Contents

1 簡介 **3**
- 1.1 可用性之🄴釋 . . . 4
  - 1.1.1 WebAssembly 平台 . . . 4

2 🄴建函式 **5**

3 🄴建常數 **33**
- 3.1 由 site module（模組）所添增的常數 . . . 34

4 🄴建型🄴 **35**
- 4.1 真值檢測 . . . 35
- 4.2 Boolean（布林）運算 --- and, or, not . . . 36
- 4.3 比較運算 . . . 36
- 4.4 數值型🄴 --- int、float、complex . . . 37
  - 4.4.1 整數型🄴的位元運算 . . . 38
  - 4.4.2 整數型🄴的附加 methods . . . 38
  - 4.4.3 浮點數的附加 methods . . . 41
  - 4.4.4 數值型🄴的雜🄴 . . . 42
- 4.5 Boolean 型🄴 - bool . . . 43
- 4.6 🄴代器型🄴 . . . 44
  - 4.6.1 Generator Types . . . 44
- 4.7 Sequence Types --- list, tuple, range . . . 44
  - 4.7.1 Common Sequence Operations . . . 44
  - 4.7.2 Immutable Sequence Types . . . 46
  - 4.7.3 Mutable Sequence Types . . . 46
  - 4.7.4 List（串列） . . . 47
  - 4.7.5 Tuples . . . 48
  - 4.7.6 Ranges . . . 49
- 4.8 Text Sequence Type --- str . . . 51
  - 4.8.1 String Methods . . . 52
  - 4.8.2 printf-style String Formatting . . . 60
- 4.9 Binary Sequence Types --- bytes, bytearray, memoryview . . . 62
  - 4.9.1 Bytes Objects . . . 62
  - 4.9.2 Bytearray Objects . . . 64
  - 4.9.3 Bytes and Bytearray Operations . . . 65
  - 4.9.4 printf-style Bytes Formatting . . . 76
  - 4.9.5 Memory Views . . . 79

4.10 Set Types --- set, frozenset . . . 86
4.11 Mapping Types --- dict . . . 88
4.11.1 字典視圖物件 . . . 92
4.12 Context Manager Types . . . 94
4.13 Type Annotation Types --- Generic Alias, Union . . . 94
4.13.1 Generic Alias Type . . . 95
4.13.2 Union Type . . . 99
4.14 Other Built-in Types . . . 101
4.14.1 模組 . . . 101
4.14.2 Classes and Class Instances . . . 101
4.14.3 函式 . . . 101
4.14.4 Methods . . . 101
4.14.5 Code Objects . . . 102
4.14.6 Type Objects . . . 102
4.14.7 The Null Object . . . 102
4.14.8 The Ellipsis Object . . . 102
4.14.9 The NotImplemented Object . . . 103
4.14.10 Internal Objects . . . 103
4.15 Special Attributes . . . 103
4.16 Integer string conversion length limitation . . . 104
4.16.1 Affected APIs . . . 105
4.16.2 Configuring the limit . . . 105
4.16.3 Recommended configuration . . . 106

5 🄵建的例外 107
5.1 例外的情境 . . . 107
5.2 繼承自🄵建的例外 . . . 108
5.3 基底類🄵 (base classes) . . . 108
5.4 實體例外 . . . 109
5.4.1 OS exceptions . . . 115
5.5 警告 . . . 116
5.6 Exception groups . . . 117
5.7 例外階層 . . . 119

6 文本處理 (Text Processing) 服務 121
6.1 string --- 常見的字串操作 . . . 121
6.1.1 字串常數 . . . 121
6.1.2 自訂字串格式 . . . 122
6.1.3 格式化文字語法 . . . 123
6.1.4 模板字串 . . . 130
6.1.5 輔助函式 . . . 132
6.2 re --- 正規表示式 (regular expression) 操作 . . . 132
6.2.1 正規表示式語法 . . . 133
6.2.2 模組🄵容 . . . 140
6.2.3 Regular Expression Objects . . . 146
6.2.4 Match Objects . . . 148
6.2.5 Regular Expression Examples . . . 151
6.3 difflib --- 計算差🄵的輔助工具 . . . 156
6.3.1 SequenceMatcher 物件 . . . 161
6.3.2 SequenceMatcher 範例 . . . 164
6.3.3 Differ Objects . . . 164
6.3.4 Differ Example . . . 165
6.3.5 A command-line interface to difflib . . . 166
6.3.6 ndiff 範例： . . . 167

6.4 textwrap --- 文字包裝與填充 . . . 169
6.5 unicodedata --- Unicode 資料庫 . . . 173
6.6 stringprep --- 網際網路字串准備 . . . 175
6.7 readline --- GNU readline 介面 . . . 177
6.7.1 Init file . . . 177
6.7.2 Line buffer . . . 177
6.7.3 History file . . . 178
6.7.4 History list . . . 178
6.7.5 Startup hooks . . . 179
6.7.6 Completion . . . 179
6.7.7 範例 . . . 180
6.8 rlcompleter --- GNU readline 的補全函式 . . . 181

7 二進位資料服務 183
7.1 struct --- 將位元組直譯🄵打包起來的二進位資料 . . . 183
7.1.1 函式與例外 . . . 184
7.1.2 Format Strings . . . 184
7.1.3 Applications . . . 189
7.1.4 Classes . . . 190
7.2 codecs --- 編解碼器🄴🄴表和基底類🄵 . . . 191
7.2.1 Codec Base Classes . . . 194
7.2.2 Encodings and Unicode . . . 201
7.2.3 Standard Encodings . . . 202
7.2.4 Python Specific Encodings . . . 205
7.2.5 encodings.idna --- Internationalized Domain Names in Applications . . . 208
7.2.6 encodings.mbcs --- Windows ANSI codepage . . . 208
7.2.7 encodings.utf_8_sig --- UTF-8 codec with BOM signature . . . 209

8 資料型🄵 211
8.1 datetime --- 日期與時間的基本型🄵 . . . 211
8.1.1 Aware and Naive Objects . . . 212
8.1.2 常數 . . . 212
8.1.3 Available Types . . . 213
8.1.4 timedelta 物件 . . . 214
8.1.5 date 物件 . . . 217
8.1.6 datetime 物件 . . . 222
8.1.7 time 物件 . . . 234
8.1.8 tzinfo 物件 . . . 238
8.1.9 timezone 物件 . . . 245
8.1.10 strftime() 與 strptime() 的行🄵 . . . 245
8.2 zoneinfo --- IANA 時區支援 . . . 250
8.2.1 Using ZoneInfo . . . 250
8.2.2 Data sources . . . 251
8.2.3 The ZoneInfo class . . . 252
8.2.4 函式 . . . 255
8.2.5 Globals . . . 255
8.2.6 Exceptions and warnings . . . 256
8.3 calendar --- 日🄵相關函式 . . . 256
8.3.1 命令列用法 . . . 261
8.4 collections --- 容器資料型態 . . . 263
8.4.1 ChainMap 物件 . . . 263
8.4.2 Counter 物件 . . . 266
8.4.3 deque 物件 . . . 269
8.4.4 defaultdict 物件 . . . 272

8.4.5 namedtuple() 擁有具名欄位之 tuple 的工廠函式 . . . 274
8.4.6 OrderedDict 物件 . . . 277
8.4.7 UserDict 物件 . . . 279
8.4.8 UserList 物件 . . . 280
8.4.9 UserString 物件 . . . 280
8.5 collections.abc --- 容器的抽象基底類F . . . 280
8.5.1 Collections Abstract Base Classes . . . 282
8.5.2 Collections Abstract Base Classes -- Detailed Descriptions . . . 284
8.5.3 Examples and Recipes . . . 286
8.6 heapq --- 堆積F列 (heap queue) 演算法 . . . 287
8.6.1 基礎範例 . . . 288
8.6.2 優先F列實作細節 . . . 289
8.6.3 原理 . . . 290
8.7 bisect --- 陣列二分演算法 (Array bisection algorithm) . . . 291
8.7.1 效能考量 . . . 292
8.7.2 搜尋一個已排序的 list . . . 292
8.7.3 範例 . . . 293
8.8 array --- 高效率的數值型陣列 . . . 294
8.9 weakref --- 弱參照 . . . 297
8.9.1 弱參照物件 . . . 301
8.9.2 範例 . . . 302
8.9.3 最終化器物件 . . . 303
8.9.4 最終化器與 __del__() 方法的比較 . . . 304
8.10 types --- 動態型F建立與F建型F名稱 . . . 305
8.10.1 Dynamic Type Creation . . . 305
8.10.2 Standard Interpreter Types . . . 307
8.10.3 Additional Utility Classes and Functions . . . 311
8.10.4 Coroutine Utility Functions . . . 312
8.11 copy --- 淺層 (shallow) 和深層 (deep) FF操作 . . . 312
8.12 pprint --- 資料美化列印器 . . . 313
8.12.1 Functions . . . 313
8.12.2 PrettyPrinter 物件 . . . 315
8.12.3 範例 . . . 316
8.13 reprlib --- repr() 的替代實作 . . . 319
8.13.1 Repr 物件 . . . 320
8.13.2 Subclassing Repr Objects . . . 322
8.14 enum --- 對列舉的支援 . . . 322
8.14.1 模組F容 . . . 323
8.14.2 資料型F . . . 324
8.14.3 通用項目與裝飾器 . . . 335
8.14.4 備F . . . 337
8.15 graphlib —-- 使用類圖 (graph-like) 結構進行操作的功能 . . . 337
8.15.1 例外 . . . 340

9 數值與數學模組 341
9.1 numbers --- 數值的抽象基底類F . . . 341
9.1.1 數值的階層 . . . 341
9.1.2 給型F實作者的F記 . . . 342
9.2 math --- 數學函式 . . . 344
9.2.1 數論與表現函式 . . . 345
9.2.2 Power and logarithmic functions . . . 348
9.2.3 Trigonometric functions . . . 350
9.2.4 Angular conversion . . . 351
9.2.5 Hyperbolic functions . . . 351

9.2.6 Special functions . . . 351
9.2.7 常數 . . . 352
9.3 cmath --- 🄵數的數學函式 . . . 353
9.3.1 轉🄵到極座標和從極座標做轉🄵 . . . 353
9.3.2 🄵函數和對數函數 . . . 354
9.3.3 三角函數 . . . 354
9.3.4 雙曲函數 . . . 355
9.3.5 分類函式 . . . 355
9.3.6 常數 . . . 356
9.4 decimal --- Decimal fixed-point and floating-point arithmetic . . . 356
9.4.1 Quick-start Tutorial . . . 358
9.4.2 Decimal objects . . . 361
9.4.3 Context objects . . . 369
9.4.4 常數 . . . 375
9.4.5 Rounding modes . . . 376
9.4.6 Signals . . . 376
9.4.7 Floating-Point Notes . . . 378
9.4.8 Working with threads . . . 380
9.4.9 Recipes . . . 380
9.4.10 Decimal FAQ . . . 383
9.5 fractions --- 有理數 . . . 386
9.6 random --- 生成🄵隨機數 . . . 389
9.6.1 簿記函式 (bookkeeping functions) . . . 390
9.6.2 回傳位元組的函式 . . . 390
9.6.3 回傳整數的函式 . . . 391
9.6.4 回傳序列的函式 . . . 391
9.6.5 離散分布 . . . 392
9.6.6 實數分布 . . . 392
9.6.7 替代🄵生器 . . . 394
9.6.8 關於 Reproducibility（復現性）的注意事項 . . . 394
9.6.9 範例 . . . 394
9.6.10 使用方案 . . . 397
9.7 statistics --- 數學統計函式 . . . 398
9.7.1 平均值與中央位置量數 . . . 399
9.7.2 離度 (spread) 的測量 . . . 399
9.7.3 兩個輸入之間的關🄴統計 . . . 399
9.7.4 函式細節 . . . 400
9.7.5 例外 . . . 408
9.7.6 NormalDist 物件 . . . 408
9.7.7 範例與錦囊妙計 . . . 409

10 函式編程模組 **415**
10.1 itertools --- 建立🄵生高效率🄵圈之🄵代器的函式 . . . 415
10.1.1 Itertool 函式 . . . 417
10.1.2 Itertools Recipes . . . 426
10.2 functools --- Higher-order functions and operations on callable objects . . . 431
10.2.1 partial 物件 . . . 441
10.3 operator --- 標准運算子替代函式 . . . 441
10.3.1 運算子與函式間的對映 . . . 446
10.3.2 原地 (in-place) 運算子 . . . 447

11 檔案與目🄵存取 **449**
11.1 pathlib --- 物件導向檔案系統路徑 . . . 449
11.1.1 基本用法 . . . 451

11.1.2 純路徑 . . . 451
11.1.3 實體路徑 . . . 461
11.1.4 與 os 模組F的工具的對應關F . . . 471
11.2 os.path --- 常見的路徑名操作 . . . 472
11.3 fileinput --- 逐列F代多個輸入串流 . . . 478
11.4 stat --- 直譯 stat() 的結果 . . . 481
11.5 filecmp --- 檔案與目F比較 . . . 487
11.5.1 The dircmp class . . . 487
11.6 tempfile --- 生成臨時檔案和目F . . . 489
11.6.1 範例 . . . 493
11.6.2 已F用的函式和變數 . . . 494
11.7 glob --- Unix 風格的路徑名稱模式擴展 . . . 494
11.8 fnmatch --- Unix 檔案名稱模式比對 . . . 497
11.9 linecache --- 隨機存取文字列 . . . 498
11.10 shutil —高階檔案操作 . . . 499
11.10.1 Directory and files operations . . . 499
11.10.2 Archiving operations . . . 505
11.10.3 Querying the size of the output terminal . . . 509

12 資料持久性 (Data Persistence) 511
12.1 pickle --- Python 物件序列化 . . . 511
12.1.1 和其他 Python 模組的關F . . . 512
12.1.2 Data stream format . . . 513
12.1.3 模組介面 . . . 513
12.1.4 What can be pickled and unpickled? . . . 517
12.1.5 Pickling Class Instances . . . 518
12.1.6 Custom Reduction for Types, Functions, and Other Objects . . . 524
12.1.7 Out-of-band Buffers . . . 525
12.1.8 Restricting Globals . . . 526
12.1.9 Performance . . . 528
12.1.10 範例 . . . 528
12.2 copyreg --- FF pickle 支援函式 . . . 529
12.2.1 範例 . . . 529
12.3 shelve --- Python object persistence . . . 529
12.3.1 Restrictions . . . 531
12.3.2 範例 . . . 532
12.4 marshal --- 內部 Python 物件序列化 . . . 532
12.5 dbm --- Unix "databases" 的介面 . . . 534
12.5.1 dbm.gnu --- GNU 資料庫管理器 . . . 536
12.5.2 dbm.ndbm --- 新資料庫管理器 . . . 537
12.5.3 dbm.dumb --- 可F式 DBM 實作 . . . 538
12.6 sqlite3 --- SQLite 資料庫的 DB-API 2.0 介面 . . . 539
12.6.1 Tutorial . . . 540
12.6.2 Reference . . . 542
12.6.3 How-to guides . . . 564
12.6.4 解釋 . . . 571

13 資料壓縮與保存 573
13.1 zlib --- 相容於 **gzip** 的壓縮 . . . 573
13.2 gzip --- **gzip** 檔案的支援 . . . 577
13.2.1 用法範例 . . . 579
13.2.2 命令列介面 . . . 580
13.3 bz2 --- **bzip2** 壓縮的支援 . . . 580
13.3.1 (De)compression of files . . . 581

13.3.2 Incremental (de)compression . . . 583
13.3.3 One-shot (de)compression . . . 584
13.3.4 用法範例 . . . 584
13.4 lzma --- 使用 LZMA 演算法進行壓縮 . . . 585
13.4.1 Reading and writing compressed files . . . 586
13.4.2 Compressing and decompressing data in memory . . . 587
13.4.3 Miscellaneous . . . 589
13.4.4 Specifying custom filter chains . . . 589
13.4.5 範例 . . . 590
13.5 zipfile --- 處理 ZIP 封存檔案 . . . 591
13.5.1 ZipFile 物件 . . . 593
13.5.2 Path Objects . . . 597
13.5.3 PyZipFile 物件 . . . 599
13.5.4 ZipInfo 物件 . . . 600
13.5.5 Command-Line Interface . . . 601
13.5.6 Decompression pitfalls . . . 602
13.6 tarfile --- 讀取與寫入 tar 封存檔案 . . . 603
13.6.1 TarFile 物件 . . . 607
13.6.2 TarInfo 物件 . . . 611
13.6.3 Extraction filters . . . 613
13.6.4 Command-Line Interface . . . 617
13.6.5 範例 . . . 618
13.6.6 Supported tar formats . . . 619
13.6.7 Unicode issues . . . 619

14 檔案格式 **621**
14.1 csv --- CSV 檔案讀取及寫入 . . . 621
14.1.1 模組🄵容 . . . 622
14.1.2 Dialect 與格式參數 . . . 626
14.1.3 讀取器物件 . . . 627
14.1.4 寫入器物件 . . . 627
14.1.5 範例 . . . 628
14.2 configparser --- 設定檔剖析器 . . . 629
14.2.1 Quick Start . . . 629
14.2.2 Supported Datatypes . . . 631
14.2.3 Fallback Values . . . 632
14.2.4 Supported INI File Structure . . . 632
14.2.5 Interpolation of values . . . 633
14.2.6 Mapping Protocol Access . . . 635
14.2.7 Customizing Parser Behaviour . . . 635
14.2.8 Legacy API Examples . . . 640
14.2.9 ConfigParser 物件 . . . 642
14.2.10 RawConfigParser 物件 . . . 646
14.2.11 例外 . . . 646
14.3 tomllib --- 剖析 TOML 檔案 . . . 647
14.3.1 範例 . . . 648
14.3.2 轉🄵表 . . . 649
14.4 netrc --- netrc 檔案處理 . . . 649
14.4.1 netrc 物件 . . . 650
14.5 plistlib --- 🄵生和剖析 Apple .plist 檔案 . . . 650
14.5.1 範例 . . . 652

15 加密服務 **653**
15.1 hashlib --- 安全雜🄵與訊息摘要 . . . 653

15.1.1 雜Ⓕ演算法 . . . 653
15.1.2 用法 . . . 654
15.1.3 建構函式 . . . 655
15.1.4 Attributes . . . 655
15.1.5 Hash Objects . . . 656
15.1.6 SHAKE variable length digests . . . 656
15.1.7 File hashing . . . 657
15.1.8 Key derivation . . . 657
15.1.9 BLAKE2 . . . 658
15.2 hmac --- 基於金鑰雜Ⓕ的訊息驗證 . . . 666
15.3 secrets --- Ⓕ生用於管理機密的安全亂數 . . . 668
15.3.1 亂數 . . . 668
15.3.2 Ⓕ生權杖（token） . . . 668
15.3.3 其他函式 . . . 669
15.3.4 應用技巧和典範實務（best practices） . . . 669

16 通用作業系統服務 671
16.1 os --- 各種作業系統介面 . . . 671
16.1.1 File Names, Command Line Arguments, and Environment Variables . . . 672
16.1.2 Python UTF-8 模式 . . . 672
16.1.3 行程參數 . . . 673
16.1.4 File Object Creation . . . 681
16.1.5 File Descriptor Operations . . . 681
16.1.6 Files and Directories . . . 694
16.1.7 行程管理 . . . 718
16.1.8 Interface to the scheduler . . . 733
16.1.9 Miscellaneous System Information . . . 734
16.1.10 Random numbers . . . 736
16.2 io —處理資料串流的核心工具 . . . 737
16.2.1 總覽 . . . 737
16.2.2 文字編碼 . . . 739
16.2.3 高階模組介面 . . . 739
16.2.4 類Ⓕ階層 . . . 740
16.2.5 Performance . . . 751
16.3 time --- 時間存取與轉Ⓕ . . . 752
16.3.1 函式 . . . 753
16.3.2 Clock ID Constants . . . 761
16.3.3 Timezone Constants . . . 763
16.4 argparse --- Parser for command-line options, arguments and sub-commands . . . 764
16.4.1 Core Functionality . . . 764
16.4.2 Quick Links for add_argument() . . . 765
16.4.3 範例 . . . 765
16.4.4 ArgumentParser 物件 . . . 767
16.4.5 The add_argument() method . . . 775
16.4.6 The parse_args() method . . . 786
16.4.7 Other utilities . . . 789
16.4.8 Upgrading optparse code . . . 798
16.4.9 Exceptions . . . 798
16.5 getopt --- 用於命令列選項的 C 風格剖析器 . . . 799
16.6 logging --- Python 的日Ⓕ記Ⓕ工具 . . . 801
16.6.1 Logger 物件 . . . 803
16.6.2 Logging Levels . . . 807
16.6.3 Handler Objects . . . 808
16.6.4 Formatter Objects . . . 810

16.6.5 Filter Objects . . . 812
16.6.6 LogRecord 物件 . . . 812
16.6.7 LogRecord attributes . . . 814
16.6.8 LoggerAdapter 物件 . . . 816
16.6.9 Thread Safety . . . 816
16.6.10 Module-Level Functions . . . 816
16.6.11 Module-Level Attributes . . . 821
16.6.12 Integration with the warnings module . . . 822
16.7 logging.config --- 日F記F配置 . . . 822
16.7.1 Configuration functions . . . 823
16.7.2 Security considerations . . . 825
16.7.3 Configuration dictionary schema . . . 825
16.7.4 Configuration file format . . . 832
16.8 logging.handlers --- 日F紀F處理器 . . . 835
16.8.1 StreamHandler . . . 836
16.8.2 FileHandler . . . 836
16.8.3 NullHandler . . . 837
16.8.4 WatchedFileHandler . . . 837
16.8.5 BaseRotatingHandler . . . 838
16.8.6 RotatingFileHandler . . . 839
16.8.7 TimedRotatingFileHandler . . . 840
16.8.8 SocketHandler . . . 841
16.8.9 DatagramHandler . . . 842
16.8.10 SysLogHandler . . . 843
16.8.11 NTEventLogHandler . . . 845
16.8.12 SMTPHandler . . . 846
16.8.13 MemoryHandler . . . 846
16.8.14 HTTPHandler . . . 847
16.8.15 QueueHandler . . . 848
16.8.16 QueueListener . . . 849
16.9 getpass --- 可F式密碼輸入工具 . . . 850
16.10 curses --- 字元儲存格顯示的終端處理 . . . 851
16.10.1 函式 . . . 852
16.10.2 Window Objects . . . 859
16.10.3 Constants . . . 866
16.11 curses.textpad --- Text input widget for curses programs . . . 879
16.11.1 Textbox objects . . . 880
16.12 curses.ascii --- ASCII 字元的工具程式 . . . 881
16.13 curses.panel --- curses 的面板堆F擴充 . . . 885
16.13.1 函式 . . . 885
16.13.2 Panel Objects . . . 885
16.14 platform --- 對底層平臺識F資料的存取 . . . 886
16.14.1 跨平台 . . . 886
16.14.2 Java 平台 . . . 888
16.14.3 Windows 平台 . . . 888
16.14.4 macOS 平台 . . . 889
16.14.5 Unix 平台 . . . 889
16.14.6 Linux 平台 . . . 889
16.15 errno --- 標准 errno 系統符號 . . . 890
16.16 ctypes --- 用於 Python 的外部函式庫 . . . 897
16.16.1 ctypes tutorial . . . 897
16.16.2 ctypes reference . . . 916

17 F行執行 (Concurrent Execution) 933

17.1 threading --- 基於執行緒的平行性 . . . 933
17.1.1 Thread-Local Data . . . 936
17.1.2 Thread Objects . . . 937
17.1.3 Lock Objects . . . 939
17.1.4 RLock 物件 . . . 940
17.1.5 Condition Objects . . . 942
17.1.6 Semaphore Objects . . . 944
17.1.7 Event Objects . . . 945
17.1.8 Timer Objects . . . 946
17.1.9 Barrier Objects . . . 946
17.1.10 Using locks, conditions, and semaphores in the with statement . . . 948
17.2 multiprocessing --- 以行程🄵基礎的平行性 . . . 948
17.2.1 簡介 . . . 948
17.2.2 Reference . . . 956
17.2.3 Programming guidelines . . . 986
17.2.4 範例 . . . 989
17.3 multiprocessing.shared_memory --- 對於共享記憶體的跨行程直接存取 . . . 995
17.4 concurrent 套件 . . . 1000
17.5 concurrent.futures --- 🄵動平行任務 . . . 1001
17.5.1 Executor 物件 . . . 1001
17.5.2 ThreadPoolExecutor . . . 1002
17.5.3 ProcessPoolExecutor . . . 1004
17.5.4 Future 物件 . . . 1005
17.5.5 模組函式 . . . 1007
17.5.6 例外類🄴 . . . 1007
17.6 subprocess --- 子行程管理 . . . 1008
17.6.1 Using the subprocess Module . . . 1008
17.6.2 Security Considerations . . . 1017
17.6.3 Popen Objects . . . 1018
17.6.4 Windows Popen Helpers . . . 1020
17.6.5 Older high-level API . . . 1022
17.6.6 Replacing Older Functions with the subprocess Module . . . 1024
17.6.7 Legacy Shell Invocation Functions . . . 1027
17.6.8 🄵解 . . . 1028
17.7 sched --- 事件排程器 . . . 1029
17.7.1 排程器物件 . . . 1030
17.8 queue --- 同步🄵列 (synchronized queue) 類🄵 . . . 1031
17.8.1 🄵列物件 . . . 1032
17.8.2 SimpleQueue 物件 . . . 1033
17.9 contextvars --- 情境變數 . . . 1034
17.9.1 Context Variables . . . 1034
17.9.2 Manual Context Management . . . 1035
17.9.3 asyncio support . . . 1037
17.10 _thread --- 低階執行緒 API . . . 1038

