screen`*. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding *`TurtleScreen`*/*`Screen`* methods.)
- The method `Turtle.fill()` has been eliminated. The behaviour of *`begin_fill()`* and *`end_fill()`* have changed slightly: now every filling process must be completed with an `end_fill()` call.
- A method *`Turtle.filling`* has been added. It returns a boolean value: `True` if a filling process is under way, `False` otherwise. This behaviour corresponds to a `fill()` call without arguments in Python 2.6.

25.10.13 Changes since Python 3.0

- The *`Turtle`* methods *`shearfactor()`*, *`shapetransform()`* and *`get_shapepoly()`* have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes. *`tiltangle()`* has been enhanced in functionality: it now can be used to get or set the tilt angle.
- The *`Screen`* method *`onkeypress()`* has been added as a complement to *`onkey()`*. As the latter binds actions to the key release event, an alias: *`onkeyrelease()`* was also added for it.

- The method *Screen.mainloop* has been added, so there is no longer a need to use the standalone *mainloop()* function when working with *Screen* and *Turtle* objects.
- Two input methods have been added: *Screen.textinput* and *Screen.numinput*. These pop up input dialogs and return strings and numbers respectively.

CHAPTER 26

開發工具

本章所描述的模組可以幫助你編寫軟體。例如*pydoc* 模組可以根據模組的🄵容生成文件；*doctest* 和*unittest* 模組則包含編寫單元測試的框架，這些測試程式碼會自動執行🄵驗證輸出結果是否正確。

本章節所描述的模組列表🄵：

26.1 `typing` --- 支援型🄵提示

在 3.5 版被加入.

原始碼： Lib/typing.py

備🄵

Python runtime 不🄵制要求函式與變數的型🄵🄵釋。他們可以被第三方工具使用，如：型🄵檢查器、IDE、linter 等。

此模組提供 runtime 型🄵提示支援。

動腦筋思考下面的函式：

```
def surface_area_of_cube(edge_length: float) -> str:
    return f"The surface area of the cube is {6 * edge_length ** 2}."
```

函式 `surface_area_of_cube` 需要一個引數且預期是一個*float* 的實例，如 `edge_length: float` 所指出的型🄵提示。這個函式預期會回傳一個*str* 的實例，如 `-> str` 所指出的提示。

🄵管型🄵提示可以是簡單類🄵，像是*float* 或*str*，他們也可以變得更🄵🄵雜。模組*typing* 提供一組更高階的型🄵提示詞🄵。

新功能會頻繁的新增至 `typing` 模組中。typing_extensions 套件🄵這些新功能提供了 backport（向後移植的）版本，提供給舊版本的 Python 使用。

也參考

型🄵小抄 (Typing cheat sheet)
型🄴提示的快速預覽（發布於 mypy 的文件中）

mypy 文件的型🄵系統參考資料 (Type System Reference) 章節
Python 的加🄴型🄵系統是基於 PEPs 進行標准化，所以這個參照 (reference) 應該在多數 Python 型🄴檢查器中廣🄵使用。（某些部分依然是特定給 mypy 使用。）

Python 的🄵態型🄵 (Static Typing)
由社群編寫的跨平台型🄵檢查器文件 (type-checker-agnostic) 詳細描述加🄵型🄵系統的功能、實用的加🄵型🄵衍伸工具、以及加🄵型🄵的最佳實踐 (best practice)。

26.1.1 Python 型🄵系統的技術規范

關於 Python 型🄴系統標准的 (canonical)、最新的技術規範可以在Python 型🄴系統的技術規範找到。

26.1.2 型🄵🄵名

一個型🄵🄵名被定義來使用 `type` 陳述式，其建立了*TypeAliasType* 的實例。在這個範例中，`Vector` 及 `list[float]` 會被當作和🄵態型🄵檢查器一樣同等對待：

```
type Vector = list[float]

def scale(scalar: float, vector: Vector) -> Vector:
    return [scalar * num for num in vector]

# passes type checking; a list of floats qualifies as a Vector.
new_vector = scale(2.0, [1.0, -4.2, 5.4])
```

型🄵🄵名對於簡化🄵雜的型🄵簽名 (complex type signature) 非常好用。舉例來🄴：

```
from collections.abc import Sequence

type ConnectionOptions = dict[str, str]
type Address = tuple[str, int]
type Server = tuple[Address, ConnectionOptions]

def broadcast_message(message: str, servers: Sequence[Server]) -> None:
    ...

# The static type checker will treat the previous type signature as
# being exactly equivalent to this one.
def broadcast_message(
    message: str,
    servers: Sequence[tuple[tuple[str, int], dict[str, str]]]
) -> None:
    ...
```

`type` 陳述式是 Python 3.12 的新功能。🄵了向後相容性，型🄵🄵名可以透過簡單的賦值來建立：

```
Vector = list[float]
```

或是用*TypeAlias* 標記，讓它明確的表示這是一個型🄵🄵名，而非一般的變數賦值：

```
from typing import TypeAlias

Vector: TypeAlias = list[float]
```

26.1.3 NewType

使用*NewType* 輔助工具 (helper) 建立獨特型🄵:

```
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(524313)
```

若它是原本型🄵的子類🄵，🄵態型🄵檢查器會將其視🄵一個新的型🄵。這對於幫助🄵取邏輯性錯誤非常有用:

```
def get_user_name(user_id: UserId) -> str:
    ...

# passes type checking
user_a = get_user_name(UserId(42351))

# fails type checking; an int is not a UserId
user_b = get_user_name(-1)
```

你依然可以在對於型🄵 `UserId` 的變數中執行所有 `int` 的操作。這讓你可以在預期接受 `int` 的地方傳遞一個 `UserId`，還能預防你意外使用無效的方法建立一個 `UserId`:

```
# 'output' is of type 'int', not 'UserId'
output = UserId(23413) + UserId(54341)
```

注意這只會透過🄵態型🄵檢查器🄵制檢查。在 runtime 中，陳述式 (statement) `Derived = NewType('Derived', Base)` 會使 `Derived` 成🄵一個 callable（可呼叫物件），會立即回傳任何你傳遞的引數。這意味著 expression （運算式）`Derived(some_value)` 不會建立一個新的類🄵或過度引入原有的函式呼叫。

更精確地🄵，expression `some_value is Derived(some_value)` 在 runtime 永遠🄵 true。

這會無法建立一個 `Derived` 的子型🄵:

```
from typing import NewType

UserId = NewType('UserId', int)

# Fails at runtime and does not pass type checking
class AdminUserId(UserId): pass
```

無論如何，這有辦法基於'衍生的' `NewType` 建立一個*NewType*:

```
from typing import NewType

UserId = NewType('UserId', int)

ProUserId = NewType('ProUserId', UserId)
```

以及針對 `ProUserId` 的型🄵檢查會如期運作。

更多細節請見 **PEP 484**。

> **備🄵**
>
> 請記得使用型🄵🄵名是宣告兩種型🄵是互相相等的。使用 `type Alias = Original` 則會讓🄵態型🄵檢查器在任何情🄵之下將 `Alias` 視🄵與 `Original` 完全相等。這當你想把🄵雜的型🄵簽名進行簡化時，非常好用。
>
> 相反的，`NewType` 宣告一個型🄵會是另外一種型🄵的子類🄵。使用 `Derived = NewType('Derived', Original)` 會使🄵態型🄵檢查器將 `Derived` 視🄵 `Original` 的子類🄵，也意味著一個型🄵🄵 `Original`

的值，不能被使用在任何預期接收到型🄵 `Derived` 的值的區域。這當你想用最小的 runtime 成本預防邏輯性錯誤而言，非常有用。

在 3.5.2 版被加入.

在 3.10 版的變更: 現在的 `NewType` 比起一個函式更像一個類🄵。因此，比起一般的函式，呼叫 `NewType` 需要額外的 runtime 成本。

在 3.11 版的變更: 呼叫 `NewType` 的效能已經恢復與 Python 3.9 相同的水准。

26.1.4 🄵釋 callable 物件

函式，或者是其他*callable* 物件，可以使用*collections.abc.Callable* 或以🄵用的*typing.Callable* 進行🄵釋。`Callable[[int], str]` 象徵🄵一個函式，可以接受一個型🄵🄵*int* 的引數，🄵回傳一個*str*。

舉例來🄵:

```
from collections.abc import Callable, Awaitable

def feeder(get_next_item: Callable[[], str]) -> None:
    ...  # 主體

def async_query(on_success: Callable[[int], None],
                on_error: Callable[[int, Exception], None]) -> None:
    ...  # 主體

async def on_update(value: str) -> None:
    ...  # 主體

callback: Callable[[str], Awaitable[None]] = on_update
```

使用下標語法 (subscription syntax) 時，必須使用到兩個值，分🄵🄵引述串列以及回傳類🄵。引數串列必須🄵一個型🄵串列：*ParamSpec*、*Concatenate* 或是一個🄴節號 (ellipsis, . . .)。回傳類🄵必🄵一個單一類🄵。

若🄴節號字面值 . . . 被當作引數串列給定，其指出一個具任何、任意參數列表的 callable 會被接受:

```
def concat(x: str, y: str) -> str:
    return x + y

x: Callable[..., str]
x = str     # OK
x = concat  # 也 OK
```

`Callable` 不如有可變數量引數的函式、*overloaded functions*、或是僅限關鍵字參數的函式，可以表示🄵雜簽名。然而，這些簽名可以透過定義一個具有 `__call__()` 方法的*Protocol* 類🄴進行表示:

```
from collections.abc import Iterable
from typing import Protocol

class Combiner(Protocol):
    def __call__(self, *vals: bytes, maxlen: int | None = None) -> list[bytes]: ...

def batch_proc(data: Iterable[bytes], cb_results: Combiner) -> bytes:
    for item in data:
        ...

def good_cb(*vals: bytes, maxlen: int | None = None) -> list[bytes]:
    ...
def bad_cb(*vals: bytes, maxitems: int | None) -> list[bytes]:
    ...
```

(繼續下一頁)

(繼續上一頁)

```
batch_proc([], good_cb)  # OK
batch_proc([], bad_cb)   # Error! Argument 2 has incompatible type because of
                         # different name and kind in the callback
```

Callable 物件可以取用其他 callable 當作引數使用，可以透過*ParamSpec* 指出他們的參數型🄵是個🄵獨立的。另外，如果這個 callable 從其他 callable 新增或🄵除引數時，將會使用到*Concatenate* 運算子。他們可以分🄵🄵用 `Callable[ParamSpecVariable, ReturnType]` 以及 `Callable[Concatenate[Arg1Type, Arg2Type, ..., ParamSpecVariable], ReturnType]` 的形式。

在 3.10 版的變更: `Callable` 現已支援*ParamSpec* 以及*Concatenate*。請參🄵 **PEP 612** 🄵讀詳細🄵容。

也參考

ParamSpec 以及*Concatenate* 的文件中，提供範例如何在 `Callable` 中使用。

26.1.5 泛型

因🄵關於物件的型🄵資訊留存在容器之🄵，且無法使用通用的方式進行🄵態推論 (statically inferred)，許多標准函式庫的容器類🄵支援以下標來表示容器🄵預期的元素。

```
from collections.abc import Mapping, Sequence

class Employee: ...

# Sequence[Employee] indicates that all elements in the sequence
# must be instances of "Employee".
# Mapping[str, str] indicates that all keys and all values in the mapping
# must be strings.
def notify_by_email(employees: Sequence[Employee],
                    overrides: Mapping[str, str]) -> None: ...
```

泛型函式及類🄵可以使用型🄵參數語法 (type parameter syntax) 進行參數化 (parameterize)：

```
from collections.abc import Sequence

def first[T](l: Sequence[T]) -> T:  # Function is generic over the TypeVar "T"
    return l[0]
```

或是直接使用*TypeVar* 工廠 (factory)：

```
from collections.abc import Sequence
from typing import TypeVar

U = TypeVar('U')                  # Declare type variable "U"

def second(l: Sequence[U]) -> U:  # Function is generic over the TypeVar "U"
    return l[1]
```

在 3.12 版的變更: 在 Python 3.12 中，泛型的語法支援是全新功能。

26.1.6 🄵釋元組 (tuple)

在 Python 大多數的容器當中，加🄵型🄵系統認🄵容器🄵的所有元素會是相同型🄵。舉例來🄵：

```
from collections.abc import Mapping

# Type checker will infer that all elements in ``x`` are meant to be ints
```

(繼續下一頁)

(繼續上一頁)

```
x: list[int] = []

# Type checker error: ``list`` only accepts a single type argument:
y: list[int, str] = [1, 'foo']

# Type checker will infer that all keys in ``z`` are meant to be strings,
# and that all values in ``z`` are meant to be either strings or ints
z: Mapping[str, str | int] = {}
```

list 只接受一個型🄵引數，所以型🄵檢查器可能在上述 `y` 賦值 (assignment) 觸發錯誤。類似的範例，*Mapping* 只接受兩個型🄵引數：第一個引數指出 keys（鍵）的型🄵；第二個引數指出 values（值）的型🄵。

然而，與其他多數的 Python 容器不同，在慣用的 (idiomatic) Python 程式碼中，元組可以擁有不完全相同型🄵的元素是相當常見的。🄵此，元組在 Python 的加🄵型🄵系統中是個特例 (special-cased)。*tuple* 接受任何數量的型🄵引數：

```
# OK: ``x`` is assigned to a tuple of length 1 where the sole element is an int
x: tuple[int] = (5,)

# OK: ``y`` is assigned to a tuple of length 2;
# element 1 is an int, element 2 is a str
y: tuple[int, str] = (5, "foo")

# Error: the type annotation indicates a tuple of length 1,
# but ``z`` has been assigned to a tuple of length 3
z: tuple[int] = (1, 2, 3)
```

🄵了標示一個元組可以🄵任意長度，且所有元素皆是相同型🄵 `T`，請使用🄵節號字面值 (literal ellipsis) `...`：`tuple[T, ...]`。🄵了標示一個空元組，請使用 `tuple[()]`。單純使用 `tuple` 作🄵🄵釋會與使用 `tuple[Any, ...]` 相等：

```
x: tuple[int, ...] = (1, 2)
# These reassignments are OK: ``tuple[int, ...]`` indicates x can be of any length
x = (1, 2, 3)
x = ()
# This reassignment is an error: all elements in ``x`` must be ints
x = ("foo", "bar")

# ``y`` can only ever be assigned to an empty tuple
y: tuple[()] = ()

z: tuple = ("foo", "bar")
# These reassignments are OK: plain ``tuple`` is equivalent to ``tuple[Any, ...]``
z = (1, 2, 3)
z = ()
```

26.1.7 類🄵物件的型🄵

一個變數被🄵釋🄵 `C` 可以接受一個型🄵🄵 `C` 的值。相對的，一個變數備🄵解🄵 `type[C]` （或已🄵用的*typing.Type[C]*）可以接受本身🄵該類🄵的值 -- 具體來🄵，他可能會接受 `C` 的類🄵物件。舉例來🄵：

```
a = 3         # Has type ``int``
b = int       # Has type ``type[int]``
c = type(a)   # Also has type ``type[int]``
```

請記得 `type[C]` 是共變 (covariant) 的：

```
class User: ...
class ProUser(User): ...
class TeamUser(User): ...
```

(繼續下一頁)

(繼續上一頁)

```
def make_new_user(user_class: type[User]) -> User:
    # ...
    return user_class()

make_new_user(User)       # OK
make_new_user(ProUser)    # Also OK: ``type[ProUser]`` is a subtype of ``type[User]``
make_new_user(TeamUser)   # Still fine
make_new_user(User())     # Error: expected ``type[User]`` but got ``User``
make_new_user(int)        # Error: ``type[int]`` is not a subtype of ``type[User]``
```

type 僅有的合法參數是類🄵、*Any*、型🄵變數以及這些型🄵任意組合成的聯集。舉例來🄵:

```
def new_non_team_user(user_class: type[BasicUser | ProUser]): ...

new_non_team_user(BasicUser)  # OK
new_non_team_user(ProUser)    # OK
new_non_team_user(TeamUser)   # Error: ``type[TeamUser]`` is not a subtype
                              # of ``type[BasicUser | ProUser]``
new_non_team_user(User)       # Also an error
```

`type[Any]` 等價於*type*，其🄵 Python metaclass 階層結構 (hierachy)。

26.1.8 Annotating generators and coroutines

A generator can be annotated using the generic type *Generator[YieldType, SendType, ReturnType]*. For example:

```
def echo_round() -> Generator[int, float, str]:
    sent = yield 0
    while sent >= 0:
        sent = yield round(sent)
    return 'Done'
```

Note that unlike many other generic classes in the standard library, the `SendType` of *Generator* behaves contravariantly, not covariantly or invariantly.

The `SendType` and `ReturnType` parameters default to `None`:

```
def infinite_stream(start: int) -> Generator[int]:
    while True:
        yield start
        start += 1
```

It is also possible to set these types explicitly:

```
def infinite_stream(start: int) -> Generator[int, None, None]:
    while True:
        yield start
        start += 1
```

Simple generators that only ever yield values can also be annotated as having a return type of either *Iterable[YieldType]* or *Iterator[YieldType]*:

```
def infinite_stream(start: int) -> Iterator[int]:
    while True:
        yield start
        start += 1
```

Async generators are handled in a similar fashion, but don't expect a `ReturnType` type argument (*AsyncGenerator[YieldType, SendType]*). The `SendType` argument defaults to `None`, so the following definitions are equivalent:

```
async def infinite_stream(start: int) -> AsyncGenerator[int]:
    while True:
        yield start
        start = await increment(start)

async def infinite_stream(start: int) -> AsyncGenerator[int, None]:
    while True:
        yield start
        start = await increment(start)
```

As in the synchronous case, *AsyncIterable[YieldType]* and *AsyncIterator[YieldType]* are available as well:

```
async def infinite_stream(start: int) -> AsyncIterator[int]:
    while True:
        yield start
        start = await increment(start)
```

Coroutines can be annotated using *Coroutine[YieldType, SendType, ReturnType]*. Generic arguments correspond to those of *Generator*, for example:

```
from collections.abc import Coroutine
c: Coroutine[list[str], str, int]  # Some coroutine defined elsewhere
x = c.send('hi')                   # Inferred type of 'x' is list[str]
async def bar() -> None:
    y = await c                    # Inferred type of 'y' is int
```

26.1.9 使用者定義泛型型🄵

一個使用者定義的類🄵可以被定義成一個泛型類🄵。

```
from logging import Logger

class LoggedVar[T]:
    def __init__(self, value: T, name: str, logger: Logger) -> None:
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('%s: %s', self.name, message)
```

這個語法指出類🄵 `LoggedVar` 透過一個單一的型🄵變數 `T` 進行參數化 (parameterised)。這使得 `T` 在類🄵中有效的成🄵型🄵。

泛型類🄵隱性繼承了*Generic*。🄵了相容 Python 3.11 及更早版本，也可以明確的繼承*Generic* 🄵指出是一個泛型類🄵：

```
from typing import TypeVar, Generic

T = TypeVar('T')
```

(繼續下一頁)

(繼續上一頁)

```
class LoggedVar(Generic[T]):
    ...
```

泛型類🄵有 `__class_getitem__()` 方法，其意味著可以在 runtime 進行參數化（如下述的 `LoggedVar[int]`）：

```
from collections.abc import Iterable

def zero_all_vars(vars: Iterable[LoggedVar[int]]) -> None:
    for var in vars:
        var.set(0)
```

一個泛型型🄵可以有任意數量的型🄵變數。所有種類的 *TypeVar* 都可以作🄵泛型型🄵的參數：

```
from typing import TypeVar, Generic, Sequence

class WeirdTrio[T, B: Sequence[bytes], S: (int, str)]:
    ...

OldT = TypeVar('OldT', contravariant=True)
OldB = TypeVar('OldB', bound=Sequence[bytes], covariant=True)
OldS = TypeVar('OldS', int, str)

class OldWeirdTrio(Generic[OldT, OldB, OldS]):
    ...
```

Generic 的每個型🄵變數引數必不相同。因此以下是無效的：

```
from typing import TypeVar, Generic
...

class Pair[M, M]:  # SyntaxError
    ...

T = TypeVar('T')

class Pair(Generic[T, T]):   # INVALID
    ...
```

泛型類🄵亦可以繼承其他類🄵：

```
from collections.abc import Sized

class LinkedList[T](Sized):
    ...
```

當繼承泛型類🄵時，部份的型🄵參數可固定：

```
from collections.abc import Mapping

class MyDict[T](Mapping[str, T]):
    ...
```

在這種情🄵下 `MyDict` 有一個單一的參數 `T`。

若使用泛型類🄵🄵🄵有特指型🄵參數，則會將每個位置視🄵*Any*。在下列的範例中 `MyIterable` 不是泛型，但隱性繼承了 `Iterable[Any]`：

```
from collections.abc import Iterable

class MyIterable(Iterable): # Same as Iterable[Any]
    ...
```

使用者定義的泛型型🄵🄵名也有支援。例如：

```
from collections.abc import Iterable

type Response[S] = Iterable[S] | int

# Return type here is same as Iterable[str] | int
def response(query: str) -> Response[str]:
    ...

type Vec[T] = Iterable[tuple[T, T]]

def inproduct[T: (int, float, complex)](v: Vec[T]) -> T: # Same as Iterable[tuple[T, T]]
    return sum(x*y for x, y in v)
```

🄵了向後相容性，泛型型🄵🄵名可以透過簡單的賦值來建立：

```
from collections.abc import Iterable
from typing import TypeVar

S = TypeVar("S")
Response = Iterable[S] | int
```

在 3.7 版的變更: *Generic* 不再是一個自訂的 metaclass。

在 3.12 版的變更: 在版本 3.12 新增了泛型及型🄵🄵名的語法支援。在之前的版本中，泛型類🄵必須顯性繼承*Generic* 或是包含一個型🄵變數在基底類🄵 (base) 當中。

使用者定義的參數運算式 (parameter expression) 泛型一樣有支援，透過 `[**P]` 格式的參數規格變數來進行表示。對於上述作🄵參數規格變數的型🄵變數，將持續被 `typing` 模組視🄵一個特定的型🄵變數。對此，其中一個例外是一個型🄵列表可以替代*ParamSpec*：

```
>>> class Z[T, **P]: ...  # T 🄵 TypeVar; P 🄵 ParamSpec
...
>>> Z[int, [dict, float]]
__main__.Z[int, [dict, float]]
```

具有*ParamSpec* 的泛型類🄵可以透過顯性繼承*Generic* 進行建立。在這種情🄵下，不需要使用 `**`：

```
from typing import ParamSpec, Generic

P = ParamSpec('P')

class Z(Generic[P]):
    ...
```

另外一個*TypeVar* 以及*ParamSpec* 之間的差🄵是，基於美觀因素，只有一個參數規格變數的泛型可以接受如 `X[[Type1, Type2, ...]]` 以及 `X[Type1, Type2, ...]` 的參數列表。在🄵部中，後者會被轉🄵🄵前者，所以在下方的範例中🄵相等的：

```
>>> class X[**P]: ...
...
>>> X[int, str]
__main__.X[[int, str]]
>>> X[[int, str]]
__main__.X[[int, str]]
```

請記得，具有*ParamSpec* 的泛型在某些情🄵下替🄵之後可能不會有正確的 `__parameters__`，因🄵參數規格主要還是用於🄵態型🄵檢查。

在 3.10 版的變更: *Generic* 現在可以透過參數運算式來進行參數化。詳細🄵容請見*ParamSpec* 以及 **PEP 612**。

一個使用者定義的泛型類🄵可以將 ABC 作🄵他們的基底類🄵，且不會有 metaclass 衝突。泛型的 metaclass 則不支援。參數化泛型的輸出將被存🄵快取，而在 `typing` 模組中多數的型🄵皆🄵*hashable* 且可以比較相等性。

26.1.10 `Any` 型🄵

Any 是一種特🄵的型🄵。一個🄵態型🄵檢查器會將每個型🄵視🄵可相容於*Any* 且*Any* 也可以相容於每個型🄵。

這意味著如果在一個🄵*Any* 的值上執行任何操作或呼叫方法是可行的，且可以賦值給任意變數：

```
from typing import Any

a: Any = None
a = []          # OK
a = 2           # OK

s: str = ''
s = a           # OK

def foo(item: Any) -> int:
    # Passes type checking; 'item' could be any type,
    # and that type might have a 'bar' method
    item.bar()
    ...
```

請注意，當賦予型🄵🄵*Any* 的值更精確的型🄵時，將不會執行任何型🄵檢查。舉例來🄵，🄵態型🄵檢查器不會在 runtime 中，將 `a` 賦值給 `s` 的情🄵下回報錯誤，🄵管 `s` 是被宣告🄵型🄵*str* 🄵接收到*int* 的值！

另外，所有缺少回傳型🄵或參數型🄵的函式將會隱性預設🄵*Any*：

```
def legacy_parser(text):
    ...
    return data

# A static type checker will treat the above
# as having the same signature as:
def legacy_parser(text: Any) -> Any:
    ...
    return data
```

當你需要混和動態及🄵態的型🄵程式碼，這個行🄵允許*Any* 被當作一個緊急出口 *(escape hatch)* 使用。

Any 的行🄵對比*object* 的行🄵。與*Any* 相似，所有的型🄵會作🄵*object* 的子型🄵。然而，不像*Any*，反之不亦然：*object* 🄵不是一個其他型🄵的子型🄵。