18 Networking and Interprocess Communication **1041**
18.1 asyncio --- 非同步 I/O . . . 1041
18.1.1 Runners (執行器) . . . 1042
18.1.2 協程與任務 . . . 1045
18.1.3 串流 . . . 1063
18.1.4 同步化原始物件 (Synchronization Primitives) . . . 1071
18.1.5 子行程 . . . 1077
18.1.6 🄵列 (Queues) . . . 1082
18.1.7 例外 . . . 1085

18.1.8 事件🄵圈 . . . 1086
18.1.9 Futures . . . 1110
18.1.10 傳輸與協定 . . . 1114
18.1.11 Policies . . . 1128
18.1.12 平臺支援 . . . 1132
18.1.13 擴充 . . . 1133
18.1.14 高階 API 索引 . . . 1135
18.1.15 低階 API 索引 . . . 1137
18.1.16 使用 asyncio 開發 . . . 1143
18.2 socket --- 低階網路介面 . . . 1147
18.2.1 Socket 系列家族 . . . 1147
18.2.2 模組🄵容 . . . 1150
18.2.3 Socket 物件 . . . 1164
18.2.4 Notes on socket timeouts . . . 1171
18.2.5 範例 . . . 1172
18.3 ssl --- socket 物件的 TLS/SSL 包裝器 . . . 1176
18.3.1 函式、常數與例外 . . . 1176
18.3.2 SSL Sockets . . . 1188
18.3.3 SSL Contexts . . . 1192
18.3.4 Certificates . . . 1201
18.3.5 範例 . . . 1203
18.3.6 Notes on non-blocking sockets . . . 1205
18.3.7 Memory BIO Support . . . 1206
18.3.8 SSL session . . . 1208
18.3.9 Security considerations . . . 1208
18.3.10 TLS 1.3 . . . 1210
18.4 select --- 等待 I/O 完成 . . . 1211
18.4.1 /dev/poll Polling Objects . . . 1213
18.4.2 Edge and Level Trigger Polling (epoll) Objects . . . 1214
18.4.3 Polling Objects . . . 1215
18.4.4 Kqueue Objects . . . 1216
18.4.5 Kevent Objects . . . 1216
18.5 selectors --- 高階 I/O 多工 . . . 1218
18.5.1 簡介 . . . 1218
18.5.2 Classes . . . 1219
18.5.3 範例 . . . 1221
18.6 signal --- 設定非同步事件的處理函式 . . . 1222
18.6.1 General rules . . . 1222
18.6.2 模組🄵容 . . . 1223
18.6.3 範例 . . . 1230
18.6.4 Note on SIGPIPE . . . 1231
18.6.5 Note on Signal Handlers and Exceptions . . . 1231
18.7 mmap --- 記憶體映射檔案的支援 . . . 1232
18.7.1 MADV_* Constants . . . 1236
18.7.2 MAP_* 常數 . . . 1237

19 網際網路資料處理 1239
19.1 email --- 郵件和 MIME 處理套件 . . . 1239
19.1.1 email.message: 表示電子郵件訊息 . . . 1240
19.1.2 email.parser: 剖析電子郵件訊息 . . . 1248
19.1.3 email.generator: 🄵生 MIME 文件 . . . 1252
19.1.4 email.policy: Policy Objects . . . 1255
19.1.5 email.errors: 例外和缺陷類🄵 . . . 1262
19.1.6 email.headerregistry: 自訂標頭物件 . . . 1264

19.1.7 email.contentmanager: 管理 MIME 內容 . . . 1270
19.1.8 email: 範例 . . . 1272
19.1.9 email.message.Message: Representing an email message using the compat32 API . . . 1279
19.1.10 email.mime: 從頭開始建立電子郵件和 MIME 物件 . . . 1287
19.1.11 email.header: 國際化標頭 . . . 1290
19.1.12 email.charset: 表示字元集合 . . . 1292
19.1.13 email.encoders: 編碼器 . . . 1295
19.1.14 email.utils: 雜項工具 . . . 1296
19.1.15 email.iterators: 內代器 . . . 1298
19.2 json --- JSON 編碼器與解碼器 . . . 1299
19.2.1 基本用法 . . . 1302
19.2.2 Encoders and Decoders . . . 1304
19.2.3 例外 . . . 1306
19.2.4 Standard Compliance and Interoperability . . . 1306
19.2.5 命令列介面 . . . 1308
19.3 mailbox --- 以各種格式操作郵件信箱 . . . 1309
19.3.1 Mailbox 物件 . . . 1310
19.3.2 Message 物件 . . . 1319
19.3.3 例外 . . . 1327
19.3.4 範例 . . . 1328
19.4 mimetypes --- 將檔案名稱對映到 MIME 類型 . . . 1329
19.4.1 MimeTypes 物件 . . . 1331
19.5 base64 --- Base16、Base32、Base64、Base85 資料編碼 . . . 1332
19.5.1 安全考量 . . . 1335
19.6 binascii --- 在二進位制和 ASCII 之間轉內 . . . 1335
19.7 quopri --- 編碼和解碼 MIME 可列印字元資料 . . . 1338

20 Structured Markup Processing Tools 1339
20.1 html --- 超連結標記語言 (HTML) 支援 . . . 1339
20.2 html.parser --- 簡單的 HTML 和 XHTML 剖析器 . . . 1340
20.2.1 HTML 剖析器應用程式範例 . . . 1340
20.2.2 HTMLParser 方法 . . . 1341
20.2.3 範例 . . . 1342
20.3 html.entities --- HTML 一般實體的定義 . . . 1344
20.4 XML 處理模組 . . . 1345
20.4.1 XML 漏洞 . . . 1345
20.4.2 defusedxml 套件 . . . 1346
20.5 xml.etree.cElementTree --- ElementTree XML API . . . 1346
20.5.1 教學 . . . 1347
20.5.2 XPath 支援 . . . 1352
20.5.3 Reference . . . 1354
20.5.4 XInclude support . . . 1357
20.5.5 Reference . . . 1358
20.6 xml.dom --- Document 物件模型 API . . . 1366
20.6.1 模組內容 . . . 1367
20.6.2 Objects in the DOM . . . 1368
20.6.3 Conformance . . . 1376
20.7 xml.dom.minidom --- 最小的 DOM 實作 . . . 1377
20.7.1 DOM 物件 . . . 1379
20.7.2 DOM 範例 . . . 1380
20.7.3 minidom and the DOM standard . . . 1381
20.8 xml.dom.pulldom --- 支援建置部分 DOM 樹 . . . 1382
20.8.1 DOMEventStream 物件 . . . 1383
20.9 xml.sax --- SAX2 剖析器支援 . . . 1384

20.9.1 SAXException 物件 . . . 1386
20.10 xml.sax.handler --- SAX 處理函式的基本類F . . . 1386
20.10.1 ContentHandler 物件 . . . 1388
20.10.2 DTDHandler 物件 . . . 1390
20.10.3 EntityResolver 物件 . . . 1390
20.10.4 ErrorHandler 物件 . . . 1390
20.10.5 LexicalHandler 物件 . . . 1391
20.11 xml.sax.saxutils --- SAX 工具程式 . . . 1391
20.12 xml.sax.xmlreader --- XML 剖析器的介面 . . . 1393
20.12.1 XMLReader 物件 . . . 1394
20.12.2 IncrementalParser 物件 . . . 1395
20.12.3 Locator Objects . . . 1395
20.12.4 InputSource 物件 . . . 1395
20.12.5 The Attributes Interface . . . 1396
20.12.6 The AttributesNS Interface . . . 1397
20.13 xml.parsers.expat --- 使用 Expat 進行快速 XML 剖析 . . . 1397
20.13.1 XMLParser 物件 . . . 1398
20.13.2 ExpatError 例外 . . . 1403
20.13.3 範例 . . . 1403
20.13.4 Content Model Descriptions . . . 1404
20.13.5 Expat error constants . . . 1405

21 網路協定 (Internet protocols) 及支援 1409
21.1 webbrowser --- 方便的網頁F覽器控制器 . . . 1409
21.1.1 Browser Controller Objects . . . 1412
21.2 wsgiref --- WSGI 工具與參考實作 . . . 1412
21.2.1 wsgiref.util -- WSGI 環境工具 . . . 1412
21.2.2 wsgiref.headers -- WSGI 回應標頭工具 . . . 1414
21.2.3 wsgiref.simple_server -- 一個簡單的 WSGI HTTP 伺服器 . . . 1415
21.2.4 wsgiref.validate --- WSGI 符合性檢查 . . . 1416
21.2.5 wsgiref.handlers -- 伺服器 / 閘道基本類F . . . 1417
21.2.6 wsgiref.types -- 用於F態型F檢查的 WSGI 型F . . . 1420
21.2.7 範例 . . . 1421
21.3 urllib --- URL 處理模組 . . . 1422
21.4 urllib.request --- 用來開F URLs 的可擴充函式庫 . . . 1422
21.4.1 Request Objects . . . 1428
21.4.2 OpenerDirector 物件 . . . 1429
21.4.3 BaseHandler 物件 . . . 1430
21.4.4 HTTPRedirectHandler 物件 . . . 1432
21.4.5 HTTPCookieProcessor 物件 . . . 1433
21.4.6 ProxyHandler 物件 . . . 1433
21.4.7 HTTPPasswordMgr 物件 . . . 1433
21.4.8 HTTPPasswordMgrWithPriorAuth 物件 . . . 1433
21.4.9 AbstractBasicAuthHandler 物件 . . . 1434
21.4.10 HTTPBasicAuthHandler 物件 . . . 1434
21.4.11 ProxyBasicAuthHandler 物件 . . . 1434
21.4.12 AbstractDigestAuthHandler 物件 . . . 1434
21.4.13 HTTPDigestAuthHandler 物件 . . . 1434
21.4.14 ProxyDigestAuthHandler 物件 . . . 1434
21.4.15 HTTPHandler 物件 . . . 1435
21.4.16 HTTPSHandler 物件 . . . 1435
21.4.17 FileHandler 物件 . . . 1435
21.4.18 DataHandler 物件 . . . 1435
21.4.19 FTPHandler 物件 . . . 1435

21.4.20 CacheFTPHandler 物件 . . . 1435
21.4.21 UnknownHandler 物件 . . . 1436
21.4.22 HTTPErrorProcessor 物件 . . . 1436
21.4.23 Examples . . . 1436
21.4.24 Legacy interface . . . 1439
21.4.25 urllib.request Restrictions . . . 1441
21.5 urllib.response --- Response classes used by urllib . . . 1442
21.6 urllib.parse --- 將 URL 剖析成元件 . . . 1442
21.6.1 URL Parsing . . . 1443
21.6.2 URL parsing security . . . 1447
21.6.3 Parsing ASCII Encoded Bytes . . . 1448
21.6.4 Structured Parse Results . . . 1448
21.6.5 URL Quoting . . . 1449
21.7 urllib.error --- urllib.request 引發的例外類🄴 . . . 1451
21.8 urllib.robotparser --- robots.txt 的剖析器 . . . 1452
21.9 http --- HTTP 模組 . . . 1453
21.9.1 HTTP 狀態碼 . . . 1454
21.9.2 HTTP 狀態分類 . . . 1456
21.9.3 HTTP 方法 . . . 1457
21.10 http.client --- HTTP 協定用🄴端 . . . 1457
21.10.1 HTTPConnection 物件 . . . 1460
21.10.2 HTTPResponse 物件 . . . 1462
21.10.3 範例 . . . 1464
21.10.4 HTTPMessage 物件 . . . 1465
21.11 ftplib --- FTP 協定用🄴端 . . . 1465
21.11.1 參考 . . . 1466
21.12 poplib --- POP3 協定用🄴端 . . . 1472
21.12.1 POP3 物件 . . . 1473
21.12.2 POP3 範例 . . . 1475
21.13 imaplib --- IMAP4 協定客🄴端 . . . 1475
21.13.1 IMAP4 物件 . . . 1477
21.13.2 IMAP4 範例 . . . 1482
21.14 smtplib --- SMTP 協定用🄴端 . . . 1482
21.14.1 SMTP 物件 . . . 1485
21.14.2 SMTP 範例 . . . 1489
21.15 uuid --- **RFC 4122** 定義的 UUID 物件 . . . 1489
21.15.1 命令列的用法 . . . 1493
21.15.2 範例 . . . 1493
21.15.3 命令列的範例 . . . 1494
21.16 socketserver --- 用於網路伺服器的框架 . . . 1494
21.16.1 Server Creation Notes . . . 1495
21.16.2 Server Objects . . . 1496
21.16.3 Request Handler Objects . . . 1498
21.16.4 範例 . . . 1499
21.17 http.server —HTTP 伺服器 . . . 1503
21.17.1 Security Considerations . . . 1509
21.18 http.cookies --- HTTP 狀態管理 . . . 1510
21.18.1 Cookie 物件 . . . 1511
21.18.2 Morsel 物件 . . . 1511
21.18.3 範例 . . . 1513
21.19 http.cookiejar --- HTTP 客🄴端的 Cookie 處理 . . . 1514
21.19.1 CookieJar 與 FileCookieJar 物件 . . . 1516
21.19.2 FileCookieJar subclasses and co-operation with web browsers . . . 1518
21.19.3 CookiePolicy 物件 . . . 1518

21.19.4 DefaultCookiePolicy 物件 . . . 1519
21.19.5 Cookie 物件 . . . 1521
21.19.6 範例 . . . 1522
21.20 xmlrpc --- XMLRPC 伺服器與用🄵模組 . . . 1523
21.21 xmlrpc.client --- XML-RPC 客🄵端存取 . . . 1523
21.21.1 ServerProxy 物件 . . . 1525
21.21.2 日期時間物件 . . . 1526
21.21.3 Binary Objects . . . 1527
21.21.4 Fault Objects . . . 1528
21.21.5 ProtocolError 物件 . . . 1528
21.21.6 MultiCall 物件 . . . 1529
21.21.7 Convenience Functions . . . 1530
21.21.8 Example of Client Usage . . . 1530
21.21.9 Example of Client and Server Usage . . . 1531
21.22 xmlrpc.server --- 基本 XML-RPC 伺服器 . . . 1531
21.22.1 SimpleXMLRPCServer 物件 . . . 1532
21.22.2 CGIXMLRPCRequestHandler . . . 1535
21.22.3 Documenting XMLRPC server . . . 1536
21.22.4 DocXMLRPCServer 物件 . . . 1537
21.22.5 DocCGIXMLRPCRequestHandler . . . 1537
21.23 ipaddress --- IPv4/IPv6 操作函式庫 . . . 1537
21.23.1 Convenience factory functions . . . 1538
21.23.2 IP Addresses . . . 1538
21.23.3 IP Network definitions . . . 1543
21.23.4 Interface objects . . . 1550
21.23.5 Other Module Level Functions . . . 1551
21.23.6 Custom Exceptions . . . 1552

22 多媒體服務 **1553**
22.1 wave --- 讀寫 WAV 檔案 . . . 1553
22.1.1 Wave_read 物件 . . . 1554
22.1.2 Wave_write 物件 . . . 1555
22.2 colorsys --- 🄵色系統間的轉🄵 . . . 1556

23 國際化 **1557**
23.1 gettext --- 多語言國際化服務 . . . 1557
23.1.1 GNU **gettext** API . . . 1557
23.1.2 Class-based API . . . 1559
23.1.3 Internationalizing your programs and modules . . . 1562
23.1.4 致謝 . . . 1565
23.2 locale --- 國際化服務 . . . 1565
23.2.1 Background, details, hints, tips and caveats . . . 1573
23.2.2 For extension writers and programs that embed Python . . . 1574
23.2.3 Access to message catalogs . . . 1574

24 程式框架 **1575**
24.1 turtle --- 龜圖學 (Turtle graphics) . . . 1575
24.1.1 介紹 . . . 1575
24.1.2 教學 . . . 1576
24.1.3 How to... . . . 1578
24.1.4 Turtle graphics reference . . . 1580
24.1.5 Methods of RawTurtle/Turtle and corresponding functions . . . 1583
24.1.6 Methods of TurtleScreen/Screen and corresponding functions . . . 1601
24.1.7 Public classes . . . 1608

24.1.8 Explanation . . . 1610
24.1.9 Help and configuration . . . 1610
24.1.10 turtledemo --- Demo scripts . . . 1613
24.1.11 Changes since Python 2.6 . . . 1614
24.1.12 Changes since Python 3.0 . . . 1615
24.2 cmd --- 以列F導向的指令直譯器支援 . . . 1615
24.2.1 Cmd 物件 . . . 1615
24.2.2 Cmd Example . . . 1617
24.3 shlex --- 簡單的語法分析 . . . 1620
24.3.1 shlex 物件 . . . 1622
24.3.2 Parsing Rules . . . 1624
24.3.3 Improved Compatibility with Shells . . . 1625

25 以 Tk 打造圖形使用者介面 (Graphical User Interfaces) 1627
25.1 tkinter --- Tcl/Tk 的 Python 介面 . . . 1627
25.1.1 Architecture . . . 1628
25.1.2 Tkinter Modules . . . 1629
25.1.3 Tkinter Life Preserver . . . 1631
25.1.4 Threading model . . . 1634
25.1.5 Handy Reference . . . 1635
25.1.6 File Handlers . . . 1641
25.2 tkinter.colorchooser --- F色選擇對話框 . . . 1641
25.3 tkinter.font --- Tkinter 字型包裝器 . . . 1642
25.4 Tkinter 對話框 . . . 1643
25.4.1 tkinter.simpledialog --- 標准 Tkinter 輸入對話框 . . . 1643
25.4.2 tkinter.filedialog --- File selection dialogs . . . 1644
25.4.3 tkinter.commondialog --- Dialog window templates . . . 1646
25.5 tkinter.messagebox --- Tkinter 訊息提示 . . . 1646
25.6 tkinter.scrolledtext --- F動文字小工具 . . . 1649
25.7 tkinter.dnd --- 拖放支援 . . . 1649
25.8 tkinter.ttk --- Tk 主題化小工具 . . . 1650
25.8.1 使用 Ttk . . . 1650
25.8.2 Ttk Widgets . . . 1651
25.8.3 Widget . . . 1651
25.8.4 Combobox . . . 1654
25.8.5 Spinbox . . . 1655
25.8.6 Notebook . . . 1656
25.8.7 Progressbar . . . 1658
25.8.8 Separator . . . 1659
25.8.9 Sizegrip . . . 1660
25.8.10 Treeview . . . 1660
25.8.11 Ttk Styling . . . 1666
25.9 tkinter.tix --- Tk 擴充小工具 . . . 1670
25.9.1 Using Tix . . . 1670
25.9.2 Tix Widgets . . . 1671
25.9.3 Tix 指令 . . . 1674
25.10 IDLE . . . 1675
25.10.1 目F . . . 1675
25.10.2 Editing and Navigation . . . 1680
25.10.3 Startup and Code Execution . . . 1683
25.10.4 Help and Preferences . . . 1686
25.10.5 idlelib . . . 1687

26 開發工具 1689

26.1 typing --- 支援型🄵提示 . . . 1689
26.1.1 Python 型🄵系統的技術規範 . . . 1690
26.1.2 型🄵🄵名 . . . 1690
26.1.3 NewType . . . 1691
26.1.4 🄵釋 callable 物件 . . . 1692
26.1.5 泛型 . . . 1693
26.1.6 🄵釋元組 (tuple) . . . 1694
26.1.7 類🄵物件的型🄵 . . . 1695
26.1.8 使用者定義泛型型🄵 . . . 1696
26.1.9 Any 型🄵 . . . 1698
26.1.10 標稱 (nominal) 子型🄵 vs 結構子型🄵 . . . 1700
26.1.11 模組🄵容 . . . 1700
26.1.12 Deprecation Timeline of Major Features . . . 1740
26.2 pydoc --- 文件🄵生器與🄵上幫助系統 . . . 1740
26.3 Python 開發模式 . . . 1742
26.3.1 Python 開發模式的影響 . . . 1742
26.3.2 ResourceWarning 範例 . . . 1743
26.3.3 檔案描述器的錯誤範例 . . . 1744
26.4 doctest --- 測試互動式 Python 範例 . . . 1745
26.4.1 Simple Usage: Checking Examples in Docstrings . . . 1747
26.4.2 Simple Usage: Checking Examples in a Text File . . . 1747
26.4.3 How It Works . . . 1748
26.4.4 Basic API . . . 1756
26.4.5 Unittest API . . . 1757
26.4.6 Advanced API . . . 1760
26.4.7 Debugging . . . 1765
26.4.8 Soapbox . . . 1768
26.5 unittest --- 單元測試框架 . . . 1769
26.5.1 簡單範例 . . . 1770
26.5.2 命令執行列介面 (Command-Line Interface) . . . 1771
26.5.3 Test Discovery（測試探索） . . . 1772
26.5.4 Organizing test code . . . 1774
26.5.5 Re-using old test code . . . 1775
26.5.6 Skipping tests and expected failures . . . 1776
26.5.7 Distinguishing test iterations using subtests . . . 1778
26.5.8 Classes and functions . . . 1779
26.5.9 Class and Module Fixtures . . . 1799
26.5.10 Signal Handling . . . 1800
26.6 unittest.mock —mock 物件函式庫 . . . 1801
26.6.1 快速導引 . . . 1802
26.6.2 Mock 類🄵 . . . 1804
26.6.3 Patchers . . . 1821
26.6.4 MagicMock 以及魔術方法支援 . . . 1830
26.6.5 輔助函式 . . . 1834
26.6.6 side_effect、return_value 和 *wraps* 的優先順序 . . . 1841
26.7 unittest.mock --- 入門指南 . . . 1843
26.7.1 使用 Mock 的方式 . . . 1843
26.7.2 Patch 裝飾器 . . . 1849
26.7.3 更多範例 . . . 1851
26.8 2to3 --- 自動將 Python 2 的程式碼轉成 Python 3 . . . 1864
26.8.1 使用 2to3 . . . 1864
26.8.2 Fixers . . . 1865
26.8.3 lib2to3 --- 2to3's library . . . 1869
26.9 test --- Python 的回歸測試 (regression tests) 套件 . . . 1870

26.9.1 撰寫 test 套件的單元測試 . . . 1870
26.9.2 使用命令列介面執行測試 . . . 1872
26.10 test.support --- Python 測試套件的工具 . . . 1872
26.11 test.support.socket_helper --- 用於 socket 測試的工具 . . . 1882
26.12 test.support.script_helper --- 用於 Python 執行測試的工具 . . . 1883
26.13 test.support.bytecode_helper --- 用於測試位元組碼能正確🄵生的支援工具 . . . 1884
26.14 test.support.threading_helper --- Utilities for threading tests . . . 1884
26.15 test.support.os_helper --- 用於 os 測試的工具 . . . 1885
26.16 test.support.import_helper --- 用於 import 測試的工具 . . . 1887
26.17 test.support.warnings_helper --- 用於 warnings 測試的工具 . . . 1889

27 除錯與效能分析 1891
27.1 稽核事件表 . . . 1891
27.2 bdb --- 偵錯器框架 . . . 1895
27.3 faulthandler --- 傾印 Python 回溯 . . . 1901
27.3.1 Dumping the traceback . . . 1902
27.3.2 Fault handler state . . . 1902
27.3.3 Dumping the tracebacks after a timeout . . . 1902
27.3.4 Dumping the traceback on a user signal . . . 1903
27.3.5 Issue with file descriptors . . . 1903
27.3.6 範例 . . . 1903
27.4 pdb --- The Python Debugger . . . 1903
27.4.1 Debugger Commands . . . 1906
27.5 Python 的分析器 . . . 1911
27.5.1 Introduction to the profilers . . . 1912
27.5.2 Instant User's Manual . . . 1912
27.5.3 profile and cProfile Module Reference . . . 1914
27.5.4 The Stats Class . . . 1916
27.5.5 What Is Deterministic Profiling? . . . 1918
27.5.6 限制 . . . 1919
27.5.7 校正 . . . 1919
27.5.8 Using a custom timer . . . 1920
27.6 timeit --- 測量小量程式片段的執行時間 . . . 1920
27.6.1 基礎範例 . . . 1921
27.6.2 Python 介面 . . . 1921
27.6.3 命令列介面 . . . 1923
27.6.4 範例 . . . 1924
27.7 trace --- 追🄵或追查 Python 陳述式執行 . . . 1925
27.7.1 Command-Line Usage . . . 1926
27.7.2 Programmatic Interface . . . 1927
27.8 tracemalloc --- 追🄵記憶體配置 . . . 1928
27.8.1 範例 . . . 1929
27.8.2 API . . . 1933

28 軟體封裝與發布 1941
28.1 ensurepip --- pip 安裝器的初始建置 (bootstrapping) . . . 1941
28.1.1 命令列介面 . . . 1942
28.1.2 模組 API . . . 1942
28.2 venv --- 建立🄵擬環境 . . . 1943
28.2.1 建立🄵擬環境 . . . 1944
28.2.2 🄵擬環境如何運作 . . . 1945
28.2.3 API . . . 1946
28.2.4 An example of extending EnvBuilder . . . 1949
28.3 zipapp —-- 管理可執行的 Python zip 封存檔案 . . . 1953

28.3.1 基本範例 . . . 1953
28.3.2 命令執行列介面 . . . 1953
28.3.3 Python API . . . 1954
28.3.4 範例 . . . 1955
28.3.5 Specifying the Interpreter . . . 1956
28.3.6 Creating Standalone Applications with zipapp . . . 1956
28.3.7 The Python Zip Application Archive Format . . . 1957

29 Python Runtime 服務 1959
29.1 sys --- 系統特定的參數與函式 . . . 1959
29.2 sys.monitoring --- Execution event monitoring . . . 1985
29.2.1 Tool identifiers . . . 1986
29.2.2 Events . . . 1986
29.2.3 Turning events on and off . . . 1989
29.2.4 Registering callback functions . . . 1989
29.3 sysconfig --- 提供 Python 設定資訊的存取 . . . 1991
29.3.1 Configuration variables . . . 1991
29.3.2 Installation paths . . . 1991
29.3.3 User scheme . . . 1992
29.3.4 Home scheme . . . 1993
29.3.5 Prefix scheme . . . 1994
29.3.6 安裝路徑函式 . . . 1995
29.3.7 其他函式 . . . 1996
29.3.8 將 sysconfig 作🄵🄵本使用 . . . 1997
29.4 builtins --- 🄵建物件 . . . 1997
29.5 __main__ --- 頂層程式碼環境 . . . 1998
29.5.1 __name__ == '__main__' . . . 1998
29.5.2 Python 套件中的 __main__.py . . . 2001
29.5.3 import __main__ . . . 2002
29.6 warnings --- 警告控制 . . . 2003
29.6.1 Warning Categories . . . 2004
29.6.2 The Warnings Filter . . . 2004
29.6.3 Temporarily Suppressing Warnings . . . 2007
29.6.4 Testing Warnings . . . 2007
29.6.5 Updating Code For New Versions of Dependencies . . . 2008
29.6.6 Available Functions . . . 2008
29.6.7 Available Context Managers . . . 2010
29.7 dataclasses --- Data Classes . . . 2010
29.7.1 模組🄵容 . . . 2011
29.7.2 Post-init processing . . . 2017
29.7.3 類🄵變數 . . . 2018
29.7.4 Init-only variables . . . 2018
29.7.5 凍結實例 . . . 2018
29.7.6 繼承 . . . 2018
29.7.7 Re-ordering of keyword-only parameters in __init__() . . . 2019
29.7.8 預設工廠函式 . . . 2019
29.7.9 可變預設值 . . . 2020
29.7.10 Descriptor-typed fields . . . 2021
29.8 contextlib --- Utilities for with-statement contexts . . . 2021
29.8.1 Utilities . . . 2022
29.8.2 Examples and Recipes . . . 2031
29.8.3 Single use, reusable and reentrant context managers . . . 2034
29.9 abc --- 抽象基底類🄵 . . . 2037
29.10 atexit --- 退出處理函式 . . . 2041

29.10.1 atexit 範例 . . . 2042
29.11 traceback --- 列印或取得堆🄵回溯 (stack traceback) . . . 2043
29.11.1 TracebackException 物件 . . . 2046
29.11.2 StackSummary 物件 . . . 2047
29.11.3 FrameSummary 物件 . . . 2048
29.11.4 Traceback Examples . . . 2049
29.12 __future__ --- Future 陳述式定義 . . . 2051
29.12.1 模組🄵容 . . . 2051
29.13 gc --- 垃圾回收器介面 (Garbage Collector interface) . . . 2053
29.14 inspect --- 檢視活動物件 . . . 2056
29.14.1 Types and members . . . 2057
29.14.2 取得原始碼 . . . 2062
29.14.3 Introspecting callables with the Signature object . . . 2063
29.14.4 類🄵與函式 . . . 2068
29.14.5 直譯器堆🄵 . . . 2070
29.14.6 Fetching attributes statically . . . 2073
29.14.7 Current State of Generators, Coroutines, and Asynchronous Generators . . . 2074
29.14.8 Code Objects Bit Flags . . . 2075
29.14.9 Buffer flags . . . 2076
29.14.10命令列介面 . . . 2077
29.15 site --- Site-specific configuration hook . . . 2077
29.15.1 sitecustomize . . . 2078
29.15.2 usercustomize . . . 2078
29.15.3 Readline configuration . . . 2079
29.15.4 模組🄵容 . . . 2079
29.15.5 命令列介面 . . . 2080

30 自訂 Python 直譯器 2081
30.1 code --- 直譯器基底類🄵 . . . 2081
30.1.1 Interactive Interpreter Objects . . . 2082
30.1.2 Interactive Console Objects . . . 2083
30.2 codeop --- 編譯 Python 程式碼 . . . 2083

31 引入模組 2085
31.1 zipimport --- 從 Zip 封存檔案匯入模組 . . . 2085
31.1.1 zipimporter 物件 . . . 2086
31.1.2 範例 . . . 2087
31.2 pkgutil --- 套件擴充工具程式 . . . 2088
31.3 modulefinder --- 搜尋🄵本所使用的模組 . . . 2091
31.3.1 ModuleFinder 的用法範例 . . . 2091
31.4 runpy --- 定位🄵執行 Python 模組 . . . 2092
31.5 importlib --- import 的實作 . . . 2095
31.5.1 簡介 . . . 2095
31.5.2 函式 . . . 2096
31.5.3 importlib.abc -- Abstract base classes related to import . . . 2097
31.5.4 importlib.machinery -- Importers and path hooks . . . 2104
31.5.5 importlib.util -- Utility code for importers . . . 2110
31.5.6 範例 . . . 2113
31.6 importlib.resources -- Package resource reading, opening and access . . . 2115
31.6.1 已🄵用函式 . . . 2117
31.7 importlib.resources.abc -- 資源的抽象基底類🄵 . . . 2118
31.8 importlib.metadata -- 存取套件的元資料 . . . 2121
31.8.1 Overview . . . 2121
31.8.2 Functional API . . . 2122

31.8.3 Distributions . . . 2125
31.8.4 Distribution Discovery . . . 2125
31.8.5 Extending the search algorithm . . . 2126
31.9 The initialization of the sys.path module search path . . . 2126
31.9.1 Virtual environments . . . 2127
31.9.2 _pth files . . . 2127
31.9.3 Embedded Python . . . 2128

32 Python 語言服務 2129
32.1 ast --- 抽象語法樹 (Abstract Syntax Trees) . . . 2129
32.1.1 抽象文法 (Abstract Grammar) . . . 2129
32.1.2 節點 (Node) 類🄵 . . . 2132
32.1.3 ast 輔助程式 . . . 2163
32.1.4 編譯器旗標 . . . 2166
32.1.5 命令列用法 . . . 2167
32.2 symtable --- 存取編譯器的符號表 . . . 2168
32.2.1 🄵生符號表 . . . 2168
32.2.2 檢查符號表 . . . 2168
32.3 token --- 與 Python 剖析樹一起使用的常數 . . . 2171
32.4 keyword --- 檢驗 Python 關鍵字 . . . 2175
32.5 tokenize --- Tokenizer for Python source . . . 2175
32.5.1 Tokenizing Input . . . 2176
32.5.2 Command-Line Usage . . . 2177
32.5.3 範例 . . . 2177
32.6 tabnanny --- 偵測不良縮排 . . . 2179
32.7 pyclbr --- Python 模組🄵覽器支援 . . . 2180
32.7.1 函式物件 . . . 2181
32.7.2 Class Objects . . . 2181
32.8 py_compile —編譯 Python 來源檔案 . . . 2182
32.8.1 Command-Line Interface . . . 2183
32.9 compileall --- 位元組編譯 Python 函式庫 . . . 2184
32.9.1 Command-line use . . . 2184
32.9.2 Public functions . . . 2186
32.10 dis --- Python bytecode 的反組譯器 . . . 2188
32.10.1 Command-line interface . . . 2189
32.10.2 Bytecode analysis . . . 2189
32.10.3 Analysis functions . . . 2190
32.10.4 Python Bytecode Instructions . . . 2192
32.10.5 Opcode collections . . . 2208
32.11 pickletools --- pickle 開發者的工具 . . . 2209
32.11.1 命令列用法 . . . 2209
32.11.2 程式化介面 . . . 2210

33 MS Windows 特有服務 2211
33.1 msvcrt --- MS VC++ runtime 提供的有用例程 . . . 2211
33.1.1 File Operations . . . 2211
33.1.2 Console I/O . . . 2212
33.1.3 Other Functions . . . 2213
33.2 winreg --- Windows 🄵🄵表存取 . . . 2213
33.2.1 函式 . . . 2213
33.2.2 常數 . . . 2219
33.2.3 Registry Handle Objects . . . 2222
33.3 winsound --- Windows 的聲音播放介面 . . . 2223

34 Unix 特有服務 **2225**
34.1 posix --- 最常見的 POSIX 系統呼叫 . . . 2225
34.1.1 對大檔案 (Large File) 的支援 . . . 2225
34.1.2 值得注意的模組🄴容 . . . 2226
34.2 pwd --- 密碼資料庫 . . . 2226
34.3 grp --- 群組資料庫 . . . 2227
34.4 termios --- POSIX 風格 tty 控制 . . . 2228
34.4.1 範例 . . . 2229
34.5 tty --- 終端機控制函式 . . . 2230
34.6 pty --- 🄴終端工具 . . . 2231
34.6.1 範例 . . . 2232
34.7 fcntl --- fcntl 和 ioctl 系統呼叫 . . . 2232
34.8 resource --- 資源使用資訊 . . . 2235
34.8.1 Resource Limits . . . 2235
34.8.2 Resource Usage . . . 2238
34.9 syslog --- Unix syslog 函式庫例程 . . . 2239
34.9.1 範例 . . . 2241

35 模組命令列介面 **2243**

36 已被取代的模組 **2245**
36.1 aifc --- 讀寫 AIFF 與 AIFC 檔案 . . . 2245
36.2 audioop --- 操作原始聲音檔案 . . . 2248
36.3 cgi --- 通用閘道器介面支援 . . . 2251
36.3.1 簡介 . . . 2251
36.3.2 Using the cgi module . . . 2252
36.3.3 Higher Level Interface . . . 2254
36.3.4 函式 . . . 2255
36.3.5 Caring about security . . . 2256
36.3.6 Installing your CGI script on a Unix system . . . 2256
36.3.7 Testing your CGI script . . . 2257
36.3.8 Debugging CGI scripts . . . 2257
36.3.9 Common problems and solutions . . . 2258
36.4 cgitb --- CGI 🄴本的回溯 (traceback) 管理程式 . . . 2258
36.5 chunk --- 讀取 IFF 分塊資料 . . . 2259
36.6 crypt --- 用於檢查 Unix 密碼的函式 . . . 2260
36.6.1 Hashing Methods . . . 2261
36.6.2 模組屬性 . . . 2261
36.6.3 模組函式 . . . 2261
36.6.4 範例 . . . 2262
36.7 imghdr --- 推測圖片種類 . . . 2263
36.8 mailcap --- Mailcap 檔案處理 . . . 2264

Python 模組索引 **2371**

索引 **2375**

reference-index 🄵明 Python 這門語言確切的文法及語意，而這份函式庫參考手🄵則是🄵明隨著 Python 一起發🄵的標准函式庫，除此之外，其🄵容也包含一些時常出現在 Python 發🄵版本中的非必要套件。

Python 的標准函式庫是非常龐大的，其提供了如下所述極多且涵蓋用途極廣的許多模組。包含一些用 C 語言撰寫，可以操作像是檔案讀寫等系統相關功能的🄵建模組，當然也有用 Python 撰寫，🄵使用標准解法解🄵許多常見問題的模組。其中有些模組則是特🄵針對 Python 的可🄵性去設計的，🄵此特地將一些平台特殊相依性的功能抽象化成可跨平台的 API。

Python 的 Windows 安裝檔基本上包含整個標准函式庫，且通常也包含許多附加的組件；而在類 Unix 作業系統方面，Python 通常是以一系列的套件被安裝，因此對於某些或全部的可選組件，可能都必須使用該作業系統提供的套件管理工具來安裝。

在標准函式庫之外，還有成千上萬且不斷增加的組件（從個🄵的程式、模組、套件到完整的應用程式開發框架），可以從 Python 套件索引 (Python Package Index) 中取得。

CHAPTER 1

簡介

「Python 函式庫」包含了許多不同的部分。

函式庫中包括被視🄵程式語言「核心」部分的資料型態，像是數字 (number) 或是串列 (list)。對於這些型🄵，Python 核心對這些字面值 (literal) 的形式做定義，🄵對它們的語意制定了一些限制，但在此同時🄵不把文字對應的語意完全定義。（另一方面，Python 在語法面上有確實的定義，例如拼字或是運算元次序）

Python 函式庫也囊括了🄵建函式與例外處理——這些物件都可以不用透過 `import` 陳述式來引入 Python 程式中就能使用。函式庫中有部份是被 Python 核心所定義的，但在這🄵僅解釋最核心的語意部分。

整個函式庫中包含了許多模組，有許多方法可以從函式庫中取用這些模組。有些模組是以 C 語言撰寫🄵建置於 Python 編譯器之中，其他的是由 Python 撰寫🄵以源碼的方式 (source form) 引入。有些模組提供的功能是專屬於 Python 的，像是把 stack trace 印出來；有些則是針對特定作業系統，去試著存取特定硬體；還有些提供對特定應用的功能與操作介面，像是 World Wide Web。模組的使用情🄵會因機器與 Python 的版本而不同，部分模組是開放所有版本以及 Port 的 Python 來使用的，但有些會因系統支援或需求在某些版本或系統下無法使用，甚至有些僅限在特定的設定環境下才能使用。

這個手🄵會「深入淺出」地介紹 Python 函式庫。它會先介紹一些🄵建函式、資料型態、和一些例外處理，再來一章章的主題式介紹相關模組。

這代表如果你從這個手🄵的最開始讀起，🄵在感到無聊時跳到下一個章節，你仍然可以得到一個對 Python 函式庫所支援的模組與其合理應用的概觀。當然，你🄵有必要像是在讀一本小🄵一樣讀這本手🄵——你可以快速🄵覽目🄵（在手🄵的最前頭）、或是你可以利用最後面的索引來查詢特定的函式或模組。最後，如果你享受🄵讀一些隨機的主題，你可以選擇一個隨機的數字🄵開始🄵讀（見 *random* 模組）。不管你想要以什🄵順序來🄵讀這個手🄵，🄵建函式會是一個很好的入門，因🄵手🄵中其他章節都預設你已經對這個章節有一定的熟悉程度。

讓我們開始吧！

1.1 可用性之🄵釋

- 如果出現「適用：Unix」🄵釋，則代表該函式普遍存在於 Unix 系統中，但這🄵不保證其存在於某特定作業系統。
- 如果🄵有分🄵🄵釋的話，有標明「適用：Unix」🄵釋的所有函式也都於 macOS 上支援，因其建於 Unix 核心之上。
- If an availability note contains both a minimum Kernel version and a minimum libc version, then both conditions must hold. For example a feature with note *Availability: Linux >= 3.17 with glibc >= 2.27* requires both Linux 3.17 or newer and glibc 2.27 or newer.

1.1.1 WebAssembly 平台

The WebAssembly platforms `wasm32-emscripten` (Emscripten) and `wasm32-wasi` (WASI) provide a subset of POSIX APIs. WebAssembly runtimes and browsers are sandboxed and have limited access to the host and external resources. Any Python standard library module that uses processes, threading, networking, signals, or other forms of inter-process communication (IPC), is either not available or may not work as on other Unix-like systems. File I/O, file system, and Unix permission-related functions are restricted, too. Emscripten does not permit blocking I/O. Other blocking operations like *`sleep()`* block the browser event loop.

The properties and behavior of Python on WebAssembly platforms depend on the Emscripten-SDK or WASI-SDK version, WASM runtimes (browser, NodeJS, wasmtime), and Python build time flags. WebAssembly, Emscripten, and WASI are evolving standards; some features like networking may be supported in the future.

For Python in the browser, users should consider Pyodide or PyScript. PyScript is built on top of Pyodide, which itself is built on top of CPython and Emscripten. Pyodide provides access to browsers' JavaScript and DOM APIs as well as limited networking capabilities with JavaScript's `XMLHttpRequest` and `Fetch` APIs.

- Process-related APIs are not available or always fail with an error. That includes APIs that spawn new processes (*`fork()`*, *`execve()`*), wait for processes (*`waitpid()`*), send signals (*`kill()`*), or otherwise interact with processes. The *`subprocess`* is importable but does not work.
- The *`socket`* module is available, but is limited and behaves differently from other platforms. On Emscripten, sockets are always non-blocking and require additional JavaScript code and helpers on the server to proxy TCP through WebSockets; see Emscripten Networking for more information. WASI snapshot preview 1 only permits sockets from an existing file descriptor.
- Some functions are stubs that either don't do anything and always return hardcoded values.
- Functions related to file descriptors, file permissions, file ownership, and links are limited and don't support some operations. For example, WASI does not permit symlinks with absolute file names.

CHAPTER 2

🄵建函式

Python 直譯器有🄴建多個可隨時使用的函式和型🄵。以下按照英文字母排序列出。

F建函式

A
abs()
aiter()
all()
anext()
any()
ascii()

B
bin()
bool()
breakpoint()
bytearray()
bytes()

C
callable()
chr()
classmethod()
compile()
complex()

D
delattr()
dict()
dir()
divmod()

E
enumerate()
eval()
exec()

F
filter()
float()
format()
frozenset()

G
getattr()
globals()

H
hasattr()
hash()
help()
hex()

I
id()
input()
int()
isinstance()
issubclass()
iter()

L
len()
list()
locals()

M
map()
max()
memoryview()
min()

N
next()

O
object()
oct()
open()
ord()

P
pow()
print()
property()

R
range()
repr()
reversed()
round()

S
set()
setattr()
slice()
sorted()
staticmethod()
str()
sum()
super()

T
tuple()
type()

V
vars()

Z
zip()

_
__import__()

abs(*x*)

Return the absolute value of a number. The argument may be an integer, a floating-point number, or an object implementing __abs__(). If the argument is a complex number, its magnitude is returned.

aiter(*async_iterable*)

回傳非同步F代器 做F非同步可F代物件。相當於呼叫 x.__aiter__()。

注意：與*iter()* 不同，*aiter()* F有兩個引數的變體。

在 3.10 版被加入.

all(*iterable*)

如果 *iterable* 的所有元素皆F真（或 iterable F空）則回傳 True。等價於：

```
def all(iterable):
    for element in iterable:
```

(繼續下一頁)

(繼續上一頁)

```
        if not element:
            return False
    return True
```

awaitable anext(*async_iterator*)

awaitable anext(*async_iterator*, *default*)

當進入 await 時，從給定的*asynchronous iterator* 中回傳下一個項目（item），🄵代完畢則回傳 *default* 。

這是🄵建函式*next()* 的非同步版本，其行🄵類似於：

呼叫 *async_iterator* 的 `__anext__()` 方法，回傳*awaitable*。等待返回🄴代器的下一個值。如果指定 *default*，當🄵代器結束時會返回該值，否則會引發*StopAsyncIteration* 。

在 3.10 版被加入.

any(*iterable*)

如果 *iterable* 的任一元素🄵真，回傳 `True`。如果 iterable 是空的，則回傳 `False`。等價於：

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

ascii(*object*)

就像函式*repr()*，回傳一個表示物件的字串，但是*repr()* 回傳的字串中非 ASCII 編碼的字元會被跳🄵 (escape)，像是 `\x`、`\u` 和 `\U`。這個函式生成的字串和 Python 2 的*repr()* 回傳的結果相似。

bin(*x*)

將一個整數轉變🄵一個前綴🄵"0b" 的二進位制字串。結果是一個有效的 Python 運算式。如果 *x* 不是 Python 的*int* 物件，那它需要定義 `__index__()` method 回傳一個整數。舉例來🄵：

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

如果不一定需要"0b" 前綴，還可以使用如下的方法。

```
>>> format(14, '#b'), format(14, 'b')
('0b1110', '1110')
>>> f'{14:#b}', f'{14:b}'
('0b1110', '1110')
```

可參考*format()* 獲取更多資訊。

class bool(*object=False*, */*)

Return a Boolean value, i.e. one of `True` or `False`. The argument is converted using the standard *truth testing procedure*. If the argument is false or omitted, this returns `False`; otherwise, it returns `True`. The *bool* class is a subclass of *int* (see 數值型🄵 --- *int*、*float*、*complex*). It cannot be subclassed further. Its only instances are `False` and `True` (see *Boolean* 型🄵 - *bool*).

在 3.7 版的變更: 現在🄵僅限位置參數。

breakpoint(**args*, ***kws*)

這個函式將呼叫*sys.breakpointhook()* 函式，🄵將 `args` 和 `kws` 傳遞給它。這將有效地讓你在特定的呼叫點進入除錯器。預設情🄵下，`sys.breakpointhook()` 呼叫*pdb.set_trace()* 不須帶任

何引數。這樣的設計是🄵了方便使用者，讓他們不需要額外地導入*pdb* 模組或輸入太多程式就可以進入除錯器。然而，可以將*sys.breakpointhook()* 設置🄵其他函式，🄵且*breakpoint()* 將自動呼叫該函式，讓你進入所選擇的除錯器。如果無法存取*sys.breakpointhook()* 這個函式，則此函式將引發*RuntimeError*。

預設情🄵下，*breakpoint()* 的行🄵可以透過 PYTHONBREAKPOINT 環境變數來更改。有關使用詳情，請參考*sys.breakpointhook()*。

請注意，如果*sys.breakpointhook()* 被替🄵了，則無法保證此功能。

Raises an *auditing event* `builtins.breakpoint` with argument `breakpointhook`.