這意味著當一個值的型🄵🄵*object* 時，型🄵檢查器會拒🄵幾乎所有的操作，🄵將賦予這個值到一個特定型🄵變數（或是當作回傳值使用）視🄵一個型🄵錯誤。舉例來🄵：

```
def hash_a(item: object) -> int:
    # Fails type checking; an object does not have a 'magic' method.
    item.magic()
    ...

def hash_b(item: Any) -> int:
    # Passes type checking
    item.magic()
    ...

# Passes type checking, since ints and strs are subclasses of object
hash_a(42)
hash_a("foo")
```

(繼續下一頁)

(繼續上一頁)

```
# Passes type checking, since Any is compatible with all types
hash_b(42)
hash_b("foo")
```

使用*object*，將指出在型🄵安全 (typesafe) 的習慣之下一個值可以🄵任意型🄵。使用*Any*，將指出這個值是個動態型🄵。

26.1.11 標稱 (nominal) 子型🄵 vs 結構子型🄵

最初 **PEP 484** 定義 Python 🄵態型🄵系統使用標懲子型🄵。這意味著只有 `A` 🄵 `B` 的子類🄵時，`A` 才被允許使用在預期是類🄵 `B` 出現的地方。

這個需求之前也被運用在抽象基底類🄵，例如*Iterable*。這種方式的問題在於，一個類🄵需要顯式的標記來支援他們，這🄴不符合 Python 風格，也不像一個常見的慣用動態型🄵 Python 程式碼。舉例來🄴，下列程式碼符合 **PEP 484**：

```
from collections.abc import Sized, Iterable, Iterator

class Bucket(Sized, Iterable[int]):
    ...
    def __len__(self) -> int: ...
    def __iter__(self) -> Iterator[int]: ...
```

PEP 544 可以透過使用上方的程式碼，且在類🄵定義時不用顯式基底類🄵解🄵這個問題，讓 `Bucket` 被🄵態型🄵檢查器隱性認🄵是 `Sized` 以及 `Iterable[int]` 兩者的子型🄵。這就是🄵所周知的結構子型🄵（或是🄵態鴨子型🄵）：

```
from collections.abc import Iterator, Iterable

class Bucket:  # 注意：🄵有基底類🄵
    ...
    def __len__(self) -> int: ...
    def __iter__(self) -> Iterator[int]: ...

def collect(items: Iterable[int]) -> int: ...
result = collect(Bucket())  # Passes type check
```

而且，基於一個特🄵的型🄵*Protocol* 建立子型🄵時，使用者可以定義新的協定🄵充份發揮結構子型🄵的優勢（請見下方範例）。

26.1.12 模組🄵容

模組 `typing` 定義了下列的類🄵、函式以及裝飾器。

特🄵型🄵原語 (primitive)

特🄵型🄵

這些可以在🄵釋中做🄵型🄵。他們🄵不支援 `[]` 的下標使用。

`typing.`**`Any`**

特🄵型🄵，指出一個不受約束 (unconstrained) 的型🄵。

- 所有型🄵皆與*Any* 相容。
- *Any* 相容於所有型🄵。

在 3.11 版的變更: *Any* 可以作🄵一個基礎類🄵。這對於在任何地方使用鴨子型🄵或是高度動態的型🄵，避免型🄵檢查器的錯誤是非常有用的。

typing.**AnyStr**

一個不受約束的型🄵變數。

定義：

```
AnyStr = TypeVar('AnyStr', str, bytes)
```

`AnyStr` 是對於函式有用的，他可以接受*str* 或*bytes* 引數但不可以將此兩種混合。

舉例來🄵：

```
def concat(a: AnyStr, b: AnyStr) -> AnyStr:
    return a + b

concat("foo", "bar")    # OK, output has type 'str'
concat(b"foo", b"bar")  # OK, output has type 'bytes'
concat("foo", b"bar")   # Error, cannot mix str and bytes
```

請注意，🄵管他的名稱相近，`AnyStr` 與*Any* 型🄵無關，更不代表是「任何字串」的意思。尤其，`AnyStr` 與 `str | bytes` 兩者不同且具有不同的使用情境：

```
# Invalid use of AnyStr:
# The type variable is used only once in the function signature,
# so cannot be "solved" by the type checker
def greet_bad(cond: bool) -> AnyStr:
    return "hi there!" if cond else b"greetings!"

# The better way of annotating this function:
def greet_proper(cond: bool) -> str | bytes:
    return "hi there!" if cond else b"greetings!"
```

Deprecated since version 3.13, will be removed in version 3.18: Deprecated in favor of the new type parameter syntax. Use `class A[T: (str, bytes)]: ...` instead of importing `AnyStr`. See **PEP 695** for more details.

In Python 3.16, `AnyStr` will be removed from `typing.__all__`, and deprecation warnings will be emitted at runtime when it is accessed or imported from `typing`. `AnyStr` will be removed from `typing` in Python 3.18.

typing.**LiteralString**

特🄵型🄵，只包含文本字串。

任何文本字串都相容於 `LiteralString`，對於另一個 `LiteralString` 亦是如此。然而，若是一個型🄵僅🄵 `str` 的物件則不相容。一個字串若是透過組合多個 `LiteralString` 型🄵的物件建立，則此字串也可以視🄵 `LiteralString`。

舉例來🄵：

```
def run_query(sql: LiteralString) -> None:
    ...

def caller(arbitrary_string: str, literal_string: LiteralString) -> None:
    run_query("SELECT * FROM students")  # OK
    run_query(literal_string)  # OK
    run_query("SELECT * FROM " + literal_string)  # OK
    run_query(arbitrary_string)  # type checker error
    run_query(  # type checker error
        f"SELECT * FROM students WHERE name = {arbitrary_string}"
    )
```

`LiteralString` 對於敏感的 API 來🄵是有用的，其中任意的使用者🄵生的字串可能會🄵生問題。舉例來🄵，上面兩個案例中🄵生的型🄵檢查器錯誤是脆弱的且容易受到 SQL 注入攻擊。

更多細節請見 **PEP 675**。

在 3.11 版被加入.

typing.**Never**

typing.**NoReturn**

Never 和 NoReturn 表示底部型🄵 (bottom type)，🄵一個🄵有任何成員的型🄵。

它們可以被用來代表一個不會回傳的函式，像是*sys.exit()*：

```
from typing import Never  # 或 NoReturn

def stop() -> Never:
    raise RuntimeError('no way')
```

或被用來定義一個不應被呼叫的函式，因🄵不會有有效的引數，、像是*assert_never()*：

```
from typing import Never  # or NoReturn

def never_call_me(arg: Never) -> None:
    pass

def int_or_str(arg: int | str) -> None:
    never_call_me(arg)  # type checker error
    match arg:
        case int():
            print("It's an int")
        case str():
            print("It's a str")
        case _:
            never_call_me(arg)  # OK, arg is of type Never (or NoReturn)
```

Never 以及 NoReturn 在型🄵系統中具有相同的意義且🄵態型🄵檢查器會將兩者視🄵相等。

在 3.6.2 版被加入: 新增*NoReturn*。

在 3.11 版被加入: 新增*Never*。

typing.**Self**

特🄵型🄵，用來表示目前類🄵之🄵 (enclosed class)。

舉例來🄵:

```
from typing import Self, reveal_type

class Foo:
    def return_self(self) -> Self:
        ...
        return self

class SubclassOfFoo(Foo): pass

reveal_type(Foo().return_self())  # Revealed type is "Foo"
reveal_type(SubclassOfFoo().return_self())  # Revealed type is "SubclassOfFoo"
```

這個🄵釋在語意上相等於下列🄵容，且形式更🄵簡潔:

```
from typing import TypeVar

Self = TypeVar("Self", bound="Foo")

class Foo:
    def return_self(self: Self) -> Self:
        ...
        return self
```

一般來🄵，如果某個東西回傳 `self` 如上方的範例所示，你則應該使用 `Self` 做🄵回傳值的🄵釋。若 `Foo.return_self` 被🄵釋🄵回傳 `"Foo"`，則型🄵檢查器應該推論這個從 `SubclassOfFoo.return_self` 回傳的物件🄵 `Foo` 型🄵，而🄵非回傳 `SubclassOfFoo` 型🄵。

其他常見的使用案例包含：

- *classmethod* 被用來作🄵替代的建構函式 (constructor) 🄵回傳 `cls` 參數的實例。
- 🄵釋一個回傳自己的 `__enter__()` 方法。

當類🄵被子類🄵化時，若方法不保證回傳一個子類🄵的實例，你不應該使用 `Self` 作🄵回傳🄵釋：

```
class Eggs:
    # Self would be an incorrect return annotation here,
    # as the object returned is always an instance of Eggs,
    # even in subclasses
    def returns_eggs(self) -> "Eggs":
        return Eggs()
```

更多細節請見 **PEP 673**。

在 3.11 版被加入.

typing.**TypeAlias**

做🄵明確宣告一個型🄵🄵名 的特🄵🄵釋。

舉例來🄵：

```
from typing import TypeAlias

Factors: TypeAlias = list[int]
```

`TypeAlias` 在舊的 Python 版本中特🄵有用，其🄵釋🄵名可以用來進行傳遞參照 (forward reference)，因🄵對於型🄵檢查器來🄵，分辨這些🄵名與一般的變數賦值相當困難：

```
from typing import Generic, TypeAlias, TypeVar

T = TypeVar("T")

# "Box" does not exist yet,
# so we have to use quotes for the forward reference on Python <3.12.
# Using ``TypeAlias`` tells the type checker that this is a type alias declaration,
# not a variable assignment to a string.
BoxOfStrings: TypeAlias = "Box[str]"

class Box(Generic[T]):
    @classmethod
    def make_box_of_strings(cls) -> BoxOfStrings: ...
```

更多細節請見 **PEP 613**。

在 3.10 版被加入.

在 3.12 版之後被🄵用：*TypeAlias* 被🄵用，請改用 `type` 陳述式來建立 *TypeAliasType* 的實例，其自然可以支援傳遞參照的使用。請注意，雖然 *TypeAlias* 以及 *TypeAliasType* 提供相似的用途且具有相似的名稱，他們是不同的，且後者不是前者的型🄵。現在還🄵有移除 *TypeAlias* 的計畫，但鼓勵使用者們遷移 (migrate) 至 `type` 陳述式。

特🄵型式

這些在🄵釋中可以當作型🄵使用。他們全都支援 `[]` 的下標使用，但每個都具有獨特的語法。

class typing.**Union**

聯集型🄵；`Union[X, Y]` 與 `X | Y` 是相等的，且都意味著 X 或 Y 兩者其一。

🄵了定義聯集，例如可以使用 `Union[int, str]` 或是使用簡寫 (shorthand) `int | str`。使用這種簡寫是非常推薦的。詳細請看：

- 引數必須🄵型🄵且必須有至少一個。
- 聯集中的聯集會是扁平化的 (flattened)，舉例來🄵：

```
Union[Union[int, str], float] == Union[int, str, float]
```

However, this does not apply to unions referenced through a type alias, to avoid forcing evaluation of the underlying *TypeAliasType*:

```
type A = Union[int, str]
Union[A, float] != Union[int, str, float]
```

- 單一引數的聯集會消失不見，舉例來🄵：

```
Union[int] == int  # 實際上建構函式會回傳 int
```

- 多余的引數會被略過，舉例來🄵：

```
Union[int, str, int] == Union[int, str] == int | str
```

- 當比較聯集時，引數的順序會被忽略，舉例來🄵：

```
Union[int, str] == Union[str, int]
```

- 你不能建立 `Union` 的子類🄵或是實例。
- 你不能寫成 `Union[X][Y]`。

在 3.7 版的變更: 請勿在 runtime 中將顯性子類🄵從聯集中移除。

在 3.10 版的變更: 現在可以將聯集寫成 `X | Y`。請見聯集型🄵運算式。

在 3.14 版的變更: *types.UnionType* is now an alias for *Union*, and both `Union[int, str]` and `int | str` create instances of the same class. To check whether an object is a `Union` at runtime, use `isinstance(obj, Union)`. For compatibility with earlier versions of Python, use `get_origin(obj) is typing.Union or get_origin(obj) is types.UnionType`.

typing.**Optional**

`Optional[X]` 與 `X | None` 是相等的（或是 `Union[X, None]`）。

請注意，這與具有預設值的選擇性引數 (optional argument) 不是相同的概念。一個具有預設值的選擇性引數的型🄵🄵釋中不具有 `Optional` 限定符 (qualifier)，單純的因🄵它就是選擇性的。舉例來🄵：

```
def foo(arg: int = 0) -> None:
    ...
```

另一方面，如果一個顯性的值 `None` 是被允許的，不論引數是不是選擇性的，`Optional` 都適用。舉例來🄵：

```
def foo(arg: Optional[int] = None) -> None:
    ...
```

在 3.10 版的變更: 現在可以將 Optional 寫成 `X | None`。請見聯集型🄵運算式。

typing.**Concatenate**

用於🄵釋高階函式的特🄵型式。

`Concatenate` 可以被用在可呼叫物件與*ParamSpec* 的接合 (conjunction) 🄵🄵釋一個高階的 Callable 物件可以新增、移除、轉🄵另一個 Callable 物件的參數。使用方法是依照這個格式 `Concatenate[Arg1Type, Arg2Type, ..., ParamSpecVariable]`。`Concatenate` 目前只在*Callable 物件*中第一個引數使用時有效。`Concatenate` 的最後一個參數必須🄵一個*ParamSpec* 或是🄵節號 (`...`)。

舉例來🄴，🄵釋一個🄵裝飾過後的函式提供*threading.Lock* 的裝飾器 `with_lock`，`Concatenate` 可以用於指出 `with_lock` 預期一個 Callable 物件，該物件可以接受 `Lock` 作🄵第一引數，🄵回傳一個具有不同型🄵簽名 Callable 物件。在這種情🄴下，*ParamSpec* 指出回傳的 Callable 物件的參數型🄵會依賴傳遞的 Callable 物件的參數型🄵：

```
from collections.abc import Callable
from threading import Lock
from typing import Concatenate

# Use this lock to ensure that only one thread is executing a function
# at any time.
my_lock = Lock()

def with_lock[**P, R](f: Callable[Concatenate[Lock, P], R]) -> Callable[P, R]:
    '''A type-safe decorator which provides a lock.'''
    def inner(*args: P.args, **kwargs: P.kwargs) -> R:
        # Provide the lock as the first argument.
        return f(my_lock, *args, **kwargs)
    return inner

@with_lock
def sum_threadsafe(lock: Lock, numbers: list[float]) -> float:
    '''Add a list of numbers together in a thread-safe manner.'''
    with lock:
        return sum(numbers)

# We don't need to pass in the lock ourselves thanks to the decorator.
sum_threadsafe([1.1, 2.2, 3.3])
```

在 3.10 版被加入.

也參考

- **PEP 612** -- 參數技術規範變數
- *ParamSpec*
- 🄵釋 *callable* 物件

typing.**Literal**

特殊型🄴格式，用於定義「文本型🄵 (literal type)」。

`Literal` 可以用於型🄵檢查器🄵指出🄵釋物件具有一個與提供的文本相同的值。

舉例來🄴：

```
def validate_simple(data: Any) -> Literal[True]:  # always returns True
    ...

type Mode = Literal['r', 'rb', 'w', 'wb']
def open_helper(file: str, mode: Mode) -> str:
    ...

open_helper('/some/path', 'r')      # Passes type check
open_helper('/other/path', 'typo')  # Error in type checker
```

`Literal[...]` 不可以進行子類🄵化。在 runtime 之中，任意的值是允許作🄵 `Literal[...]` 的型🄵引數，但型🄵檢查器可能會加🄵限制。更多有關文本型🄵的詳細資訊請看 **PEP 586**。

其他細節：

- 引數必須🄵文本值且必須有至少一個。

- 巢狀的 `Literal` 會是扁平化的 (flattened)，舉例來🄵：

```
assert Literal[Literal[1, 2], 3] == Literal[1, 2, 3]
```

However, this does not apply to `Literal` types referenced through a type alias, to avoid forcing evaluation of the underlying *TypeAliasType*:

```
type A = Literal[1, 2]
assert Literal[A, 3] != Literal[1, 2, 3]
```

- 多余的引數會被略過，舉例來🄵：

```
assert Literal[1, 2, 1] == Literal[1, 2]
```

- 當比較文本時，引數的順序會被忽略，舉例來🄵：

```
assert Literal[1, 2] == Literal[2, 1]
```

- 你不能建立 `Literal` 的子類🄵或是實例。
- 你不能寫成 `Literal[X][Y]`。

在 3.8 版被加入.

在 3.9.1 版的變更: `Literal` 現在可以🄵除重🄵 (de-deplicate) 的參數。`Literal` 物件的相等性比較不再依照相依性排序。`Literal` 物件現在會在相等性比較期間，若任一個其中的參數無法*hashable* 時，則會引發一個*TypeError* 例外。

typing.**ClassVar**

特殊型🄵建構，用來標記類🄵變數。

如同在 **PEP 526** 中的介紹，一個變數🄵解被包裝在 ClassVar 中時，會指出一個給定的屬性 (attribute) 意圖被當作類🄵變數使用，且不該被設定成該類🄵的實例。使用方法如下：

```
class Starship:
    stats: ClassVar[dict[str, int]] = {} # 類🄵變數
    damage: int = 10                     # 實例變數
```

ClassVar 只接受型🄵請不得使用下標。

ClassVar 🄵不代表該類🄵本身，而且不應該和*isinstance()* 或是*issubclass()* 一起使用。*ClassVar* 不會改變 Python runtime 的行🄵，但它可以被第三方的型🄵檢查器使用。舉例來🄵，一個型🄵檢查器可能會標記下方的程式碼🄵一個錯誤：

```
enterprise_d = Starship(3000)
enterprise_d.stats = {} # Error, setting class variable on instance
Starship.stats = {}     # This is OK
```

在 3.5.3 版被加入.

在 3.13 版的變更: *ClassVar* can now be nested in *Final* and vice versa.

typing.**Final**

特殊型🄵建構，用來指出給型🄵檢查器的最終名稱。

最終名稱不可以在任何作用域 (scope) 中重新賦值。在類🄵作用域中宣告的最終名稱，不得在子類🄵中進行覆寫 (override)。

舉例來🄵：

```
MAX_SIZE: Final = 9000
MAX_SIZE += 1  # Error reported by type checker

class Connection:
```

(繼續下一頁)

(繼續上一頁)

```
    TIMEOUT: Final[int] = 10

class FastConnector(Connection):
    TIMEOUT = 1  # Error reported by type checker
```

這些屬性 (property) 不會在 runtime 時進行檢查。更多詳細資訊請看 **PEP 591**。

在 3.8 版被加入.

在 3.13 版的變更: *Final* can now be nested in *ClassVar* and vice versa.

typing.**Required**

特殊型🄵建構，用來標記一個*TypedDict* 鍵值是必須的。

主要用於 `total=False` 的 TypedDict。更多細節請見*TypedDict* 與 **PEP 655**。

在 3.11 版被加入.

typing.**NotRequired**

特殊型🄵建構，用來標記一個*TypedDict* 鍵值是可能消失的。

更多細節請見*TypedDict* 與 **PEP 655**。

在 3.11 版被加入.

typing.**ReadOnly**

特殊型🄵建構，用來標記一個*TypedDict* 的項目是唯讀的。

舉例來🄵:

```
class Movie(TypedDict):
   title: ReadOnly[str]
   year: int

def mutate_movie(m: Movie) -> None:
   m["year"] = 1999  # allowed
   m["title"] = "The Matrix"  # 型🄵檢查器錯誤
```

這些屬性 (property) 不會在 runtime 時進行檢查。

更多細節請見*TypedDict* 與 **PEP 705**。

在 3.13 版被加入.

typing.**Annotated**

Special typing form to add context-specific metadata to an annotation.

Add metadata `x` to a given type `T` by using the annotation `Annotated[T, x]`. Metadata added using `Annotated` can be used by static analysis tools or at runtime. At runtime, the metadata is stored in a `__metadata__` attribute.

If a library or tool encounters an annotation `Annotated[T, x]` and has no special logic for the metadata, it should ignore the metadata and simply treat the annotation as `T`. As such, `Annotated` can be useful for code that wants to use annotations for purposes outside Python's static typing system.

Using `Annotated[T, x]` as an annotation still allows for static typechecking of `T`, as type checkers will simply ignore the metadata `x`. In this way, `Annotated` differs from the *@no_type_check* decorator, which can also be used for adding annotations outside the scope of the typing system, but completely disables typechecking for a function or class.

The responsibility of how to interpret the metadata lies with the tool or library encountering an `Annotated` annotation. A tool or library encountering an `Annotated` type can scan through the metadata elements to determine if they are of interest (e.g., using *isinstance()*).

Annotated[<type>, <metadata>]

Here is an example of how you might use `Annotated` to add metadata to type annotations if you were doing range analysis:

```
@dataclass
class ValueRange:
    lo: int
    hi: int

T1 = Annotated[int, ValueRange(-10, 5)]
T2 = Annotated[T1, ValueRange(-20, 3)]
```

The first argument to `Annotated` must be a valid type. Multiple metadata elements can be supplied as `Annotated` supports variadic arguments. The order of the metadata elements is preserved and matters for equality checks:

```
@dataclass
class ctype:
     kind: str

a1 = Annotated[int, ValueRange(3, 10), ctype("char")]
a2 = Annotated[int, ctype("char"), ValueRange(3, 10)]

assert a1 != a2  # 順序是有意義的
```

It is up to the tool consuming the annotations to decide whether the client is allowed to add multiple metadata elements to one annotation and how to merge those annotations.

Nested `Annotated` types are flattened. The order of the metadata elements starts with the innermost annotation:

```
assert Annotated[Annotated[int, ValueRange(3, 10)], ctype("char")] == Annotated[
    int, ValueRange(3, 10), ctype("char")
]
```

However, this does not apply to `Annotated` types referenced through a type alias, to avoid forcing evaluation of the underlying *TypeAliasType*:

```
type From3To10[T] = Annotated[T, ValueRange(3, 10)]
assert Annotated[From3To10[int], ctype("char")] != Annotated[
   int, ValueRange(3, 10), ctype("char")
]
```

Duplicated metadata elements are not removed:

```
assert Annotated[int, ValueRange(3, 10)] != Annotated[
    int, ValueRange(3, 10), ValueRange(3, 10)
]
```

`Annotated` can be used with nested and generic aliases:

```
@dataclass
class MaxLen:
    value: int

type Vec[T] = Annotated[list[tuple[T, T]], MaxLen(10)]

# When used in a type annotation, a type checker will treat "V" the same as
# ``Annotated[list[tuple[int, int]], MaxLen(10)]``:
type V = Vec[int]
```

`Annotated` cannot be used with an unpacked *TypeVarTuple*:

```
type Variadic[*Ts] = Annotated[*Ts, Ann1] = Annotated[T1, T2, T3, ..., Ann1]  # 無效
```

where `T1`, `T2`, ... are *TypeVars*. This is invalid as only one type should be passed to Annotated.

By default, *get_type_hints()* strips the metadata from annotations. Pass `include_extras=True` to have the metadata preserved:

```
>>> from typing import Annotated, get_type_hints
>>> def func(x: Annotated[int, "metadata"]) -> None: pass
...
>>> get_type_hints(func)
{'x': <class 'int'>, 'return': <class 'NoneType'>}
>>> get_type_hints(func, include_extras=True)
{'x': typing.Annotated[int, 'metadata'], 'return': <class 'NoneType'>}
```

At runtime, the metadata associated with an `Annotated` type can be retrieved via the `__metadata__` attribute:

```
>>> from typing import Annotated
>>> X = Annotated[int, "very", "important", "metadata"]
>>> X
typing.Annotated[int, 'very', 'important', 'metadata']
>>> X.__metadata__
('very', 'important', 'metadata')
```

If you want to retrieve the original type wrapped by `Annotated`, use the `__origin__` attribute:

```
>>> from typing import Annotated, get_origin
>>> Password = Annotated[str, "secret"]
>>> Password.__origin__
<class 'str'>
```

Note that using *get_origin()* will return `Annotated` itself:

```
>>> get_origin(Password)
typing.Annotated
```

PEP 593 - Flexible function and variable annotations
The PEP introducing `Annotated` to the standard library.

在 3.9 版被加入.

`typing.`**`TypeIs`**

Special typing construct for marking user-defined type predicate functions.

`TypeIs` can be used to annotate the return type of a user-defined type predicate function. `TypeIs` only accepts a single type argument. At runtime, functions marked this way should return a boolean and take at least one positional argument.

`TypeIs` aims to benefit *type narrowing* -- a technique used by static type checkers to determine a more precise type of an expression within a program's code flow. Usually type narrowing is done by analyzing conditional code flow and applying the narrowing to a block of code. The conditional expression here is sometimes referred to as a "type predicate":

```
def is_str(val: str | float):
    # "isinstance" type predicate
    if isinstance(val, str):
```

(繼續下一頁)

(繼續上一頁)

```
        # Type of ``val`` is narrowed to ``str``
        ...
    else:
        # Else, type of ``val`` is narrowed to ``float``.
        ...
```

Sometimes it would be convenient to use a user-defined boolean function as a type predicate. Such a function should use `TypeIs[...]` or *TypeGuard* as its return type to alert static type checkers to this intention. `TypeIs` usually has more intuitive behavior than `TypeGuard`, but it cannot be used when the input and output types are incompatible (e.g., `list[object]` to `list[int]`) or when the function does not return `True` for all instances of the narrowed type.