在 3.7 版被加入.

class bytearray(*source=b''*)

class bytearray(*source*, *encoding*)

class bytearray(*source*, *encoding*, *errors*)

回傳一個新的 bytes 陣列。*bytearray* class 是一個可變的整數序列，包含範圍🄵 0 <= x < 256 的整數。它有可變序列大部分常見的 method（如在*Mutable Sequence Types* 中所述），同時也有*bytes* 型🄵大部分的 method，參見*Bytes and Bytearray Operations*。

選擇性參數 *source* 可以被用來以不同的方式初始化陣列：

- 如果是一個 *string*，你必須提供 *encoding* 參數（以及選擇性地提供 *errors* ）；*bytearray()* 會使用*str.encode()* method 來將 string 轉變成 bytes。
- 如果是一個 *integer*，陣列則會有該數值的長度，🄵以 null bytes 來當作初始值。
- 如果是一個符合 buffer 介面的物件，該物件的唯讀 buffer 會被用來初始化 bytes 陣列。
- 如果是一個 *iterable*，它的元素必須是範圍🄵 `0 <= x < 256` 的整數，🄵且會被用作陣列的初始值。

如果🄵有引數，則建立長度🄵 0 的陣列。

可參考*Binary Sequence Types --- bytes, bytearray, memoryview* 和*Bytearray Objects*。

class bytes(*source=b''*)

class bytes(*source*, *encoding*)

class bytes(*source*, *encoding*, *errors*)

回傳一個新的"bytes" 物件，會是一個元素是範圍🄵 `0 <= x < 256` 整數的不可變序列。*bytes* 是*bytearray* 的不可變版本—它的同樣具備不改變物件的 method，也有相同的索引和切片操作。

因此，建構函式的引數和*bytearray()* 相同。

Bytes 物件還可以用文字建立，參見 strings。

可參考*Binary Sequence Types --- bytes, bytearray, memoryview*、*Bytes Objects* 和*Bytes and Bytearray Operations*。

callable(*object*)

如果引數 *object* 是可呼叫的，回傳*True*，否則回傳*False*。如果回傳 `True`，呼叫仍可能會失敗；但如果回傳 `False`，則呼叫 *object* 肯定會失敗。注意 class 是可呼叫的（呼叫 class 會回傳一個新的實例）；如果實例的 class 有定義 `__call__()` method，則它是可呼叫的。

在 3.2 版被加入: 這個函式一開始在 Python 3.0 被移除，但在 Python 3.2 又被重新加入。

chr(*i*)

回傳代表字元之 Unicode 編碼位置🄵整數 *i* 的字串。例如，`chr(97)` 回傳字串 `'a'`，而 `chr(8364)` 回傳字串 `'€'`。這是*ord()* 的逆函式。

引數的有效範圍是 0 到 1,114,111（16 進制表示🄵 0x10FFFF）。如果 *i* 超過這個範圍，會引發*ValueError*。

@classmethod

把一個 method 封裝成 class method（類🄵方法）。

一個 class method 把自己的 class 作🄵第一個引數，就像一個實例 method 把實例自己作🄵第一個引數。請用以下慣例來宣告 class method：

```
class C:
    @classmethod
    def f(cls, arg1, arg2): ...
```

`@classmethod` 語法是一個函式*decorator* —參見 function 中關於函式定義的詳細介紹。

一個 class method 可以在 class（如 `C.f()`）或實例（如 `C().f()`）上呼叫。實例除了它的 class 資訊，其他都會被忽略。如果一個 class method 在 subclass 上呼叫，subclass 會作🄵第一個引數傳入。

Class method 和 C++ 與 Java 的 static method 是有區🄵的。如果你想🄵解 static method，請看本節的*staticmethod()*。關於 class method 的更多資訊，請參考 types。

在 3.9 版的變更: Class methods 現在可以包裝其他描述器，例如*property()*

在 3.10 版的變更: Class method 現在繼承了 method 屬性（`__module__`、`__name__`、`__qualname__`、`__doc__` 和 `__annotations__`），🄵擁有一個新的 `__wrapped__` 屬性。

在 3.11 版的變更: Class methods 不能再包裝其他的描述器，例如*property()*。

compile(*source*, *filename*, *mode*, *flags=0*, *dont_inherit=False*, *optimize=-1*)

將 *source* 編譯成程式碼或 AST 物件。程式碼物件可以被*exec()* 或*eval()* 執行。*source* 可以是一般的字串、bytes 字串、或者 AST 物件。參見*ast* module（模組）的🄵明文件🄵解如何使用 AST 物件。

filename 引數必須是程式碼的檔名；如果程式碼不是從檔案中讀取，可以傳入一些可辨識的值（經常會使用 `'<string>'` 來替代）。

mode 引數指定了編譯程式碼時必須用的模式。如果 *source* 是一系列的陳述式，可以是 `'exec'`；如果是單一運算式，可以是 `'eval'`；如果是單個互動式陳述式，可以是 `'single'`（在最後一種情🄵下，如果運算式執行結果不是 `None` 則會被印出來）。

可選引數 *flags* 和 *dont_inherit* 控制🄵用哪個編譯器選項以及允許哪個未來功能。如果兩者都不存在（或兩者都🄵零），則會呼叫與*compile()* 相同旗標的程式碼來編譯。如果給定 *flags* 引數而未給定 *dont_inherit*（或🄵零）則無論如何都會使用由 *flags* 引數所指定的編譯器選項和未來陳述式。如果 *dont_inherit* 是一個非零整數，則使用 *flags* 引數 - - 周圍程式碼中的旗標（未來功能和編譯器選項）將被忽略。

編譯器選項和 future 陳述式使用 bits 來表示，可以一起被位元操作 OR 來表示🄵數個選項。需要被具體定義特徵的位元域可以透過*__future__* module 中*_Feature* 實例中的*compiler_flag* 屬性來獲得。編譯器旗標可以在*ast* module 中搜尋有 `PyCF_` 前綴的名稱。

引數 *optimize* 用來指定編譯器的最佳化級🄵；預設值 `-1` 選擇與直譯器的 `-O` 選項相同的最佳化級🄵。其他級🄵🄵 `0`（🄵有最佳化；`__debug__` 🄵真值）、`1`（assert 被🄵除，`__debug__` 🄵假值）或 `2`（🄵明字串 (docstring) 也被🄵除）。

如果編譯的原始碼無效，此函式會引發*SyntaxError*，如果原始碼包含 null bytes，則會引發*ValueError*。

如果您想解析 Python 程式碼🄵 AST 運算式，請參🄵*ast.parse()*。

引發一個附帶引數 `source`、`filename` 的稽核事件 `compile`。此事件也可能由隱式編譯 (implicit compilation) 所引發。

備🄵

在 `'single'` 或 `'eval'` 模式編譯多行程式碼時，輸入必須以至少一個🄵行符結尾。這使*code* module 更容易檢測陳述式的完整性。

警告

如果編譯足🄵大或者足🄵🄵雜的字串成 AST 物件時，Python 直譯器會因🄵 Python AST 編譯器的 stack 深度限制而崩潰。

在 3.2 版的變更: 允許使用 Windows 和 Mac 的🄵行符號。此外，在 `'exec'` 模式不需要以🄵行符號結尾。增加了 *optimize* 參數。

在 3.5 版的變更: 在之前的版本，*source* 中包含 null bytes 會引發*TypeError*。

在 3.8 版被加入: `ast.PyCF_ALLOW_TOP_LEVEL_AWAIT` 現在可以傳遞旗標以🄵用對頂層 `await`、`async for` 和 `async with` 的支援。

class complex(*number=0*, */*)

class complex(*string*, */*)

class complex(*real=0*, *imag=0*)

Convert a single string or number to a complex number, or create a complex number from real and imaginary parts.

例如:

```
>>> complex('+1.23')
(1.23+0j)
>>> complex('-4.5j')
-4.5j
>>> complex('-1.23+4.5j')
(-1.23+4.5j)
>>> complex('\t( -1.23+4.5J )\n')
(-1.23+4.5j)
>>> complex('-Infinity+NaNj')
(-inf+nanj)
>>> complex(1.23)
(1.23+0j)
>>> complex(imag=-4.5)
-4.5j
>>> complex(-1.23, 4.5)
(-1.23+4.5j)
```

If the argument is a string, it must contain either a real part (in the same format as for *float()*) or an imaginary part (in the same format but with a `'j'` or `'J'` suffix), or both real and imaginary parts (the sign of the imaginary part is mandatory in this case). The string can optionally be surrounded by whitespaces and the round parentheses `'('` and `')'`, which are ignored. The string must not contain whitespace between `'+'`, `'-'`, the `'j'` or `'J'` suffix, and the decimal number. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises *ValueError*. More precisely, the input must conform to the *complexvalue* production rule in the following grammar, after parentheses and leading and trailing whitespace characters are removed:

```
complexvalue   ::=   floatvalue |
                     floatvalue ("j" | "J") |
                     floatvalue sign absfloatvalue ("j" | "J")
```

If the argument is a number, the constructor serves as a numeric conversion like *int* and *float*. For a general Python object `x`, `complex(x)` delegates to `x.__complex__()`. If `__complex__()` is not defined then it falls back to `__float__()`. If `__float__()` is not defined then it falls back to `__index__()`.

If two arguments are provided or keyword arguments are used, each argument may be any numeric type (including complex). If both arguments are real numbers, return a complex number with the real component *real* and the imaginary component *imag*. If both arguments are complex numbers, return a complex number with the real component `real.real-imag.imag` and the imaginary component `real.imag+imag.real`. If one of arguments is a real number, only its real component is used in the above expressions.

If all arguments are omitted, returns `0j`.

🄵數型🄵在數值型🄵 --- *int*、*float*、*complex* 中有相關描述。

在 3.6 版的變更: 可以使用底🄵將程式碼文字中的數字進行分組。

在 3.8 版的變更: 如果 `__complex__()` 和 `__float__()` 未定義，則會回退到 `__index__()`。

delattr(*object*, *name*)

這是*setattr()* 相關的函式。引數是一個物件和一個字串，該字串必須是物件中某個屬性名稱。如果物件允許，該函式將🄵除指定的屬性。例如 `delattr(x, 'foobar')` 等價於 `del x.foobar`。*name* 不必是個 Python 識🄵符 (identifier)（請見*setattr()*）。

class dict(***kwarg*)

class dict(*mapping*, ***kwarg*)

class dict(*iterable*, ***kwarg*)

建立一個新的 dictionary（字典）。*dict* 物件是一個 dictionary class。參見*dict* 和*Mapping Types --- dict* 來🄵解這個 class。

其他容器型🄵，請參見🄵建的*list*、*set* 和*tuple* class，以及*collections* module。

dir()

dir(*object*)

如果🄵有引數，則回傳當前區域作用域 (local scope) 中的名稱列表。如果有引數，它會嘗試回傳該物件的有效屬性列表。

如果物件有一個名🄵 `__dir__()` 的 method，那🄵該 method 將被呼叫，🄵且必須回傳一個屬性列表。這允許實現自定義 `__getattr__()` 或 `__getattribute__()` 函式的物件能🄵自定義*dir()* 來報告它們的屬性。

如果物件不提供 `__dir__()`，這個函式會嘗試從物件已定義的*__dict__* 屬性和型🄵物件收集資訊。結果列表🄵不總是完整的，如果物件有自定義 `__getattr__()`，那結果可能不准確。

預設的*dir()* 機制對不同型🄵的物件有不同行🄵，它會試圖回傳最相關而非最完整的資訊：

- 如果物件是 module 物件，則列表包含 module 的屬性名稱。
- 如果物件是型🄵或 class 物件，則列表包含它們的屬性名稱，🄵且遞🄵查詢其基礎的所有屬性。
- 否則，包含物件的屬性名稱列表、它的 class 屬性名稱，🄵且遞🄵查詢它的 class 的所有基礎 class 的屬性。

回傳的列表按字母表排序，例如：

```
>>> import struct
>>> dir()   # show the names in the module namespace
['__builtins__', '__name__', 'struct']
>>> dir(struct)   # show the names in the struct module
['Struct', '__all__', '__builtins__', '__cached__', '__doc__', '__file__',
 '__initializing__', '__loader__', '__name__', '__package__',
```

(繼續下一頁)

(繼續上一頁)

```
 '_clearcache', 'calcsize', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
...         return ['area', 'perimeter', 'location']
...
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']
```

備🄵

因🄵*dir()* 主要是🄵了便於在互動式提示字元時使用，所以它會試圖回傳人們感興趣的名稱集合，而不是試圖保證結果的嚴格性或一致性，它具體的行🄵也可能在不同版本之間改變。例如，當引數是一個 class 時，metaclass 的屬性不包含在結果列表中。

divmod(*a*, *b*)

Take two (non-complex) numbers as arguments and return a pair of numbers consisting of their quotient and remainder when using integer division. With mixed operand types, the rules for binary arithmetic operators apply. For integers, the result is the same as `(a // b, a % b)`. For floating-point numbers the result is `(q, a % b)`, where *q* is usually `math.floor(a / b)` but may be 1 less than that. In any case `q * b + a % b` is very close to *a*, if `a % b` is non-zero it has the same sign as *b*, and `0 <= abs(a % b) < abs(b)`.

enumerate(*iterable*, *start=0*)

回傳一個列舉 (enumerate) 物件。*iterable* 必須是一個序列、*iterator* 或其他支援🄵代的物件。*enumerate()* 回傳之 iterator 的*__next__()* method 回傳一個 tuple（元組），🄵面包含一個計數值（從 *start* 開始，預設🄵 0）和透過🄵代 *iterable* 獲得的值。

```
>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]
```

等價於：

```
def enumerate(iterable, start=0):
    n = start
    for elem in iterable:
        yield n, elem
        n += 1
```

eval(*expression*, *globals=None*, *locals=None*)

參數

- **expression** (*str* | code object) -- A Python expression.
- **globals** (*dict* | `None`) -- The global namespace (default: `None`).
- **locals** (*mapping* | `None`) -- The local namespace (default: `None`).

回傳

The result of the evaluated expression.

Raises
Syntax errors are reported as exceptions.

expression 引數會被視🄵一條 Python 運算式（技術上而言，是條件列表）來剖析及求值，而 *globals* 和 *locals* dictionaries 分🄵用作全域和區域命名空間。如果 *globals* dictionary 存在但缺少 `__builtins__` 的鍵值，那 *expression* 被剖析之前，將🄵該鍵插入對🄵建*builtins* module dictionary 的引用。這🄵一來，在將 `__builtins__` dictionary 傳入*eval()* 之前，你可以透過將它插入 *globals* 來控制你需要哪些🄵建函式來執行程式碼。如果 *locals* 被省略，那它的預設值是 *globals* dictionary。如果兩個 dictionary 引數都被省略，則在*eval()* 被呼叫的環境中執行運算式。請注意，*eval()* 在封閉 (enclosing) 環境中無法存取巢狀作用域 (non-locals)。

範例：

```
>>> x = 1
>>> eval('x+1')
2
```

這個函式也可以用來執行任意程式碼物件（如被*compile()* 建立的那些）。這種情🄵下，傳入的引數是程式碼物件而不是字串。如果編譯該物件時的 *mode* 引數是 `'exec'`，那🄵*eval()* 回傳值🄵 `None`。

提示：*exec()* 函式支援動態執行陳述式。*globals()* 和*locals()* 函式分🄵回傳當前的全域性和局部性 dictionary，它們對於將引數傳遞給*eval()* 或*exec()* 可能會方便許多。

如果給定來源是一個字串，那🄵其前後的空格和定位字元會被移除。

另外可以參🄵*ast.literal_eval()*，該函式可以安全執行僅包含文字的運算式字串。

引發一個附帶程式碼物件🄵引數的稽核事件 `exec`。也可能會引發程式碼編譯事件。

exec(*object*, *globals=None*, *locals=None*, */*, *, *closure=None*)

這個函式支援動態執行 Python 程式碼。*object* 必須是字串或者程式碼物件。如果是字串，那🄵該字串將被剖析🄵一系列 Python 陳述式🄵執行（除非發生語法錯誤）。[1] 如果是程式碼物件，它將被直接執行。無論哪種情🄵，被執行的程式碼都需要和檔案輸入一樣是有效的（可參🄵語言參考手🄵中關於 file-input 的章節）。請注意，即使在傳遞給*exec()* 函式的程式碼的上下文中，`nonlocal`、`yield` 和 `return` 陳述式也不能在函式之外使用。該函式回傳值是 `None`。

In all cases, if the optional parts are omitted, the code is executed in the current scope. If only *globals* is provided, it must be a dictionary (and not a subclass of dictionary), which will be used for both the global and the local variables. If *globals* and *locals* are given, they are used for the global and local variables, respectively. If provided, *locals* can be any mapping object. Remember that at the module level, globals and locals are the same dictionary.

> **備🄵**
>
> 大部分使用者只需要傳入 *globals* 引數，而不用傳遞 *locals*。如果 exec 有兩個不同的 *globals* 和 *locals* 物件，程式碼就像嵌入在 class 定義中一樣執行。

如果 *globals* dictionary 不包含 `__builtins__` 鍵值，則將🄵該鍵插入對🄵建*builtins* module dictionary 的引用。這🄵一來，在將 `__builtins__` dictionary 傳入*exec()* 之前，你可以透過將它插入 *globals* 來控制你需要哪些🄵建函式來執行程式碼。

closure 引數會指定一個閉包 (closure)—它是一個 cellvar（格變數）的 tuple。只有在 *object* 是一個含有自由變數 (free variable) 的程式碼物件時，它才有效。Tuple 的長度必須與程式碼物件所引用的自由變數數量完全匹配。

[1] 剖析器只接受 Unix 風格的行結束符。如果您從檔案中讀取程式碼，請確保用🄵行符號轉🄵模式轉🄵 Windows 或 Mac 風格的🄵行符號。

引發一個附帶程式碼物件🄵引數的稽核事件 `exec`。也可能會引發程式碼編譯事件。

備🄵

🄵建*globals()* 和*locals()* 函式各自回傳當前的全域性和本地 dictionary，因此可以將它們傳遞給*exec()* 的第二個和第三個引數。

備🄵

預設情🄵下，*locals* 的行🄵如下面*locals()* 函式描述的一樣：不要試圖改變預設的 *locals* dictionary。如果您想在*exec()* 函式回傳時知道程式碼對 *locals* 的變動，請明確地傳遞 *locals* dictionary 。

在 3.11 版的變更: 增加了 *closure* 參數。

filter(*function*, *iterable*)

用 *iterable* 中函式 *function* 🄵 True 的那些元素，構建一個新的 iterator。*iterable* 可以是一個序列、一個支援🄵代的容器、或一個 iterator。如果 *function* 是 `None`，則會假設它是一個識🄵性函式，即 *iterable* 中所有假值元素會被移除。

請注意，`filter(function, iterable)` 相當於一個生成器運算式，當 function 不是 `None` 的時候🄵 `(item for item in iterable if function(item))`；function 是 `None` 的時候🄵 `(item for item in iterable if item)`。

請參🄵*itertools.filterfalse()*，只有 *function* 🄵 false 時才選取 *iterable* 中元素的互補函式。

class float(*number=0.0*, */*)

class float(*string*, */*)

Return a floating-point number constructed from a number or a string.

例如：

```
>>> float('+1.23')
1.23
>>> float('   -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf
```

如果引數是字串，則它必須是包含十進位制數字的字串，字串前面可以有符號，之前也可以有空格。選擇性的符號有 `'+'` 和 `'-'`；`'+'` 對建立的值🄵有影響。引數也可以是 NaN（非數字）或正負無窮大的字串。確切地🄵，除去首尾的空格後，輸入必須遵循以下語法中 *floatvalue* 的生成規則：

```
sign           ::=  "+" | "-"
infinity       ::=  "Infinity" | "inf"
nan            ::=  "nan"
digit          ::=  <a Unicode decimal digit, i.e. characters in Unicode general category
digitpart      ::=  digit (["_"] digit)*
```

```
number          ::=   [digitpart] "." digitpart | digitpart ["."]
exponent        ::=   ("e" | "E") [sign] digitpart
floatnumber     ::=   number [exponent]
absfloatvalue   ::=   floatnumber | infinity | nan
floatvalue      ::=   [sign] absfloatvalue
```

字母大小寫不影響，例如，"inf"、"Inf"、"INFINITY"、"iNfINity" 都可以表示正無窮大。

Otherwise, if the argument is an integer or a floating-point number, a floating-point number with the same value (within Python's floating-point precision) is returned. If the argument is outside the range of a Python float, an *OverflowError* will be raised.

對於一般的 Python 物件 `x`，`float(x)` 會委派給 `x.__float__()`。如果未定義 `__float__()` 則會回退到 `__index__()`。

如果F有引數，則回傳 `0.0`。

數值型F --- int、float、complex 描述了浮點數型F。

在 3.6 版的變更: 可以使用底F將程式碼文字中的數字進行分組。

在 3.7 版的變更: 現在F僅限位置參數。

在 3.8 版的變更: 如果 `__float__()` 未定義，則會回退到 `__index__()`。

format(*value*, *format_spec=''*)

將 *value* 轉FF *format_spec* 控制的" 格式化" 表示。*format_spec* 的解釋取F於 *value* 引數的型F，但是大多數F建型F使用標準格式化語法：*格式規格 (Format Specification) 迷你語言*。

預設的 *format_spec* 是一個空字串，它通常和呼叫*str(value)* 的效果相同。

呼叫 `format(value, format_spec)` 會轉F成 `type(value).__format__(value, format_spec)`，當搜尋 value 的 `__format__()` method 時，會忽略實例中的字典。如果搜尋到*object* 這個 method 但 *format_spec* 不F空，或是 *format_spec* 或回傳值不是字串，則會引發*TypeError*。

在 3.4 版的變更: 當 *format_spec* 不是空字串時，`object().__format__(format_spec)` 會引發*TypeError*。

class frozenset(*iterable=set()*)

回傳一個新的*frozenset* 物件，它包含選擇性引數 *iterable* 中的元素。`frozenset` 是一個F建的 class。有關此 class 的文件，請參F*frozenset* 和*Set Types --- set, frozenset*。

請參FF建的*set*、*list*、*tuple* 和*dict* class，以及*collections* module 來了解其它的容器。

getattr(*object*, *name*)

getattr(*object*, *name*, *default*)

回傳 *object* 之具名屬性的值。*name* 必須是字串。如果該字串是物件屬性之一的名稱，則回傳該屬性的值。例如，`getattr(x, 'foobar')` 等同於 `x.foobar`。如果指定的屬性不存在，且提供了 *default* 值，則回傳其值，否則引發*AttributeError*。*name* 不必是個 Python 識F符 (identifier)（請見*setattr()*）。

> **備F**
>
> 由於私有名稱改編 (private name mangling) 是發生在編譯期，因此你必須手動改編私有屬性（有兩個前導底F的屬性）的名稱，才能使用*getattr()* 來取得它。

globals()

回傳代表當前 module 命名空間的 dictionary。對於在函式中的程式碼來F，這在定義函式時設定且不論該函式是在何處呼叫都會保持相同。

hasattr(*object*, *name*)

該引數是一個物件和一個字串。如果字串是物件屬性之一的名稱，則回傳 `True`，否則回傳 `False`。(此功能是透過呼叫 `getattr(object, name)` 🄵檢查是否引發*`AttributeError`* 來實作的。)

hash(*object*)

回傳該物件的雜🄵值（如果它有的話）。雜🄵值是整數。它們在 dictionary 查詢元素時用來快速比較 dictionary 的鍵。相同大小的數字數值有相同的雜🄵值（即使它們型🄵不同，如 1 和 1.0）。

> **備🄵**
>
> 請注意，如果物件帶有自訂的 `__hash__()` 方法，*`hash()`* 將根據運行機器的位元長度來截斷回傳值。

help()

help(*request*)

🄵動🄵建的幫助系統（此函式主要以互動式使用）。如果🄵有引數，直譯器控制台🄵會🄵動互動式幫助系統。如果引數是一個字串，則會在 module、函式、class、method、關鍵字或🄵明文件主題中搜索該字串，🄵在控制台上列印幫助資訊。如果引數是其他任意物件，則會生成該物件的幫助頁。

請注意，呼叫*`help()`* 時，如果斜🄵 (/) 出現在函式的參數列表中，這表示斜🄵前面的參數是僅限位置 (positional-only) 參數。有關更多資訊，請參🄵常見問答集中的僅限位置參數條目。

此函式會被*`site`* module 加入到🄵建命名空間。

在 3.4 版的變更: 對於*`pydoc`* 和*`inspect`* 的變更，使得可呼叫物件回報的的簽名 (signature) 更加全面和一致。

hex(*x*)

將整數轉🄵🄵以"0x" 🄵前綴的小寫十六進位制字串。如果 *x* 不是 Python *`int`* 物件，則必須定義一個 `__index__()` method 🄵且回傳一個整數。舉例來🄵:

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

如果要將整數轉🄵🄵大寫或小寫的十六進位制字串，🄵可選擇有無"0x" 前綴，則可以使用如下方法:

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

可參考*`format()`* 獲取更多資訊。

另請參🄵*`int()`* 將十六進位制字串轉🄵🄵以 16 🄵基數的整數。

> **備🄵**
>
> 如果要獲取浮點數的十六進位制字串形式，請使用*`float.hex()`* method。

id(*object*)

回傳物件的" 識𝔽性" 。該值是一個整數，在此物件的生命𝔽期中保證是唯一且𝔽定的。兩個生命期不重𝔽的物件可能具有相同的*id()* 值。

CPython 實作細節： 這是該物件在記憶體中的位址。

Raises an *auditing event* `builtins.id` with argument `id`.

input()

input(*prompt*)

如果有提供 *prompt* 引數，則將其寫入標準輸出，末尾不帶𝔽行符。接下來，該函式從輸入中讀取一行，將其轉𝔽𝔽字串（去除末尾的𝔽行符）𝔽回傳。當讀取到 EOF 時，則引發*EOFError*。例如：

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

如果載入了*readline* module，*input()* 將使用它來提供𝔽雜的行編輯和歷史記𝔽功能。

引發一個附帶讀取輸入前的引數 `prompt` 的稽核事件 `builtins.input`。

引發一個附帶成功讀取結果的稽核事件 `builtins.input/result`。

class int(*number=0*, */*)

class int(*string*, */*, *base=10*)

Return an integer object constructed from a number or a string, or return `0` if no arguments are given.

例如：

```
>>> int(123.45)
123
>>> int('123')
123
>>> int('   -12_345\n')
-12345
>>> int('FACE', 16)
64206
>>> int('0xface', 0)
64206
>>> int('01110011', base=2)
115
```

If the argument defines `__int__()`, `int(x)` returns `x.__int__()`. If the argument defines `__index__()`, it returns `x.__index__()`. If the argument defines `__trunc__()`, it returns `x.__trunc__()`. For floating-point numbers, this truncates towards zero.