Using `-> TypeIs[NarrowedType]` tells the static type checker that for a given function:

1. 回傳值是一個布林值。
2. If the return value is `True`, the type of its argument is the intersection of the argument's original type and `NarrowedType`.
3. If the return value is `False`, the type of its argument is narrowed to exclude `NarrowedType`.

舉例來🄴:

```
from typing import assert_type, final, TypeIs

class Parent: pass
class Child(Parent): pass
@final
class Unrelated: pass

def is_parent(val: object) -> TypeIs[Parent]:
    return isinstance(val, Parent)

def run(arg: Child | Unrelated):
    if is_parent(arg):
        # Type of ``arg`` is narrowed to the intersection
        # of ``Parent`` and ``Child``, which is equivalent to
        # ``Child``.
        assert_type(arg, Child)
    else:
        # Type of ``arg`` is narrowed to exclude ``Parent``,
        # so only ``Unrelated`` is left.
        assert_type(arg, Unrelated)
```

The type inside `TypeIs` must be consistent with the type of the function's argument; if it is not, static type checkers will raise an error. An incorrectly written `TypeIs` function can lead to unsound behavior in the type system; it is the user's responsibility to write such functions in a type-safe manner.

If a `TypeIs` function is a class or instance method, then the type in `TypeIs` maps to the type of the second parameter (after `cls` or `self`).

In short, the form `def foo(arg: TypeA) -> TypeIs[TypeB]: ...`, means that if `foo(arg)` returns `True`, then `arg` is an instance of `TypeB`, and if it returns `False`, it is not an instance of `TypeB`.

`TypeIs` also works with type variables. For more information, see **PEP 742** (Narrowing types with `TypeIs`).

在 3.13 版被加入.

`typing.`**`TypeGuard`**

Special typing construct for marking user-defined type predicate functions.

Type predicate functions are user-defined functions that return whether their argument is an instance of a particular type. `TypeGuard` works similarly to *TypeIs*, but has subtly different effects on type checking behavior (see below).

Using `-> TypeGuard` tells the static type checker that for a given function:

1. 回傳值是一個布林值。
2. If the return value is `True`, the type of its argument is the type inside `TypeGuard`.

`TypeGuard` also works with type variables. See **PEP 647** for more details.

舉例來🄴:

```
def is_str_list(val: list[object]) -> TypeGuard[list[str]]:
    '''Determines whether all objects in the list are strings'''
    return all(isinstance(x, str) for x in val)

def func1(val: list[object]):
    if is_str_list(val):
        # Type of ``val`` is narrowed to ``list[str]``.
        print(" ".join(val))
    else:
        # Type of ``val`` remains as ``list[object]``.
        print("Not a list of strings!")
```

`TypeIs` 和 `TypeGuard` 在以下幾個方面有所不同:

- `TypeIs` requires the narrowed type to be a subtype of the input type, while `TypeGuard` does not. The main reason is to allow for things like narrowing `list[object]` to `list[str]` even though the latter is not a subtype of the former, since `list` is invariant.
- When a `TypeGuard` function returns `True`, type checkers narrow the type of the variable to exactly the `TypeGuard` type. When a `TypeIs` function returns `True`, type checkers can infer a more precise type combining the previously known type of the variable with the `TypeIs` type. (Technically, this is known as an intersection type.)
- When a `TypeGuard` function returns `False`, type checkers cannot narrow the type of the variable at all. When a `TypeIs` function returns `False`, type checkers can narrow the type of the variable to exclude the `TypeIs` type.

在 3.10 版被加入.

`typing.`**`Unpack`**

Typing operator to conceptually mark an object as having been unpacked.

For example, using the unpack operator `*` on a *type variable tuple* is equivalent to using `Unpack` to mark the type variable tuple as having been unpacked:

```
Ts = TypeVarTuple('Ts')
tup: tuple[*Ts]
# Effectively does:
tup: tuple[Unpack[Ts]]
```

In fact, `Unpack` can be used interchangeably with `*` in the context of *`typing.TypeVarTuple`* and *`builtins.tuple`* types. You might see `Unpack` being used explicitly in older versions of Python, where `*` couldn't be used in certain places:

```
# In older versions of Python, TypeVarTuple and Unpack
# are located in the `typing_extensions` backports package.
from typing_extensions import TypeVarTuple, Unpack

Ts = TypeVarTuple('Ts')
tup: tuple[*Ts]         # Syntax error on Python <= 3.10!
tup: tuple[Unpack[Ts]]  # Semantically equivalent, and backwards-compatible
```

`Unpack` can also be used along with *`typing.TypedDict`* for typing `**kwargs` in a function signature:

```
from typing import TypedDict, Unpack

class Movie(TypedDict):
    name: str
    year: int

# This function expects two keyword arguments - `name` of type `str`
# and `year` of type `int`.
def foo(**kwargs: Unpack[Movie]): ...
```

See **PEP 692** for more details on using `Unpack` for `**kwargs` typing.

在 3.11 版被加入.

Building generic types and type aliases

The following classes should not be used directly as annotations. Their intended purpose is to be building blocks for creating generic types and type aliases.

These objects can be created through special syntax (type parameter lists and the `type` statement). For compatibility with Python 3.11 and earlier, they can also be created without the dedicated syntax, as documented below.

class typing.**Generic**

Abstract base class for generic types.

A generic type is typically declared by adding a list of type parameters after the class name:

```
class Mapping[KT, VT]:
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.
```

Such a class implicitly inherits from `Generic`. The runtime semantics of this syntax are discussed in the Language Reference.

This class can then be used as follows:

```
def lookup_name[X, Y](mapping: Mapping[X, Y], key: X, default: Y) -> Y:
    try:
        return mapping[key]
    except KeyError:
        return default
```

Here the brackets after the function name indicate a generic function.

For backwards compatibility, generic classes can also be declared by explicitly inheriting from `Generic`. In this case, the type parameters must be declared separately:

```
KT = TypeVar('KT')
VT = TypeVar('VT')

class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.
```

class typing.**TypeVar**(*name*, **constraints*, *bound=None*, *covariant=False*, *contravariant=False*, *infer_variance=False*, *default=typing.NoDefault*)

Type variable.

The preferred way to construct a type variable is via the dedicated syntax for generic functions, generic classes, and generic type aliases:

```
class Sequence[T]:  # T 是一個 TypeVar
    ...
```

This syntax can also be used to create bounded and constrained type variables:

```
class StrSequence[S: str]:  # S is a TypeVar with a `str` upper bound;
    ...                     # we can say that S is "bounded by `str`"

class StrOrBytesSequence[A: (str, bytes)]:  # A is a TypeVar constrained to str or bytes
    ...
```

However, if desired, reusable type variables can also be constructed manually, like so:

```
T = TypeVar('T')  # 可以是任何東西
S = TypeVar('S', bound=str)  # 可以是任何 str 的子型🄵
A = TypeVar('A', str, bytes)  # 必須是 str 或 bytes
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function and type alias definitions. See *Generic* for more information on generic types. Generic functions work as follows:

```
def repeat[T](x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x."""
    return [x]*n

def print_capitalized[S: str](x: S) -> S:
    """Print x capitalized, and return x."""
    print(x.capitalize())
    return x

def concatenate[A: (str, bytes)](x: A, y: A) -> A:
    """Add two strings or bytes objects together."""
    return x + y
```

Note that type variables can be *bounded*, *constrained*, or neither, but cannot be both bounded *and* constrained.

The variance of type variables is inferred by type checkers when they are created through the type parameter syntax or when `infer_variance=True` is passed. Manually created type variables may be explicitly marked covariant or contravariant by passing `covariant=True` or `contravariant=True`. By default, manually created type variables are invariant. See **PEP 484** and **PEP 695** for more details.

Bounded type variables and constrained type variables have different semantics in several important ways. Using a *bounded* type variable means that the `TypeVar` will be solved using the most specific type possible:

```
x = print_capitalized('a string')
reveal_type(x)  # revealed type is str

class StringSubclass(str):
    pass

y = print_capitalized(StringSubclass('another string'))
reveal_type(y)  # revealed type is StringSubclass

z = print_capitalized(45)  # error: int is not a subtype of str
```

The upper bound of a type variable can be a concrete type, abstract type (ABC or Protocol), or even a union of types:

```
# Can be anything with an __abs__ method
def print_abs[T: SupportsAbs](arg: T) -> None:
    print("Absolute value:", abs(arg))

U = TypeVar('U', bound=str|bytes)  # Can be any subtype of the union str|bytes
V = TypeVar('V', bound=SupportsAbs)  # Can be anything with an __abs__ method
```

Using a *constrained* type variable, however, means that the `TypeVar` can only ever be solved as being exactly one of the constraints given:

```
a = concatenate('one', 'two')
reveal_type(a)  # revealed type is str

b = concatenate(StringSubclass('one'), StringSubclass('two'))
reveal_type(b)  # revealed type is str, despite StringSubclass being passed in

c = concatenate('one', b'two')  # error: type variable 'A' can be either str or bytes␣
↪in a function call, but not both
```

在 runtime `isinstance(x, T)` 會引發 *TypeError*。

__name__

The name of the type variable.

__covariant__

Whether the type var has been explicitly marked as covariant.

__contravariant__

Whether the type var has been explicitly marked as contravariant.

__infer_variance__

Whether the type variable's variance should be inferred by type checkers.

在 3.12 版被加入.

__bound__

The upper bound of the type variable, if any.

在 3.12 版的變更: For type variables created through type parameter syntax, the bound is evaluated only when the attribute is accessed, not when the type variable is created (see lazy-evaluation).

evaluate_bound()

An *evaluate function* corresponding to the *__bound__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__bound__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format.

在 3.14 版被加入.

__constraints__

A tuple containing the constraints of the type variable, if any.

在 3.12 版的變更: For type variables created through type parameter syntax, the constraints are evaluated only when the attribute is accessed, not when the type variable is created (see lazy-evaluation).

evaluate_constraints()

An *evaluate function* corresponding to the *__constraints__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__constraints__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format.

在 3.14 版被加入.

__default__

The default value of the type variable, or *typing.NoDefault* if it has no default.

在 3.13 版被加入.

evaluate_default()

An *evaluate function* corresponding to the *__default__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__default__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format.

在 3.14 版被加入.

has_default()

Return whether or not the type variable has a default value. This is equivalent to checking whether *__default__* is not the *typing.NoDefault* singleton, except that it does not force evaluation of the lazily evaluated default value.

在 3.13 版被加入.

在 3.12 版的變更: Type variables can now be declared using the type parameter syntax introduced by **PEP 695**. The `infer_variance` parameter was added.

在 3.13 版的變更: 新增對預設值的支援。

class typing.**TypeVarTuple**(*name*, *, *default=typing.NoDefault*)

Type variable tuple. A specialized form of *type variable* that enables *variadic* generics.

Type variable tuples can be declared in type parameter lists using a single asterisk (`*`) before the name:

```
def move_first_element_to_last[T, *Ts](tup: tuple[T, *Ts]) -> tuple[*Ts, T]:
    return (*tup[1:], tup[0])
```

Or by explicitly invoking the `TypeVarTuple` constructor:

```
T = TypeVar("T")
Ts = TypeVarTuple("Ts")

def move_first_element_to_last(tup: tuple[T, *Ts]) -> tuple[*Ts, T]:
    return (*tup[1:], tup[0])
```

A normal type variable enables parameterization with a single type. A type variable tuple, in contrast, allows parameterization with an *arbitrary* number of types by acting like an *arbitrary* number of type variables wrapped in a tuple. For example:

```
# T is bound to int, Ts is bound to ()
# Return value is (1,), which has type tuple[int]
move_first_element_to_last(tup=(1,))

# T is bound to int, Ts is bound to (str,)
# Return value is ('spam', 1), which has type tuple[str, int]
move_first_element_to_last(tup=(1, 'spam'))

# T is bound to int, Ts is bound to (str, float)
# Return value is ('spam', 3.0, 1), which has type tuple[str, float, int]
move_first_element_to_last(tup=(1, 'spam', 3.0))

# This fails to type check (and fails at runtime)
# because tuple[()] is not compatible with tuple[T, *Ts]
# (at least one element is required)
move_first_element_to_last(tup=())
```

Note the use of the unpacking operator `*` in `tuple[T, *Ts]`. Conceptually, you can think of `Ts` as a tuple of type variables `(T1, T2, ...)`. `tuple[T, *Ts]` would then become `tuple[T, *(T1, T2, ...)]`,

which is equivalent to `tuple[T, T1, T2, ...]`. (Note that in older versions of Python, you might see this written using *Unpack* instead, as `Unpack[Ts]`.)

Type variable tuples must *always* be unpacked. This helps distinguish type variable tuples from normal type variables:

```
x: Ts          # 無效
x: tuple[Ts]   # 無效
x: tuple[*Ts]  # 正確的做法
```

Type variable tuples can be used in the same contexts as normal type variables. For example, in class definitions, arguments, and return types:

```
class Array[*Shape]:
    def __getitem__(self, key: tuple[*Shape]) -> float: ...
    def __abs__(self) -> "Array[*Shape]": ...
    def get_shape(self) -> tuple[*Shape]: ...
```

Type variable tuples can be happily combined with normal type variables:

```
class Array[DType, *Shape]:  # This is fine
    pass

class Array2[*Shape, DType]:  # This would also be fine
    pass

class Height: ...
class Width: ...

float_array_1d: Array[float, Height] = Array()      # Totally fine
int_array_2d: Array[int, Height, Width] = Array()  # Yup, fine too
```

However, note that at most one type variable tuple may appear in a single list of type arguments or type parameters:

```
x: tuple[*Ts, *Ts]            # 無效
class Array[*Shape, *Shape]:  # 無效
    pass
```

Finally, an unpacked type variable tuple can be used as the type annotation of `*args`:

```
def call_soon[*Ts](
    callback: Callable[[*Ts], None],
    *args: *Ts
) -> None:
    ...
    callback(*args)
```

In contrast to non-unpacked annotations of `*args` - e.g. `*args: int`, which would specify that *all* arguments are `int` - `*args: *Ts` enables reference to the types of the *individual* arguments in `*args`. Here, this allows us to ensure the types of the `*args` passed to `call_soon` match the types of the (positional) arguments of `callback`.

See **PEP 646** for more details on type variable tuples.

__name__

The name of the type variable tuple.

__default__

The default value of the type variable tuple, or *typing.NoDefault* if it has no default.

在 3.13 版被加入.

evaluate_default()

An *evaluate function* corresponding to the *__default__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__default__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format.

在 3.14 版被加入.

has_default()

Return whether or not the type variable tuple has a default value. This is equivalent to checking whether *__default__* is not the *typing.NoDefault* singleton, except that it does not force evaluation of the lazily evaluated default value.

在 3.13 版被加入.

在 3.11 版被加入.

在 3.12 版的變更: Type variable tuples can now be declared using the type parameter syntax introduced by **PEP 695**.

在 3.13 版的變更: 新增對預設值的支援。

class typing.**ParamSpec**(*name*, *, *bound=None*, *covariant=False*, *contravariant=False*, *default=typing.NoDefault*)

Parameter specification variable. A specialized version of *type variables*.

In type parameter lists, parameter specifications can be declared with two asterisks (`**`):

```
type IntFunc[**P] = Callable[P, int]
```

For compatibility with Python 3.11 and earlier, `ParamSpec` objects can also be created as follows:

```
P = ParamSpec('P')
```

Parameter specification variables exist primarily for the benefit of static type checkers. They are used to forward the parameter types of one callable to another callable -- a pattern commonly found in higher order functions and decorators. They are only valid when used in `Concatenate`, or as the first argument to `Callable`, or as parameters for user-defined Generics. See *Generic* for more information on generic types.

For example, to add basic logging to a function, one can create a decorator `add_logging` to log function calls. The parameter specification variable tells the type checker that the callable passed into the decorator and the new callable returned by it have inter-dependent type parameters:

```
from collections.abc import Callable
import logging

def add_logging[T, **P](f: Callable[P, T]) -> Callable[P, T]:
    '''A type-safe decorator to add logging to a function.'''
    def inner(*args: P.args, **kwargs: P.kwargs) -> T:
        logging.info(f'{f.__name__} was called')
        return f(*args, **kwargs)
    return inner

@add_logging
def add_two(x: float, y: float) -> float:
    '''Add two numbers together.'''
    return x + y
```

Without `ParamSpec`, the simplest way to annotate this previously was to use a *TypeVar* with upper bound `Callable[..., Any]`. However this causes two problems:

1. The type checker can't type check the `inner` function because `*args` and `**kwargs` have to be typed *Any*.

2. *cast()* may be required in the body of the `add_logging` decorator when returning the `inner` function, or the static type checker must be told to ignore the `return inner`.

args

kwargs

Since `ParamSpec` captures both positional and keyword parameters, `P.args` and `P.kwargs` can be used to split a `ParamSpec` into its components. `P.args` represents the tuple of positional parameters in a given call and should only be used to annotate `*args`. `P.kwargs` represents the mapping of keyword parameters to their values in a given call, and should be only be used to annotate `**kwargs`. Both attributes require the annotated parameter to be in scope. At runtime, `P.args` and `P.kwargs` are instances respectively of *ParamSpecArgs* and *ParamSpecKwargs*.

__name__

The name of the parameter specification.

__default__

The default value of the parameter specification, or *typing.NoDefault* if it has no default.

在 3.13 版被加入.

evaluate_default()

An *evaluate function* corresponding to the *__default__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__default__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format.

在 3.14 版被加入.

has_default()

Return whether or not the parameter specification has a default value. This is equivalent to checking whether *__default__* is not the *typing.NoDefault* singleton, except that it does not force evaluation of the lazily evaluated default value.

在 3.13 版被加入.

Parameter specification variables created with `covariant=True` or `contravariant=True` can be used to declare covariant or contravariant generic types. The `bound` argument is also accepted, similar to *TypeVar*. However the actual semantics of these keywords are yet to be decided.

在 3.10 版被加入.

在 3.12 版的變更: Parameter specifications can now be declared using the type parameter syntax introduced by **PEP 695**.

在 3.13 版的變更: 新增對預設值的支援。

備🄵

Only parameter specification variables defined in global scope can be pickled.

也參考

- **PEP 612** -- 參數技術規範變數
- *Concatenate*
- 🄵釋 *callable* 物件

typing.**ParamSpecArgs**

typing.**ParamSpecKwargs**

Arguments and keyword arguments attributes of a *ParamSpec*. The `P.args` attribute of a `ParamSpec` is an instance of `ParamSpecArgs`, and `P.kwargs` is an instance of `ParamSpecKwargs`. They are intended for runtime introspection and have no special meaning to static type checkers.

Calling *get_origin()* on either of these objects will return the original `ParamSpec`:

```
>>> from typing import ParamSpec, get_origin
>>> P = ParamSpec("P")
>>> get_origin(P.args) is P
True
>>> get_origin(P.kwargs) is P
True
```

在 3.10 版被加入.

class typing.**TypeAliasType**(*name*, *value*, *, *type_params=()*)

The type of type aliases created through the `type` statement.

舉例來🄵:

```
>>> type Alias = int
>>> type(Alias)
<class 'typing.TypeAliasType'>
```

在 3.12 版被加入.

__name__

The name of the type alias:

```
>>> type Alias = int
>>> Alias.__name__
'Alias'
```

__module__

The module in which the type alias was defined:

```
>>> type Alias = int
>>> Alias.__module__
'__main__'
```

__type_params__

The type parameters of the type alias, or an empty tuple if the alias is not generic:

```
>>> type ListOrSet[T] = list[T] | set[T]
>>> ListOrSet.__type_params__
(T,)
>>> type NotGeneric = int
>>> NotGeneric.__type_params__
()
```

__value__

The type alias's value. This is lazily evaluated, so names used in the definition of the alias are not resolved until the `__value__` attribute is accessed:

```
>>> type Mutually = Recursive
>>> type Recursive = Mutually
>>> Mutually
Mutually
>>> Recursive
Recursive
```

(繼續下一頁)

(繼續上一頁)

```
>>> Mutually.__value__
Recursive
>>> Recursive.__value__
Mutually
```

evaluate_value()

An *evaluate function* corresponding to the *__value__* attribute. When called directly, this method supports only the *VALUE* format, which is equivalent to accessing the *__value__* attribute directly, but the method object can be passed to *annotationlib.call_evaluate_function()* to evaluate the value in a different format:

```
>>> type Alias = undefined
>>> Alias.__value__
Traceback (most recent call last):
...
NameError: name 'undefined' is not defined
>>> from annotationlib import Format, call_evaluate_function
>>> Alias.evaluate_value(Format.VALUE)
Traceback (most recent call last):
...
NameError: name 'undefined' is not defined
>>> call_evaluate_function(Alias.evaluate_value, Format.FORWARDREF)
ForwardRef('undefined')
```

在 3.14 版被加入.

Unpacking

Type aliases support star unpacking using the `*Alias` syntax. This is equivalent to using `Unpack[Alias]` directly:

```
>>> type Alias = tuple[int, str]
>>> type Unpacked = tuple[bool, *Alias]
>>> Unpacked.__value__
tuple[bool, typing.Unpack[Alias]]
```

在 3.14 版被加入.

Other special directives

These functions and classes should not be used directly as annotations. Their intended purpose is to be building blocks for creating and declaring types.

class typing.**NamedTuple**

Typed version of *collections.namedtuple()*.

用法:

```
class Employee(NamedTuple):
    name: str
    id: int
```

這等價於:

```
Employee = collections.namedtuple('Employee', ['name', 'id'])
```

To give a field a default value, you can assign to it in the class body:

```
class Employee(NamedTuple):
    name: str
```

(繼續下一頁)

(繼續上一頁)

```
    id: int = 3

employee = Employee('Guido')
assert employee.id == 3
```

Fields with a default value must come after any fields without a default.

The resulting class has an extra attribute `__annotations__` giving a dict that maps the field names to the field types. (The field names are in the `_fields` attribute and the default values are in the `_field_defaults` attribute, both of which are part of the *`namedtuple()`* API.)

`NamedTuple` subclasses can also have docstrings and methods:

```
class Employee(NamedTuple):
    """Represents an employee."""
    name: str
    id: int = 3

    def __repr__(self) -> str:
        return f'<Employee {self.name}, id={self.id}>'
```

`NamedTuple` subclasses can be generic:

```
class Group[T](NamedTuple):
    key: T
    group: list[T]
```

Backward-compatible usage:

```
# For creating a generic NamedTuple on Python 3.11
T = TypeVar("T")

class Group(NamedTuple, Generic[T]):
    key: T
    group: list[T]

# A functional syntax is also supported
Employee = NamedTuple('Employee', [('name', str), ('id', int)])
```

在 3.6 版的變更: Added support for **PEP 526** variable annotation syntax.

在 3.6.1 版的變更: Added support for default values, methods, and docstrings.

在 3.8 版的變更: The `_field_types` and `__annotations__` attributes are now regular dictionaries instead of instances of `OrderedDict`.

在 3.9 版的變更: Removed the `_field_types` attribute in favor of the more standard `__annotations__` attribute which has the same information.

在 3.11 版的變更: Added support for generic namedtuples.

在 3.14 版的變更: Using *`super()`* (and the `__class__` *closure variable*) in methods of `NamedTuple` subclasses is unsupported and causes a *`TypeError`*.

Deprecated since version 3.13, will be removed in version 3.15: The undocumented keyword argument syntax for creating NamedTuple classes (`NT = NamedTuple("NT", x=int)`) is deprecated, and will be disallowed in 3.15. Use the class-based syntax or the functional syntax instead.

Deprecated since version 3.13, will be removed in version 3.15: When using the functional syntax to create a NamedTuple class, failing to pass a value to the 'fields' parameter (`NT = NamedTuple("NT")`) is deprecated. Passing `None` to the 'fields' parameter (`NT = NamedTuple("NT", None)`) is also deprecated. Both will be disallowed in Python 3.15. To create a NamedTuple class with 0 fields, use `class NT(NamedTuple): pass` or `NT = NamedTuple("NT", [])`.

class typing.**NewType**(*name*, *tp*)

Helper class to create low-overhead *distinct types*.

A `NewType` is considered a distinct type by a typechecker. At runtime, however, calling a `NewType` returns its argument unchanged.

用法:

```
UserId = NewType('UserId', int)  # Declare the NewType "UserId"
first_user = UserId(1)  # "UserId" returns the argument unchanged at runtime
```

__module__

The module in which the new type is defined.

__name__

The name of the new type.

__supertype__

The type that the new type is based on.

在 3.5.2 版被加入.

在 3.10 版的變更: `NewType` is now a class rather than a function.

class typing.**Protocol**(*Generic*)

Base class for protocol classes.

Protocol classes are defined like this:

```
class Proto(Protocol):
    def meth(self) -> int:
        ...
```

Such classes are primarily used with static type checkers that recognize structural subtyping (static duck-typing), for example:

```
class C:
    def meth(self) -> int:
        return 0

def func(x: Proto) -> int:
    return x.meth()

func(C())  # Passes static type check
```

See **PEP 544** for more details. Protocol classes decorated with *runtime_checkable()* (described later) act as simple-minded runtime protocols that check only the presence of given attributes, ignoring their type signatures. Protocol classes without this decorator cannot be used as the second argument to *isinstance()* or *issubclass()*.

Protocol classes can be generic, for example:

```
class GenProto[T](Protocol):
    def meth(self) -> T:
        ...
```

In code that needs to be compatible with Python 3.11 or older, generic Protocols can be written as follows:

```
T = TypeVar("T")

class GenProto(Protocol[T]):
    def meth(self) -> T:
        ...
```

在 3.8 版被加入.

@typing.**runtime_checkable**

Mark a protocol class as a runtime protocol.

Such a protocol can be used with *isinstance()* and *issubclass()*. This allows a simple-minded structural check, very similar to "one trick ponies" in *collections.abc* such as *Iterable*. For example:

```
@runtime_checkable
class Closable(Protocol):
    def close(self): ...

assert isinstance(open('/some/file'), Closable)

@runtime_checkable
class Named(Protocol):
    name: str

import threading
assert isinstance(threading.Thread(name='Bob'), Named)
```

This decorator raises *TypeError* when applied to a non-protocol class.

> **備🄵**
>
> `runtime_checkable()` will check only the presence of the required methods or attributes, not their type signatures or types. For example, *ssl.SSLObject* is a class, therefore it passes an *issubclass()* check against *Callable*. However, the `ssl.SSLObject.__init__` method exists only to raise a *TypeError* with a more informative message, therefore making it impossible to call (instantiate) *ssl.SSLObject*.

> **備🄵**
>
> An *isinstance()* check against a runtime-checkable protocol can be surprisingly slow compared to an `isinstance()` check against a non-protocol class. Consider using alternative idioms such as *hasattr()* calls for structural checks in performance-sensitive code.

在 3.8 版被加入.

在 3.12 版的變更: The internal implementation of *isinstance()* checks against runtime-checkable protocols now uses *inspect.getattr_static()* to look up attributes (previously, *hasattr()* was used). As a result, some objects which used to be considered instances of a runtime-checkable protocol may no longer be considered instances of that protocol on Python 3.12+, and vice versa. Most users are unlikely to be affected by this change.

在 3.12 版的變更: The members of a runtime-checkable protocol are now considered "frozen" at runtime as soon as the class has been created. Monkey-patching attributes onto a runtime-checkable protocol will still work, but will have no impact on *isinstance()* checks comparing objects to the protocol. See What's new in Python 3.12 for more details.

class typing.**TypedDict**(*dict*)

Special construct to add type hints to a dictionary. At runtime it is a plain *dict*.

`TypedDict` declares a dictionary type that expects all of its instances to have a certain set of keys, where each key is associated with a value of a consistent type. This expectation is not checked at runtime but is only enforced by type checkers. Usage:

```
class Point2D(TypedDict):
    x: int
    y: int
```

(繼續下一頁)

(繼續上一頁)

```
    label: str

a: Point2D = {'x': 1, 'y': 2, 'label': 'good'}  # OK
b: Point2D = {'z': 3, 'label': 'bad'}           # Fails type check

assert Point2D(x=1, y=2, label='first') == dict(x=1, y=2, label='first')
```

An alternative way to create a `TypedDict` is by using function-call syntax. The second argument must be a literal *`dict`*:

```
Point2D = TypedDict('Point2D', {'x': int, 'y': int, 'label': str})
```

This functional syntax allows defining keys which are not valid identifiers, for example because they are keywords or contain hyphens, or when key names must not be mangled like regular private names:

```
# raises SyntaxError
class Point2D(TypedDict):
    in: int  # 'in' is a keyword
    x-y: int  # name with hyphens

class Definition(TypedDict):
    __schema: str  # mangled to `_Definition__schema`

# OK, functional syntax
Point2D = TypedDict('Point2D', {'in': int, 'x-y': int})
Definition = TypedDict('Definition', {'__schema': str})  # not mangled
```

By default, all keys must be present in a `TypedDict`. It is possible to mark individual keys as non-required using *`NotRequired`*:

```
class Point2D(TypedDict):
    x: int
    y: int
    label: NotRequired[str]

# 替代語法
Point2D = TypedDict('Point2D', {'x': int, 'y': int, 'label': NotRequired[str]})
```

This means that a `Point2D` `TypedDict` can have the `label` key omitted.

It is also possible to mark all keys as non-required by default by specifying a totality of `False`:

```
class Point2D(TypedDict, total=False):
    x: int
    y: int

# 替代語法
Point2D = TypedDict('Point2D', {'x': int, 'y': int}, total=False)
```

This means that a `Point2D` `TypedDict` can have any of the keys omitted. A type checker is only expected to support a literal `False` or `True` as the value of the `total` argument. `True` is the default, and makes all items defined in the class body required.

Individual keys of a `total=False` `TypedDict` can be marked as required using *`Required`*:

```
class Point2D(TypedDict, total=False):
    x: Required[int]
    y: Required[int]
    label: str

# 替代語法
```

(繼續下一頁)

(繼續上一頁)

```
Point2D = TypedDict('Point2D', {
    'x': Required[int],
    'y': Required[int],
    'label': str
}, total=False)
```

It is possible for a `TypedDict` type to inherit from one or more other `TypedDict` types using the class-based syntax. Usage:

```
class Point3D(Point2D):
    z: int
```

`Point3D` has three items: `x`, `y` and `z`. It is equivalent to this definition:

```
class Point3D(TypedDict):
    x: int
    y: int
    z: int
```

A `TypedDict` cannot inherit from a non-`TypedDict` class, except for *`Generic`*. For example:

```
class X(TypedDict):
    x: int

class Y(TypedDict):
    y: int

class Z(object): pass  # 一個非 TypedDict 的類🄵

class XY(X, Y): pass  # OK

class XZ(X, Z): pass  # 引發 TypeError
```

A `TypedDict` can be generic:

```
class Group[T](TypedDict):
    key: T
    group: list[T]
```

To create a generic `TypedDict` that is compatible with Python 3.11 or lower, inherit from *`Generic`* explicitly:

```
T = TypeVar("T")

class Group(TypedDict, Generic[T]):
    key: T
    group: list[T]
```

A `TypedDict` can be introspected via annotations dicts (see annotations-howto for more information on annotations best practices), *`__total__`*, *`__required_keys__`*, and *`__optional_keys__`*.

`__total__`

`Point2D.__total__` gives the value of the `total` argument. Example:

```
>>> from typing import TypedDict
>>> class Point2D(TypedDict): pass
>>> Point2D.__total__
True
>>> class Point2D(TypedDict, total=False): pass
>>> Point2D.__total__
False
>>> class Point3D(Point2D): pass
```

(繼續下一頁)

(繼續上一頁)

```
>>> Point3D.__total__
True
```

This attribute reflects *only* the value of the `total` argument to the current `TypedDict` class, not whether the class is semantically total. For example, a `TypedDict` with `__total__` set to `True` may have keys marked with *`NotRequired`*, or it may inherit from another `TypedDict` with `total=False`. Therefore, it is generally better to use *`__required_keys__`* and *`__optional_keys__`* for introspection.

`__required_keys__`

在 3.9 版被加入.

`__optional_keys__`

`Point2D.__required_keys__` and `Point2D.__optional_keys__` return *`frozenset`* objects containing required and non-required keys, respectively.

Keys marked with *`Required`* will always appear in `__required_keys__` and keys marked with *`NotRequired`* will always appear in `__optional_keys__`.

For backwards compatibility with Python 3.10 and below, it is also possible to use inheritance to declare both required and non-required keys in the same `TypedDict` . This is done by declaring a `TypedDict` with one value for the `total` argument and then inheriting from it in another `TypedDict` with a different value for `total`:

```
>>> class Point2D(TypedDict, total=False):
...     x: int
...     y: int
...
>>> class Point3D(Point2D):
...     z: int
...
>>> Point3D.__required_keys__ == frozenset({'z'})
True
>>> Point3D.__optional_keys__ == frozenset({'x', 'y'})
True
```

在 3.9 版被加入.

備🄵

If `from __future__ import annotations` is used or if annotations are given as strings, annotations are not evaluated when the `TypedDict` is defined. Therefore, the runtime introspection that `__required_keys__` and `__optional_keys__` rely on may not work properly, and the values of the attributes may be incorrect.

Support for *`ReadOnly`* is reflected in the following attributes:

`__readonly_keys__`

A *`frozenset`* containing the names of all read-only keys. Keys are read-only if they carry the *`ReadOnly`* qualifier.

在 3.13 版被加入.

`__mutable_keys__`

A *`frozenset`* containing the names of all mutable keys. Keys are mutable if they do not carry the *`ReadOnly`* qualifier.

在 3.13 版被加入.

See the TypedDict section in the typing documentation for more examples and detailed rules.

在 3.8 版被加入.

在 3.11 版的變更: Added support for marking individual keys as *Required* or *NotRequired*. See **PEP 655**.

在 3.11 版的變更: Added support for generic `TypedDict`s.

在 3.13 版的變更: Removed support for the keyword-argument method of creating `TypedDict`s.

在 3.13 版的變更: Support for the *ReadOnly* qualifier was added.

Deprecated since version 3.13, will be removed in version 3.15: When using the functional syntax to create a TypedDict class, failing to pass a value to the 'fields' parameter (`TD = TypedDict("TD")`) is deprecated. Passing `None` to the 'fields' parameter (`TD = TypedDict("TD", None)`) is also deprecated. Both will be disallowed in Python 3.15. To create a TypedDict class with 0 fields, use `class TD(TypedDict): pass` or `TD = TypedDict("TD", {})`.

協定

The following protocols are provided by the `typing` module. All are decorated with *@runtime_checkable*.

class typing.**SupportsAbs**

An ABC with one abstract method `__abs__` that is covariant in its return type.

class typing.**SupportsBytes**

一個有抽象方法 `__bytes__` 的 ABC。

class typing.**SupportsComplex**

一個有抽象方法 `__complex__` 的 ABC。

class typing.**SupportsFloat**

一個有抽象方法 `__float__` 的 ABC。

class typing.**SupportsIndex**

一個有抽象方法 `__index__` 的 ABC。

在 3.8 版被加入.

class typing.**SupportsInt**

一個有抽象方法 `__int__` 的 ABC。

class typing.**SupportsRound**

An ABC with one abstract method `__round__` that is covariant in its return type.

ABCs and Protocols for working with I/O

class typing.**IO**[*AnyStr*]()

class typing.**TextIO**[*AnyStr*]()

class typing.**BinaryIO**[*AnyStr*]()

Generic class `IO[AnyStr]` and its subclasses `TextIO(IO[str])` and `BinaryIO(IO[bytes])` represent the types of I/O streams such as returned by *open()*. Please note that these classes are not protocols, and their interface is fairly broad.

The protocols *io.Reader* and *io.Writer* offer a simpler alternative for argument types, when only the `read()` or `write()` methods are accessed, respectively:

```
def read_and_write(reader: Reader[str], writer: Writer[bytes]):
    data = reader.read()
    writer.write(data.encode())
```

Also consider using *collections.abc.Iterable* for iterating over the lines of an input stream:

```
def read_config(stream: Iterable[str]):
    for line in stream:
        ...
```

函式與裝飾器

typing.**cast**(*typ*, *val*)

Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don't check anything (we want this to be as fast as possible).

typing.**assert_type**(*val*, *typ*, /)

Ask a static type checker to confirm that *val* has an inferred type of *typ*.

At runtime this does nothing: it returns the first argument unchanged with no checks or side effects, no matter the actual type of the argument.

When a static type checker encounters a call to `assert_type()`, it emits an error if the value is not of the specified type:

```
def greet(name: str) -> None:
    assert_type(name, str)  # OK, inferred type of `name` is `str`
    assert_type(name, int)  # type checker error
```

This function is useful for ensuring the type checker's understanding of a script is in line with the developer's intentions:

```
def complex_function(arg: object):
    # Do some complex type-narrowing logic,
    # after which we hope the inferred type will be `int`
    ...
    # Test whether the type checker correctly understands our function
    assert_type(arg, int)
```

在 3.11 版被加入.

typing.**assert_never**(*arg*, /)

Ask a static type checker to confirm that a line of code is unreachable.

舉例來🄵:

```
def int_or_str(arg: int | str) -> None:
    match arg:
        case int():
            print("It's an int")
        case str():
            print("It's a str")
        case _ as unreachable:
            assert_never(unreachable)
```

Here, the annotations allow the type checker to infer that the last case can never execute, because `arg` is either an *int* or a *str*, and both options are covered by earlier cases.

If a type checker finds that a call to `assert_never()` is reachable, it will emit an error. For example, if the type annotation for `arg` was instead `int | str | float`, the type checker would emit an error pointing out that `unreachable` is of type *float*. For a call to `assert_never` to pass type checking, the inferred type of the argument passed in must be the bottom type, *Never*, and nothing else.

At runtime, this throws an exception when called.

也參考

Unreachable Code and Exhaustiveness Checking has more information about exhaustiveness checking with static typing.

在 3.11 版被加入.

typing.**reveal_type**(*obj*, /)

Ask a static type checker to reveal the inferred type of an expression.

When a static type checker encounters a call to this function, it emits a diagnostic with the inferred type of the argument. For example:

```
x: int = 1
reveal_type(x)  # Revealed type is "builtins.int"
```

This can be useful when you want to debug how your type checker handles a particular piece of code.

At runtime, this function prints the runtime type of its argument to *sys.stderr* and returns the argument unchanged (allowing the call to be used within an expression):

```
x = reveal_type(1)  # 印出 "Runtime type is int"
print(x)  # 印出 "1"
```

Note that the runtime type may be different from (more or less specific than) the type statically inferred by a type checker.

Most type checkers support `reveal_type()` anywhere, even if the name is not imported from `typing`. Importing the name from `typing`, however, allows your code to run without runtime errors and communicates intent more clearly.

在 3.11 版被加入.

@typing.**dataclass_transform**(**, eq_default=True, order_default=False, kw_only_default=False, frozen_default=False, field_specifiers=(), **kwargs*)

Decorator to mark an object as providing *dataclass*-like behavior.

`dataclass_transform` may be used to decorate a class, metaclass, or a function that is itself a decorator. The presence of `@dataclass_transform()` tells a static type checker that the decorated object performs runtime "magic" that transforms a class in a similar way to *@dataclasses.dataclass*.

Example usage with a decorator function:

```
@dataclass_transform()
def create_model[T](cls: type[T]) -> type[T]:
    ...
    return cls

@create_model
class CustomerModel:
    id: int
    name: str
```

On a base class:

```
@dataclass_transform()
class ModelBase: ...

class CustomerModel(ModelBase):
    id: int
    name: str
```

On a metaclass:

```
@dataclass_transform()
class ModelMeta(type): ...

class ModelBase(metaclass=ModelMeta): ...

class CustomerModel(ModelBase):
```

(繼續下一頁)

(繼續上一頁)

```
    id: int
    name: str
```

The `CustomerModel` classes defined above will be treated by type checkers similarly to classes created with *`@dataclasses.dataclass`*. For example, type checkers will assume these classes have `__init__` methods that accept `id` and `name`.

The decorated class, metaclass, or function may accept the following bool arguments which type checkers will assume have the same effect as they would have on the *`@dataclasses.dataclass`* decorator: `init`, `eq`, `order`, `unsafe_hash`, `frozen`, `match_args`, `kw_only`, and `slots`. It must be possible for the value of these arguments (`True` or `False`) to be statically evaluated.

The arguments to the `dataclass_transform` decorator can be used to customize the default behaviors of the decorated class, metaclass, or function:

參數

- **`eq_default`** (`bool`) -- Indicates whether the `eq` parameter is assumed to be `True` or `False` if it is omitted by the caller. Defaults to `True`.
- **`order_default`** (`bool`) -- Indicates whether the `order` parameter is assumed to be `True` or `False` if it is omitted by the caller. Defaults to `False`.
- **`kw_only_default`** (`bool`) -- Indicates whether the `kw_only` parameter is assumed to be `True` or `False` if it is omitted by the caller. Defaults to `False`.
- **`frozen_default`** (`bool`) -- Indicates whether the `frozen` parameter is assumed to be `True` or `False` if it is omitted by the caller. Defaults to `False`.

  在 3.12 版被加入.
- **`field_specifiers`** (*`tuple[Callable[..., Any], ...]`*) -- Specifies a static list of supported classes or functions that describe fields, similar to *`dataclasses.field()`*. Defaults to `()`.
- **`**kwargs`** (*`Any`*) -- Arbitrary other keyword arguments are accepted in order to allow for possible future extensions.

Type checkers recognize the following optional parameters on field specifiers:

表格 1: **Recognised parameters for field specifiers**

Parameter name	Description
`init`	Indicates whether the field should be included in the synthesized `__init__` method. If unspecified, `init` defaults to `True`.
`default`	Provides the default value for the field.
`default_factory`	Provides a runtime callback that returns the default value for the field. If neither `default` nor `default_factory` are specified, the field is assumed to have no default value and must be provided a value when the class is instantiated.
`factory`	An alias for the `default_factory` parameter on field specifiers.
`kw_only`	Indicates whether the field should be marked as keyword-only. If `True`, the field will be keyword-only. If `False`, it will not be keyword-only. If unspecified, the value of the `kw_only` parameter on the object decorated with `dataclass_transform` will be used, or if that is unspecified, the value of `kw_only_default` on `dataclass_transform` will be used.
`alias`	Provides an alternative name for the field. This alternative name is used in the synthesized `__init__` method.

At runtime, this decorator records its arguments in the `__dataclass_transform__` attribute on the decorated object. It has no other runtime effect.

更多細節請見 **PEP 681**。

在 3.11 版被加入.

`@typing.`**`overload`**

Decorator for creating overloaded functions and methods.

The `@overload` decorator allows describing functions and methods that support multiple different combinations of argument types. A series of `@overload`-decorated definitions must be followed by exactly one non-`@overload`-decorated definition (for the same function/method).

`@overload`-decorated definitions are for the benefit of the type checker only, since they will be overwritten by the non-`@overload`-decorated definition. The non-`@overload`-decorated definition, meanwhile, will be used at runtime but should be ignored by a type checker. At runtime, calling an `@overload`-decorated function directly will raise *`NotImplementedError`*.

An example of overload that gives a more precise type than can be expressed using a union or a type variable:

```
@overload
def process(response: None) -> None:
    ...
@overload
def process(response: int) -> tuple[int, str]:
    ...
@overload
def process(response: bytes) -> str:
    ...
def process(response):
    ...  # 實際的實作在這邊
```

See **PEP 484** for more details and comparison with other typing semantics.

在 3.11 版的變更: Overloaded functions can now be introspected at runtime using *`get_overloads()`*.

`typing.`**`get_overloads`**(*func*)

Return a sequence of *`@overload`*-decorated definitions for *func*.

func is the function object for the implementation of the overloaded function. For example, given the definition of `process` in the documentation for *`@overload`*, `get_overloads(process)` will return a sequence of three function objects for the three defined overloads. If called on a function with no overloads, `get_overloads()` returns an empty sequence.

`get_overloads()` can be used for introspecting an overloaded function at runtime.

在 3.11 版被加入.

`typing.`**`clear_overloads`**()

Clear all registered overloads in the internal registry.

This can be used to reclaim the memory used by the registry.

在 3.11 版被加入.

`@typing.`**`final`**

Decorator to indicate final methods and final classes.

Decorating a method with `@final` indicates to a type checker that the method cannot be overridden in a subclass. Decorating a class with `@final` indicates that it cannot be subclassed.

舉例來🄵:

```
class Base:
    @final
    def done(self) -> None:
        ...
class Sub(Base):
    def done(self) -> None:  # 型🄵檢查器回報的錯誤
        ...
```

(繼續下一頁)

(繼續上一頁)

```
@final
class Leaf:
    ...
class Other(Leaf):  # 型🄴檢查器回報的錯誤
    ...
```

這些屬性 (property) 不會在 runtime 時進行檢查。更多詳細資訊請看 **PEP 591**。

在 3.8 版被加入.

在 3.11 版的變更: The decorator will now attempt to set a `__final__` attribute to `True` on the decorated object. Thus, a check like `if getattr(obj, "__final__", False)` can be used at runtime to determine whether an object `obj` has been marked as final. If the decorated object does not support setting attributes, the decorator returns the object unchanged without raising an exception.

`@typing.`**`no_type_check`**

Decorator to indicate that annotations are not type hints.

This works as a class or function *decorator*. With a class, it applies recursively to all methods and classes defined in that class (but not to methods defined in its superclasses or subclasses). Type checkers will ignore all annotations in a function or class with this decorator.

`@no_type_check` mutates the decorated object in place.

`@typing.`**`no_type_check_decorator`**

Decorator to give another decorator the *`no_type_check()`* effect.

This wraps the decorator with something that wraps the decorated function in *`no_type_check()`*.

Deprecated since version 3.13, will be removed in version 3.15: No type checker ever added support for `@no_type_check_decorator`. It is therefore deprecated, and will be removed in Python 3.15.

`@typing.`**`override`**

Decorator to indicate that a method in a subclass is intended to override a method or attribute in a superclass.

Type checkers should emit an error if a method decorated with `@override` does not, in fact, override anything. This helps prevent bugs that may occur when a base class is changed without an equivalent change to a child class.

舉例來🄴:

```
class Base:
    def log_status(self) -> None:
        ...

class Sub(Base):
    @override
    def log_status(self) -> None:  # Okay: overrides Base.log_status
        ...

    @override
    def done(self) -> None:  # Error reported by type checker
        ...
```

There is no runtime checking of this property.

The decorator will attempt to set an `__override__` attribute to `True` on the decorated object. Thus, a check like `if getattr(obj, "__override__", False)` can be used at runtime to determine whether an object `obj` has been marked as an override. If the decorated object does not support setting attributes, the decorator returns the object unchanged without raising an exception.

更多細節請見 **PEP 698**。

在 3.12 版被加入.

@typing.**type_check_only**

Decorator to mark a class or function as unavailable at runtime.

This decorator is itself not available at runtime. It is mainly intended to mark classes that are defined in type stub files if an implementation returns an instance of a private class:

```
@type_check_only
class Response:  # private or not available at runtime
    code: int
    def get_header(self, name: str) -> str: ...

def fetch_response() -> Response: ...
```

Note that returning instances of private classes is not recommended. It is usually preferable to make such classes public.

Introspection helpers

typing.**get_type_hints**(*obj*, *globalns=None*, *localns=None*, *include_extras=False*)

Return a dictionary containing type hints for a function, method, module or class object.

This is often the same as `obj.__annotations__`, but this function makes the following changes to the annotations dictionary:

- Forward references encoded as string literals or *ForwardRef* objects are handled by evaluating them in *globalns*, *localns*, and (where applicable) *obj*'s type parameter namespace. If *globalns* or *localns* is not given, appropriate namespace dictionaries are inferred from *obj*.
- `None` is replaced with *types.NoneType*.
- If *@no_type_check* has been applied to *obj*, an empty dictionary is returned.
- If *obj* is a class `C`, the function returns a dictionary that merges annotations from `C`'s base classes with those on `C` directly. This is done by traversing `C.__mro__` and iteratively combining `__annotations__` dictionaries. Annotations on classes appearing earlier in the *method resolution order* always take precedence over annotations on classes appearing later in the method resolution order.
- The function recursively replaces all occurrences of `Annotated[T, ...]` with `T`, unless *include_extras* is set to `True` (see *Annotated* for more information).

See also *annotationlib.get_annotations()*, a lower-level function that returns annotations more directly.

> **警示**
>
> This function may execute arbitrary code contained in annotations. See *Security implications of introspecting annotations* for more information.

> **備🄵**
>
> If any forward references in the annotations of *obj* are not resolvable or are not valid Python code, this function will raise an exception such as *NameError*. For example, this can happen with imported *type aliases* that include forward references, or with names imported under *if TYPE_CHECKING*.

在 3.9 版的變更: 新增 `include_extras` 參數（如 **PEP 593** 中所述）。更多資訊請見*Annotated* 的文件。

在 3.11 版的變更: Previously, `Optional[t]` was added for function and method annotations if a default value equal to `None` was set. Now the annotation is returned unchanged.

typing.**get_origin**(*tp*)

Get the unsubscripted version of a type: for a typing object of the form `X[Y, Z, ...]` return `X`.

If `X` is a typing-module alias for a builtin or *collections* class, it will be normalized to the original class. If `X` is an instance of *ParamSpecArgs* or *ParamSpecKwargs*, return the underlying *ParamSpec*. Return `None` for unsupported objects.

舉例：

```
assert get_origin(str) is None
assert get_origin(Dict[str, int]) is dict
assert get_origin(Union[int, str]) is Union
assert get_origin(Annotated[str, "metadata"]) is Annotated
P = ParamSpec('P')
assert get_origin(P.args) is P
assert get_origin(P.kwargs) is P
```

在 3.8 版被加入.

typing.**get_args**(*tp*)

Get type arguments with all substitutions performed: for a typing object of the form `X[Y, Z, ...]` return `(Y, Z, ...)`.

If `X` is a union or *Literal* contained in another generic type, the order of `(Y, Z, ...)` may be different from the order of the original arguments `[Y, Z, ...]` due to type caching. Return `()` for unsupported objects.

舉例：

```
assert get_args(int) == ()
assert get_args(Dict[int, str]) == (int, str)
assert get_args(Union[int, str]) == (int, str)
```

在 3.8 版被加入.

typing.**get_protocol_members**(*tp*)

Return the set of members defined in a *Protocol*.

```
>>> from typing import Protocol, get_protocol_members
>>> class P(Protocol):
...     def a(self) -> str: ...
...     b: int
>>> get_protocol_members(P) == frozenset({'a', 'b'})
True
```

Raise *TypeError* for arguments that are not Protocols.

在 3.13 版被加入.

typing.**is_protocol**(*tp*)

確定一個型🄵是否*Protocol*。

舉例來🄵：

```
class P(Protocol):
    def a(self) -> str: ...
    b: int

is_protocol(P)     # => True
is_protocol(int)   # => False
```

在 3.13 版被加入.

typing.**is_typeddict**(*tp*)

Check if a type is a *TypedDict*.

舉例來🄵:

```
class Film(TypedDict):
    title: str
    year: int

assert is_typeddict(Film)
assert not is_typeddict(list | str)

# TypedDict is a factory for creating typed dicts,
# not a typed dict itself
assert not is_typeddict(TypedDict)
```

在 3.10 版被加入.

class typing.**ForwardRef**

Class used for internal typing representation of string forward references.

For example, `List["SomeClass"]` is implicitly transformed into `List[ForwardRef("SomeClass")]`. `ForwardRef` should not be instantiated by a user, but may be used by introspection tools.

> **備🄵**
>
> **PEP 585** generic types such as `list["SomeClass"]` will not be implicitly transformed into `list[ForwardRef("SomeClass")]` and thus will not automatically resolve to `list[SomeClass]`.

在 3.7.4 版被加入.

在 3.14 版的變更: This is now an alias for *annotationlib.ForwardRef*. Several undocumented behaviors of this class have been changed; for example, after a `ForwardRef` has been evaluated, the evaluated value is no longer cached.

typing.**evaluate_forward_ref**(*forward_ref*, *, *owner=None*, *globals=None*, *locals=None*, *type_params=None*, *format=annotationlib.Format.VALUE*)

Evaluate an *annotationlib.ForwardRef* as a *type hint*.

This is similar to calling *annotationlib.ForwardRef.evaluate()*, but unlike that method, `evaluate_forward_ref()` also recursively evaluates forward references nested within the type hint.

See the documentation for *annotationlib.ForwardRef.evaluate()* for the meaning of the *owner*, *globals*, *locals*, *type_params*, and *format* parameters.

> **警示**
>
> This function may execute arbitrary code contained in annotations. See *Security implications of introspecting annotations* for more information.

在 3.14 版被加入.

typing.**NoDefault**

A sentinel object used to indicate that a type parameter has no default value. For example:

```
>>> T = TypeVar("T")
>>> T.__default__ is typing.NoDefault
True
>>> S = TypeVar("S", default=None)
>>> S.__default__ is None
True
```

在 3.13 版被加入.

常數

typing.**TYPE_CHECKING**

A special constant that is assumed to be `True` by 3rd party static type checkers. It's `False` at runtime.

A module which is expensive to import, and which only contain types used for typing annotations, can be safely imported inside an `if TYPE_CHECKING:` block. This prevents the module from actually being imported at runtime; annotations aren't eagerly evaluated (see **PEP 649**) so using undefined symbols in annotations is harmless--as long as you don't later examine them. Your static type analysis tool will set `TYPE_CHECKING` to `True` during static type analysis, which means the module will be imported and the types will be checked properly during such analysis.

用法:

```
if TYPE_CHECKING:
    import expensive_mod

def fun(arg: expensive_mod.SomeType) -> None:
    local_var: expensive_mod.AnotherType = other_fun()
```

If you occasionally need to examine type annotations at runtime which may contain undefined symbols, use *annotationlib.get_annotations()* with a `format` parameter of *annotationlib.Format.STRING* or *annotationlib.Format.FORWARDREF* to safely retrieve the annotations without raising *NameError*.

在 3.5.2 版被加入.

🄵用的🄵名

This module defines several deprecated aliases to pre-existing standard library classes. These were originally included in the `typing` module in order to support parameterizing these generic classes using `[]`. However, the aliases became redundant in Python 3.9 when the corresponding pre-existing classes were enhanced to support `[]` (see **PEP 585**).

The redundant types are deprecated as of Python 3.9. However, while the aliases may be removed at some point, removal of these aliases is not currently planned. As such, no deprecation warnings are currently issued by the interpreter for these aliases.

If at some point it is decided to remove these deprecated aliases, a deprecation warning will be issued by the interpreter for at least two releases prior to removal. The aliases are guaranteed to remain in the `typing` module without deprecation warnings until at least Python 3.14.

Type checkers are encouraged to flag uses of the deprecated types if the program they are checking targets a minimum Python version of 3.9 or newer.

🄵建型🄵的🄵名

class typing.**Dict**(*dict, MutableMapping[KT, VT]*)

🄵用*dict* 的🄵名。

Note that to annotate arguments, it is preferred to use an abstract collection type such as *Mapping* rather than to use *dict* or `typing.Dict`.

在 3.9 版之後被🄵用: *builtins.dict* now supports subscripting (`[]`). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**List**(*list, MutableSequence[T]*)

🄵用*list* 的🄵名。

Note that to annotate arguments, it is preferred to use an abstract collection type such as *Sequence* or *Iterable* rather than to use *list* or `typing.List`.

在 3.9 版之後被🄵用: *builtins.list* now supports subscripting (`[]`). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Set**(*set, MutableSet[T]*)

🄵用*builtins.set* 的🄵名。

Note that to annotate arguments, it is preferred to use an abstract collection type such as *collections.abc.Set* rather than to use *set* or *typing.Set*.

在 3.9 版之後被🄵用: *builtins.set* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**FrozenSet**(*frozenset, AbstractSet[T_co]*)

🄵用*builtins.frozenset* 的🄵名。

在 3.9 版之後被🄵用: *builtins.frozenset* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

typing.**Tuple**

🄵用*tuple* 的🄵名。

tuple and Tuple are special-cased in the type system; see *🄵釋元組 (tuple)* for more details.

在 3.9 版之後被🄵用: *builtins.tuple* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Type**(*Generic[CT_co]*)

🄵用*type* 的🄵名。

See *類🄵物件的型🄵* for details on using *type* or typing.Type in type annotations.

在 3.5.2 版被加入.

在 3.9 版之後被🄵用: *builtins.type* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

collections 中型🄵的🄵名

class typing.**DefaultDict**(*collections.defaultdict, MutableMapping[KT, VT]*)

🄵用*collections.defaultdict* 的🄵名。

在 3.5.2 版被加入.

在 3.9 版之後被🄵用: *collections.defaultdict* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**OrderedDict**(*collections.OrderedDict, MutableMapping[KT, VT]*)

🄵用*collections.OrderedDict* 的🄵名。

在 3.7.2 版被加入.

在 3.9 版之後被🄵用: *collections.OrderedDict* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**ChainMap**(*collections.ChainMap, MutableMapping[KT, VT]*)

🄵用*collections.ChainMap* 的🄵名。

在 3.6.1 版被加入.

在 3.9 版之後被🄵用: *collections.ChainMap* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Counter**(*collections.Counter, Dict[T, int]*)

🄵用*collections.Counter* 的🄵名。

在 3.6.1 版被加入.

在 3.9 版之後被🄵用: *collections.Counter* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Deque**(*deque, MutableSequence[T]*)

🄵用*collections.deque* 的🄵名。

在 3.6.1 版被加入.

在 3.9 版之後被🄵用: *collections.deque* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

Aliases to other concrete types

class typing.**Pattern**

class typing.**Match**

Deprecated aliases corresponding to the return types from *re.compile()* and *re.match()*.

These types (and the corresponding functions) are generic over *AnyStr*. `Pattern` can be specialised as `Pattern[str]` or `Pattern[bytes]`; `Match` can be specialised as `Match[str]` or `Match[bytes]`.

在 3.9 版之後被🄵用: Classes `Pattern` and `Match` from *re* now support `[]`. See **PEP 585** and 泛型🄵名型🄵.

class typing.**Text**

🄵用*str* 的🄵名。

`Text` is provided to supply a forward compatible path for Python 2 code: in Python 2, `Text` is an alias for `unicode`.

Use `Text` to indicate that a value must contain a unicode string in a manner that is compatible with both Python 2 and Python 3:

```
def add_unicode_checkmark(text: Text) -> Text:
    return text + u' \u2713'
```

在 3.5.2 版被加入.

在 3.11 版之後被🄵用: Python 2 is no longer supported, and most type checkers also no longer support type checking Python 2 code. Removal of the alias is not currently planned, but users are encouraged to use *str* instead of `Text`.

collections.abc 中容器 ABC 的🄵名

class typing.**AbstractSet**(*Collection[T_co]*)

🄵用*collections.abc.Set* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Set* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

class typing.**ByteString**(*Sequence[int]*)

Deprecated alias to *collections.abc.ByteString*.

Use `isinstance(obj, collections.abc.Buffer)` to test if `obj` implements the buffer protocol at runtime. For use in type annotations, either use *Buffer* or a union that explicitly specifies the types your code supports (e.g., `bytes | bytearray | memoryview`).

`ByteString` was originally intended to be an abstract class that would serve as a supertype of both *bytes* and *bytearray*. However, since the ABC never had any methods, knowing that an object was an instance of `ByteString` never actually told you anything useful about the object. Other common buffer types such as *memoryview* were also never understood as subtypes of `ByteString` (either at runtime or by static type checkers).

See **PEP 688** for more details.

Deprecated since version 3.9, will be removed in version 3.17.

class typing.**Collection**(*Sized, Iterable[T_co], Container[T_co]*)

🄵用*collections.abc.Collection* 的🄵名。

在 3.6 版被加入.

在 3.9 版之後被🄵用: *collections.abc.Collection* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Container**(*Generic[T_co]*)

🄵用*collections.abc.Container* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Container* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**ItemsView**(*MappingView, AbstractSet[tuple[KT_co, VT_co]]*)

🄵用*collections.abc.ItemsView* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.ItemsView* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**KeysView**(*MappingView, AbstractSet[KT_co]*)

🄵用*collections.abc.KeysView* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.KeysView* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Mapping**(*Collection[KT], Generic[KT, VT_co]*)

🄵用*collections.abc.Mapping* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Mapping* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**MappingView**(*Sized*)

🄵用*collections.abc.MappingView* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.MappingView* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**MutableMapping**(*Mapping[KT, VT]*)

🄵用*collections.abc.MutableMapping* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.MutableMapping* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**MutableSequence**(*Sequence[T]*)

🄵用*collections.abc.MutableSequence* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.MutableSequence* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**MutableSet**(*AbstractSet[T]*)

🄵用*collections.abc.MutableSet* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.MutableSet* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**Sequence**(*Reversible[T_co], Collection[T_co]*)

🄵用*collections.abc.Sequence* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Sequence* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

class typing.**ValuesView**(*MappingView, Collection[_VT_co]*)

🄵用*collections.abc.ValuesView* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.ValuesView* now supports subscripting ([]). See **PEP 585** and *泛型🄵名型🄵*.

collections.abc 中非同步 ABC 的🄵名

class typing.**Coroutine**(*Awaitable[ReturnType], Generic[YieldType, SendType, ReturnType]*)

🄵用*collections.abc.Coroutine* 的🄵名。

See *Annotating generators and coroutines* for details on using *collections.abc.Coroutine* and `typing.Coroutine` in type annotations.

在 3.5.3 版被加入.

在 3.9 版之後被🄵用: *collections.abc.Coroutine* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

class typing.**AsyncGenerator**(*AsyncIterator[YieldType], Generic[YieldType, SendType]*)

🄵用*collections.abc.AsyncGenerator* 的🄵名。

See *Annotating generators and coroutines* for details on using *collections.abc.AsyncGenerator* and `typing.AsyncGenerator` in type annotations.

在 3.6.1 版被加入.

在 3.9 版之後被🄵用: *collections.abc.AsyncGenerator* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

在 3.13 版的變更: `SendType` 參數現在有預設值。

class typing.**AsyncIterable**(*Generic[T_co]*)

🄵用*collections.abc.AsyncIterable* 的🄵名。

在 3.5.2 版被加入.

在 3.9 版之後被🄵用: *collections.abc.AsyncIterable* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

class typing.**AsyncIterator**(*AsyncIterable[T_co]*)

🄵用*collections.abc.AsyncIterator* 的🄵名。

在 3.5.2 版被加入.

在 3.9 版之後被🄵用: *collections.abc.AsyncIterator* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

class typing.**Awaitable**(*Generic[T_co]*)

🄵用*collections.abc.Awaitable* 的🄵名。

在 3.5.2 版被加入.

在 3.9 版之後被🄵用: *collections.abc.Awaitable* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

Aliases to other ABCs in collections.abc

class typing.**Iterable**(*Generic[T_co]*)

🄵用*collections.abc.Iterable* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Iterable* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

class typing.**Iterator**(*Iterable[T_co]*)

🄵用*collections.abc.Iterator* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Iterator* now supports subscripting (`[]`). See **PEP 585** and 泛型🄵名型🄵.

typing.**Callable**

🄵用*collections.abc.Callable* 的🄵名。

See 🄵釋 *callable 物件* for details on how to use *collections.abc.Callable* and typing.Callable in type annotations.

在 3.9 版之後被🄵用: *collections.abc.Callable* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

在 3.10 版的變更: Callable 現已支援*ParamSpec* 以及*Concatenate*。請參🄵 **PEP 612** 🄵讀詳細🄵容。

class typing.**Generator**(*Iterator[YieldType], Generic[YieldType, SendType, ReturnType]*)

🄵用*collections.abc.Generator* 的🄵名。

See *Annotating generators and coroutines* for details on using *collections.abc.Generator* and typing.Generator in type annotations.

在 3.9 版之後被🄵用: *collections.abc.Generator* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

在 3.13 版的變更: Default values for the send and return types were added.

class typing.**Hashable**

🄵用*collections.abc.Hashable* 的🄵名。

在 3.12 版之後被🄵用: 改🄵直接使用*collections.abc.Hashable*。

class typing.**Reversible**(*Iterable[T_co]*)

🄵用*collections.abc.Reversible* 的🄵名。

在 3.9 版之後被🄵用: *collections.abc.Reversible* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

class typing.**Sized**

🄵用*collections.abc.Sized* 的🄵名。

在 3.12 版之後被🄵用: 改🄵直接使用*collections.abc.Sized*。

contextlib ABC 的🄵名

class typing.**ContextManager**(*Generic[T_co, ExitT_co]*)

Deprecated alias to *contextlib.AbstractContextManager*.

The first type parameter, T_co, represents the type returned by the __enter__() method. The optional second type parameter, ExitT_co, which defaults to bool | None, represents the type returned by the __exit__() method.

在 3.5.4 版被加入.

在 3.9 版之後被🄵用: *contextlib.AbstractContextManager* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

在 3.13 版的變更: Added the optional second type parameter, ExitT_co.

class typing.**AsyncContextManager**(*Generic[T_co, AExitT_co]*)

Deprecated alias to *contextlib.AbstractAsyncContextManager*.

The first type parameter, T_co, represents the type returned by the __aenter__() method. The optional second type parameter, AExitT_co, which defaults to bool | None, represents the type returned by the __aexit__() method.

在 3.6.2 版被加入.

在 3.9 版之後被🄵用: *contextlib.AbstractAsyncContextManager* now supports subscripting ([]). See **PEP 585** and 泛型🄵名型🄵.

在 3.13 版的變更: Added the optional second type parameter, AExitT_co.

26.1.13 主要功能的🄵用時程表

Certain features in `typing` are deprecated and may be removed in a future version of Python. The following table summarizes major deprecations for your convenience. This is subject to change, and not all deprecations are listed.

Feature	🄵 用於	Projected removal	PEP/issue
`typing` versions of standard collections	3.9	Undecided (see 🄵用的🄵名 for more information)	**PEP 585**
typing.ByteString	3.9	3.17	gh-91896
typing.Text	3.11	Undecided	gh-92332
typing.Hashable 和 *typing.Sized*	3.12	Undecided	gh-94309
typing.TypeAlias	3.12	Undecided	**PEP 695**
@typing.no_type_check_decorator	3.13	3.15	gh-106309
typing.AnyStr	3.13	3.18	gh-105578

26.2 pydoc --- 文件🄵生器與🄵上幫助系統

原始碼： Lib/pydoc.py

`pydoc` 模組會自動從 Python 模組🄵生文件。文件可以以文字頁面的形式呈現在主控台上、提供給網頁🄵覽器，或儲存🄵 HTML 檔案。

對於模組、類🄵、函式和方法，所顯示的文件是從物件的🄵明字串（也就是物件的*__doc__* 屬性）以及遞🄵地從其可文件化成員的🄵明字串所取得。如果🄵有🄵明字串，`pydoc` 會嘗試從原始碼檔案中，類🄵、函式或方法定義正上方的🄵解區塊，或從模組的頂部取得描述（參見*inspect.getcomments()*）。

🄵建函式*help()* 會在互動式直譯器中呼叫🄵上幫助系統，它會使用 `pydoc` 在主控台上以文字形式🄵生文件。同樣的文字文件也可以在 Python 直譯器外部檢視，方法是在作業系統的命令提示字元中，將 **pydoc** 當作🄵本執行。例如，執行：

```
python -m pydoc sys
```

在 shell 提示字元下，將會顯示*sys* 模組的文件，其風格類似於 Unix **man** 命令所顯示的使用手🄵。**pydoc** 的引數可以是函式、模組或套件的名稱，或是一個指向模組中或套件中模組🄵的類🄵、方法或函式的點號參照 (dotted reference)。如果 **pydoc** 的引數看起來像一個路徑（也就是🄵，它包含你作業系統的路徑分隔符，例如 Unix 中的斜🄵），🄵且指向一個已存在的 Python 原始碼檔案，那🄵就會🄵該檔案🄵生文件。

> **備🄵**
>
> 🄵了找到物件及其文件，`pydoc` 會引入要文件化的模組。因此，任何在模組層級的程式碼都會在那個時候被執行。使用 `if __name__ == '__main__':` 的防護措施，可以確保程式碼只在檔案作🄵🄵本被呼叫時執行，而不會在被引入時就執行。

當在主控台印出輸出🄵容時，**pydoc** 會嘗試將輸出🄵容做分頁以便於🄵讀。如果 `MANPAGER` 或 `PAGER` 環境變數其中之一被設定，**pydoc** 將會使用其值作🄵分頁程式。當兩者都被設定時，會使用 `MANPAGER`。

在引數前指定一個 `-w` 旗標，將會使 HTML 文件被寫入目前目🄵的一個檔案中，而不是在主控台上顯示文字。

在引數前指定一個 `-k` 旗標，將會搜尋所有可用模組的摘要行 (synopsis lines)，尋找作🄵引數給出的關鍵字，其方式同樣類似於 Unix 的 **man** 命令。一個模組的摘要行是其🄵明字串的第一行。

你也可以使用 **pydoc** 在本機上🄵動一個 HTTP 伺服器，它會向來訪的網頁🄵覽器提供文件。**python -m pydoc -p 1234** 將會在 1234 埠🄵動一個 HTTP 伺服器，讓你可以用你偏好的網頁🄵覽器在 `http://localhost:1234/` 🄵覽文件。指定 `0` 作🄵通訊埠編號將會選擇一個任意未使用的通訊埠。

python -m pydoc -n <hostname> 將會🄵動伺服器🄵在給定的主機名稱上監聽。預設的主機名稱是'localhost'，但如果你希望伺服器能被其他機器連🄵，你可能會想改變伺服器回應的主機名稱。在開發期間，如果你想在容器🄵執行 pydoc，這點特🄵有用。

python -m pydoc -b 將會🄵動伺服器，🄵額外開🄵一個網頁🄵覽器到模組索引頁面。每個提供的頁面頂部都有一個導覽列，你可以在那🄵 *Get*（取得）個🄵項目的幫助、*Search*（搜尋）所有在其摘要行中包含關鍵字的模組，以及前往 *Module index*（模組索引）、*Topics*（主題）和 *Keywords*（關鍵字）頁面。

當 **pydoc** 🄵生文件時，它會使用目前的環境和路徑來定位模組。因此，呼叫 **pydoc spam** 所🄵生的文件，會完全對應到你🄵動 Python 直譯器🄵輸入 `import spam` 時所取得的模組版本。

核心模組的文件被假定存放在 `https://docs.python.org/X.Y/library/`，其中 `X` 和 `Y` 是 Python 直譯器的主版本號和次版本號。這可以透過將 `PYTHONDOCS` 環境變數設定🄵不同的 URL 或包含函式庫參考使用手🄵的本機目🄵來覆寫。

在 3.2 版的變更: 新增 `-b` 選項。

在 3.3 版的變更: 移除 `-g` 命令列選項。

在 3.4 版的變更: `pydoc` 現在使用 *inspect.signature()* 而不是 *inspect.getfullargspec()* 來從可呼叫物件中提取簽章資訊。

在 3.7 版的變更: 新增 `-n` 選項。

26.3 Python 開發模式

在 3.7 版被加入.

Python 開發模式引入了額外的 runtime 檢查，預設🄵用這些檢查的成本太高。如果程式碼正確，它不應比預設值更詳細；僅當偵測到問題時才會發出新警告。

可以使用 `-X dev` 命令列選項或將 `PYTHONDEVMODE` 環境變數設🄵 1 來🄵用它。

另請參🄵 Python 除錯建置。

26.3.1 Python 開發模式的影響

🄵用 Python 開發模式類似以下指令，但具有如下所述的附加效果：

```
PYTHONMALLOC=debug PYTHONASYNCIODEBUG=1 python -W default -X faulthandler
```

Python 開發模式的效果：

- 新增 `default` 警告過濾器。以下警告會被顯示：
  - *DeprecationWarning*
  - *ImportWarning*
  - *PendingDeprecationWarning*
  - *ResourceWarning*

  一般來🄵，上述警告會被預設的警告過濾器給過濾掉。

  它的行🄵就像使用 `-W default` 命令列選項一樣。

  使用 `-W error` 命令列選項或將 `PYTHONWARNINGS` 環境變數設🄵 `error` 會將警告視🄵錯誤。
- 在記憶體分配器上安裝除錯 hook（🄵🄵）以檢查：
  - 緩衝區下溢 (underflow)
  - 緩衝區溢位 (overflow)

  - 記憶體分配器 API 違規
  - GIL 的不安全使用

  請參🄵 `PyMem_SetupDebugHooks()` C 函式。

  它的行🄵就好像是將 `PYTHONMALLOC` 環境變數設定🄵 `debug` 一樣。

  若要🄵用 Python 開發模式而不在記憶體分配器上安裝偵錯 hook，請將 `PYTHONMALLOC` 環境變數設🄵 `default`。

- 在 Python 🄵動時呼叫 *`faulthandler.enable()`* 來🄵 *`SIGSEGV`*、*`SIGFPE`*、*`SIGABRT`*、*`SIGBUS`* 和 *`SIGILL`* 訊號安裝處理函式以在當機時傾印 (dump) Python 回溯 (traceback)。

  它的行🄵就像使用 `-X faulthandler` 命令列選項或將 `PYTHONFAULTHANDLER` 環境變數設定🄵 `1`。

- 🄵用 *asyncio 除錯模式*。例如 *`asyncio`* 會檢查未被等待的 (not awaited) 協程🄵記🄵 (log) 它們。

  它的行🄵就像將 `PYTHONASYNCIODEBUG` 環境變數設定🄵 1 一樣。

- 檢查字串編碼和解碼操作的 *encoding* 和 *errors* 引數。例如：*`open()`*、*`str.encode()`* 和 *`bytes.decode()`*。

  預設情🄵下，🄵了獲得最佳效能，僅在第一個編碼/解碼錯誤時檢查 *errors* 引數，🄵且有時會因🄵是空字串而忽略 *encoding* 引數。

- *`io.IOBase`* 解構函式會記🄵 `close()` 例外。

- 將 *`sys.flags`* 的 *`dev_mode`* 屬性設🄵 `True`。

Python 開發模式預設不會🄵用 *`tracemalloc`* 模組，因🄵（效能和記憶體的）開銷太大。🄵用 *`tracemalloc`* 模組可提供有關某些錯誤來源的附加資訊。例如 *`ResourceWarning`* 記🄵了分配資源之處的回溯、緩衝區溢位錯誤記🄵了分配記憶體區塊的回溯。

Python 開發模式不會防止 `-O` 命令列選項🄵除 `assert` 陳述式，也不會防止將 *`__debug__`* 設定🄵 `False`。

Python 開發模式只能在 Python 🄵動時🄵用。它的值可以從 *`sys.flags.dev_mode`* 讀取。

在 3.8 版的變更: *`io.IOBase`* 解構函式現在會記🄵 `close()` 例外。

在 3.9 版的變更: 現在會🄵字串編碼和解碼操作檢查 *encoding* 和 *errors* 引數。

26.3.2 ResourceWarning 范例

計算命令列中指定的文字檔案列數的🄵本範例：

```
import sys

def main():
    fp = open(sys.argv[1])
    nlines = len(fp.readlines())
    print(nlines)
    # The file is closed implicitly

if __name__ == "__main__":
    main()
```

該🄵本不會明確關閉檔案。預設情🄵下，Python 不會發出任何警告。使用 README.txt 的範例，該檔案有 269 列：

```
$ python script.py README.txt
269
```

🄵用 Python 開發模式會顯示 *`ResourceWarning`* 警告：

```
$ python -X dev script.py README.txt
269
script.py:10: ResourceWarning: unclosed file <_io.TextIOWrapper name='README.rst' mode='r'␣
↪encoding='UTF-8'>
  main()
ResourceWarning: Enable tracemalloc to get the object allocation traceback
```

此外，🄵用*tracemalloc* 會顯示檔案被開🄴的那一列：

```
$ python -X dev -X tracemalloc=5 script.py README.rst
269
script.py:10: ResourceWarning: unclosed file <_io.TextIOWrapper name='README.rst' mode='r'␣
↪encoding='UTF-8'>
  main()
Object allocated at (most recent call last):
  File "script.py", lineno 10
    main()
  File "script.py", lineno 4
    fp = open(sys.argv[1])
```

修復方法是明確關閉該檔案。以下是使用情境管理器的範例：

```
def main():
    # Close the file explicitly when exiting the with block
    with open(sys.argv[1]) as fp:
        nlines = len(fp.readlines())
    print(nlines)
```

不明確關閉資源可能會使資源開🄴的時間比預期的長得多；它可能會在退出 Python 時導致嚴重問題。在 CPython 中很糟糕，但在 PyPy 中更糟。明確關閉資源使應用程式更具確定性和可靠性。

26.3.3 檔案描述器的錯誤范例

顯示自身第一列的🄵本：

```
import os

def main():
    fp = open(__file__)
    firstline = fp.readline()
    print(firstline.rstrip())
    os.close(fp.fileno())
    # The file is closed implicitly

main()
```

預設情🄵下，Python 不會發出任何警告：

```
$ python script.py
import os
```

Python 開發模式在最終化 (finalize) 檔案物件時顯示*ResourceWarning* 🄴記🄵"Bad file descriptor" 錯誤：

```
$ python -X dev script.py
import os
script.py:10: ResourceWarning: unclosed file <_io.TextIOWrapper name='script.py' mode='r'␣
↪encoding='UTF-8'>
  main()
ResourceWarning: Enable tracemalloc to get the object allocation traceback
Exception ignored in: <_io.TextIOWrapper name='script.py' mode='r' encoding='UTF-8'>
Traceback (most recent call last):
```

(繼續下一頁)

(繼續上一頁)

```
  File "script.py", line 10, in <module>
    main()
OSError: [Errno 9] Bad file descriptor
```

`os.close(fp.fileno())` 會關閉檔案描述器。當檔案物件最終化函式 (finalizer) 嘗試再次關閉檔案描述器時，它會失敗🄴出現 `Bad file descriptor` 錯誤。檔案描述器只能關閉一次。在最壞的情🄵下，將它關閉兩次可能會導致崩潰 (crash)（相關範例請參🄵 bpo-18748）。

修復方法是🄵除 `os.close(fp.fileno())` 那列，或使用 `closefd=False` 開🄵檔案。

26.4 `doctest` --- 測試互動式 Python 范例

原始碼： Lib/doctest.py

The *doctest* module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module's docstrings are up-to-date by verifying that all interactive examples still work as documented.
- 透過驗證測試檔案或測試物件中的互動式範例是否按預期運作來執行🄵歸測試。
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of "literate testing" or "executable documentation".

Here's a complete but small example module:

```
"""
This is the "example" module.