如果引數不是數字或如果有給定 *base*，則它必須是個字串、*bytes* 或*bytearray* 實例，表示基數 (radix) *base* 中的整數。可選地，字串之前可以有 + 或 -（中間𝔽有空格）、可有個前導的零、也可被空格包圍、或在數字間有單一底𝔽。

一個 n 進制的整數字串，包含各個代表 0 到 n-1 的數字，0–9 可以用任何 Unicode 十進制數字表示，10–35 可以用 `a` 到 `z`（或 `A` 到 `Z`）表示。預設的 *base* 是 10。允許的進位制有 0、2–36。2、8、16 進位制的字串可以在程式碼中用 `0b`/`0B`、`0o`/`0O`、`0x`/`0X` 前綴來表示，如同程式碼中的整數文字。進位制𝔽 0 的字串將以和程式碼整數字面值 (integer literal in code) 類似的方式來直譯，最後由前綴𝔽定的結果會是 2、

8、10、16 進制中的一個，所以 `int('010', 0)` 是非法的，但 `int('010')` 和 `int('010', 8)` 是有效的。

整數型𝔽定義請參𝔽*數值型𝔽 --- int、float、complex*。

在 3.4 版的變更: 如果 *base* 不是*int* 的實例，但 *base* 物件有 `base.__index__` method，則會呼叫該 method 來獲取此進位制所需的整數。以前的版本使用 `base.__int__` 而不是 `base.__index__`。

在 3.6 版的變更: 可以使用底𝔼將程式碼文字中的數字進行分組。

在 3.7 版的變更: 第一個參數𝔽僅限位置參數。

在 3.8 版的變更: 如果未定義 `__int__()` 則會回退到 `__index__()`。

在 3.11 版的變更: 對 `__trunc__()` 的委派已𝔽用。

在 3.11 版的變更: *int* 的字串輸入和字串表示法可以被限制，以避免阻斷服務攻擊 (denial of service attack)。在字串 *x* 轉𝔽𝔽*int* 時已超出限制，或是在*int* 轉𝔽𝔽字串時將會超出限制時，會引發*ValueError*。請參𝔽*整數字串轉𝔽的長度限制*𝔽明文件。

isinstance(*object*, *classinfo*)

如果 *object* 引數是 *classinfo* 引數的實例，或者是（直接、間接或*virtual*）subclass 的實例，則回傳 `True`。如果 *object* 不是給定型𝔽的物件，函式始終回傳 `False`。如果 *classinfo* 是包含物件型𝔽的 tuple（或多個遞𝔽 tuple）或一個包含多種型𝔽的*Union Type*，若 *object* 是其中的任何一個物件的實例則回傳 `True`。如果 *classinfo* 既不是型𝔽，也不是型𝔽 tuple 或型𝔽的遞𝔽 tuple，那𝔽會引發*TypeError* 𝔽常。若是先前檢查已經成功，*TypeError* 可能不會再因𝔽不合格的型𝔽而被引發。

在 3.10 版的變更: *classinfo* 可以是一個*Union Type*。

issubclass(*class*, *classinfo*)

如果 *class* 是 *classinfo* 的 subclass（直接、間接或*virtual*），則回傳 `True`。*classinfo* 可以是 class 物件的 tuple（或遞𝔽地其他類似 tuple）或是一個*Union Type*，此時若 *class* 是 *classinfo* 中任一元素的 subclass 時則回傳 `True`。其他情𝔽，會引發*TypeError*。

在 3.10 版的變更: *classinfo* 可以是一個*Union Type*。

iter(*object*)

iter(*object*, *sentinel*)

回傳一個*iterator* 物件。根據是否存在第二個引數，第一個引數的意義是非常不同的。如果𝔽有第二個引數，*object* 必須是支援*iterable* 協定（有 `__iter__()` method）的集合物件，或必須支援序列協定（有 `__getitem__()` 方法，且數字引數從 0 開始）。如果它不支援這些協定，會引發*TypeError*。如果有第二個引數 *sentinel*，那𝔽 *object* 必須是可呼叫的物件，這種情𝔽下生成的 iterator，每次𝔽代呼叫*__next__()* 時會不帶引數地呼叫 *object*；如果回傳的結果是 *sentinel* 則引發*StopIteration*，否則回傳呼叫結果。

另請參𝔽𝔽*代器型𝔽*。

iter() 的第二種形式有一個好用的應用，是能𝔽建立一個區塊𝔽讀器 (block-reader)。例如，從二進位資料庫檔案中讀取固定寬度的區塊，直到檔案的結尾：

```
from functools import partial
with open('mydata.db', 'rb') as f:
    for block in iter(partial(f.read, 64), b''):
        process_block(block)
```

len(*s*)

回傳物件的長度（元素個數）。引數可以是序列（如 string、bytes、tuple、list 或 range）或集合（如 dictionary、set 或 frozen set）。

CPython 實作細節： 如果物件長度大於*sys.maxsize*，像是*range(2 ** 100)*，則 `len` 會引發*OverflowError*。

class list

class list(*iterable*)

除了是函式，`list` 也是可變序列型🄵，詳情請參🄵*List（串列）* 和*Sequence Types --- list, tuple, range*。

locals()

更新🄵回傳表示當前本地符號表的 dictionary。在函式區塊而不是 class 區塊中呼叫`locals()` 時會回傳自由變數。請注意，在 module 階層中，`locals()` 和`globals()` 是相同的 dictionary。

> **備🄵**
>
> 此 dictionary 的🄵容不應該被更動；更改可能不會影響直譯器使用的本地變數或自由變數的值。

map(*function*, *iterable*, **iterables*)

🄵生一個將 *function* 應用於 *iterable* 中所有元素，🄵收集回傳結果的 iterator。如果傳遞了額外的 *iterables* 引數，則 *function* 必須接受相同個數的引數，🄵使用所有從 iterables 中同時獲取的元素。當有多個 iterables 時，最短的 iteratable 耗盡時 iterator 也會結束。如果函式的輸入已經被編排🄵引數的 tuple，請參🄵`itertools.starmap()`。

max(*iterable*, *, *key*=*None*)

max(*iterable*, *, *default*, *key*=*None*)

max(*arg1*, *arg2*, **args*, *key*=*None*)

回傳 iterable 中最大的元素，或者回傳兩個以上的引數中最大的。

如果只提供了一個位置引數，它必須是個*iterable*，iterable 中最大的元素會被回傳。如果提供了兩個或以上的位置引數，則回傳最大的位置引數。

這個函式有兩個選擇性的僅限關鍵字引數。*key* 引數能指定單一引數所使用的排序函式，如同`list.sort()` 的使用方式。*default* 引數是當 iterable 🄵空時回傳的物件。如果 iterable 🄵空，🄵且🄵有提供 *default*，則會引發`ValueError`。

如果有多個最大元素，則此函式將回傳第一個找到的。這和其他穩定排序工具如 `sorted(iterable, key=keyfunc, reverse=True)[0]` 和 `heapq.nlargest(1, iterable, key=keyfunc)` 一致。

在 3.4 版的變更: 新增 *default* 僅限關鍵字參數。

在 3.8 版的變更: *key* 可以🄵 `None`。

class memoryview(*object*)

回傳由給定的引數所建立之「memory view（記憶體檢視）」物件。有關詳細資訊，請參🄵*Memory Views*。

min(*iterable*, *, *key*=*None*)

min(*iterable*, *, *default*, *key*=*None*)

min(*arg1*, *arg2*, **args*, *key*=*None*)

回傳 iterable 中最小的元素，或者回傳兩個以上的引數中最小的。

如果只提供了一個位置引數，它必須是*iterable*，iterable 中最小的元素會被回傳。如果提供了兩個以上的位置引數，則回傳最小的位置引數。

這個函式有兩個選擇性的僅限關鍵字引數。*key* 引數能指定單一引數所使用的排序函式，如同`list.sort()` 的使用方式。*default* 引數是當 iterable 🄵空時回傳的物件。如果 iterable 🄵空，🄵且🄵有提供 *default*，則會引發`ValueError`。

如果有多個最小元素，則此函式將回傳第一個找到的。這和其他穩定排序工具如 `sorted(iterable, key=keyfunc)[0]` 和 `heapq.nsmallest(1, iterable, key=keyfunc)` 一致。

在 3.4 版的變更: 新增 *default* 僅限關鍵字參數。

在 3.8 版的變更: *key* 可以🄵 None。

next(*iterator*)

next(*iterator*, *default*)

透過呼叫*iterator* 的*__next__()* method 獲取下一個元素。如果 iterator 耗盡，則回傳給定的預設值 *default*，如果🄵有預設值則引發*StopIteration*。

class object

回傳一個🄵有特徵的新物件。*object* 是所有 class 的基礎，它具有所有 Python class 實例的通用 method。這個函式不接受任何引數。

備🄵

由於*object* 🄵有*__dict__*，因此無法將任意屬性賦給*object* class 的實例。

oct(*x*)

將一個整數轉變🄵一個前綴🄵"0o" 的八進位制字串。回傳結果是一個有效的 Python 運算式。如果 *x* 不是 Python 的*int* 物件，那它需要定義 __index__() method 回傳一個整數。舉例來🄵:

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

如果要將整數轉🄵🄵八進位制字串，不論是否具備"0o" 前綴，都可以使用下面的方法。

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'{10:#o}', f'{10:o}'
('0o12', '12')
```

可參考*format()* 獲取更多資訊。

open(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)

開🄵 *file* 🄵回傳對應的*檔案物件*。如果該檔案不能開🄵，則引發*OSError*。關於使用此函式的更多方法，請參🄵 tut-files。

file 是一個*類路徑物件*，是將被開🄵之檔案的路徑（🄵對路徑或當前工作目🄵的相對路徑），或是要被包裝 (wrap) 檔案的整數檔案描述器 (file descriptor)。(如果有給定檔案描述器，它會隨著回傳的 I/O 物件關閉而關閉，除非 *closefd* 被設🄵 False。)

mode 是一個選擇性字串，用於指定開🄵檔案的模式。預設值是 'r'，這意味著它以文字模式開🄵🄵讀取。其他常見模式有：寫入 'w'（會舍去已經存在的檔案）、唯一性建立 'x'、追加寫入 'a'（在一些 Unix 系統上，無論當前的檔案指標在什🄵位置，所有寫入都會追加到檔案末尾）。在文字模式，如果🄵有指定 *encoding*，則根據電腦平臺來🄵定使用的編碼：呼叫*locale.getencoding()* 來獲取當前的本地編碼。(要讀取和寫入原始 bytes，請使用二進位制模式且不要指定 *encoding*。) 可用的模式有：

字元	意義
`'r'`	讀取（預設）
`'w'`	寫入，會先清除檔案🄴容
`'x'`	唯一性建立，如果文件已存在則會失敗
`'a'`	寫入，如果檔案存在則在其末端附加🄴容
`'b'`	二進制模式
`'t'`	文字模式（預設）
`'+'`	更新（讀取🄴寫入）

預設的模式是 `'r'`（開🄴🄴讀取文字，同 `'rt'`）。`'w+'` 和 `'w+b'` 模式會開🄴🄴清除檔案。`'r+'` 和 `'r+b'` 模式會開🄴且保留檔案🄴容。

如總覽中所述，Python 能區分二進制和文字的 I/O。在二進制模式下開🄴的檔案（*mode* 引數中含有 `'b'`）會將其🄴容以 *bytes* 物件回傳，而不進行任何解碼。在文字模式（預設情🄴，或當 *mode* 引數中含有 `'t'`），檔案的🄴容會以 *str* 回傳，其位元組已經先被解碼，使用的是取🄴於平台的編碼系統或是給定的 *encoding*。

備🄵

Python 不會使用底層作業系統對於文字檔案的操作概念；所有的處理都是由 Python 獨自完成的，因此能獨立於不同平台。

buffering 是一個選擇性的整數，用於設定緩衝策略。傳入 0 表示關閉緩衝（僅在二進制模式下被允許），1 表示行緩衝（line buffering，僅在文字模式下可用），而 >1 的整數是指示一個大小固定的區塊緩衝區 (chunk buffer)，其位元組的數量。請注意，此類指定緩衝區大小的方式適用於二進制緩衝 I/O，但是 `TextIOWrapper`（以 `mode='r+'` 開🄴的檔案）會有另一種緩衝方式。若要在 `TextIOWrapper` 中停用緩衝，可考慮使用 *io.TextIOWrapper.reconfigure()* 的 `write_through` 旗標。若未給定 *buffering* 引數，則預設的緩衝策略會運作如下：

- 二進制檔案會以固定大小的區塊進行緩衝；緩衝區的大小是使用🄴發式嘗試 (heuristic trying) 來🄴定底層設備的「區塊大小」，🄴會回退到 *io.DEFAULT_BUFFER_SIZE*。在許多系統上，緩衝區的長度通常🄴 4096 或 8192 個位元組。
- 「互動式」文字檔（*isatty()* 回傳 `True` 的檔案）會使用列緩衝。其他文字檔則使用上述的二進制檔案緩衝策略。

encoding 是用於解碼或編碼檔案的編碼系統之名稱。它只應該在文字模式下使用。預設的編碼系統會取🄴於平台（根據 *locale.getencoding()* 回傳的🄴容），但 Python 支援的任何 *text encoding*（文字編碼）都是可以使用的。關於支援的編碼系統清單，請參🄴 *codecs* module。

errors 是一個選擇性的字串，用於指定要如何處理編碼和解碼的錯誤——它不能在二進制模式下使用。有許多不同的標準錯誤處理程式（error handler，在 *Error Handlers* 有列出清單），不過任何已🄴🄴到 *codecs.register_error()* 的錯誤處理程式名稱也都是有效的。標準的名稱包括：

- `'strict'` 如果發生編碼錯誤，則引發 *ValueError* 例外。預設值 `None` 也有相同的效果。
- `'ignore'` 忽略錯誤。請注意，忽略編碼錯誤可能導致資料遺失。
- `'replace'` 會在格式不正確的資料位置插入一個替🄴標🄴（像是 `'?'`）。
- `'surrogateescape'` 會將任何不正確的位元組表示🄴低位代理碼元 (low surrogate code unit)，範圍從 U+DC80 到 U+DCFF。在寫入資料時，這些代理碼元將會被還原回 `surrogateescape` 錯誤處理程式當時所處理的那些相同位元組。這對於處理未知編碼方式的檔案會很好用。
- `'xmlcharrefreplace'` 僅在寫入檔案時可支援。編碼系統不支援的字元會被替🄴🄴適當的 XML 字元參考 (character reference) `&#nnn;`。

- 'backslashreplace' 會用 Python 的反斜F跳F序列 (backslashed escape sequence) 替F格式不正確的資料。
- 'namereplace'（也僅在寫入時支援）會將不支援的字元替FF \N{...} 跳F序列。

newline 會F定如何剖析資料串流 (stream) 中的F行字元。它可以是 None、''、'\n'、'\r' 或 '\r\n'。它的運作規則如下：

- 從資料串流讀取輸入時，如果 *newline* 是 None，則會F用通用F行模式。輸入資料中的行結尾可以是 '\n'、'\r' 或 '\r\n'，這些符號會被轉FF '\n' 之後再回傳給呼叫方。如果是 ''，也會F用通用F行模式，但在回傳給呼叫方時，行尾符號不會被轉F。如果它是任何其他有效的值，則輸入資料的行只會由給定的字串做結尾，且在回傳給呼叫方時，行尾符號不會被轉F。
- 將輸出寫入資料串流時，如果 *newline* 是 None，則被寫入的任何 '\n' 字元都會轉FF系統預設的行分隔符號*os.linesep*。如果 *newline* 是 '' 或 '\n'，則不做任何轉F。如果 *newline* 是任何其他有效的值，則寫入的任何 '\n' 字元都將轉FF給定的字串。

如果 *closefd* 是 False，且給定的 *file* 引數是一個檔案描述器而不是檔名，則當檔案關閉時，底層的檔案描述器會保持開F狀態。如果有給定一個檔名，則 *closefd* 必須是 True（預設值）；否則將引發錯誤。

透過以 *opener* 傳遞一個可呼叫物件，就可以自訂開F函式。然後透過以引數 (*file*, *flags*) 呼叫 *opener*，就能取得檔案物件的底層檔案描述器。*opener* 必須回傳一個開F的檔案描述器（將*os.open* 作F *opener* 傳入，在功能上的結果會相當於傳入 None）。

新建立的檔案是*不可繼承的*。

下面的範例使用*os.open()* 函式回傳值當作*dir_fd* 的參數，從給定的目F中用相對路徑開F檔案：

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
...
>>> with open('spamspam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spamspam.txt', file=f)
...
>>> os.close(dir_fd)  # don't leak a file descriptor
```

open() 函式回傳的*file object* 型F取F於模式。當*open()* 是在文字模式中開F檔案時（'w'、'r'、'wt'、'rt' 等），它會回傳*io.TextIOBase* 的一個 subclass（具體來F，就是*io.TextIOWrapper*）。使用有緩衝的二進制模式開F檔案時，回傳的 class 則會是*io.BufferedIOBase* 的 subclass。確切的 class 各不相同：在讀取的二進制模式，它會回傳*io.BufferedReader*；在寫入和附加的二進制模式，它會回傳*io.BufferedWriter*，而在讀 / 寫模式，它會回傳*io.BufferedRandom*。當緩衝被停用時，會回傳原始資料串流*io.FileIO*，它是*io.RawIOBase* 的一個 subclass。

另請參F檔案操作模組，例如*fileinput*、*io*（定義了*open()* 的 module ）、*os*、*os.path*、*tempfile* 以及*shutil*。

Raises an *auditing event* open with arguments path, mode, flags.

mode 和 flags 引數可能會被原始的呼叫所修改或推論 (infer)。

在 3.3 版的變更:

- 增加了 *opener* 參數。
- 增加了 'x' 模式。
- 過去引發的*IOError*，現在是*OSError* 的F名。
- 如果檔案已存在但使用了唯一性建立模式 ('x')，現在會引發*FileExistsError*。

在 3.4 版的變更:

- 檔案在此版本開始是不可繼承的。

在 3.5 版的變更:

- 如果系統呼叫被中斷，但訊號處理程式🄵有引發例外，此函式現在會重試系統呼叫，而不是引發 *InterruptedError* 例外（原因詳見 **PEP 475**）。
- 增加了 `'namereplace'` 錯誤處理程式。

在 3.6 版的變更:

- 增加對於實作 *os.PathLike* 物件的支援。
- 在 Windows 上，開🄵一個控制臺緩衝區可能會回傳 *io.RawIOBase* 的 subclass，而不是 *io.FileIO*。

在 3.11 版的變更: `'U'` 模式被移除。

ord(*c*)

對於代表單個 Unicode 字元的字串，回傳代表它 Unicode 編碼位置的整數。例如 `ord('a')` 回傳整數 `97`、`ord('€')`（歐元符號）回傳 `8364`。這是 *chr()* 的逆函式。

pow(*base*, *exp*, *mod=None*)

回傳 *base* 的 *exp* 次方；如果 *mod* 存在，則回傳 *base* 的 *exp* 次方對 *mod* 取余數（比直接呼叫 `pow(base, exp) % mod` 計算更高效）。兩個引數形式的 `pow(exp, exp)` 等價於次方運算子：`base**exp`。

The arguments must have numeric types. With mixed operand types, the coercion rules for binary arithmetic operators apply. For *int* operands, the result has the same type as the operands (after coercion) unless the second argument is negative; in that case, all arguments are converted to float and a float result is delivered. For example, `pow(10, 2)` returns `100`, but `pow(10, -2)` returns `0.01`. For a negative base of type *int* or *float* and a non-integral exponent, a complex result is delivered. For example, `pow(-9, 0.5)` returns a value close to `3j`. Whereas, for a negative base of type *int* or *float* with an integral exponent, a float result is delivered. For example, `pow(-9, 2.0)` returns `81.0`.

對於 *int* 運算元 *base* 和 *exp*，如果有給定 *mod*，則 *mod* 也必須是整數型🄵，且 *mod* 必須不🄵零。如果有給定 *mod* 且 *exp* 🄵負，則 *base* 必須與 *mod* 互質。在這種情🄵下，會回傳 `pow(inv_base, -exp, mod)`，其中 *inv_base* 是 *base* 對 *mod* 的模倒數 (inverse modulo)。

以下是一個計算 `38` 對 `97` 取模倒數的範例:

```
>>> pow(38, -1, mod=97)
23
>>> 23 * 38 % 97 == 1
True
```

在 3.8 版的變更: 對於 *int* 運算元，現在 `pow` 的三引數形式允許第二個引數🄵負數，也容許模倒數的計算。

在 3.8 版的變更: 允許關鍵字引數。在此之前只支援位置引數。

print(**objects*, *sep=' '*, *end='\n'*, *file=None*, *flush=False*)

將 *objects* 列印到文字資料串流 *file*，用 *sep* 分隔🄵以 *end* 結尾。如果有給定 *sep*、*end*、*file* 和 *flush*，那🄵它們必須是關鍵字引數的形式。

所有的非關鍵字引數都會像是 *str()* 操作一樣地被轉🄵🄵字串，🄵寫入資料串流，彼此以 *sep* 分隔，🄵以 *end* 結尾。*sep* 和 *end* 都必須是字串；它們也可以是 `None`，這表示使用預設值。如果🄵有給定 *objects*，*print()* 就只會寫入 *end*。

file 引數必須是一個有 `write(string)` method 的物件；如果🄵有給定或被設🄵 `None`，則將使用 *sys.stdout*。因🄵要列印的引數會被轉🄵🄵文字字串，所以 *print()* 不能用於二進位模式的檔案物件。對於此類物件，請改用 `file.write(...)`。

輸出緩衝通常會由 *file* 🄵定。但是如果 *flush* 🄵 true，則資料串流會被🄵制清除。

在 3.3 版的變更: 增加了 *flush* 關鍵字引數。

class property(*fget=None*, *fset=None*, *fdel=None*, *doc=None*)

回傳 property 屬性。

fget 是一個用於取得屬性值的函式，*fset* 是一個用於設定屬性值的函式，*fdel* 是一個用於🄵除屬性值的函式，而 *doc* 會🄵該屬性建立一個🄵明字串。

一個典型的用途是定義一個受管理的屬性 x：

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

    x = property(getx, setx, delx, "I'm the 'x' property.")
```

如果 *c* 是 *C* 的一個實例，則 `c.x` 將會呼叫取得器 (getter)，`c.x = value` 會呼叫設定器 (setter)，而 `del c.x` 會呼叫🄵除器 (deleter)。

如果有給定 *doc*，它將會是 property 屬性的🄵明字串。否則，property 會🄵🄵 *fget* 的🄵明字串（如果它存在的話）。這樣一來，就能🄵輕松地使用*property()* 作🄵裝飾器來建立唯讀屬性：

```
class Parrot:
    def __init__(self):
        self._voltage = 100000

    @property
    def voltage(self):
        """Get the current voltage."""
        return self._voltage
```

The `@property` decorator turns the `voltage()` method into a ”getter” for a read-only attribute with the same name, and it sets the docstring for *voltage* to ”Get the current voltage.”

@getter

@setter

@deleter

A property object has `getter`, `setter`, and `deleter` methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```
class C:
    def __init__(self):
        self._x = None

    @property
```

(繼續下一頁)

(繼續上一頁)

```
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (`x` in this case.)

The returned property object also has the attributes `fget`, `fset`, and `fdel` corresponding to the constructor arguments.

在 3.5 版的變更: The docstrings of property objects are now writeable.

class range(*stop*)

class range(*start*, *stop*, *step=1*)

Rather than being a function, *range* is actually an immutable sequence type, as documented in *Ranges* and *Sequence Types --- list, tuple, range*.

repr(*object*)

Return a string containing a printable representation of an object. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to *eval()*; otherwise, the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method. If *sys.displayhook()* is not accessible, this function will raise *RuntimeError*.

This class has a custom representation that can be evaluated:

```
class Person:
   def __init__(self, name, age):
      self.name = name
      self.age = age

   def __repr__(self):
      return f"Person('{self.name}', {self.age})"
```

reversed(*seq*)

Return a reverse *iterator*. *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at `0`).

round(*number*, *ndigits=None*)

Return *number* rounded to *ndigits* precision after the decimal point. If *ndigits* is omitted or is `None`, it returns the nearest integer to its input.

For the built-in types supporting *round()*, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both `round(0.5)` and `round(-0.5)` are `0`, and `round(1.5)` is `2`). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or `None`. Otherwise, the return value has the same type as *number*.

For a general Python object `number`, `round` delegates to `number.__round__`.

> **備🄵**
>
> The behavior of *`round()`* for floats can be surprising: for example, `round(2.675, 2)` gives `2.67` instead of the expected `2.68`. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See tut-fp-issues for more information.

class set

class set(*iterable*)

Return a new *`set`* object, optionally with elements taken from *iterable*. `set` is a built-in class. See *`set`* and *Set Types --- set, frozenset* for documentation about this class.

For other containers see the built-in *`frozenset`*, *`list`*, *`tuple`*, and *`dict`* classes, as well as the *`collections`* module.

setattr(*object*, *name*, *value*)

This is the counterpart of *`getattr()`*. The arguments are an object, a string, and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, `setattr(x, 'foobar', 123)` is equivalent to `x.foobar = 123`.

name need not be a Python identifier as defined in identifiers unless the object chooses to enforce that, for example in a custom `__getattribute__()` or via `__slots__`. An attribute whose name is not an identifier will not be accessible using the dot notation, but is accessible through *`getattr()`* etc..

> **備🄵**
>
> Since private name mangling happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to set it with *`setattr()`*.

class slice(*stop*)

class slice(*start*, *stop*, *step=None*)

Return a *slice* object representing the set of indices specified by `range(start, stop, step)`. The *start* and *step* arguments default to `None`.

start

stop

step

Slice objects have read-only data attributes `start`, `stop`, and `step` which merely return the argument values (or their default). They have no other explicit functionality; however, they are used by NumPy and other third-party packages.

Slice objects are also generated when extended indexing syntax is used. For example: `a[start:stop:step]` or `a[start:stop, i]`. See *`itertools.islice()`* for an alternate version that returns an *iterator*.

在 3.12 版的變更: Slice objects are now *hashable* (provided *`start`*, *`stop`*, and *`step`* are hashable).

sorted(*iterable*, */*, ***, *key=None*, *reverse=False*)

Return a new sorted list from the items in *iterable*.

有兩個選擇性引數，只能使用關鍵字引數來指定。

key specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). The default value is `None` (compare the elements directly).

reverse is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

Use *functools.cmp_to_key()* to convert an old-style *cmp* function to a *key* function.

The built-in *sorted()* function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal --- this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

The sort algorithm uses only < comparisons between items. While defining an `__lt__()` method will suffice for sorting, **PEP 8** recommends that all six rich comparisons be implemented. This will help avoid bugs when using the same data with other ordering tools such as *max()* that rely on a different underlying method. Implementing all six comparisons also helps avoid confusion for mixed type comparisons which can call reflected the `__gt__()` method.

For sorting examples and a brief sorting tutorial, see sortinghowto.

@staticmethod

Transform a method into a static method.

A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C:
    @staticmethod
    def f(arg1, arg2, argN): ...
```

`@staticmethod` 語法是一個函式*decorator* - 參見 function 中的詳細介紹。

A static method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). Moreover, the static method *descriptor* is also callable, so it can be used in the class definition (such as `f()`).

Static methods in Python are similar to those found in Java or C++. Also, see *classmethod()* for a variant that is useful for creating alternate class constructors.

Like all decorators, it is also possible to call `staticmethod` as a regular function and do something with its result. This is needed in some cases where you need a reference to a function from a class body and you want to avoid the automatic transformation to instance method. For these cases, use this idiom:

```
def regular_function():
    ...

class C:
    method = staticmethod(regular_function)
```

關於 static method 的更多資訊，請參考 types。

在 3.10 版的變更: Static methods now inherit the method attributes (`__module__`, `__name__`, `__qualname__`, `__doc__` and `__annotations__`), have a new `__wrapped__` attribute, and are now callable as regular functions.

class str(*object=''*)

class str(*object=b''*, *encoding='utf-8'*, *errors='strict'*)

Return a *str* version of *object*. See *str()* for details.

`str` is the built-in string *class*. For general information about strings, see *Text Sequence Type --- str*.

sum(*iterable*, */*, *start=0*)

Sums *start* and the items of an *iterable* from left to right and returns the total. The *iterable*'s items are normally numbers, and the start value is not allowed to be a string.

For some use cases, there are good alternatives to *sum()*. The preferred, fast way to concatenate a sequence of strings is by calling `''.join(sequence)`. To add floating-point values with extended precision, see *math.fsum()*. To concatenate a series of iterables, consider using *itertools.chain()*.

在 3.8 版的變更: *start* 參數可被指定🄴關鍵字引數。

在 3.12 版的變更: Summation of floats switched to an algorithm that gives higher accuracy on most builds.

class super

class super(*type*, *object_or_type=None*)

Return a proxy object that delegates method calls to a parent or sibling class of *type*. This is useful for accessing inherited methods that have been overridden in a class.

The *object_or_type* determines the *method resolution order* to be searched. The search starts from the class right after the *type*.

For example, if *__mro__* of *object_or_type* is `D -> B -> C -> A -> object` and the value of *type* is `B`, then *super()* searches `C -> A -> object`.

The *__mro__* attribute of the *object_or_type* lists the method resolution search order used by both *getattr()* and *super()*. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

If the second argument is omitted, the super object returned is unbound. If the second argument is an object, `isinstance(obj, type)` must be true. If the second argument is a type, `issubclass(type2, type)` must be true (this is useful for classmethods).

There are two typical use cases for *super*. In a class hierarchy with single inheritance, *super* can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of *super* in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement "diamond diagrams" where multiple base classes implement the same method. Good design dictates that such implementations have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
        super().method(arg)    # This does the same thing as:
                               # super(C, self).method(arg)
```

In addition to method lookups, *super()* also works for attribute lookups. One possible use case for this is calling *descriptors* in a parent or sibling class.

Note that *super()* is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattribute__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, *super()* is undefined for implicit lookups using statements or operators such as `super()[name]`.

Also note that, aside from the zero argument form, *super()* is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references. The zero argument form only works inside a class definition, as the compiler fills in the necessary details to correctly retrieve the class being defined, as well as accessing the current instance for ordinary methods.

For practical suggestions on how to design cooperative classes using *super()*, see guide to using super().

class tuple

class tuple(*iterable*)

Rather than being a function, `tuple` is actually an immutable sequence type, as documented in *Tuples* and *Sequence Types --- list, tuple, range*.

class type(*object*)

class type(*name*, *bases*, *dict*, ***kwds*)

With one argument, return the type of an *object*. The return value is a type object and generally the same object as returned by `object.__class__`.

The `isinstance()` built-in function is recommended for testing the type of an object, because it takes subclasses into account.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute. The *bases* tuple contains the base classes and becomes the `__bases__` attribute; if empty, `object`, the ultimate base of all classes, is added. The *dict* dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the `__dict__` attribute. The following two statements create identical `type` objects:

```
>>> class X:
...     a = 1
...
>>> X = type('X', (), dict(a=1))
```

另請參🄵*Type Objects*。

Keyword arguments provided to the three argument form are passed to the appropriate metaclass machinery (usually `__init_subclass__()`) in the same way that keywords in a class definition (besides *metaclass*) would.

另請參🄵 class-customization。

在 3.6 版的變更: Subclasses of `type` which don't override `type.__new__` may no longer use the one-argument form to get the type of an object.

vars()

vars(*object*)

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, classes use a `types.MappingProxyType` to prevent direct dictionary updates).

Without an argument, `vars()` acts like `locals()`. Note, the locals dictionary is only useful for reads since updates to the locals dictionary are ignored.

A `TypeError` exception is raised if an object is specified but it doesn't have a `__dict__` attribute (for example, if its class defines the `__slots__` attribute).

zip(**iterables*, *strict=False*)

Iterate over several iterables in parallel, producing tuples with an item from each one.

例如:

```
>>> for item in zip([1, 2, 3], ['sugar', 'spice', 'everything nice']):
...     print(item)
...
(1, 'sugar')
(2, 'spice')
(3, 'everything nice')
```

More formally: *zip()* returns an iterator of tuples, where the *i*-th tuple contains the *i*-th element from each of the argument iterables.

Another way to think of *zip()* is that it turns rows into columns, and columns into rows. This is similar to transposing a matrix.

zip() is lazy: The elements won't be processed until the iterable is iterated on, e.g. by a `for` loop or by wrapping in a *list*.

One thing to consider is that the iterables passed to *zip()* could have different lengths; sometimes by design, and sometimes because of a bug in the code that prepared these iterables. Python offers three different approaches to dealing with this issue:

- By default, *zip()* stops when the shortest iterable is exhausted. It will ignore the remaining items in the longer iterables, cutting off the result to the length of the shortest iterable:

```
>>> list(zip(range(3), ['fee', 'fi', 'fo', 'fum']))
[(0, 'fee'), (1, 'fi'), (2, 'fo')]
```

- *zip()* is often used in cases where the iterables are assumed to be of equal length. In such cases, it's recommended to use the `strict=True` option. Its output is the same as regular *zip()*:

```
>>> list(zip(('a', 'b', 'c'), (1, 2, 3), strict=True))
[('a', 1), ('b', 2), ('c', 3)]
```

  Unlike the default behavior, it raises a *ValueError* if one iterable is exhausted before the others:

```
>>> for item in zip(range(3), ['fee', 'fi', 'fo', 'fum'], strict=True):
...     print(item)
...
(0, 'fee')
(1, 'fi')
(2, 'fo')
Traceback (most recent call last):
  ...
ValueError: zip() argument 2 is longer than argument 1
```

  Without the `strict=True` argument, any bug that results in iterables of different lengths will be silenced, possibly manifesting as a hard-to-find bug in another part of the program.

- Shorter iterables can be padded with a constant value to make all the iterables have the same length. This is done by *itertools.zip_longest()*.

Edge cases: With a single iterable argument, *zip()* returns an iterator of 1-tuples. With no arguments, it returns an empty iterator.

Tips and tricks:

- The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into n-length groups using `zip(*[iter(s)]*n, strict=True)`. This repeats the *same* iterator `n` times so that each output tuple has the result of `n` calls to the iterator. This has the effect of dividing the input into n-length chunks.

- *zip()* in conjunction with the `*` operator can be used to unzip a list:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> list(zip(x, y))
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
```

(繼續下一頁)

(繼續上一頁)

```
>>> x == list(x2) and y == list(y2)
True
```

在 3.10 版的變更: 增加了 `strict` 引數。

__import__(*name*, *globals=None*, *locals=None*, *fromlist=()*, *level=0*)

> **備🄵**
>
> This is an advanced function that is not needed in everyday Python programming, unlike *importlib.import_module()*.

This function is invoked by the `import` statement. It can be replaced (by importing the *builtins* module and assigning to `builtins.__import__`) in order to change semantics of the `import` statement, but doing so is **strongly** discouraged as it is usually simpler to use import hooks (see **PEP 302**) to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of *__import__()* is also discouraged in favor of *importlib.import_module()*.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all and uses its *globals* only to determine the package context of the `import` statement.

level specifies whether to use absolute or relative imports. `0` (the default) means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling *__import__()* (see **PEP 328** for the details).

When the *name* variable is of the form `package.module`, normally, the top-level package (the name up till the first dot) is returned, *not* the module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.

For example, the statement `import spam` results in bytecode resembling the following code:

```
spam = __import__('spam', globals(), locals(), [], 0)
```

The statement `import spam.ham` results in this call:

```
spam = __import__('spam.ham', globals(), locals(), [], 0)
```

Note how *__import__()* returns the toplevel module here because this is the object that is bound to a name by the `import` statement.

On the other hand, the statement `from spam.ham import eggs, sausage as saus` results in

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
eggs = _temp.eggs
saus = _temp.sausage
```

Here, the `spam.ham` module is returned from *__import__()*. From this object, the names to import are retrieved and assigned to their respective names.

If you simply want to import a module (potentially within a package) by name, use *importlib.import_module()*.

在 3.3 版的變更: Negative values for *level* are no longer supported (which also changes the default value to 0).

在 3.9 版的變更: When the command line options `-E` or `-I` are being used, the environment variable `PYTHONCASEOK` is now ignored.

🄵解

CHAPTER 3

🄵建常數

有一小部分的常數存在於🄵建命名空間中。他們是：

False

在*bool* 型🄵中的 false 值。對於 `False` 的賦值是不合法的，🄵且會🄵出*SyntaxError*。

True

在*bool* 型🄵中的 true 值。對於 `True` 的賦值是不合法的，🄵且會🄵出*SyntaxError*。

None

型🄵 `NoneType` 的唯一值。`None` 經常被使用來表達缺少值，例如未傳送預設的引數至函式時，相對應參數即會被賦予 `None`。對於 `None` 的賦值是不合法的，🄵且會🄵出*SyntaxError*。`None` 是型🄵*NoneType* 的唯一實例。

NotImplemented

會被二元特殊方法 (binary special methods)（如：`__eq__()`、`__lt__()`、`__add__()`、`__rsub__()` 等）所回傳的特殊值，代表著該運算🄵有針對其他型🄵的實作。同理也可以被原地二元特殊方法 (in-place binary special methods)（如：`__imul__()`、`__iand__()` 等）回傳。它不應該被作🄵 boolean（布林）來解讀。`NotImplemented` 是型🄵*types.NotImplementedType* 的唯一實例。

備🄵

當一個二元 (binary) 或原地 (in-place) 方法回傳 `NotImplemented`，直譯器會嘗試反映該操作到其他型🄵（或是其他後援 (fallback)，取🄵於是哪種運算子）。如果所有的常識都回傳 `NotImplemented`，直譯器會🄵出適當的例外。不正確的回傳 `NotImplemented` 會造成誤導的錯誤訊息或是 `NotImplemented` 值被傳回到 Python 程式碼中。

請參見實作算術操作 以找到更多範例。

備🄵

`NotImplementedError` 與 `NotImplemented` [F]不一樣且不可互[F]。即使它們有相似的名稱與用途。欲知更多如何使用它們的細節，請參見*`NotImplementedError`*。

在 3.9 版的變更: 在 boolean（布林）上下文中解讀 `NotImplemented` 已經被[F]用。雖然目前會被解讀成 true，但會發出一個*`DeprecationWarning`*。在未來版本的 Python 將會[F]出*`TypeError`*。

`Ellipsis`

與[F]節號"`...`" 字面相同。[F]一特殊值，大多用於結合使用者定義資料型[F]的延伸切片語法 (extended slicing syntax)。`Ellipsis` 是型[F]*`types.EllipsisType`* 的唯一實例。

`__debug__`

如果 Python [F]有被以 `-O` 選項[F]動，則此常數[F] true。請參見 `assert` 陳述式。

備[F]

`None`，*`False`*，*`True`*，以及*`__debug__`* 都是不能被重新賦值的（任何對它們的賦值，即使是屬性的名稱，也會[F]出*`SyntaxError`*）。因此，它們可以被視[F]"真正的"常數。

3.1 由 `site` module（模組）所添增的常數

`site` module（模組）（在[F]動期間自動 import，除非有給予 `-S` 指令行選項）會添增一些常數到[F]建命名空間 (built-in namespace) 中。它們在互動式直譯器中是很有幫助的，但不應該在程式 (programs) 中被使用。

`quit`(*code=None*)

`exit`(*code=None*)

當印出物件時，會印出一個訊息："Use quit() or Ctrl-D (i.e. EOF) to exit"。當被呼叫時，則會[F]出*`SystemExit`* [F]帶有指定的返回碼（exit code）。

`copyright`

`credits`

當印出或是呼叫此物件時，分[F]會印出版權與致謝的文字。

`license`

當印出此物件時，會印出訊息"Type license() to see the full license text"。當被呼叫時，則會以分頁形式印出完整的許可證文字（一次一整個畫面）。

CHAPTER 4

🄵建型🄵

以下章節描述了直譯器中內建的標准型🄵。

主要🄵建型🄵🄵數字、序列、映射、class（類🄵）、實例和例外。

有些集合類🄵是 mutable（可變的）。那些用於原地 (in-place) 加入、移除或重新排列其成員且不回傳特定項的 method（方法），也只會回傳 None 而非集合實例自己。

某些操作已被多種物件型🄵支援；特🄵是實務上所有物件都已經可以做相等性比較、真值檢測及被轉🄵🄵字串（使用*repr()* 函式或稍有差🄵的*str()* 函式），後者🄵當物件傳入*print()* 函式印出時在背後被呼叫的函式。

4.1 真值檢測

任何物件都可以進行檢測以判斷是否🄵真值，以便在 if 或 while 條件中使用，或是作🄵如下所述 boolean（布林）運算之運算元所用。

預設情🄵下，一個物件會被視🄵真值，除非它的 class 定義了會回傳 False 的 __bool__() method 或是定義了會回傳零的 __len__() method。[1] 以下列出了大部分會被視🄵 false 的🄵建物件：

- 定義🄵 false 之常數：None 與 False
- 任何數值型🄵的零：0、0.0、0j、Decimal(0)、Fraction(0, 1)
- 空的序列和集合：''、()、[]、{}、set()、range(0)

除非另有特🄵🄵明，🄵生 boolean 結果的操作或🄵建函式都會回傳 0 或 False 作🄵假值、1 或 True 作🄵真值。（重要例外：boolean 運算 or 和 and 回傳的是其中一個運算元。）

[1] Additional information on these special methods may be found in the Python Reference Manual (customization).

4.2 Boolean（布林）運算 --- and, or, not

下方🄵 Boolean 運算，按優先順序排序：

運算	結果	🄵解
`x or y`	假如 *x* 🄵真，則 *x*，否則 *y*	(1)
`x and y`	假如 *x* 🄵假，則 *x*，否則 *y*	(2)
`not x`	假如 *x* 🄵假，則 `True`，否則 `False`	(3)

🄵解：

(1) 這是一個短路運算子，所以他只有在第一個引數🄵假時，才會對第二個引數求值。

(2) 這是一個短路運算子，所以他只有在第一個引數🄵真時，才會對第二個引數求值。

(3) `not` 比非 Boolean 運算子有較低的優先權，因此 `not a == b` 可直譯🄵 `not (a == b)`，而 `a == not b` 會導致語法錯誤。

4.3 比較運算

在 Python 🄵共有 8 種比較運算。他們的優先順序都相同（皆優先於 Boolean 運算）。比較運算可以任意的串連；例如，`x < y <= z` 等同於 `x < y and y <= z`，差🄵只在於前者的 *y* 只有被求值一次（但在這兩個例子中，當 `x < y` 🄵假時，*z* 皆不會被求值）。

這個表格統整所有比較運算：

運算	含義
`<`	小於
`<=`	小於等於
`>`	大於
`>=`	大於等於
`==`	等於
`!=`	不等於
`is`	物件識🄵性
`is not`	否定的物件識🄵性

除了不同的數值型🄵外，不同型🄵的物件不能進行相等比較。運算子 == 總有定義，但在某些物件型🄵（例如，class 物件）時，運算子會等同於 `is`。其他運算子 <、<=、> 及 >= 皆僅在有意義的部分有所定義；例如，當其中一個引數🄵🄵數時，將引發一個 *TypeError* 的例外。

一個 class 的非相同實例通常會比較🄵不相等，除非 class 有定義 `__eq__()` method。

一個 class 的實例不可以與其他相同 class 的實例或其他物件型🄵進行排序，除非 class 定義足🄵的 method，包含 `__lt__()`、`__le__()`、`__gt__()` 及 `__ge__()`（一般來🄵，使用 `__lt__()` 及 `__eq__()` 就可以滿足常規意義上的比較運算子）。

無法自定義 `is` 與 `is not` 運算子的行🄵；這兩個運算子也可以運用在任意兩個物件且不會引發例外。

此外，擁有相同的語法優先序的 `in` 及 `not in` 兩種運算皆被可🄵代物件或者有實作 `__contains__()` method 的型🄵所支援。

4.4 數值型🄵 --- int、float、complex

There are three distinct numeric types: *integers*, *floating-point numbers*, and *complex numbers*. In addition, Booleans are a subtype of integers. Integers have unlimited precision. Floating-point numbers are usually implemented using `double` in C; information about the precision and internal representation of floating-point numbers for the machine on which your program is running is available in *sys.float_info*. Complex numbers have a real and imaginary part, which are each a floating-point number. To extract these parts from a complex number *z*, use `z.real` and `z.imag`. (The standard library includes the additional numeric types *fractions.Fraction*, for rationals, and *decimal.Decimal*, for floating-point numbers with user-definable precision.)

Numbers are created by numeric literals or as the result of built-in functions and operators. Unadorned integer literals (including hex, octal and binary numbers) yield integers. Numeric literals containing a decimal point or an exponent sign yield floating-point numbers. Appending `'j'` or `'J'` to a numeric literal yields an imaginary number (a complex number with a zero real part) which you can add to an integer or float to get a complex number with real and imaginary parts.

Python 完全支援混和運算：當一個二元運算子的運算元有不同數值型🄵時，「較窄」型🄵的運算元會被拓寬到另一個型🄵的運算元；在此處，整數窄於浮點數，浮點數又窄於🄵數。不同型🄵的數字間的比較等同於這些數字的精確值進行比較。[2]

建構函式：*int()*、*float()* 及*complex()* 可以用來🄵生特定型🄵的數字。

所有數值型🄵（除🄵數外）皆支援以下的運算（有關運算的先後順序，詳見 operator-summary）：

運算	結果	🄵解	完整文件
`x + y`	*x* 及 *y* 的加總		
`x - y`	*x* 及 *y* 的相🄵		
`x * y`	*x* 及 *y* 的相乘		
`x / y`	*x* 及 *y* 相除之商		
`x // y`	*x* 及 *y* 的整數除法	(1)(2)	
`x % y`	`x / y` 的余數	(2)	
`-x`	*x* 的負數		
`+x`	*x* 不變		
`abs(x)`	*x* 的🄵對值或量 (magnitude)		*abs()*
`int(x)`	將 *x* 轉🄵整數	(3)(6)	*int()*
`float(x)`	將 *x* 轉🄵浮點數	(4)(6)	*float()*
`complex(re, im)`	一個🄵數，其實部🄵 *re*，🄵部🄵 *im*。*im* 預設🄵零。	(6)	*complex()*
`c.conjugate()`	🄵🄵數 *c* 的共🄵🄵數		
`divmod(x, y)`	一對 `(x // y, x % y)`	(2)	*divmod()*
`pow(x, y)`	*x* 的 *y* 次方	(5)	*pow()*
`x ** y`	*x* 的 *y* 次方	(5)	

🄵解：

(1) 也被稱🄵整數除法。對於型🄵🄵*int* 的運算元來🄵，結果之型🄵會是*int*。對於型🄵🄵*float* 的運算元來🄵，結果之型🄵會是*float*。一般來🄵，結果會是一個整數，但其型🄵不一定會是*int*。結果總是會往負無窮大的方向取整數值：`1//2` 🄵 `0`、`(-1)//2` 🄵 `-1`、`1//(-2)` 🄵 `-1` 及 `(-1)//(-2)` 🄵 `0`。

(2) 不可用於🄵數。在適當情形下，可使用*abs()* 轉🄵🄵浮點數。

(3) 從*float* 轉🄵🄵*int* 會導致截斷🄵排除小數部分。詳見*math.floor()* 及*math.ceil()* 以了解更多轉🄵方式。

(4) 浮點數也接受帶有可選的前綴"+" 及"-" 的"nan" 及"inf" 字串，其分🄵代表非數字（NaN）及正負無窮。

(5) Python 將 `pow(0, 0)` 及 `0 ** 0` 定義🄵 `1` 這是程式語言的普遍做法。

[2] As a consequence, the list `[1, 2]` is considered equal to `[1.0, 2.0]`, and similarly for tuples.

(6) 字面數值接受包含數字 0 到 9 或任何等效的 Unicode 字元（具有 Nd 屬性的 code points（碼位））。

請參🄵 Unicode 標准以了解具有 Nd 屬性的 code points 完整列表。

所有*numbers.Real* 型🄵（*int* 及*float*）也適用下列運算：

運算	結果
math.trunc(x)	*x* 截斷🄵*Integral*
round(x[, n])	*x* 進位至小數點後第 *n* 位，使用偶數舍入法。若省略 *n*，則預設🄵 0。
math.floor(x)	小於等於 *x* 的最大*Integral*
math.ceil(x)	大於等於 *x* 的最小*Integral*

關於其他數值運算請詳見*math* 及*cmath* modules（模組）。

4.4.1 整數型🄵的位元運算

位元運算只對整數有意義。位元運算的計算結果就如同對二的補數執行無窮多個符號位元。

二元位元運算的優先順序皆低於數字運算，但高於比較運算；一元運算 ~ 與其他一元數值運算有一致的優先順序（+ 及 -）。

這個表格列出所有位元運算🄵以優先順序由先至後排序。

運算	結果	🄵解
x | y	*x* 及 *y* 的位元 或	(4)
x ^ y	*x* 及 *y* 的位元 邏輯互斥或	(4)
x & y	*x* 及 *y* 的位元 與	(4)
x << n	*x* 往左移動 *n* 個位元	(1)(2)
x >> n	*x* 往右移動 *n* 個位元	(1)(3)
~x	反轉 *x* 的位元	

🄵解：

(1) 負數位移是不被允許🄵會引發*ValueError* 的錯誤。

(2) 向左移動 *n* 個位元等同於乘以 pow(2, n)。

(3) 向右移動 *n* 個位元等同於向下除法除以 pow(2, n)。

(4) 在有限的二的補數表示法中執行這些計算（一個有效位元寬度🄵 1 + max(x.bit_length(), y.bit_length()) 或以上）🄵至少有一個額外的符號擴展位元，便足以得到與無窮多個符號位元相同的結果。

4.4.2 整數型🄵的附加 methods

整數型🄵實作了*numbers.Integral* 抽象基底類🄵。此外，它提供了一些 methods：

int.**bit_length**()

回傳以二進位表示一個整數所需要的位元數，不包括符號及首位的零：

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

更准確來🄴, 若 x 非🄴零, 則 x.bit_length() 會得出滿足 2**(k-1) <= abs(x) < 2**k 的單一正整數 k。同樣地, 當 abs(x) 足🄴小到能正確地取得舍入的對數, 則 k = 1 + int(log(abs(x), 2))。若 x 🄴零, 則 x.bit_length() 會回傳 0。

等同於:

```
def bit_length(self):
    s = bin(self)       # binary representation:  bin(-37) --> '-0b100101'
    s = s.lstrip('-0b') # remove leading zeros and minus sign
    return len(s)       # len('100101') --> 6
```

在 3.1 版被加入.

int.**bit_count**()

回傳在🄴對值表示的二進位中 1 的個數。這也被稱作母體計數。舉例來🄴:

```
>>> n = 19
>>> bin(n)
'0b10011'
>>> n.bit_count()
3
>>> (-n).bit_count()
3
```

等同於:

```
def bit_count(self):
    return bin(self).count("1")
```

在 3.10 版被加入.

int.**to_bytes**(*length=1*, *byteorder='big'*, *, *signed=False*)

回傳表示一個整數的一列位元組。

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xfc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='little')
b'\xe8\x03'
```

此整數會使用 *length* 位元組表示，🄵且預設🄴 1。如果該整數無法用給定的位元組數來表示，則會引發*OverflowError*。

byteorder 引數🄴定了用來表示整數的位元組順序🄴且預設🄴 "big"。如果 byteorder 是 "big"，最重要的位元組位於位元組陣列的開頭。如果 byteorder 是 "little"，最重要的位元組位於位元組陣列的結尾。

signed 引數🄴定是否使用二的補數來表示整數。如果 *signed* 是 False 🄴且給定了一個負整數，則會引發*OverflowError*。*signed* 的預設值是 False。

預設值可以方便地將一個整數轉🄵🄵單一位元組物件：

```
>>> (65).to_bytes()
b'A'
```

然而，使用預設引數時，不要嘗試轉🄴大於 255 的值，否則你將會得到一個*OverflowError*。

等同於：

```
def to_bytes(n, length=1, byteorder='big', signed=False):
    if byteorder == 'little':
        order = range(length)
    elif byteorder == 'big':
        order = reversed(range(length))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    return bytes((n >> i*8) & 0xff for i in order)
```

在 3.2 版被加入.