The example module supplies one function, factorial().  For example,

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.

    >>> [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> factorial(30)
    265252859812191058636308480000000
    >>> factorial(-1)
    Traceback (most recent call last):
        ...
    ValueError: n must be >= 0

    Factorials of floats are OK, but the float must be an exact integer:
    >>> factorial(30.1)
    Traceback (most recent call last):
        ...
    ValueError: n must be exact integer
    >>> factorial(30.0)
    265252859812191058636308480000000

    It must also not be ridiculously large:
    >>> factorial(1e100)
    Traceback (most recent call last):
```

(繼續下一頁)

(繼續上一頁)

```
        ...
    OverflowError: n too large
    """

    import math
    if not n >= 0:
        raise ValueError("n must be >= 0")
    if math.floor(n) != n:
        raise ValueError("n must be exact integer")
    if n+1 == n:  # catch a value like 1e300
        raise OverflowError("n too large")
    result = 1
    factor = 2
    while factor <= n:
        result *= factor
        factor += 1
    return result

if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

If you run `example.py` directly from the command line, *doctest* works its magic:

```
$ python example.py
$
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and *doctest* prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
        ...
    OverflowError: n too large
ok
2 items passed all tests:
   1 test in __main__
   6 tests in __main__.factorial
7 tests in 2 items.
7 passed.
Test passed.
$
```

That's all you need to know to start making productive use of *doctest*! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially

useful examples can be found in the standard test file `Lib/test/test_doctest/test_doctest.py`.

在 3.13 版被加入: Output is colorized by default and can be controlled using environment variables.

26.4.1 Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module `M` with:

```
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

`doctest` then examines docstrings in module `M`.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures.`, where *N* is the number of examples that failed.

Run it with the `-v` switch instead:

```
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to *`testmod()`*, or prohibit it by passing `verbose=False`. In either of those cases, *`sys.argv`* is not examined by *`testmod()`* (so passing `-v` or not has no effect).

There is also a command line shortcut for running *`testmod()`*, see section 命令列用法.

For more information on *`testmod()`*, see section 基礎 *API*.

26.4.2 Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the *`testfile()`* function:

```
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
======================

Using ``factorial``
-------------------

This is an example text file in reStructuredText format.  First import
``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with *testmod()*, *testfile()* won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, *testfile()* looks for files in the calling module's directory. See section 基礎 *API* for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like *testmod()*, *testfile()*'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument *verbose*.

There is also a command line shortcut for running *testfile()*, see section 命令列用法.

For more information on *testfile()*, see section 基礎 *API*.

26.4.3 命令列用法

可以從命令列以🄵本方式叫用*doctest* 模組:

```
python -m doctest [-v] [-o OPTION] [-f] file [file ...]
```

-v, --verbose

Detailed report of all examples tried is printed to standard output, along with assorted summaries at the end:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run *testmod()* on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

If the file name does not end with `.py`, `doctest` infers that it must be run with *testfile()* instead:

```
python -m doctest -v example.txt
```

-o, --option <option>

Option flags control various aspects of doctest's behavior, see section 可選旗標.

在 3.4 版被加入.

-f, --fail-fast

This is shorthand for `-o FAIL_FAST`.

在 3.4 版被加入.

26.4.4 運作方式

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched. In addition, there are cases when you want tests to be part of a module but not part of the help text, which requires that the tests not be included in the docstring. Doctest looks for a module-level variable called

`__test__` and uses it to locate other tests. If `M.__test__` exists, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from `M.__test__` are searched, and strings are treated as if they were docstrings. In output, a key `K` in `M.__test__` appears with name `M.__test__.K`.

For example, place this block of code at the top of `example.py`:

```
__test__ = {
    'numbers': """
>>> factorial(6)
720

>>> [factorial(n) for n in range(6)]
[1, 1, 2, 6, 24, 120]
"""
}
```

The value of `example.__test__["numbers"]` will be treated as a docstring and all the tests inside it will be run. It is important to note that the value can be mapped to a function, class object, or module; if so, `doctest` searches them recursively for docstrings, which are then scanned for tests.

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

備🄵

`doctest` can only automatically discover classes and functions that are defined at the module level or inside other classes.

Since nested classes and functions only exist when an outer function is called, they cannot be discovered. Define them outside to make them visible.

How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn't trying to do an exact emulation of any specific Python shell.

```
>>> # 🄵解會被忽略
>>> x = 12
>>> x
12
>>> if x == 13:
...     print("yes")
... else:
...     print("no")
...     print("NO")
...     print("NO!!!")
...
no
NO
NO!!!
>>>
```

Any expected output must immediately follow the final `'>>> '` or `'... '` line containing the code, and the expected output (if any) extends to the next `'>>> '` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.
- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output *are* expanded, this means that if the

code output includes hard tabs, the only way the doctest can pass is if the *NORMALIZE_WHITESPACE* option or *directive* is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom *DocTestParser* class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).
- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
...
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```
>>> def f(x):
...     '''Backslashes in a raw docstring: m\\n'''
...
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n
```

- The starting column doesn't matter:

```
>>> assert "Easy!"
      >>> import math
          >>> math.floor(1.9)
          1
```

and as many leading whitespace characters are stripped from the expected output as appeared in the initial `'>>> '` line that started the example.

What's the Execution Context?

By default, each time *doctest* finds a docstring to test, it uses a *shallow copy* of `M`'s globals, so that running tests doesn't change the module's real globals, and so that one test in `M` can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in `M`, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globs=your_dict` to *testmod()* or *testfile()* instead.

What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback.[1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

簡單範例:

```
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: list.remove(x): x not in list
```

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.

That doctest succeeds if *ValueError* is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
    line
detail
```

The last three lines (starting with *ValueError*) are compared against the exception's type and detail, and the rest are ignored.

Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```
>>> raise ValueError('multi\n    line\ndetail')
Traceback (most recent call last):
    ...
ValueError: multi
    line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's *ELLIPSIS* option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether *ValueError* is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.
- Each line of the traceback stack (if present) must be indented further than the first line of the example, *or* start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
- When the *IGNORE_EXCEPTION_DETAIL* doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.
- The interactive shell omits the traceback header line for some *SyntaxError*s. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.
- For some exceptions, Python displays the position of the error using ^ markers and tildes:

  ```
  >>> 1 + None
    File "<stdin>", line 1
      1 + None
      ~~^~~~~
  TypeError: unsupported operand type(s) for +: 'int' and 'NoneType'
  ```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the ^ marker in the wrong location:

```
>>> 1 + None
  File "<stdin>", line 1
    1 + None
    ^~~~~~~~
TypeError: unsupported operand type(s) for +: 'int' and 'NoneType'
```

可選旗標

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in *doctest directives*, and may be passed to the doctest command line interface via the `-o` option.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:

`doctest.`**`DONT_ACCEPT_TRUE_FOR_1`**

By default, if an expected output block contains just `1`, an actual output block containing just `1` or just `True` is considered to be a match, and similarly for `0` versus `False`. When *DONT_ACCEPT_TRUE_FOR_1* is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting "little integer" output still work in these cases. This option will probably go away, but not for several years.

`doctest.`**`DONT_ACCEPT_BLANKLINE`**

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When *DONT_ACCEPT_BLANKLINE* is specified, this substitution is not allowed.

`doctest.`**`NORMALIZE_WHITESPACE`**

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. *NORMALIZE_WHITESPACE* is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

`doctest.`**`ELLIPSIS`**

When specified, an ellipsis marker (`...`) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it's best to keep usage of this simple. Complicated uses can lead to the same kinds of "oops, it matched too much!" surprises that `.*` is prone to in regular expressions.

`doctest.`**`IGNORE_EXCEPTION_DETAIL`**

When specified, doctests expecting exceptions pass so long as an exception of the expected type is raised, even if the details (message and fully qualified exception name) don't match.

For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail if, say, a *TypeError* is raised instead. It will also ignore any fully qualified name included before the exception class, which can vary between implementations and versions of Python and the code/libraries in use. Hence, all three of these variations will work with the flag specified:

```
>>> raise Exception('message')
Traceback (most recent call last):
Exception: message

>>> raise Exception('message')
Traceback (most recent call last):
builtins.Exception: message

>>> raise Exception('message')
```

(繼續下一頁)

(繼續上一頁)

```
Traceback (most recent call last):
__main__.Exception: message
```

Note that *ELLIPSIS* can also be used to ignore the details of the exception message, but such a test may still fail based on whether the module name is present or matches exactly.

在 3.2 版的變更: *IGNORE_EXCEPTION_DETAIL* now also ignores any information relating to the module containing the exception under test.

doctest.**SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example's output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily "commenting out" examples.

doctest.**COMPARISON_FLAGS**

A bitmask or'ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.**REPORT_UDIFF**

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.**REPORT_CDIFF**

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.**REPORT_NDIFF**

When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit `1` where actual output contains letter `l`, a line is inserted with a caret marking the mismatching column positions.

doctest.**REPORT_ONLY_FIRST_FAILURE**

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When *REPORT_ONLY_FIRST_FAILURE* is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

doctest.**FAIL_FAST**

When specified, exit after the first failing example and don't attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won't even produce debugging output.

doctest.**REPORTING_FLAGS**

A bitmask or'ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn't useful unless you intend to extend *doctest* internals via subclassing:

doctest.**register_optionflag**(*name*)

Create a new option flag with a given name, and return the new flag's integer value. *register_optionflag()* can be used when subclassing *OutputChecker* or *DocTestRunner* to create new options that are supported by your subclasses. *register_optionflag()* should always be called using the following idiom:

```
MY_FLAG = register_optionflag('MY_FLAG')
```

Directives

Doctest directives may be used to modify the *option flags* for an individual example. Doctest directives are special Python comments following an example's source code:

```
directive:             "#" "doctest:" directive_options
directive_options:     directive_option ("," directive_option)*
directive_option:      on_or_off directive_option_name
on_or_off:             "+" | "-"
directive_option_name: "DONT_ACCEPT_BLANKLINE" | "NORMALIZE_WHITESPACE" | ...
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

舉例來🄵，這個測試會通過：

```
>>> print(list(range(20)))  # doctest: +NORMALIZE_WHITESPACE
[0,   1,  2,  3,  4,  5,  6,  7,  8,  9,
10,  11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0,    1, ...,   18,    19]
```

If multiple directive comments are used for a single example, then they are combined:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS
...                         # doctest: +NORMALIZE_WHITESPACE
[0,    1, ...,   18,    19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```
>>> print(list(range(5)) + list(range(10, 20)) + list(range(30, 40)))
... # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via + in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via - in a directive can be useful.

警告

doctest is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn't guarantee about output. For example, when printing a set, Python doesn't guarantee that the element is printed in any particular order, so a test like

```
>>> foo()
{"spam", "eggs"}
```

is vulnerable! One workaround is to do

```
>>> foo() == {"spam", "eggs"}
True
```

instead. Another is to do

```
>>> d = sorted(foo())
>>> d
['eggs', 'spam']
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds an address
<C object at 0x00AC18F0>
```

The *ELLIPSIS* directive gives a nice approach for the last example:

```
>>> C()  # doctest: +ELLIPSIS
<C object at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for some floating-point calculations, and C libraries vary widely in quality here.

```
>>> 1000**0.1  # risky
1.9952623149688797
>>> round(1000**0.1, 9) # safer
1.995262315
>>> print(f'{1000**0.1:.4f}') # much safer
1.9953
```

Numbers of the form `I/2.**J` are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.

26.4.5 基礎 API

The functions *testmod()* and *testfile()* provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections *Simple Usage: Checking Examples in Docstrings* and *Simple Usage: Checking Examples in a Text File*.

doctest.**testfile**(*filename*, *module_relative=True*, *name=None*, *package=None*, *globs=None*, *verbose=None*, *report=True*, *optionflags=0*, *extraglobs=None*, *raise_on_error=False*, *parser=DocTestParser()*, *encoding=None*)

All arguments except *filename* are optional, and should be specified in keyword form.

Test examples in the file named *filename*. Return `(failure_count, test_count)`.

Optional argument *module_relative* specifies how the filename should be interpreted:

- If *module_relative* is `True` (the default), then *filename* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, *filename* should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).

- If *module_relative* is `False`, then *filename* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *name* gives the name of the test; by default, or if `None`, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is `False`.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like *dict.update()*: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if `None`, it's true if and only if `'-v'` is in *sys.argv*.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument *optionflags* (default value `0`) takes the bitwise OR of option flags. See section 可選旗標.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

doctest.**testmod**(*m=None*, *name=None*, *globs=None*, *verbose=None*, *report=True*, *optionflags=0*, *extraglobs=None*, *raise_on_error=False*, *exclude_empty=False*)

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

回傳 `(failure_count, test_count)`。

Optional argument *name* gives the name of the module; by default, or if `None`, `m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using *doctest.master.summarize* in conjunction with *testmod()* continues to get output for objects with no tests. The *exclude_empty* argument to the newer *DocTestFinder* constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise_on_error*, and *globs* are the same as for function *testfile()* above, except that *globs* defaults to `m.__dict__`.

doctest.**run_docstring_examples**(*f*, *globs*, *verbose=False*, *name='NoName'*, *compileflags=None*, *optionflags=0*)

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to `"NoName"`.

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if `None`, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function *testfile()* above.

26.4.6 Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. *doctest* provides two functions that can be used to create *unittest* test suites from modules and text files containing doctests. To integrate with *unittest* test discovery, include a *load_tests* function in your test module:

```
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating *unittest.TestSuite* instances from text files and modules with doctests:

doctest.**DocFileSuite**(**paths*, *module_relative=True*, *package=None*, *setUp=None*, *tearDown=None*, *globs=None*, *optionflags=0*, *parser=DocTestParser()*, *encoding=None*)

Convert doctest tests from one or more text files to a *unittest.TestSuite*.

The returned *unittest.TestSuite* is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a *failureException* exception is raised showing the name of the file containing the test and a (sometimes approximate) line number. If all the examples in a file are skipped, then the synthesized unit test is also marked as skipped.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument *module_relative* specifies how the filenames in *paths* should be interpreted:

- If *module_relative* is `True` (the default), then each filename in *paths* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If *module_relative* is `False`, then each filename in *paths* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in *paths*. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is `False`.

Optional argument *setUp* specifies a set-up function for the test suite. This is called before running the tests in each file. The *setUp* function will be passed a *DocTest* object. The *setUp* function can access the test globals as the *globs* attribute of the test passed.

Optional argument *tearDown* specifies a tear-down function for the test suite. This is called after running the tests in each file. The *tearDown* function will be passed a *DocTest* object. The *tearDown* function can access the test globals as the *globs* attribute of the test passed.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section 可選旗標. See function *set_unittest_reportflags()* below for a better way to set reporting options.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using *DocFileSuite()*.

doctest.**DocTestSuite**(*module=None*, *globs=None*, *extraglobs=None*, *test_finder=None*, *setUp=None*, *tearDown=None*, *optionflags=0*, *checker=None*)

Convert doctest tests for a module to a *unittest.TestSuite*.

The returned *unittest.TestSuite* is to be run by the unittest framework and runs each doctest in the module. Each docstring is run as a separate unit test. If any of the doctests fail, then the synthesized unit test fails, and a *unittest.TestCase.failureException* exception is raised showing the name of the file containing the test and a (sometimes approximate) line number. If all the examples in a docstring are skipped, then the

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is the module's `__dict__`.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above, but they are called for each docstring.

This function uses the same search technique as *testmod()*.

在 3.5 版的變更: *DocTestSuite()* returns an empty *unittest.TestSuite* if *module* contains no docstrings instead of raising *ValueError*.

Under the covers, *DocTestSuite()* creates a *unittest.TestSuite* out of `doctest.DocTestCase` instances, and `DocTestCase` is a subclass of *unittest.TestCase*. `DocTestCase` isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of *unittest* integration.

Similarly, *DocFileSuite()* creates a *unittest.TestSuite* out of `doctest.DocFileCase` instances, and `DocFileCase` is a subclass of `DocTestCase`.

So both ways of creating a *unittest.TestSuite* run instances of `DocTestCase`. This is important for a subtle reason: when you run *doctest* functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you're writing a *unittest* framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through `unittest` to `doctest` test runners.

For this reason, *doctest* also supports a notion of `doctest` reporting flags specific to *unittest* support, via this function:

doctest.**set_unittest_reportflags**(*flags*)

Set the *doctest* reporting flags to use.

Argument *flags* takes the bitwise OR of option flags. See section 可選旗標. Only "reporting flags" can be used.

This is a module-global setting, and affects all future doctests run by module *unittest*: the `runTest()` method of `DocTestCase` looks at the option flags specified for the test case when the `DocTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`'s `unittest` reporting flags are bitwise ORed into the option flags, and the option flags so augmented are passed to the *DocTestRunner* instance created to run the doctest. If any reporting flags were specified when the `DocTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the *unittest* reporting flags in effect before the function was called is returned by the function.

26.4.7 Advanced API

The basic API is a simple wrapper that's intended to make doctest easy to use. It is fairly flexible, and should meet most users' needs; however, if you require more fine-grained control over testing, or wish to extend doctest's capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- *Example*: A single Python *statement*, paired with its expected output.
- *DocTest*: A collection of *Example*s, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- *DocTestFinder*: Finds all docstrings in a given module, and uses a *DocTestParser* to create a *DocTest* from every docstring that contains interactive examples.
- *DocTestParser*: Creates a *DocTest* object from a string (such as an object's docstring).
- *DocTestRunner*: Executes the examples in a *DocTest*, and uses an *OutputChecker* to verify their output.
- *OutputChecker*: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:

```
                          list of:
+------+                  +---------+
|module| --DocTestFinder-> | DocTest | --DocTestRunner-> results
+------+    |        ^     +---------+     |        ^     (printed)
            |        |     | Example |     |        |
            v        |     |   ...   |     v        |
           DocTestParser   | Example |   OutputChecker
                           +---------+
```

DocTest 物件

class doctest.**DocTest**(*examples*, *globs*, *name*, *filename*, *lineno*, *docstring*)

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

DocTest defines the following attributes. They are initialized by the constructor, and should not be modified directly.

examples

A list of *Example* objects encoding the individual interactive Python examples that should be run by this test.

globs

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in *globs* after the test is run.

name

A string name identifying the *DocTest*. Typically, this is the name of the object or file that the test was extracted from.

filename

The name of the file that this *DocTest* was extracted from; or `None` if the filename is unknown, or if the `DocTest` was not extracted from a file.

lineno

The line number within *filename* where this *DocTest* begins, or `None` if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

docstring

The string that the test was extracted from, or `None` if the string is unavailable, or if the test was not extracted from a string.

Example 物件

class doctest.**Example**(*source*, *want*, *exc_msg=None*, *lineno=0*, *indent=0*, *options=None*)

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

Example defines the following attributes. They are initialized by the constructor, and should not be modified directly.

source

A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

want

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). *want* ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

exc_msg

The exception message generated by the example, if the example is expected to generate an exception; or `None` if it is not expected to generate an exception. This exception message is compared against the return value of *traceback.format_exception_only()*. *exc_msg* ends with a newline unless it's `None`. The constructor adds a newline if needed.

lineno

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

indent

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

options

A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the *DocTestRunner*'s *optionflags*). By default, no options are set.

DocTestFinder 物件

class doctest.**DocTestFinder**(*verbose=False*, *parser=DocTestParser()*, *recurse=True*, *exclude_empty=True*)

A processing class used to extract the *DocTest*s that are relevant to a given object, from its docstring and the docstrings of its contained objects. *DocTest*s can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument *verbose* can be used to display the objects searched by the finder. It defaults to `False` (no output).

The optional argument *parser* specifies the *DocTestParser* object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument *recurse* is false, then *DocTestFinder.find()* will only examine the given object, and not any contained objects.

If the optional argument *exclude_empty* is false, then *DocTestFinder.find()* will include tests for objects with empty docstrings.

DocTestFinder 定義了以下方法：

find(*obj[, name][, module][, globs][, extraglobs]*)

Return a list of the *DocTest*s that are defined by *obj*'s docstring, or by any of its contained objects' docstrings.

The optional argument *name* specifies the object's name; this name will be used to construct names for the returned *DocTest*s. If *name* is not specified, then `obj.__name__` is used.

The optional parameter *module* is the module that contains the given object. If the module is not specified or is `None`, then the test finder will attempt to automatically determine the correct module. The object's module is used:

- As a default namespace, if *globs* is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than *module* are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If *module* is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if *module* is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each *DocTest* is formed by combining *globs* and *extraglobs* (bindings in *extraglobs* override bindings in *globs*). A new shallow copy of the globals dictionary is created for each `DocTest`. If *globs* is not specified, then it defaults to the module's `__dict__`, if specified, or `{}` otherwise. If *extraglobs* is not specified, then it defaults to `{}`.

DocTestParser 物件

class doctest.**DocTestParser**

A processing class used to extract interactive examples from a string, and use them to create a *DocTest* object.

DocTestParser 定義了以下方法：

get_doctest(*string*, *globs*, *name*, *filename*, *lineno*)

Extract all doctest examples from the given string, and collect them into a *DocTest* object.

globs, *name*, *filename*, and *lineno* are attributes for the new `DocTest` object. See the documentation for *DocTest* for more information.

get_examples(*string*, *name='<string>'*)

Extract all doctest examples from the given string, and return them as a list of *Example* objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

parse(*string*, *name='<string>'*)

Divide the given string into examples and intervening text, and return them as a list of alternating *Example*s and strings. Line numbers for the `Example`s are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

TestResults 物件

class doctest.**TestResults**(*failed*, *attempted*)

failed

失敗的測試數量。

attempted

嘗試的測試數量。

skipped

跳過的測試數量。

在 3.13 版被加入.

DocTestRunner 物件

class doctest.**DocTestRunner**(*checker=None*, *verbose=None*, *optionflags=0*)

A processing class used to execute and verify the interactive examples in a *DocTest*.

The comparison between expected outputs and actual outputs is done by an *OutputChecker*. This comparison may be customized with a number of option flags; see section 可選旗標 for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of `OutputChecker` to the constructor.

The test runner's display output can be controlled in two ways. First, an output function can be passed to *run()*; this function will be called with strings that should be displayed. It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods *report_start()*, *report_success()*, *report_unexpected_exception()*, and *report_failure()*.

The optional keyword argument *checker* specifies the *OutputChecker* object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument *verbose* controls the *DocTestRunner*'s verbosity. If *verbose* is `True`, then information is printed about each example, as it is run. If *verbose* is `False`, then only failures are printed. If *verbose* is unspecified, or `None`, then verbose output is used iff the command-line switch `-v` is used.

The optional keyword argument *optionflags* can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section 可選旗標.

The test runner accumulates statistics. The aggregated number of attempted, failed and skipped examples is also available via the *tries*, *failures* and *skips* attributes. The *run()* and *summarize()* methods return a *TestResults* instance.

DocTestRunner 定義了以下方法：

report_start(*out*, *test*, *example*)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

example is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

report_success(*out*, *test*, *example*, *got*)

Report that the given example ran successfully. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

example is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

report_failure(*out*, *test*, *example*, *got*)

Report that the given example failed. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

example is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

report_unexpected_exception(*out*, *test*, *example*, *exc_info*)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of *DocTestRunner* to customize their output; it should not be called directly.

example is the example about to be processed. *exc_info* is a tuple containing information about the unexpected exception (as returned by *sys.exc_info()*). *test* is the test containing *example*. *out* is the output function that was passed to *DocTestRunner.run()*.

run(*test*, *compileflags=None*, *out=None*, *clear_globs=True*)

Run the examples in *test* (a *DocTest* object), and display the results using the writer function *out*. Return a *TestResults* instance.

The examples are run in the namespace `test.globs`. If *clear_globs* is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use *clear_globs=False*.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to *globs*.

The output of each example is checked using the *DocTestRunner*'s output checker, and the results are formatted by the `DocTestRunner.report_*()` methods.

summarize(*verbose=None*)

Print a summary of all the test cases that have been run by this DocTestRunner, and return a *TestResults* instance.

The optional *verbose* argument controls how detailed the summary is. If the verbosity is not specified, then the *DocTestRunner*'s verbosity is used.

DocTestParser 有以下屬性：

tries

嘗試的範例數量。

failures

失敗的範例數量。

skips

跳過的範例數量。

在 3.13 版被加入.

OutputChecker 物件

class doctest.**OutputChecker**

A class used to check the whether the actual output from a doctest example matches the expected output. *OutputChecker* defines two methods: *check_output()*, which compares a given pair of outputs, and returns `True` if they match; and *output_difference()*, which returns a string describing the differences between two outputs.

OutputChecker 定義了以下方法：

check_output(*want*, *got*, *optionflags*)

Return `True` iff the actual output from an example (*got*) matches the expected output (*want*). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section 可選旗標 for more information about option flags.

output_difference(*example*, *got*, *optionflags*)

Return a string describing the differences between the expected output for a given example (*example*) and the actual output (*got*). *optionflags* is the set of option flags used to compare *want* and *got*.

26.4.8 偵錯

Doctest 提供了幾種偵錯 doctest 範例的機制：

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, *pdb*.
- The *DebugRunner* class is a subclass of *DocTestRunner* that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.
- The *unittest* cases generated by *DocTestSuite()* support the *debug()* method defined by *unittest.TestCase*.
- You can add a call to *pdb.set_trace()* in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```
"""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print(x+3)
...     import pdb; pdb.set_trace()
>>> f(3)
9
"""
```

Then an interactive Python session may look like this:

```
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
  1     def g(x):
  2         print(x+3)
  3  ->     import pdb; pdb.set_trace()
[EOF]
(Pdb) p x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()->None
-> g(x*2)
(Pdb) list
  1     def f(x):
  2  ->     g(x*2)
[EOF]
(Pdb) p x
3
```

(繼續下一頁)

(繼續上一頁)

```
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)
>>>
```

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

doctest.**script_from_examples**(*s*)

Convert text with examples to a script.

Argument *s* is a string containing doctest examples. The string is converted to a Python script, where doctest examples in *s* are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
print(doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
"""))
```

displays:

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

doctest.**testsource**(*module*, *name*)

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for *script_from_examples()* above. For example, if module `a.py` contains a top-level function `f()`, then

```
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function `f()`'s docstring, with doctests converted to code, and the rest placed in comments.

doctest.**debug**(*module*, *name*, *pm=False*)

Debug the doctests for an object.

The *module* and *name* arguments are the same as for function *testsource()* above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, *pdb*.

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument *pm* controls whether post-mortem debugging is used. If *pm* has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via *pdb.post_mortem()*, passing the traceback object from the unhandled exception. If *pm* is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate *exec()* call to *pdb.run()*.

doctest.**debug_src**(*src*, *pm=False*, *globs=None*)

Debug the doctests in a string.

This is like function *debug()* above, except that a string containing doctest examples is specified directly, via the *src* argument.

Optional argument *pm* has the same meaning as in function *debug()* above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The *DebugRunner* class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially *DebugRunner*'s docstring (which is a doctest!) for more details:

class doctest.**DebugRunner**(*checker=None*, *verbose=None*, *optionflags=0*)

A subclass of *DocTestRunner* that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an *UnexpectedException* exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a *DocTestFailure* exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for *DocTestRunner* in section *Advanced API*.

There are two exceptions that may be raised by *DebugRunner* instances:

exception doctest.**DocTestFailure**(*test*, *example*, *got*)

An exception raised by *DocTestRunner* to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

DocTestFailure 定義了以下屬性:

DocTestFailure.**test**

The *DocTest* object that was being run when the example failed.

DocTestFailure.**example**

The *Example* that failed.

DocTestFailure.**got**

The example's actual output.

exception doctest.**UnexpectedException**(*test*, *example*, *exc_info*)

An exception raised by *DocTestRunner* to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

UnexpectedException 定義了以下屬性:

UnexpectedException.**test**

The *DocTest* object that was being run when the example failed.

UnexpectedException.**example**

The *Example* that failed.

UnexpectedException.**exc_info**

A tuple containing information about the unexpected exception, as returned by *sys.exc_info()*.

26.4.9 Soapbox

As mentioned in the introduction, *doctest* has grown to have three primary uses:

1. Checking examples in docstrings.
2. 回歸測試。
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned---it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my *doctest* examples stops working after a "harmless" change.

Doctest also makes an excellent tool for regression testing, especially if you don't skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using *testfile()* or *DocFileSuite()*. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a *__test__* dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
            obj = globals()[name]
        else:
            obj = __test__[name]
        doctest.run_docstring_examples(obj, globals(), name=name,
                                       optionflags=flags)
    else:
        fail, total = doctest.testmod(optionflags=flags)
        print(f"{fail} failures out of {total} tests")
```

26.5 unittest --- 單元測試框架

原始碼： Lib/unittest/__init__.py

（假如你已經熟悉相關基礎的測試概念，你可能會希望跳過以下段落，直接參考*assert 方法清單*。）

unittest 原生的單元測試框架最初由 JUnit 開發，和其他程式語言相似有主要的單元測試框架。支援自動化測試，對測試分享安裝與關閉程式碼，集合所有匯總的測試，🄵且獨立各個測試報告框架。

unittest 用來作🄵實現支援一些重要的物件導向方法的概念：

test fixture
: 一個 *test fixture* 代表執行一個或多個測試所需要的准備，以及其他相關清理操作，例如可以是建立臨時性的或是代理用 (proxy) 資料庫、目🄵、或是🄵動一個伺服器程序。

test case（測試用例）
: 一個 *test case* 是一個獨立的單元測試。這是用來確認一個特定設定的輸入的特殊回饋。*unittest* 提供一個基礎類🄵，類🄵*TestCase*，可以用來建立一個新的測試條例。

test suite（測試套件）
: *test suite* 是一個搜集測試條例，測試套件，或是兩者皆有。它需要一起被執行🄵用來匯總測試。

test runner（測試執行器）
: *test runner* 是一個編排測試執行與提供結果給使用者的一個元件。執行器可以使用圖形化介面，文字介面或是回傳一個特🄵值用來標示出執行測試的結果。

也參考

***doctest* 模組**
: 另一個執行測試的模組，但使用不一樣的測試方法與規範。

Simple Smalltalk Testing: With Patterns
: Kent Beck 的原始論文討論使用*unittest* 這樣模式的測試框架。

pytest
: 第三方的單元測試框架，但在撰寫測試時使用更輕量的語法。例如：`assert func(10) == 42`。

The Python Testing Tools Taxonomy
: 一份詳細的 Python 測試工具列表，包含 functional testing 框架和 mock object 函式庫。

Testing in Python Mailing List
: 一個專門興趣的群組用來討論 Python 中的測試方式與測試工具。

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot, Jenkins, GitHub Actions, or AppVeyor.

26.5.1 簡單范例

unittest 模組提供一系列豐富的工具用來建構與執行測試。本節將展示這一系列工具中一部份，它們已能滿足大部份使用者需求。

這是一段簡短的🄵本用來測試 3 個字串方法：

```
import unittest

class TestStringMethods(unittest.TestCase):

    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')
```

(繼續下一頁)

(繼續上一頁)

```
    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

測試用例 (test case) 可以透過繼承*unittest.TestCase* 類🄵來建立。這🄵定義了三個獨立的物件方法，名稱皆以 `test` 開頭。這樣的命名方式能告知 test runner 哪些物件方法🄵定義的測試。

每個測試的關鍵🄵呼叫*assertEqual()* 來確認是否🄵期望的結果；*assertTrue()* 或是*assertFalse()* 用來驗證一個條件式；*assertRaises()* 用來驗證是否觸發一個特定的 exception。使用這些物件方法來取代 `assert` 陳述句，將能使 test runner 收集所有的測試結果🄵🄵生一個報表。

The *setUp()* and *tearDown()* methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section *Organizing test code*.

最後將顯示一個簡單的方法去執行測試*unittest.main()* 提供一個命令列介面測試🄵本。當透過命令列執行，輸出結果將會像是：

```
...
----------------------------------------------------------------------
Ran 3 tests in 0.000s

OK
```

在測試時加入 `-v` 選項將指示*unittest.main()* 提高 verbosity 層級，🄵生以下的輸出：

```
test_isupper (__main__.TestStringMethods.test_isupper) ... ok
test_split (__main__.TestStringMethods.test_split) ... ok
test_upper (__main__.TestStringMethods.test_upper) ... ok

----------------------------------------------------------------------
Ran 3 tests in 0.001s

OK
```

以上的例子顯示大多數使用*unittest* 特徵足以滿足大多數日常測試的需求。接下來第一部分文件的剩余部分將繼續探索完整特徵設定。

在 3.11 版的變更: The behavior of returning a value from a test method (other than the default `None` value), is now deprecated.

26.5.2 命令列介面

單元測試模組可以透過命令列執行測試模組，物件甚至個🄵的測試方法：

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

你可以通過一個串列與任何模組名稱的組合，完全符合類🄵與方法的名稱。

測試模組可以根據檔案路徑指定：

```
python -m unittest tests/test_something.py
```

這允許你使用 shell 檔案名稱補完功能 (filename completion) 來指定測試模組。給定的檔案路徑必須亦能被當作模組 import。此路徑轉🄵🄵模組名稱的方式🄵移除'.py' 🄵將路徑分隔符 (path separator) 轉🄵成'.'。假如你的測試檔案無法被 import 成模組，你應該直接執行該測試檔案。

通過增加 -v 的旗標數，可以在你執行測試時得到更多細節（更高的 verbosity）：

```
python -m unittest -v test_module
```

若執行時不代任何引數，將執行*Test Discovery*（測試探索）：

```
python -m unittest
```

列出所有命令列選項：

```
python -m unittest -h
```

在 3.2 版的變更: 在早期的版本可以個🄵執行測試方法和不需要模組或是類🄵。

在 3.14 版被加入: Output is colorized by default and can be controlled using environment variables.

命令列模式選項

unittest 支援以下命令列選項：

-b, --buffer

Standard output 與 standard error stream 將在測試執行被緩衝 (buffer)。這些輸出在測試通過時被🄵🄵。若是測試錯誤或失則，這些輸出將會正常地被印出，🄵且被加入至錯誤訊息中。

-c, --catch

`Control-C` 測試執行過程中等待正確的測試結果🄵回報目前🄵止所有的測試結果。第二個 `Control-C` 🄵出一般例外*`KeyboardInterrupt`*。

參照*Signal Handling* 針對函式提供的功能。

-f, --failfast

在第一次錯誤或是失敗停止執行測試。

-k

Only run test methods and classes that match the pattern or substring. This option may be used multiple times, in which case all test cases that match any of the given patterns are included.

Patterns that contain a wildcard character (`*`) are matched against the test name using *`fnmatch.fnmatchcase()`*; otherwise simple case-sensitive substring matching is used.

Patterns are matched against the fully qualified test method name as imported by the test loader.

For example, `-k foo` matches `foo_tests.SomeTest.test_something`, `bar_tests.SomeTest.test_foo`, but not `bar_tests.FooTest.test_something`.

--locals

透過 traceback 顯示本地變數。

--durations `N`

Show the N slowest test cases (N=0 for all).

在 3.2 版被加入: 增加命令列模式選項 `-b` 、`-c` 與 `-f`。

在 3.5 版被加入: 命令列選項 `--locals`。

在 3.7 版被加入: 命令列選項 `-k`。

在 3.12 版被加入: 命令列選項 `--durations`。

對執行所有的專案或是一個子集合測試，命令列模式可以可以被用來做測試探索。

26.5.3 Test Discovery（測試探索）

在 3.2 版被加入.

單元測試支援簡單的 test discovery（測試探索）。🄵了相容於測試探索，所有的測試檔案都要是模組或是套件，🄵能從專案的最上層目🄵中 import（代表它們的檔案名稱必須是有效的 identifiers）。

Test discovery（測試探索）實作在*TestLoader.discover()*，但也可以被用於命令列模式。基本的命令列模式用法如下：

```
cd project_directory
python -m unittest discover
```

備🄵

`python -m unittest` 作🄵捷徑，其功能相當於 `python -m unittest discover`。假如你想傳遞引數至探索測試的話，一定要明確地加入 `discover` 子指令。

`discover` 子命令有以下幾個選項：

-v, --verbose
詳細 (verbose) 輸出

-s, --start-directory directory
開始尋找的資料夾（預設🄵 .）

-p, --pattern pattern
匹配測試檔案的模式（預設🄵 `test*.py`）

-t, --top-level-directory directory
專案的最高階層目🄵（預設🄵開始的資料夾）

-s, *-p*, 和*-t* 選項依照傳遞位置作🄵引數排序順序。以下兩個命令列被視🄵等價：

```
python -m unittest discover -s project_directory -p "*_test.py"
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

警示

Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the *load_tests protocol*.

在 3.4 版的變更: Test discovery supports *namespace packages*.

在 3.11 版的變更: Test discovery dropped the *namespace packages* support. It has been broken since Python 3.7. Start directory and its subdirectories containing tests must be regular package that have `__init__.py` file.

If the start directory is the dotted name of the package, the ancestor packages can be namespace packages.

在 3.14 版的變更: Test discovery supports *namespace package* as start directory again. To avoid scanning directories unrelated to Python, tests are not searched in subdirectories that do not contain `__init__.py`.

26.5.4 Organizing test code

The basic building blocks of unit testing are *test cases* --- single scenarios that must be set up and checked for correctness. In `unittest`, test cases are represented by `unittest.TestCase` instances. To make your own test cases you must write subclasses of `TestCase` or use `FunctionTestCase`.

The testing code of a `TestCase` instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest `TestCase` subclass will simply implement a test method (i.e. a method whose name starts with `test`) in order to perform specific testing code:

```
import unittest

class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the *assert* methods* provided by the `TestCase` base class. If the test fails, an exception will be raised with an explanatory message, and `unittest` will identify the test case as a *failure*. Any other exceptions will be treated as *errors*.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for every single test we run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50,50),
                         'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100,150)
        self.assertEqual(self.widget.size(), (100,150),
                         'wrong size after resize')
```

> **備🄵**
>
> The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the test method has been run:

```
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')
```

(繼續下一頁)

(繼續上一頁)

```
    def tearDown(self):
        self.widget.dispose()
```

If *setUp()* succeeded, *tearDown()* will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *test fixture*. A new TestCase instance is created as a unique test fixture used to execute each individual test method. Thus *setUp()*, *tearDown()*, and __init__() will be called once per test.

It is recommended that you use TestCase implementations to group tests together according to the features they test. *unittest* provides a mechanism for this: the *test suite*, represented by *unittest*'s *TestSuite* class. In most cases, calling *unittest.main()* will do the right thing and collect all the module's test cases for you and execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_widget_size'))
    suite.addTest(WidgetTestCase('test_widget_resize'))
    return suite

if __name__ == '__main__':
    runner = unittest.TextTestRunner()
    runner.run(suite())
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.

26.5.5 Re-using old test code

Some users will find that they have existing test code that they would like to run from *unittest*, without converting every old test function to a *TestCase* subclass.

For this reason, *unittest* provides a *FunctionTestCase* class. This subclass of *TestCase* can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```
testcase = unittest.FunctionTestCase(testSomething,
                                     setUp=makeSomethingDB,
                                     tearDown=deleteSomethingDB)
```

> **備🄵**
>
> Even though *FunctionTestCase* can be used to quickly convert an existing test base over to a *unittest*-based system, this approach is not recommended. Taking the time to set up proper *TestCase* subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the *doctest* module. If so, *doctest* provides a DocTestSuite class that can automatically build *unittest.TestSuite* instances from the existing *doctest*-based tests.

26.5.6 Skipping tests and expected failures

在 3.1 版被加入.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an "expected failure," a test that is broken and will fail, but shouldn't be counted as a failure on a *TestResult*.

Skipping a test is simply a matter of using the *skip()* *decorator* or one of its conditional variants, calling *TestCase.skipTest()* within a *setUp()* or test method, or raising *SkipTest* directly.

Basic skipping looks like this:

```
class MyTestCase(unittest.TestCase):

    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of the library.
        pass

    @unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
    def test_windows_support(self):
        # windows specific testing code
        pass

    def test_maybe_skipped(self):
        if not external_resource_available():
            self.skipTest("external resource not available")
        # test code that depends on the external resource
        pass
```

This is the output of running the example above in verbose mode:

```
test_format (__main__.MyTestCase.test_format) ... skipped 'not supported in this library␣
↪version'
test_nothing (__main__.MyTestCase.test_nothing) ... skipped 'demonstrating skipping'
test_maybe_skipped (__main__.MyTestCase.test_maybe_skipped) ... skipped 'external resource␣
↪not available'
test_windows_support (__main__.MyTestCase.test_windows_support) ... skipped 'requires Windows
↪'

----------------------------------------------------------------------
Ran 4 tests in 0.005s

OK (skipped=4)
```

Classes can be skipped just like methods:

```
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

TestCase.setUp() can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the *expectedFailure()* decorator.

```
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls *skip()* on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{!r} doesn't have {!r}".format(obj, attr))
```

The following decorators and exception implement test skipping and expected failures:

`@unittest.`**`skip`**`(`*reason*`)`

Unconditionally skip the decorated test. *reason* should describe why the test is being skipped.

`@unittest.`**`skipIf`**`(`*condition*`, `*reason*`)`

Skip the decorated test if *condition* is true.

`@unittest.`**`skipUnless`**`(`*condition*`, `*reason*`)`

Skip the decorated test unless *condition* is true.

`@unittest.`**`expectedFailure`**

Mark the test as an expected failure or error. If the test fails or errors in the test function itself (rather than in one of the *test fixture* methods) then it will be considered a success. If the test passes, it will be considered a failure.

`exception` `unittest.`**`SkipTest`**`(`*reason*`)`

This exception is raised to skip a test.

Usually you can use *TestCase.skipTest()* or one of the skipping decorators instead of raising this directly.

Skipped tests will not have *setUp()* or *tearDown()* run around them. Skipped classes will not have *setUpClass()* or *tearDownClass()* run. Skipped modules will not have *setUpModule()* or *tearDownModule()* run.

26.5.7 Distinguishing test iterations using subtests

在 3.4 版被加入.

When there are very small differences among your tests, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the *subTest()* context manager.

舉例來🄵，以下測試：

```
class NumbersTest(unittest.TestCase):

    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even.
        """
        for i in range(0, 6):
```

(繼續下一頁)

(繼續上一頁)

```
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

會有以下輸出：

```
======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=1)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0

======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=3)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0

======================================================================
FAIL: test_even (__main__.NumbersTest.test_even) (i=5)
Test that numbers between 0 and 5 are all even.
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 11, in test_even
    self.assertEqual(i % 2, 0)
    ^^^^^^^^^^^^^^^^^^^^^^^^^^
AssertionError: 1 != 0
```

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of `i` wouldn't be displayed:

```
======================================================================
FAIL: test_even (__main__.NumbersTest.test_even)
----------------------------------------------------------------------
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```

26.5.8 類🄵與函式

This section describes in depth the API of *unittest*.

Test cases

class unittest.**TestCase**(*methodName='runTest'*)

Instances of the *TestCase* class represent the logical test units in the *unittest* universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of *TestCase* will run a single base method: the method named *methodName*. In most uses of *TestCase*, you will neither change the *methodName* nor reimplement the default `runTest()` method.

在 3.2 版的變更: *TestCase* can be instantiated successfully without providing a *methodName*. This makes it easier to experiment with *TestCase* from the interactive interpreter.

TestCase instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

setUp()

Method called to prepare the test fixture. This is called immediately before calling the test method; other than *AssertionError* or *SkipTest*, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

tearDown()

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than *AssertionError* or *SkipTest*, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the *setUp()* succeeds, regardless of the outcome of the test method. The default implementation does nothing.

setUpClass()

A class method called before tests in an individual class are run. `setUpClass` is called with the class as the only argument and must be decorated as a *classmethod()*:

```
@classmethod
def setUpClass(cls):
    ...
```

更多細節請見*Class and Module Fixtures*。

在 3.2 版被加入.

tearDownClass()

A class method called after tests in an individual class have run. `tearDownClass` is called with the class as the only argument and must be decorated as a *classmethod()*:

```
@classmethod
def tearDownClass(cls):
    ...
```

更多細節請見*Class and Module Fixtures*。

在 3.2 版被加入.

run(*result=None*)

Run the test, collecting the result into the *TestResult* object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the *defaultTestResult()* method) and used. The result object is returned to *run()*'s caller.

The same effect may be had by simply calling the *TestCase* instance.

在 3.3 版的變更: Previous versions of `run` did not return the result. Neither did calling an instance.

skipTest(*reason*)

Calling this during a test method or *setUp()* skips the current test. See *Skipping tests and expected failures* for more information.

在 3.1 版被加入.

subTest(*msg=None*, ***params*)

Return a context manager which executes the enclosed code block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

更多資訊請見*Distinguishing test iterations using subtests*。

在 3.4 版被加入.

debug()

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The `TestCase` class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

方法	Checks that	New in
`assertEqual(a, b)`	`a == b`	
`assertNotEqual(a, b)`	`a != b`	
`assertTrue(x)`	`bool(x) is True`	
`assertFalse(x)`	`bool(x) is False`	
`assertIs(a, b)`	`a is b`	3.1
`assertIsNot(a, b)`	`a is not b`	3.1
`assertIsNone(x)`	`x is None`	3.1
`assertIsNotNone(x)`	`x is not None`	3.1
`assertIn(a, b)`	`a in b`	3.1
`assertNotIn(a, b)`	`a not in b`	3.1
`assertIsInstance(a, b)`	`isinstance(a, b)`	3.2
`assertNotIsInstance(a, b)`	`not isinstance(a, b)`	3.2
`assertIsSubclass(a, b)`	`issubclass(a, b)`	3.14
`assertNotIsSubclass(a, b)`	`not issubclass(a, b)`	3.14

All the assert methods accept a *msg* argument that, if specified, is used as the error message on failure (see also `longMessage`). Note that the *msg* keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context manager.

assertEqual(*first*, *second*, *msg=None*)

Test that *first* and *second* are equal. If the values do not compare equal, the test will fail.

In addition, if *first* and *second* are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the *list of type-specific methods*).

在 3.1 版的變更: Added the automatic calling of type-specific equality function.

在 3.2 版的變更: `assertMultiLineEqual()` added as the default type equality function for comparing strings.

assertNotEqual(*first*, *second*, *msg=None*)

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

assertTrue(*expr*, *msg=None*)

assertFalse(*expr*, *msg=None*)

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

assertIs(*first*, *second*, *msg=None*)

assertIsNot(*first*, *second*, *msg=None*)

Test that *first* and *second* are (or are not) the same object.

在 3.1 版被加入.

assertIsNone(*expr*, *msg=None*)

assertIsNotNone(*expr*, *msg=None*)

Test that *expr* is (or is not) `None`.

在 3.1 版被加入.

assertIn(*member*, *container*, *msg=None*)

assertNotIn(*member*, *container*, *msg=None*)

Test that *member* is (or is not) in *container*.

在 3.1 版被加入.

assertIsInstance(*obj*, *cls*, *msg=None*)

assertNotIsInstance(*obj*, *cls*, *msg=None*)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by `isinstance()`). To check for the exact type, use `assertIs(type(obj), cls)`.

在 3.2 版被加入.

assertIsSubclass(*cls*, *superclass*, *msg=None*)

assertNotIsSubclass(*cls*, *superclass*, *msg=None*)

Test that *cls* is (or is not) a subclass of *superclass* (which can be a class or a tuple of classes, as supported by `issubclass()`). To check for the exact type, use `assertIs(cls, superclass)`.

在 3.14 版被加入.