在 3.11 版的變更: 🄵 `length` 和 `byteorder` 添加了預設引數值。

classmethod `int`.**from_bytes**(*bytes*, *byteorder='big'*, ***, *signed=False*)

回傳由給定的位元組陣列表示的整數。

```
>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680
```

引數 *bytes* 必須是一個類位元組物件或是一個🄴生位元組的可🄴代物件。

byteorder 引數🄴定了用來表示整數的位元組順序🄵且預設🄵 `"big"`。如果 *byteorder* 是 `"big"`，最重要的位元組位於位元組陣列的開頭。如果 *byteorder* 是 `"little"`，最重要的位元組位於位元組陣列的結尾。若要請求主機系統的本機位元組順序，請使用*sys.byteorder* 作🄴位元組順序值。

signed 引數指示是否使用二的補數來表示整數。

等同於：

```
def from_bytes(bytes, byteorder='big', signed=False):
    if byteorder == 'little':
        little_ordered = list(bytes)
    elif byteorder == 'big':
        little_ordered = list(reversed(bytes))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    n = sum(b << i*8 for i, b in enumerate(little_ordered))
    if signed and little_ordered and (little_ordered[-1] & 0x80):
        n -= 1 << 8*len(little_ordered)

    return n
```

在 3.2 版被加入.

在 3.11 版的變更: 🄵 `byteorder` 添加了預設引數值。

`int.`**`as_integer_ratio`**`()`

回傳一對整數，其比率等於原始整數🄵且有一個正分母。整數（整個數值）的整數比率總是整數作🄵分子，🄵且 `1` 作🄵分母。

在 3.8 版被加入.

`int.`**`is_integer`**`()`

回傳 `True`。🄵了與*`float.is_integer()`* 的鴨子型🄵相容而存在。

在 3.12 版被加入.

4.4.3 浮點數的附加 methods

浮點數型🄵實作了*`numbers.Real` 抽象基底類*🄵。浮點數也有下列附加 methods。

`float.`**`as_integer_ratio`**`()`

回傳一對整數，其比率完全等於原始浮點數。比率是在最低條件下🄵且有一個正分母。在無窮大時引發*`OverflowError`*，在 NaN 時引發*`ValueError`*。

`float.`**`is_integer`**`()`

如果浮點數實例是有限的🄵且具有整數值，則回傳 `True`，否則回傳 `False`:

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

兩個 methods 皆支援十六進位字串之間的轉🄵。由於 Python 的浮點數🄵部以二進位數值儲存，將浮點數轉🄵🄵或從 十 進位字串通常涉及一個小的四舍五入誤差。相反地，十六進位字串允許精確表示和指定浮點數。這在除錯和數值工作中可能會有用。

`float.`**`hex`**`()`

回傳浮點數的十六進位字串表示。對於有限浮點數，此表示方式總是包含一個前導 `0x` 及一個尾部 `p` 和指數。

`classmethod` `float.`**`fromhex`**`(`*`s`*`)`

Class method 回傳由十六進位字串 *s* 表示的浮點數。字串 *s* 可能有前導及尾部的空白。

請注意*`float.hex()`* 是一個實例 method，而*`float.fromhex()`* 是一個 class method。

一個十六進位字串的形式如下:

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

其中可選的 `sign` 可以是 `+` 或 `-`，`integer` 和 `fraction` 是十六進位數字的字串，而 `exponent` 是一個十進位整數🄵且有一個可選的前導符號。大小寫不重要，🄵且整數或小數部分至少有一個十六進位數字。這個語法與 C99 標準的第 6.4.4.2 節指定的語法相似，也與 Java 1.5 以後的語法相似。特🄵是*`float.hex()`* 的輸出可用作 C 或 Java 程式碼中的十六進位浮點數文字，🄵且 C 的 `%a` 格式字元或 Java 的 `Double.toHexString` 🄵生的十六進位字串可被*`float.fromhex()`* 接受。

請注意指數是以十進位而非十六進位寫入，🄵且它給出了乘以🄵數的 2 的次方。例如，十六進位字串 `0x3.a7p10` 表示浮點數 `(3 + 10./16 + 7./16**2) * 2.0**10`，或 `3740.0`:

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

對 3740.0 應用反向轉[F]會給出一個不同的十六進位字串，它表示相同的數字：

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

4.4.4 數值型[F]的雜[F]

對於數字 x 和 y，可能是不同型[F]，當 x == y 時，hash(x) == hash(y) 是一個要求（詳見 __hash__() method 的文件以獲得更多細節）。[F]了實作的便利性和效率跨越各種數值型[F]（包括*int*、*float*、*decimal.Decimal* 和*fractions.Fraction*）Python 的數值型[F]的雜[F]是基於一個數學函式，它對於任何有理數都是定義的，因此適用於所有*int* 和*fractions.Fraction* 的實例，以及所有有限的*float* 和*decimal.Decimal* 的實例。基本上，這個函式是由簡化的 modulo（模數）P 給出的一個固定的質數 P。P 的值作[F]*sys.hash_info* 的*modulus* 屬性提供給 Python。

CPython 實作細節：目前在具有 32 位元 C longs 的機器上所使用的質數是 P = 2**31 - 1，而在具有 64 位元 C longs 的機器上[F] P = 2**61 - 1 。

以下是詳細的規則：

- 如果 x = m / n 是一個非負的有理數，[F]且 n 不可被 P 整除，則將 hash(x) 定義[F] m * invmod(n, P) % P。其中 invmod(n, P) [F] n 對模數 P 的倒數。
- 如果 x = m / n 是一個非負的有理數，[F]且 n 可被 P 整除（但 m 不行），則 n [F]有 inverse modulo（模倒數）P，[F]且不適用於上述規則；在這種情[F]下，將 hash(x) 定義[F]常數值 sys.hash_info.inf。
- 如果 x = m / n 是一個負的有理數，則將 hash(x) 定義[F] -hash(-x)。如果結果的雜[F]是 -1，則將其替[F][F] -2。
- 特定值 sys.hash_info.inf 和 -sys.hash_info.inf （分[F]）被用作正無窮大或負無窮大的雜[F]值。
- 對於一個*complex* 值 z，實部和[F]部的雜[F]值藉由 hash(z.real) + sys.hash_info.imag * hash(z.imag) 的計算進行組合，對 2**sys.hash_info.width 取模數使其介於 range(-2**(sys.hash_info.width - 1), 2**(sys.hash_info.width - 1))。同樣地，如果結果是 -1，則將其替[F][F] -2。

[F]了闡明上述規則，這[F]有一些 Python 程式碼範例，等同於[F]建的雜[F]，用於計算有理數、*float* 或*complex* 的雜[F]：

```
import sys, math

def hash_fraction(m, n):
    """Compute the hash of a rational number m / n.

    Assumes m and n are integers, with n positive.
    Equivalent to hash(fractions.Fraction(m, n)).

    """
    P = sys.hash_info.modulus
    # Remove common factors of P.  (Unnecessary if m and n already coprime.)
    while m % P == n % P == 0:
        m, n = m // P, n // P

    if n % P == 0:
```

(繼續下一頁)

(繼續上一頁)

```
        hash_value = sys.hash_info.inf
    else:
        # Fermat's Little Theorem: pow(n, P-1, P) is 1, so
        # pow(n, P-2, P) gives the inverse of n modulo P.
        hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
    if m < 0:
        hash_value = -hash_value
    if hash_value == -1:
        hash_value = -2
    return hash_value

def hash_float(x):
    """Compute the hash of a float x."""

    if math.isnan(x):
        return object.__hash__(x)
    elif math.isinf(x):
        return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
    else:
        return hash_fraction(*x.as_integer_ratio())

def hash_complex(z):
    """Compute the hash of a complex number z."""

    hash_value = hash_float(z.real) + sys.hash_info.imag * hash_float(z.imag)
    # do a signed reduction modulo 2**sys.hash_info.width
    M = 2**(sys.hash_info.width - 1)
    hash_value = (hash_value & (M - 1)) - (hash_value & M)
    if hash_value == -1:
        hash_value = -2
    return hash_value
```

4.5 Boolean 型🄵 - `bool`

Boolean 值代表 truth values（真值）。*bool* 型🄴有兩個常數實例：`True` 和 `False`。

🄵建函式*bool()* 將任何值轉🄵🄵 boolean 值，如果該值可以被直譯🄵一個 truth value（真值）（見上面的*真值檢測*章節）。

對於邏輯運算，使用*boolean 運算子* `and`、`or` 和 `not`。當將位元運算子 `&`、`|`、`^` 應用於兩個 boolean 值時，它們會回傳一個等同於邏輯運算"and"、"or"、"xor" 的 boolean 值。然而，應該優先使用邏輯運算子 `and`、`or` 和 `!=` 而不是 `&`、`|` 和 `^`。

在 3.12 版之後被🄴用: 位元反轉運算子 ~ 的使用已被🄴用🄴且將在 Python 3.14 中引發錯誤。

bool 是*int* 的子類🄵（見*數值型🄵 --- int、float、complex*）。在許多數值情境中，`False` 和 `True` 分🄴像整數 0 和 1 一樣。然而，不鼓勵依賴這一點；請使用*int()* 進行顯式轉🄴。

4.6 F代器型F

Python 支援對容器的F代概念。這是實作兩種不同的 methods；這些方法被用於允許使用者自定義的 classes 以支援F代。序列則總是支援這些F代 methods，在下方有更詳細的描述。

需要F容器物件定義一個 method 來提供可F代物件支援：

container.**__iter__**()

回傳一個F代器物件。該物件需要支援下述的F代器協定。如果一個容器支援不同型F的F代，則可以提供額外的 methods 來專門請求這些F代型F的F代器。（支援多種形式F代的物件的一個例子是支援廣度優先和深度優先遍歷的樹結構。）此 method 對應 Python/C API 中 Python 物件的型F結構的 `tp_iter` 插槽。

F代器物件本身需要支援下列兩個 methods，他們一起形成了 F代器協定：

iterator.**__iter__**()

回傳F代器物件本身。這是F了允許容器和F代器都可以與 `for` 和 `in` 在陳述式中使用。此 method 對應於 Python/C API 中 Python 物件的型F結構的 `tp_iter` 插槽。

iterator.**__next__**()

從F代器回傳下一個項目。如果F有更多項目，則引發 *StopIteration* 例外。此 method 對應於 Python/C API 中 Python 物件的型F結構的 `tp_iternext` 插槽。

Python 定義了幾個F代器物件來支援對一般和特定序列型F、字典和其他更專門的形式的F代。這些特定型F除了實作F代器協定外F不重要。

一旦F代器的 *__next__()* method 引發 *StopIteration*，則它必須在後續呼叫中繼續這樣做。不遵守此屬性的實作被認F是有問題的。

4.6.1 Generator Types

Python's *generator*s provide a convenient way to implement the iterator protocol. If a container object's *__iter__()* method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `__next__()` methods. More information about generators can be found in the documentation for the yield expression.

4.7 Sequence Types --- `list`, `tuple`, `range`

There are three basic sequence types: lists, tuples, and range objects. Additional sequence types tailored for processing of *binary data* and *text strings* are described in dedicated sections.

4.7.1 Common Sequence Operations

The operations in the following table are supported by most sequence types, both mutable and immutable. The *collections.abc.Sequence* ABC is provided to make it easier to correctly implement these operations on custom sequence types.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type, *n*, *i*, *j* and *k* are integers and *x* is an arbitrary object that meets any type and value restrictions imposed by *s*.

The `in` and `not in` operations have the same priorities as the comparison operations. The `+` (concatenation) and `*` (repetition) operations have the same priority as the corresponding numeric operations.[3]

[3] They must have since the parser can't tell the type of the operands.

運算	結果	🄵解
`x in s`	`True` if an item of *s* is equal to *x*, else `False`	(1)
`x not in s`	`False` if an item of *s* is equal to *x*, else `True`	(1)
`s + t`	the concatenation of *s* and *t*	(6)(7)
`s * n` 或 `n * s`	equivalent to adding *s* to itself *n* times	(2)(7)
`s[i]`	*i*th item of *s*, origin 0	(3)
`s[i:j]`	slice of *s* from *i* to *j*	(3)(4)
`s[i:j:k]`	slice of *s* from *i* to *j* with step *k*	(3)(5)
`len(s)`	length of *s*	
`min(s)`	smallest item of *s*	
`max(s)`	largest item of *s*	
`s.index(x[, i[, j]])`	index of the first occurrence of *x* in *s* (at or after index *i* and before index *j*)	(8)
`s.count(x)`	total number of occurrences of *x* in *s*	

Sequences of the same type also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see comparisons in the language reference.)

Forward and reversed iterators over mutable sequences access values using an index. That index will continue to march forward (or backward) even if the underlying sequence is mutated. The iterator terminates only when an *IndexError* or a *StopIteration* is encountered (or when the index drops below zero).

🄵解:

(1) While the `in` and `not in` operations are used only for simple containment testing in the general case, some specialised sequences (such as *str*, *bytes* and *bytearray*) also use them for subsequence testing:

```
>>> "gg" in "eggs"
True
```

(2) Values of *n* less than `0` are treated as `0` (which yields an empty sequence of the same type as *s*). Note that items in the sequence *s* are not copied; they are referenced multiple times. This often haunts new Python programmers; consider:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

What has happened is that `[[]]` is a one-element list containing an empty list, so all three elements of `[[]] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Further explanation is available in the FAQ entry faq-multidimensional-list.

(3) If *i* or *j* is negative, the index is relative to the end of sequence *s*: `len(s) + i` or `len(s) + j` is substituted. But note that `-0` is still `0`.

(4) The slice of *s* from *i* to *j* is defined as the sequence of items with index *k* such that `i <= k < j`. If *i* or *j* is greater than `len(s)`, use `len(s)`. If *i* is omitted or `None`, use `0`. If *j* is omitted or `None`, use `len(s)`. If *i* is greater than or equal to *j*, the slice is empty.

(5) The slice of *s* from *i* to *j* with step *k* is defined as the sequence of items with index `x = i + n*k` such that `0 <= n < (j-i)/k`. In other words, the indices are `i`, `i+k`, `i+2*k`, `i+3*k` and so on, stopping when *j* is reached (but never including *j*). When *k* is positive, *i* and *j* are reduced to `len(s)` if they are greater. When *k* is negative, *i* and *j* are reduced to `len(s) - 1` if they are greater. If *i* or *j* are omitted or `None`, they become "end" values (which end depends on the sign of *k*). Note, *k* cannot be zero. If *k* is `None`, it is treated like `1`.

(6) Concatenating immutable sequences always results in a new object. This means that building up a sequence by repeated concatenation will have a quadratic runtime cost in the total sequence length. To get a linear runtime cost, you must switch to one of the alternatives below:

- if concatenating *str* objects, you can build a list and use *str.join()* at the end or else write to an *io.StringIO* instance and retrieve its value when complete
- if concatenating *bytes* objects, you can similarly use *bytes.join()* or *io.BytesIO*, or you can do in-place concatenation with a *bytearray* object. *bytearray* objects are mutable and have an efficient overallocation mechanism
- if concatenating *tuple* objects, extend a *list* instead
- for other types, investigate the relevant class documentation

(7) Some sequence types (such as *range*) only support item sequences that follow specific patterns, and hence don't support sequence concatenation or repetition.

(8) `index` raises *ValueError* when *x* is not found in *s*. Not all implementations support passing the additional arguments *i* and *j*. These arguments allow efficient searching of subsections of the sequence. Passing the extra arguments is roughly equivalent to using `s[i:j].index(x)`, only without copying any data and with the returned index being relative to the start of the sequence rather than the start of the slice.

4.7.2 Immutable Sequence Types

The only operation that immutable sequence types generally implement that is not also implemented by mutable sequence types is support for the *hash()* built-in.

This support allows immutable sequences, such as *tuple* instances, to be used as *dict* keys and stored in *set* and *frozenset* instances.

Attempting to hash an immutable sequence that contains unhashable values will result in *TypeError*.

4.7.3 Mutable Sequence Types

The operations in the following table are defined on mutable sequence types. The *collections.abc.MutableSequence* ABC is provided to make it easier to correctly implement these operations on custom sequence types.

In the table *s* is an instance of a mutable sequence type, *t* is any iterable object and *x* is an arbitrary object that meets any type and value restrictions imposed by *s* (for example, *bytearray* only accepts integers that meet the value restriction `0 <= x <= 255`).

運算	結果	🄵解
`s[i] = x`	item *i* of *s* is replaced by *x*	
`s[i:j] = t`	slice of *s* from *i* to *j* is replaced by the contents of the iterable *t*	
`del s[i:j]`	same as `s[i:j] = []`	
`s[i:j:k] = t`	the elements of `s[i:j:k]` are replaced by those of *t*	(1)
`del s[i:j:k]`	removes the elements of `s[i:j:k]` from the list	
`s.append(x)`	appends *x* to the end of the sequence (same as `s[len(s):len(s)] = [x]`)	
`s.clear()`	removes all items from *s* (same as `del s[:]`)	(5)
`s.copy()`	creates a shallow copy of *s* (same as `s[:]`)	(5)
`s.extend(t)` 或 `s += t`	extends *s* with the contents of *t* (for the most part the same as `s[len(s):len(s)] = t`)	
`s *= n`	updates *s* with its contents repeated *n* times	(6)
`s.insert(i, x)`	inserts *x* into *s* at the index given by *i* (same as `s[i:i] = [x]`)	
`s.pop()` 或 `s.pop(i)`	retrieves the item at *i* and also removes it from *s*	(2)
`s.remove(x)`	remove the first item from *s* where `s[i]` is equal to *x*	(3)
`s.reverse()`	reverses the items of *s* in place	(4)

🄵解:

(1) If *k* is not equal to `1`, *t* must have the same length as the slice it is replacing.

(2) The optional argument *i* defaults to `-1`, so that by default the last item is removed and returned.

(3) `remove()` raises *ValueError* when *x* is not found in *s*.

(4) The `reverse()` method modifies the sequence in place for economy of space when reversing a large sequence. To remind users that it operates by side effect, it does not return the reversed sequence.

(5) `clear()` and `copy()` are included for consistency with the interfaces of mutable containers that don't support slicing operations (such as *dict* and *set*). `copy()` is not part of the *collections.abc.MutableSequence* ABC, but most concrete mutable sequence classes provide it.

在 3.3 版被加入: `clear()` and `copy()` methods.

(6) The value *n* is an integer, or an object implementing `__index__()`. Zero and negative values of *n* clear the sequence. Items in the sequence are not copied; they are referenced multiple times, as explained for `s * n` under *Common Sequence Operations*.

4.7.4 List（串列）

Lists are mutable sequences, typically used to store collections of homogeneous items (where the precise degree of similarity will vary by application).

class list([*iterable*])

Lists may be constructed in several ways:

- Using a pair of square brackets to denote the empty list: `[]`
- Using square brackets, separating items with commas: `[a]`, `[a, b, c]`
- Using a list comprehension: `[x for x in iterable]`
- Using the type constructor: `list()` or `list(iterable)`

The constructor builds a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For example, `list('abc')` returns `['a', 'b', 'c']` and `list( (1, 2, 3) )` returns `[1, 2, 3]`. If no argument is given, the constructor creates a new empty list, `[]`.

Many other operations also produce lists, including the *sorted()* built-in.

Lists implement all of the *common* and *mutable* sequence operations. Lists also provide the following additional method:

sort(*, *key=None*, *reverse=False*)

This method sorts the list in place, using only < comparisons between items. Exceptions are not suppressed - if any comparison operations fail, the entire sort operation will fail (and the list will likely be left in a partially modified state).

sort() accepts two arguments that can only be passed by keyword (*keyword-only arguments*):

key specifies a function of one argument that is used to extract a comparison key from each list element (for example, `key=str.lower`). The key corresponding to each item in the list is calculated once and then used for the entire sorting process. The default value of `None` means that list items are sorted directly without calculating a separate key value.

The *functools.cmp_to_key()* utility is available to convert a 2.x style *cmp* function to a *key* function.

reverse is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

This method modifies the sequence in place for economy of space when sorting a large sequence. To remind users that it operates by side effect, it does not return the sorted sequence (use *sorted()* to explicitly request a new sorted list instance).

The *sort()* method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal --- this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

For sorting examples and a brief sorting tutorial, see sortinghowto.

CPython 實作細節： While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python makes the list appear empty for the duration, and raises *ValueError* if it can detect that the list has been mutated during a sort.

4.7.5 Tuples

Tuples are immutable sequences, typically used to store collections of heterogeneous data (such as the 2-tuples produced by the *enumerate()* built-in). Tuples are also used for cases where an immutable sequence of homogeneous data is needed (such as allowing storage in a *set* or *dict* instance).

class tuple([*iterable*])

Tuples may be constructed in a number of ways:

- Using a pair of parentheses to denote the empty tuple: `()`
- Using a trailing comma for a singleton tuple: `a,` or `(a,)`
- Separating items with commas: `a, b, c` or `(a, b, c)`
- Using the *tuple()* built-in: `tuple()` or `tuple(iterable)`

The constructor builds a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is

returned unchanged. For example, `tuple('abc')` returns `('a', 'b', 'c')` and `tuple( [1, 2, 3] )` returns `(1, 2, 3)`. If no argument is given, the constructor creates a new empty tuple, `()`.

Note that it is actually the comma which makes a tuple, not the parentheses. The parentheses are optional, except in the empty tuple case, or when they are needed to avoid syntactic ambiguity. For example, `f(a, b, c)` is a function call with three arguments, while `f((a, b, c))` is a function call with a 3-tuple as the sole argument.

Tuples implement all of the *common* sequence operations.

For heterogeneous collections of data where access by name is clearer than access by index, *`collections.namedtuple()`* may be a more appropriate choice than a simple tuple object.

4.7.6 Ranges

The *`range`* type represents an immutable sequence of numbers and is commonly used for looping a specific number of times in `for` loops.

class range(*stop*)

class range(*start*, *stop*[, *step*])

The arguments to the range constructor must be integers (either built-in *`int`* or any object that implements the `__index__()` special method). If the *step* argument is omitted, it defaults to `1`. If the *start* argument is omitted, it defaults to `0`. If *step* is zero, *`ValueError`* is raised.

For a positive *step*, the contents of a range `r` are determined by the formula `r[i] = start + step*i` where `i >= 0` and `r[i] < stop`.

For a negative *step*, the contents of the range are still determined by the formula `r[i] = start + step*i`, but the constraints are `i >= 0` and `r[i] > stop`.

A range object will be empty if `r[0]` does not meet the value constraint. Ranges do support negative indices, but these are interpreted as indexing from the end of the sequence determined by the positive indices.

Ranges containing absolute values larger than *`sys.maxsize`* are permitted but some features (such as *`len()`*) may raise *`OverflowError`*.

Range examples:

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

Ranges implement all of the *common* sequence operations except concatenation and repetition (due to the fact that range objects can only represent sequences that follow a strict pattern and repetition and concatenation will usually violate that pattern).

start

The value of the *start* parameter (or `0` if the parameter was not supplied)

stop

The value of the *stop* parameter

step

The value of the *step* parameter (or `1` if the parameter was not supplied)

The advantage of the *range* type over a regular *list* or *tuple* is that a *range* object will always take the same (small) amount of memory, no matter the size of the range it represents (as it only stores the `start`, `stop` and `step` values, calculating individual items and subranges as needed).