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

方法	Checks that	New in
`assertRaises(exc, fun, *args, **kwds)`	`fun(*args, **kwds)` 會引發 *exc*	
`assertRaisesRegex(exc, r, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *exc* and the message matches regex *r*	3.1
`assertWarns(warn, fun, *args, **kwds)`	`fun(*args, **kwds)` 會引發 *warn*	3.2
`assertWarnsRegex(warn, r, fun, *args, **kwds)`	`fun(*args, **kwds)` raises *warn* and the message matches regex *r*	3.2
`assertLogs(logger, level)`	The `with` block logs on *logger* with minimum *level*	3.4
`assertNoLogs(logger, level)`	**The `with` block does not log on** *logger* with minimum *level*	3.10

assertRaises(*exception*, *callable*, **args*, ***kwds*)

assertRaises(*exception*, *, *msg=None*)

Test that an exception is raised when *callable* is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if *exception* is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as *exception*.

If only the *exception* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, *assertRaises()* accepts the additional keyword argument *msg*.

The context manager will store the caught exception object in its `exception` attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

在 3.1 版的變更: 新增*assertRaises()* 可作🄵情境管理器使用的能力。

在 3.2 版的變更: 新增 `exception` 屬性。

在 3.3 版的變更: 新增作🄵情境管理器使用時的 *msg* 引數。

assertRaisesRegex(*exception*, *regex*, *callable*, **args*, ***kwds*)

assertRaisesRegex(*exception*, *regex*, *, *msg=None*)

Like *assertRaises()* but also tests that *regex* matches on the string representation of the raised exception. *regex* may be a regular expression object or a string containing a regular expression suitable for use by *re.search()*. Examples:

```
self.assertRaisesRegex(ValueError, "invalid literal for.*XYZ'$",
                       int, 'XYZ')
```

或是:

```
with self.assertRaisesRegex(ValueError, 'literal'):
   int('XYZ')
```

在 3.1 版被加入: 以 `assertRaisesRegexp` 🄵名新增。

在 3.2 版的變更: 重新命名🄵*assertRaisesRegex()*。

在 3.3 版的變更: 新增作🄵情境管理器使用時的 *msg* 引數。

assertWarns(*warning*, *callable*, **args*, ***kwds*)

assertWarns(*warning*, *, *msg=None*)

Test that a warning is triggered when *callable* is called with any positional or keyword arguments that are also passed to *assertWarns()*. The test passes if *warning* is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as *warnings*.

If only the *warning* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, *assertWarns()* accepts the additional keyword argument *msg*.

The context manager will store the caught warning object in its `warning` attribute, and the source line which triggered the warnings in the `filename` and `lineno` attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```
with self.assertWarns(SomeWarning) as cm:
    do_something()

self.assertIn('myfile.py', cm.filename)
self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

在 3.2 版被加入.

在 3.3 版的變更: 新增作🄵情境管理器使用時的 *msg* 引數。

assertWarnsRegex(*warning*, *regex*, *callable*, **args*, ***kwds*)

assertWarnsRegex(*warning*, *regex*, *, *msg=None*)

Like *assertWarns()* but also tests that *regex* matches on the message of the triggered warning. *regex* may be a regular expression object or a string containing a regular expression suitable for use by *re.search()*. Example:

```
self.assertWarnsRegex(DeprecationWarning,
                      r'legacy_function\(\) is deprecated',
                      legacy_function, 'XYZ')
```

或是:

```
with self.assertWarnsRegex(RuntimeWarning, 'unsafe frobnicating'):
    frobnicate('/etc/passwd')
```

在 3.2 版被加入.

在 3.3 版的變更: 新增作🄵情境管理器使用時的 *msg* 引數。

assertLogs(*logger=None*, *level=None*)

A context manager to test that at least one message is logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a *logging.Logger* object or a *str* giving the name of a logger. The default is the root logger, which will catch all messages that were not blocked by a non-propagating descendent logger.

If given, *level* should be either a numeric logging level or its string equivalent (for example either `"ERROR"` or *logging.ERROR*). The default is *logging.INFO*.

The test passes if at least one message emitted inside the `with` block matches the *logger* and *level* conditions, otherwise it fails.

The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

records

A list of *logging.LogRecord* objects of the matching log messages.

output

A list of *str* objects with the formatted output of matching messages.

範例:

```
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message',
                             'ERROR:foo.bar:second message'])
```

在 3.4 版被加入.

assertNoLogs(*logger=None*, *level=None*)

A context manager to test that no messages are logged on the *logger* or one of its children, with at least the given *level*.

If given, *logger* should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages.

If given, *level* should be either a numeric logging level or its string equivalent (for example either `"ERROR"` or `logging.ERROR`). The default is `logging.INFO`.

Unlike `assertLogs()`, nothing will be returned by the context manager.

在 3.10 版被加入.

There are also other methods used to perform more specific checks, such as:

方法	Checks that	New in
`assertAlmostEqual(a, b)`	`round(a-b, 7) == 0`	
`assertNotAlmostEqual(a, b)`	`round(a-b, 7) != 0`	
`assertGreater(a, b)`	`a > b`	3.1
`assertGreaterEqual(a, b)`	`a >= b`	3.1
`assertLess(a, b)`	`a < b`	3.1
`assertLessEqual(a, b)`	`a <= b`	3.1
`assertRegex(s, r)`	`r.search(s)`	3.1
`assertNotRegex(s, r)`	`not r.search(s)`	3.2
`assertCountEqual(a, b)`	*a* and *b* have the same elements in the same number, regardless of their order.	3.2
`assertStartsWith(a, b)`	`a.startswith(b)`	3.14
`assertNotStartsWith(a, b)`	`not a.startswith(b)`	3.14
`assertEndsWith(a, b)`	`a.endswith(b)`	3.14
`assertNotEndsWith(a, b)`	`not a.endswith(b)`	3.14
`assertHasAttr(a, b)`	`hastattr(a, b)`	3.14
`assertNotHasAttr(a, b)`	`not hastattr(a, b)`	3.14

assertAlmostEqual(*first*, *second*, *places=7*, *msg=None*, *delta=None*)

assertNotAlmostEqual(*first*, *second*, *places=7*, *msg=None*, *delta=None*)

Test that *first* and *second* are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal *places* (default 7), and comparing to zero. Note that these methods round the values to the given number of *decimal places* (i.e. like the `round()` function) and not *significant digits*.

If *delta* is supplied instead of *places* then the difference between *first* and *second* must be less or equal to (or greater than) *delta*.

Supplying both *delta* and *places* raises a `TypeError`.

在 3.2 版的變更: `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the *delta* keyword argument.

assertGreater(*first*, *second*, *msg=None*)

assertGreaterEqual(*first*, *second*, *msg=None*)

assertLess(*first*, *second*, *msg=None*)

assertLessEqual(*first*, *second*, *msg=None*)

Test that *first* is respectively >, >=, < or <= than *second* depending on the method name. If not, the test will fail:

```
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

在 3.1 版被加入.

assertRegex(*text*, *regex*, *msg=None*)

assertNotRegex(*text*, *regex*, *msg=None*)

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by *re.search()*.

在 3.1 版被加入: 以 `assertRegexpMatches` 🄵名新增。

在 3.2 版的變更: `assertRegexpMatches()` 方法已重新命名🄵*assertRegex()*。

在 3.2 版被加入: *assertNotRegex()*。

assertCountEqual(*first*, *second*, *msg=None*)

Test that sequence *first* contains the same elements as *second*, regardless of their order. When they don't, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing *first* and *second*. It verifies whether each element has the same count in both sequences. Equivalent to: `assertEqual(Counter(list(first)), Counter(list(second)))` but works with sequences of unhashable objects as well.

在 3.2 版被加入.

assertStartsWith(*s*, *prefix*, *msg=None*)

assertNotStartsWith(*s*, *prefix*, *msg=None*)

Test that the Unicode or byte string *s* starts (or does not start) with a *prefix*. *prefix* can also be a tuple of strings to try.

在 3.14 版被加入.

assertEndsWith(*s*, *suffix*, *msg=None*)

assertNotEndsWith(*s*, *suffix*, *msg=None*)

Test that the Unicode or byte string *s* ends (or does not end) with a *suffix*. *suffix* can also be a tuple of strings to try.

在 3.14 版被加入.

assertHasAttr(*obj*, *name*, *msg=None*)

assertNotHasAttr(*obj*, *name*, *msg=None*)

Test that the object *obj* has (or has not) an attribute *name*.

在 3.14 版被加入.

The *assertEqual()* method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using *addTypeEqualityFunc()*:

addTypeEqualityFunc(*typeobj*, *function*)

Registers a type-specific method called by *assertEqual()* to check if two objects of exactly the same *typeobj* (not subclasses) compare equal. *function* must take two positional arguments and a third msg=None keyword argument just as *assertEqual()* does. It must raise *self.failureException(msg)* when inequality between the first two parameters is detected -- possibly providing useful information and explaining the inequalities in details in the error message.

在 3.1 版被加入.

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

方法	Used to compare	New in
`assertMultiLineEqual(a, b)`	字串	3.1
`assertSequenceEqual(a, b)`	序列	3.1
`assertListEqual(a, b)`	串列	3.1
`assertTupleEqual(a, b)`	元組	3.1
`assertSetEqual(a, b)`	集合或凍結集合	3.1
`assertDictEqual(a, b)`	字典	3.1

assertMultiLineEqual(*first*, *second*, *msg=None*)

Test that the multiline string *first* is equal to the string *second*. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

在 3.1 版被加入.

assertSequenceEqual(*first*, *second*, *msg=None*, *seq_type=None*)

Tests that two sequences are equal. If a *seq_type* is supplied, both *first* and *second* must be instances of *seq_type* or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

在 3.1 版被加入.

assertListEqual(*first*, *second*, *msg=None*)

assertTupleEqual(*first*, *second*, *msg=None*)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

在 3.1 版被加入.

assertSetEqual(*first*, *second*, *msg=None*)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of *first* or *second* does not have a `set.difference()` method.

在 3.1 版被加入.

assertDictEqual(*first*, *second*, *msg=None*)

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

在 3.1 版被加入.

Finally the `TestCase` provides the following methods and attributes:

fail(*msg=None*)

Signals a test failure unconditionally, with *msg* or `None` for the error message.

failureException

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to "play fair" with the framework. The initial value of this attribute is `AssertionError`.

longMessage

This class attribute determines what happens when a custom failure message is passed as the msg argument to an assertXYY call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, self.longMessage, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

在 3.1 版被加入.

maxDiff

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are *assertSequenceEqual()* (including all the sequence comparison methods that delegate to it), *assertDictEqual()* and *assertMultiLineEqual()*.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

在 3.2 版被加入.

Testing frameworks can use the following methods to collect information on the test:

countTestCases()

Return the number of tests represented by this test object. For *TestCase* instances, this will always be `1`.

defaultTestResult()

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the *run()* method).

For *TestCase* instances, this will always be an instance of *TestResult*; subclasses of *TestCase* should override this as necessary.

id()

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

shortDescription()

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or `None`.

在 3.1 版的變更: In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the *TextTestResult* in Python 3.2.

addCleanup(*function*, /, **args*, ***kwargs*)

Add a function to be called after *tearDown()* to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into *addCleanup()* when they are added.

If *setUp()* fails, meaning that *tearDown()* is not called, then any cleanup functions added will still be called.

在 3.1 版被加入.

enterContext(*cm*)

Enter the supplied *context manager*. If successful, also add its `__exit__()` method as a cleanup function by *addCleanup()* and return the result of the `__enter__()` method.

在 3.11 版被加入.

doCleanups()

This method is called unconditionally after *tearDown()*, or after *setUp()* if *setUp()* raises an exception.

It is responsible for calling all the cleanup functions added by *addCleanup()*. If you need cleanup functions to be called *prior* to *tearDown()* then you can call *doCleanups()* yourself.

doCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

在 3.1 版被加入.

classmethod addClassCleanup(*function*, */*, **args*, ***kwargs*)

Add a function to be called after *tearDownClass()* to cleanup resources used during the test class. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into *addClassCleanup()* when they are added.

If *setUpClass()* fails, meaning that *tearDownClass()* is not called, then any cleanup functions added will still be called.

在 3.8 版被加入.

classmethod enterClassContext(*cm*)

Enter the supplied *context manager*. If successful, also add its `__exit__()` method as a cleanup function by *addClassCleanup()* and return the result of the `__enter__()` method.

在 3.11 版被加入.

classmethod doClassCleanups()

This method is called unconditionally after *tearDownClass()*, or after *setUpClass()* if *setUpClass()* raises an exception.

It is responsible for calling all the cleanup functions added by *addClassCleanup()*. If you need cleanup functions to be called *prior* to *tearDownClass()* then you can call *doClassCleanups()* yourself.

doClassCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

在 3.8 版被加入.

class unittest.**IsolatedAsyncioTestCase**(*methodName='runTest'*)

This class provides an API similar to *TestCase* and also accepts coroutines as test functions.

在 3.8 版被加入.

loop_factory

The *loop_factory* passed to *asyncio.Runner*. Override in subclasses with *asyncio.EventLoop* to avoid using the asyncio policy system.

在 3.13 版被加入.

async asyncSetUp()

Method called to prepare the test fixture. This is called after `setUp()`. This is called immediately before calling the test method; other than *AssertionError* or *SkipTest*, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

async asyncTearDown()

Method called immediately after the test method has been called and the result recorded. This is called before `tearDown()`. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than *AssertionError* or *SkipTest*, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the *asyncSetUp()* succeeds, regardless of the outcome of the test method. The default implementation does nothing.

addAsyncCleanup(*function*, */*, **args*, ***kwargs*)

This method accepts a coroutine that can be used as a cleanup function.

async enterAsyncContext(*cm*)

Enter the supplied *asynchronous context manager*. If successful, also add its `__aexit__()` method as a cleanup function by *`addAsyncCleanup()`* and return the result of the `__aenter__()` method.

在 3.11 版被加入.

run(*result=None*)

Sets up a new event loop to run the test, collecting the result into the *`TestResult`* object passed as *result*. If *result* is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to *`run()`*'s caller. At the end of the test all the tasks in the event loop are cancelled.

An example illustrating the order:

```
from unittest import IsolatedAsyncioTestCase

events = []

class Test(IsolatedAsyncioTestCase):

    def setUp(self):
        events.append("setUp")

    async def asyncSetUp(self):
        self._async_connection = await AsyncConnection()
        events.append("asyncSetUp")

    async def test_response(self):
        events.append("test_response")
        response = await self._async_connection.get("https://example.com")
        self.assertEqual(response.status_code, 200)
        self.addAsyncCleanup(self.on_cleanup)

    def tearDown(self):
        events.append("tearDown")

    async def asyncTearDown(self):
        await self._async_connection.close()
        events.append("asyncTearDown")

    async def on_cleanup(self):
        events.append("cleanup")

if __name__ == "__main__":
    unittest.main()
```

After running the test, `events` would contain `["setUp", "asyncSetUp", "test_response", "asyncTearDown", "tearDown", "cleanup"]`.

class unittest.**FunctionTestCase**(*testFunc*, *setUp=None*, *tearDown=None*, *description=None*)

This class implements the portion of the *`TestCase`* interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a *`unittest`*-based test framework.

Grouping tests

class unittest.**TestSuite**(*tests=()*)

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a *TestSuite* instance is the same as iterating over the suite, running each test individually.

If *tests* is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

TestSuite objects behave much like *TestCase* objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to *TestSuite* instances:

addTest(*test*)

Add a *TestCase* or *TestSuite* to the suite.

addTests(*tests*)

Add all the tests from an iterable of *TestCase* and *TestSuite* instances to this test suite.

This is equivalent to iterating over *tests*, calling *addTest()* for each element.

TestSuite shares the following methods with *TestCase*:

run(*result*)

Run the tests associated with this suite, collecting the result into the test result object passed as *result*. Note that unlike *TestCase.run()*, *TestSuite.run()* requires the result object to be passed in.

debug()

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

countTestCases()

Return the number of tests represented by this test object, including all individual tests and sub-suites.

__iter__()

Tests grouped by a *TestSuite* are always accessed by iteration. Subclasses can lazily provide tests by overriding `__iter__()`. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before *TestSuite.run()* must be the same for each call iteration. After *TestSuite.run()*, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides `TestSuite._removeTestAtIndex()` to preserve test references.

在 3.2 版的變更: In earlier versions the *TestSuite* accessed tests directly rather than through iteration, so overriding `__iter__()` wasn't sufficient for providing tests.

在 3.4 版的變更: In earlier versions the *TestSuite* held references to each *TestCase* after *TestSuite.run()*. Subclasses can restore that behavior by overriding `TestSuite._removeTestAtIndex()`.

In the typical usage of a *TestSuite* object, the *run()* method is invoked by a `TestRunner` rather than by the end-user test harness.

Loading and running tests

class unittest.**TestLoader**

The *TestLoader* class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the *unittest* module provides an instance that can be shared as *unittest.defaultTestLoader*. Using a subclass or instance, however, allows customization of some configurable properties.

TestLoader objects have the following attributes:

errors

A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

在 3.5 版被加入.

TestLoader objects have the following methods:

loadTestsFromTestCase(*testCaseClass*)

Return a suite of all test cases contained in the *TestCase*-derived `testCaseClass`.

A test case instance is created for each method named by *getTestCaseNames()*. By default these are the method names beginning with `test`. If *getTestCaseNames()* returns no methods, but the `runTest()` method is implemented, a single test case is created for that method instead.

loadTestsFromModule(*module*, *, *pattern=None*)

Return a suite of all test cases contained in the given module. This method searches *module* for classes derived from *TestCase* and creates an instance of the class for each test method defined for the class.

> **備🄵**
>
> While using a hierarchy of *TestCase*-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the *load_tests protocol*. The *pattern* argument is passed as the third argument to `load_tests`.

在 3.2 版的變更: Support for `load_tests` added.

在 3.5 版的變更: Support for a keyword-only argument *pattern* has been added.

在 3.12 版的變更: The undocumented and unofficial *use_load_tests* parameter has been removed.

loadTestsFromName(*name*, *module=None*)

Return a suite of all test cases given a string specifier.

The specifier *name* is a "dotted name" that may resolve either to a module, a test case class, a test method within a test case class, a *TestSuite* instance, or a callable object which returns a *TestCase* or *TestSuite* instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as "a test method within a test case class", rather than "a callable object".

For example, if you have a module `SampleTests` containing a *TestCase*-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

在 3.5 版的變更: If an *ImportError* or *AttributeError* occurs while traversing *name* then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by self.errors.

loadTestsFromNames(*names*, *module=None*)

Similar to *loadTestsFromName()*, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

getTestCaseNames(*testCaseClass*)

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of `TestCase`.

discover(*start_dir*, *pattern='test*.py'*, *top_level_dir=None*)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then *top_level_dir* must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to `SkipTest` being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the load_tests function itself calls `loader.discover`.

If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves.

top_level_dir is stored internally, and used as a default to any nested calls to `discover()`. That is, if a package's `load_tests` calls `loader.discover()`, it does not need to pass this argument.

start_dir can be a dotted module name as well as a directory.

在 3.2 版被加入.

在 3.4 版的變更: Modules that raise `SkipTest` on import are recorded as skips, not errors.

start_dir can be a *namespace packages*.

Paths are sorted before being imported so that execution order is the same even if the underlying file system's ordering is not dependent on file name.

在 3.5 版的變更: Found packages are now checked for `load_tests` regardless of whether their path matches *pattern*, because it is impossible for a package name to match the default pattern.

在 3.11 版的變更: *start_dir* can not be a *namespace packages*. It has been broken since Python 3.7, and Python 3.11 officially removes it.

在 3.13 版的變更: *top_level_dir* is only stored for the duration of *discover* call.

在 3.14 版的變更: *start_dir* can once again be a *namespace package*.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

testMethodPrefix

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*` methods.

sortTestMethodsUsing

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*` methods.

suiteClass

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the *TestSuite* class.

This affects all the `loadTestsFrom*` methods.

testNamePatterns

List of Unix shell-style wildcard test name patterns that test methods have to match to be included in test suites (see `-k` option).

If this attribute is not `None` (the default), all test methods to be included in test suites must match one of the patterns in this list. Note that matches are always performed using *fnmatch.fnmatchcase()*, so unlike patterns passed to the `-k` option, simple substring patterns will have to be converted using `*` wildcards.

This affects all the `loadTestsFrom*` methods.

在 3.7 版被加入.

class unittest.**TestResult**

This class is used to compile information about which tests have succeeded and which have failed.

A *TestResult* object stores the results of a set of tests. The *TestCase* and *TestSuite* classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of *unittest* may want access to the *TestResult* object generated by running a set of tests for reporting purposes; a *TestResult* instance is returned by the `TestRunner.run()` method for this purpose.

TestResult instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

errors

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

failures

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the *assert* methods*.

skipped

A list containing 2-tuples of *TestCase* instances and strings holding the reason for skipping the test.

在 3.1 版被加入.

expectedFailures

A list containing 2-tuples of *TestCase* instances and strings holding formatted tracebacks. Each tuple represents an expected failure or error of the test case.

unexpectedSuccesses

A list containing *TestCase* instances that were marked as expected failures, but succeeded.

collectedDurations

A list containing 2-tuples of test case names and floats representing the elapsed time of each test which was run.

在 3.12 版被加入.

shouldStop

Set to `True` when the execution of tests should stop by *stop()*.

testsRun

The total number of tests run so far.

buffer

If set to true, `sys.stdout` and `sys.stderr` will be buffered in between *startTest()* and *stopTest()* being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

在 3.2 版被加入.

failfast

If set to true *stop()* will be called on the first failure or error, halting the test run.

在 3.2 版被加入.

tb_locals

If set to true then local variables will be shown in tracebacks.

在 3.5 版被加入.

wasSuccessful()

Return `True` if all tests run so far have passed, otherwise returns `False`.

在 3.4 版的變更: Returns `False` if there were any *unexpectedSuccesses* from tests marked with the *expectedFailure()* decorator.

stop()

This method can be called to signal that the set of tests being run should be aborted by setting the *shouldStop* attribute to `True`. `TestRunner` objects should respect this flag and return without running any additional tests.

For example, this feature is used by the *TextTestRunner* class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide `TestRunner` implementations can use this in a similar manner.

The following methods of the *TestResult* class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

startTest(*test*)

Called when the test case *test* is about to be run.

stopTest(*test*)

Called after the test case *test* has been executed, regardless of the outcome.

startTestRun()

Called once before any tests are executed.

在 3.1 版被加入.

stopTestRun()

Called once after all tests are executed.

在 3.1 版被加入.

addError(*test*, *err*)

Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by *sys.exc_info()*: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's *errors* attribute, where *formatted_err* is a formatted traceback derived from *err*.

addFailure(*test*, *err*)

Called when the test case *test* signals a failure. *err* is a tuple of the form returned by *sys.exc_info()*: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's *failures* attribute, where *formatted_err* is a formatted traceback derived from *err*.

addSuccess(*test*)

Called when the test case *test* succeeds.

The default implementation does nothing.

addSkip(*test*, *reason*)

Called when the test case *test* is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple `(test, reason)` to the instance's *skipped* attribute.

addExpectedFailure(*test*, *err*)

Called when the test case *test* fails or errors, but was marked with the *expectedFailure()* decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's *expectedFailures* attribute, where *formatted_err* is a formatted traceback derived from *err*.

addUnexpectedSuccess(*test*)

Called when the test case *test* was marked with the *expectedFailure()* decorator, but succeeded.

The default implementation appends the test to the instance's *unexpectedSuccesses* attribute.

addSubTest(*test*, *subtest*, *outcome*)

Called when a subtest finishes. *test* is the test case corresponding to the test method. *subtest* is a custom *TestCase* instance describing the subtest.

If *outcome* is *None*, the subtest succeeded. Otherwise, it failed with an exception where *outcome* is a tuple of the form returned by *sys.exc_info()*: `(type, value, traceback)`.

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

在 3.4 版被加入.

addDuration(*test*, *elapsed*)

Called when the test case finishes. *elapsed* is the time represented in seconds, and it includes the execution of cleanup functions.

在 3.12 版被加入.

class unittest.**TextTestResult**(*stream*, *descriptions*, *verbosity*, *, *durations=None*)

A concrete implementation of *TestResult* used by the *TextTestRunner*. Subclasses should accept `**kwargs` to ensure compatibility as the interface changes.

在 3.2 版被加入.

在 3.12 版的變更: 新增 *durations* 關鍵字參數。

unittest.**defaultTestLoader**

Instance of the *TestLoader* class intended to be shared. If no customization of the *TestLoader* is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.**TextTestRunner**(*stream=None*, *descriptions=True*, *verbosity=1*, *failfast=False*, *buffer=False*, *resultclass=None*, *warnings=None*, *, *tb_locals=False*, *durations=None*)

A basic test runner implementation that outputs results to a stream. If *stream* is `None`, the default, *sys.stderr* is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept `**kwargs` as the interface to construct runners changes when features are added to unittest.

By default this runner shows *DeprecationWarning*, *PendingDeprecationWarning*, *ResourceWarning* and *ImportWarning* even if they are *ignored by default*. This behavior can be overridden using Python's `-Wd` or `-Wa` options (see Warning control) and leaving *warnings* to `None`.

在 3.2 版的變更: 新增 *warnings* 參數。

在 3.2 版的變更: The default stream is set to *sys.stderr* at instantiation time rather than import time.

在 3.5 版的變更: 新增 *tb_locals* 參數。

在 3.12 版的變更: 新增 *durations* 參數。

_makeResult()

This method returns the instance of `TestResult` used by *run()*. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.