Range objects implement the *collections.abc.Sequence* ABC, and provide features such as containment tests, element index lookup, slicing and support for negative indices (see *Sequence Types --- list, tuple, range*):

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
False
>>> 10 in r
True
>>> r.index(10)
5
>>> r[5]
10
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18
```

Testing range objects for equality with == and != compares them as sequences. That is, two range objects are considered equal if they represent the same sequence of values. (Note that two range objects that compare equal might have different *start*, *stop* and *step* attributes, for example `range(0) == range(2, 1, 3)` or `range(0, 3, 2) == range(0, 4, 2)`.)

在 3.2 版的變更: Implement the Sequence ABC. Support slicing and negative indices. Test *int* objects for membership in constant time instead of iterating through all items.

在 3.3 版的變更: Define '==' and '!=' to compare range objects based on the sequence of values they define (instead of comparing based on object identity).

Added the *start*, *stop* and *step* attributes.

也參考

- The linspace recipe shows how to implement a lazy version of range suitable for floating-point applications.

4.8 Text Sequence Type --- str

Textual data in Python is handled with *str* objects, or *strings*. Strings are immutable *sequences* of Unicode code points. String literals are written in a variety of ways:

- Single quotes: `'allows embedded "double" quotes'`
- Double quotes: `"allows embedded 'single' quotes"`
- Triple quoted: `'''Three single quotes'''`, `"""Three double quotes"""`

Triple quoted strings may span multiple lines - all associated whitespace will be included in the string literal.

String literals that are part of a single expression and have only whitespace between them will be implicitly converted to a single string literal. That is, `("spam " "eggs") == "spam eggs"`.

See strings for more about the various forms of string literal, including supported escape sequences, and the `r` ("raw") prefix that disables most escape sequence processing.

Strings may also be created from other objects using the *str* constructor.

Since there is no separate "character" type, indexing a string produces strings of length 1. That is, for a non-empty string *s*, `s[0] == s[0:1]`.

There is also no mutable string type, but *str.join()* or *io.StringIO* can be used to efficiently construct strings from multiple fragments.

在 3.3 版的變更: For backwards compatibility with the Python 2 series, the `u` prefix is once again permitted on string literals. It has no effect on the meaning of string literals and cannot be combined with the `r` prefix.

class str(*object=''*)

class str(*object=b''*, *encoding='utf-8'*, *errors='strict'*)

Return a *string* version of *object*. If *object* is not provided, returns the empty string. Otherwise, the behavior of `str()` depends on whether *encoding* or *errors* is given, as follows.

If neither *encoding* nor *errors* is given, `str(object)` returns `type(object).__str__(object)`, which is the "informal" or nicely printable string representation of *object*. For string objects, this is the string itself. If *object* does not have a `__str__()` method, then *str()* falls back to returning *repr(object)*.

If at least one of *encoding* or *errors* is given, *object* should be a *bytes-like object* (e.g. *bytes* or *bytearray*). In this case, if *object* is a *bytes* (or *bytearray*) object, then `str(bytes, encoding, errors)` is equivalent to *bytes.decode(encoding, errors)*. Otherwise, the bytes object underlying the buffer object is obtained before calling *bytes.decode()*. See *Binary Sequence Types --- bytes, bytearray, memoryview* and bufferobjects for information on buffer objects.

Passing a *bytes* object to *str()* without the *encoding* or *errors* arguments falls under the first case of returning the informal string representation (see also the `-b` command-line option to Python). For example:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

For more information on the `str` class and its methods, see *Text Sequence Type --- str* and the *String Methods* section below. To output formatted strings, see the f-strings and 格式化文字語法 sections. In addition, see the 文本處理 *(Text Processing)* 服務 section.

4.8.1 String Methods

Strings implement all of the *common* sequence operations, along with the additional methods described below.

Strings also support two styles of string formatting, one providing a large degree of flexibility and customization (see `str.format()`, 格式化文字語法 and 自訂字串格式) and the other based on C `printf` style formatting that handles a narrower range of types and is slightly harder to use correctly, but is often faster for the cases it can handle (*printf-style String Formatting*).

The 文本處理 *(Text Processing)* 服務 section of the standard library covers a number of other modules that provide various text related utilities (including regular expression support in the `re` module).

`str.`**`capitalize`**`()`

Return a copy of the string with its first character capitalized and the rest lowercased.

在 3.8 版的變更: The first character is now put into titlecase rather than uppercase. This means that characters like digraphs will only have their first letter capitalized, instead of the full character.

`str.`**`casefold`**`()`

Return a casefolded copy of the string. Casefolded strings may be used for caseless matching.

Casefolding is similar to lowercasing but more aggressive because it is intended to remove all case distinctions in a string. For example, the German lowercase letter `'ß'` is equivalent to `"ss"`. Since it is already lowercase, `lower()` would do nothing to `'ß'`; `casefold()` converts it to `"ss"`.

The casefolding algorithm is described in section 3.13 'Default Case Folding' of the Unicode Standard.

在 3.3 版被加入.

`str.`**`center`**`(`*width*`[`, *fillchar*`])`

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.`**`count`**`(`*sub*`[`, *start*`[`, *end*`]])`

Return the number of non-overlapping occurrences of substring *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

If *sub* is empty, returns the number of empty strings between characters which is the length of the string plus one.

`str.`**`encode`**`(`*encoding='utf-8'*, *errors='strict'*`)`

Return the string encoded to `bytes`.

encoding defaults to `'utf-8'`; see *Standard Encodings* for possible values.

errors controls how encoding errors are handled. If `'strict'` (the default), a `UnicodeError` exception is raised. Other possible values are `'ignore'`, `'replace'`, `'xmlcharrefreplace'`, `'backslashreplace'` and any other name registered via `codecs.register_error()`. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless an encoding error actually occurs, *Python* 開發模式 is enabled or a debug build is used.

在 3.1 版的變更: 新增關鍵字引數的支援。

在 3.9 版的變更: The value of the *errors* argument is now checked in *Python* 開發模式 and in debug mode.

`str.`**`endswith`**`(`*suffix*`[`, *start*`[`, *end*`]])`

Return `True` if the string ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

str.**expandtabs**(*tabsize=8*)

Return a copy of the string where all tab characters are replaced by one or more spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* characters (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the string, the current column is set to zero and the string is examined character by character. If the character is a tab (`\t`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the character is a newline (`\n`) or return (`\r`), it is copied and the current column is reset to zero. Any other character is copied unchanged and the current column is incremented by one regardless of how the character is represented when printed.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012     0123    01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123    01234'
```

str.**find**(*sub*[, *start*[, *end*]])

Return the lowest index in the string where substring *sub* is found within the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

備🄵

The *find()* method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> 'Py' in 'Python'
True
```

str.**format**(**args*, ***kwargs*)

Perform a string formatting operation. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`. Each replacement field contains either the numeric index of a positional argument, or the name of a keyword argument. Returns a copy of the string where each replacement field is replaced with the string value of the corresponding argument.

```
>>> "The sum of 1 + 2 is {0}".format(1+2)
'The sum of 1 + 2 is 3'
```

See 格式化文字語法 for a description of the various formatting options that can be specified in format strings.

備🄵

When formatting a number (*int*, *float*, *complex*, *decimal.Decimal* and subclasses) with the `n` type (ex: `'{:n}'.format(1234)`), the function temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale to decode `decimal_point` and `thousands_sep` fields of `localeconv()` if they are non-ASCII or longer than 1 byte, and the `LC_NUMERIC` locale is different than the `LC_CTYPE` locale. This temporary change affects other threads.

在 3.7 版的變更: When formatting a number with the `n` type, the function sets temporarily the `LC_CTYPE` locale to the `LC_NUMERIC` locale in some cases.

str.**format_map**(*mapping*)

Similar to `str.format(**mapping)`, except that `mapping` is used directly and not copied to a *dict*. This is useful if for example `mapping` is a dict subclass:

```
>>> class Default(dict):
...     def __missing__(self, key):
...         return key
...
>>> '{name} was born in {country}'.format_map(Default(name='Guido'))
'Guido was born in country'
```

在 3.2 版被加入.

str.**index**(*sub*[, *start*[, *end*]])

Like *find()*, but raise *ValueError* when the substring is not found.

str.**isalnum**()

Return `True` if all characters in the string are alphanumeric and there is at least one character, `False` otherwise. A character `c` is alphanumeric if one of the following returns `True`: `c.isalpha()`, `c.isdecimal()`, `c.isdigit()`, or `c.isnumeric()`.

str.**isalpha**()

Return `True` if all characters in the string are alphabetic and there is at least one character, `False` otherwise. Alphabetic characters are those characters defined in the Unicode character database as "Letter", i.e., those with general category property being one of "Lm", "Lt", "Lu", "Ll", or "Lo". Note that this is different from the Alphabetic property defined in the section 4.10 'Letters, Alphabetic, and Ideographic' of the Unicode Standard.

str.**isascii**()

Return `True` if the string is empty or all characters in the string are ASCII, `False` otherwise. ASCII characters have code points in the range U+0000-U+007F.

在 3.7 版被加入.

str.**isdecimal**()

Return `True` if all characters in the string are decimal characters and there is at least one character, `False` otherwise. Decimal characters are those that can be used to form numbers in base 10, e.g. U+0660, ARABIC-INDIC DIGIT ZERO. Formally a decimal character is a character in the Unicode General Category "Nd".

str.**isdigit**()

Return `True` if all characters in the string are digits and there is at least one character, `False` otherwise. Digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers. Formally, a digit is a character that has the property value Numeric_Type=Digit or Numeric_Type=Decimal.

str.**isidentifier**()

Return `True` if the string is a valid identifier according to the language definition, section identifiers.

keyword.iskeyword() can be used to test whether string `s` is a reserved identifier, such as `def` and `class`.

範例:

```
>>> from keyword import iskeyword

>>> 'hello'.isidentifier(), iskeyword('hello')
(True, False)
>>> 'def'.isidentifier(), iskeyword('def')
(True, True)
```

str.**islower**()

Return `True` if all cased characters[4] in the string are lowercase and there is at least one cased character, `False` otherwise.

[4] Cased characters are those with general category property being one of "Lu" (Letter, uppercase), "Ll" (Letter, lowercase), or "Lt" (Letter, titlecase).

str.**isnumeric**()

Return `True` if all characters in the string are numeric characters, and there is at least one character, `False` otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH. Formally, numeric characters are those with the property value Numeric_Type=Digit, Numeric_Type=Decimal or Numeric_Type=Numeric.

str.**isprintable**()

Return `True` if all characters in the string are printable or the string is empty, `False` otherwise. Nonprintable characters are those characters defined in the Unicode character database as "Other" or "Separator", excepting the ASCII space (0x20) which is considered printable. (Note that printable characters in this context are those which should not be escaped when *repr()* is invoked on a string. It has no bearing on the handling of strings written to *sys.stdout* or *sys.stderr*.)

str.**isspace**()

Return `True` if there are only whitespace characters in the string and there is at least one character, `False` otherwise.

A character is *whitespace* if in the Unicode character database (see *unicodedata*), either its general category is `Zs` ("Separator, space"), or its bidirectional class is one of `WS`, `B`, or `S`.

str.**istitle**()

Return `True` if the string is a titlecased string and there is at least one character, for example uppercase characters may only follow uncased characters and lowercase characters only cased ones. Return `False` otherwise.

str.**isupper**()

Return `True` if all cased characters[Page 54, 4] in the string are uppercase and there is at least one cased character, `False` otherwise.

```
>>> 'BANANA'.isupper()
True
>>> 'banana'.isupper()
False
>>> 'baNana'.isupper()
False
>>> ' '.isupper()
False
```

str.**join**(*iterable*)

Return a string which is the concatenation of the strings in *iterable*. A *TypeError* will be raised if there are any non-string values in *iterable*, including *bytes* objects. The separator between elements is the string providing this method.

str.**ljust**(*width*[, *fillchar*])

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

str.**lower**()

Return a copy of the string with all the cased characters[Page 54, 4] converted to lowercase.

The lowercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

str.**lstrip**([*chars*])

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.lstrip()
'spacious   '
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

See *str.removeprefix()* for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> 'Arthur: three!'.lstrip('Arthur: ')
'ee!'
>>> 'Arthur: three!'.removeprefix('Arthur: ')
'three!'
```

static str.**maketrans**(*x*[, *y*[, *z*]])

This static method returns a translation table usable for *str.translate()*.

If there is only one argument, it must be a dictionary mapping Unicode ordinals (integers) or characters (strings of length 1) to Unicode ordinals, strings (of arbitrary lengths) or None. Character keys will then be converted to ordinals.

If there are two arguments, they must be strings of equal length, and in the resulting dictionary, each character in x will be mapped to the character at the same position in y. If there is a third argument, it must be a string, whose characters will be mapped to None in the result.

str.**partition**(*sep*)

Split the string at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing the string itself, followed by two empty strings.

str.**removeprefix**(*prefix*, /)

If the string starts with the *prefix* string, return `string[len(prefix):]`. Otherwise, return a copy of the original string:

```
>>> 'TestHook'.removeprefix('Test')
'Hook'
>>> 'BaseTestCase'.removeprefix('Test')
'BaseTestCase'
```

在 3.9 版被加入.

str.**removesuffix**(*suffix*, /)

If the string ends with the *suffix* string and that *suffix* is not empty, return `string[:-len(suffix)]`. Otherwise, return a copy of the original string:

```
>>> 'MiscTests'.removesuffix('Tests')
'Misc'
>>> 'TmpDirMixin'.removesuffix('Tests')
'TmpDirMixin'
```

在 3.9 版被加入.

str.**replace**(*old*, *new*[, *count*])

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

str.**rfind**(*sub*[, *start*[, *end*]])

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

str.**rindex**(*sub*[, *start*[, *end*]])

Like *rfind()* but raises *ValueError* when the substring *sub* is not found.

str.**rjust**(*width*[, *fillchar*])

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

str.**rpartition**(*sep*)

Split the string at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty strings, followed by the string itself.

str.**rsplit**(*sep=None*, *maxsplit=-1*)

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any whitespace string is a separator. Except for splitting from the right, *rsplit()* behaves like *split()* which is described in detail below.

str.**rstrip**([*chars*])

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.rstrip()
'   spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

See *str.removesuffix()* for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> 'Monty Python'.rstrip(' Python')
'M'
>>> 'Monty Python'.removesuffix(' Python')
'Monty'
```

str.**split**(*sep=None*, *maxsplit=-1*)

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters as a single delimiter (to split with multiple delimiters, use *re.split()*). Splitting an empty string with a specified separator returns `['']`.

舉例來🄵:

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
['1', '2,3']
>>> '1,2,,3,'.split(',')
['1', '2', '', '3', '']
>>> '1<>2<>3<4'.split('<>')
['1', '2', '3<4']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the string has

leading or trailing whitespace. Consequently, splitting an empty string or a string consisting of just whitespace with a `None` separator returns `[]`.

舉例來F:

```
>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> '   1   2   3   '.split()
['1', '2', '3']
```

`str.`**`splitlines`**(*keepends=False*)

Return a list of the lines in the string, breaking at line boundaries. Line breaks are not included in the resulting list unless *keepends* is given and true.

This method splits on the following line boundaries. In particular, the boundaries are a superset of *universal newlines*.

Representation	描述
`\n`	Line Feed
`\r`	Carriage Return
`\r\n`	Carriage Return + Line Feed
`\v` 或 `\x0b`	Line Tabulation
`\f` 或 `\x0c`	Form Feed
`\x1c`	File Separator
`\x1d`	Group Separator
`\x1e`	Record Separator
`\x85`	Next Line (C1 Control Code)
`\u2028`	Line Separator
`\u2029`	Paragraph Separator

在 3.2 版的變更: `\v` and `\f` added to list of line boundaries.

舉例來F:

```
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']
```

Unlike *`split()`* when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']
```

For comparison, `split('\n')` gives:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

str.**startswith**(*prefix*[, *start*[, *end*]])

Return `True` if string starts with the *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test string beginning at that position. With optional *end*, stop comparing string at that position.

str.**strip**([*chars*])

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

The outermost leading and trailing *chars* argument values are stripped from the string. Characters are removed from the leading end until reaching a string character that is not contained in the set of characters in *chars*. A similar action takes place on the trailing end. For example:

```
>>> comment_string = '#....... Section 3.2.1 Issue #32 .......'
>>> comment_string.strip('.#! ')
'Section 3.2.1 Issue #32'
```

str.**swapcase**()

Return a copy of the string with uppercase characters converted to lowercase and vice versa. Note that it is not necessarily true that `s.swapcase().swapcase() == s`.

str.**title**()

Return a titlecased version of the string where words start with an uppercase character and the remaining characters are lowercase.

舉例來🄵:

```
>>> 'Hello world'.title()
'Hello World'
```

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> "they're bill's friends from the UK".title()
"They'Re Bill'S Friends From The Uk"
```

The *`string.capwords()`* function does not have this problem, as it splits words on spaces only.

Alternatively, a workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+('[A-Za-z]+)?",
...                   lambda mo: mo.group(0).capitalize(),
...                   s)
...
>>> titlecase("they're bill's friends.")
"They're Bill's Friends."
```

`str.`**`translate`**`(`*table*`)`

Return a copy of the string in which each character has been mapped through the given translation table. The table must be an object that implements indexing via `__getitem__()`, typically a *mapping* or *sequence*. When indexed by a Unicode ordinal (an integer), the table object can do any of the following: return a Unicode ordinal or a string, to map the character to one or more other characters; return `None`, to delete the character from the return string; or raise a *`LookupError`* exception, to map the character to itself.

You can use *`str.maketrans()`* to create a translation map from character-to-character mappings in different formats.

See also the *`codecs`* module for a more flexible approach to custom character mappings.

`str.`**`upper`**`()`

Return a copy of the string with all the cased characters[Page 54, 4] converted to uppercase. Note that `s.upper().isupper()` might be `False` if `s` contains uncased characters or if the Unicode category of the resulting character(s) is not "Lu" (Letter, uppercase), but e.g. "Lt" (Letter, titlecase).

The uppercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

`str.`**`zfill`**`(`*width*`)`

Return a copy of the string left filled with ASCII `'0'` digits to make a string of length *width*. A leading sign prefix (`'+'`/`'-'`) is handled by inserting the padding *after* the sign character rather than before. The original string is returned if *width* is less than or equal to `len(s)`.

舉例來🄵:

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

4.8.2 `printf`-style String Formatting

備🄵

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). Using the newer formatted string literals, the *`str.format()`* interface, or *template strings* may help avoid these errors. Each of these alternatives provides their own trade-offs and benefits of simplicity, flexibility, and/or extensibility.

String objects have one unique built-in operation: the `%` operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given `format % values` (where *format* is a string), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object.[5] Otherwise, *values* must be a tuple with exactly the number of items specified by the format string, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.

[5] To format only a tuple you should therefore provide a singleton tuple whose only element is the tuple to be formatted.

4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the string *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print('%(language)s has %(number)03d quote types.' %
...       {'language': "Python", "number": 2})
Python has 002 quote types.
```

In this case no `*` specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

Flag	含義
`'#'`	The value conversion will use the ”alternate form” (where defined below).
`'0'`	The conversion will be zero padded for numeric values.
`'-'`	The converted value is left adjusted (overrides the `'0'` conversion if both are given).
`' '`	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
`'+'`	A sign character (`'+'` or `'-'`) will precede the conversion (overrides a ”space” flag).

A length modifier (`h`, `l`, or `L`) may be present, but is ignored as it is not necessary for Python -- so e.g. `%ld` is identical to `%d`.

The conversion types are:

Conversion	含義	🄵解
`'d'`	Signed integer decimal.	
`'i'`	Signed integer decimal.	
`'o'`	Signed octal value.	(1)
`'u'`	Obsolete type -- it is identical to `'d'`.	(6)
`'x'`	Signed hexadecimal (lowercase).	(2)
`'X'`	Signed hexadecimal (uppercase).	(2)
`'e'`	Floating-point exponential format (lowercase).	(3)
`'E'`	Floating-point exponential format (uppercase).	(3)
`'f'`	Floating-point decimal format.	(3)
`'F'`	Floating-point decimal format.	(3)
`'g'`	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'G'`	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'c'`	Single character (accepts integer or single character string).	
`'r'`	String (converts any Python object using *repr()*).	(5)
`'s'`	String (converts any Python object using *str()*).	(5)
`'a'`	String (converts any Python object using *ascii()*).	(5)
`'%'`	No argument is converted, results in a `'%'` character in the result.	

F解:

(1) The alternate form causes a leading octal specifier (`'0o'`) to be inserted before the first digit.

(2) The alternate form causes a leading `'0x'` or `'0X'` (depending on whether the `'x'` or `'X'` format was used) to be inserted before the first digit.

(3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

(4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

(5) If precision is `N`, the output is truncated to `N` characters.

(6) 參F **PEP 237**。

Since Python strings have an explicit length, `%s` conversions do not assume that `'\0'` is the end of the string.

在 3.1 版的變更: `%f` conversions for numbers whose absolute value is over 1e50 are no longer replaced by `%g` conversions.

4.9 Binary Sequence Types --- `bytes`, `bytearray`, `memoryview`

The core built-in types for manipulating binary data are *bytes* and *bytearray*. They are supported by *memoryview* which uses the buffer protocol to access the memory of other binary objects without needing to make a copy.

The *array* module supports efficient storage of basic data types like 32-bit integers and IEEE754 double-precision floating values.

4.9.1 Bytes Objects

Bytes objects are immutable sequences of single bytes. Since many major binary protocols are based on the ASCII text encoding, bytes objects offer several methods that are only valid when working with ASCII compatible data and are closely related to string objects in a variety of other ways.

class bytes([*source*[, *encoding*[, *errors*]]])

Firstly, the syntax for bytes literals is largely the same as that for string literals, except that a `b` prefix is added:

- Single quotes: `b'still allows embedded "double" quotes'`
- Double quotes: `b"still allows embedded 'single' quotes"`
- Triple quoted: `b'''3 single quotes'''`, `b"""3 double quotes"""`

Only ASCII characters are permitted in bytes literals (regardless of the declared source code encoding). Any binary values over 127 must be entered into bytes literals using the appropriate escape sequence.

As with string literals, bytes literals may also use a `r` prefix to disable processing of escape sequences. See strings for more about the various forms of bytes literal, including supported escape sequences.

While bytes literals and representations are based on ASCII text, bytes objects actually behave like immutable sequences of integers, with each value in the sequence restricted such that `0 <= x < 256` (attempts to violate this restriction will trigger *ValueError*). This is done deliberately to emphasise that while many binary formats include ASCII based elements and can be usefully manipulated with some text-oriented algorithms, this is not generally the case for arbitrary binary data (blindly applying text processing algorithms to binary data formats that are not ASCII compatible will usually lead to data corruption).

In addition to the literal forms, bytes objects can be created in a number of other ways:

- A zero-filled bytes object of a specified length: `bytes(10)`
- From an iterable of integers: `bytes(range(20))`
- Copying existing binary data via the buffer protocol: `bytes(obj)`

Also see the *bytes* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytes type has an additional class method to read data in that format:

classmethod fromhex(*string*)

This *bytes* class method returns a bytes object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytes.fromhex('2Ef0 F1f2  ')
b'.\xf0\xf1\xf2'
```

在 3.7 版的變更: *bytes.fromhex()* now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytes object into its hexadecimal representation.

hex(*[sep[, bytes_per_sep]]*)

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

If you want to make the hex string easier to read, you can specify a single character separator *sep* parameter to include in the output. By default, this separator will be included between each byte. A second optional *bytes_per_sep* parameter controls the spacing. Positive values calculate the separator position from the right, negative values from the left.

```
>>> value = b'\xf0\xf1\xf2'
>>> value.hex('-')
'f0-f1-f2'
>>> value.hex('_', 2)
'f0_f1f2'
>>> b'UUDDLRLRAB'.hex(' ', -4)
'55554444 4c524c52 4142'
```

在 3.5 版被加入.

在 3.8 版的變更: *bytes.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

Since bytes objects are sequences of integers (akin to a tuple), for a bytes object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytes object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytes objects uses the literal format (`b'...'`) since it is often more useful than e.g. `bytes([46, 46, 46])`. You can always convert a bytes object into a list of integers using `list(b)`.

4.9.2 Bytearray Objects

bytearray objects are a mutable counterpart to *bytes* objects.

class bytearray([*source*[, *encoding*[, *errors*]]])

There is no dedicated literal syntax for bytearray objects, instead they are always created by calling the constructor:

- Creating an empty instance: `bytearray()`
- Creating a zero-filled instance with a given length: `bytearray(10)`
- From an iterable of integers: `bytearray(range(20))`
- Copying existing binary data via the buffer protocol: `bytearray(b'Hi!')`

As bytearray objects are mutable, they support the *mutable* sequence operations in addition to the common bytes and bytearray operations described in *Bytes and Bytearray Operations*.

Also see the *bytearray* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytearray type has an additional class method to read data in that format:

classmethod fromhex(*string*)

This *bytearray* class method returns bytearray object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytearray.fromhex('2Ef0 F1f2  ')
bytearray(b'.\xf0\xf1\xf2')
```

在 3.7 版的變更: *bytearray.fromhex()* now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytearray object into its hexadecimal representation.

hex([*sep*[, *bytes_per_sep*]])

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> bytearray(b'\xf0\xf1\xf2').hex()
'f0f1f2'
```

在 3.5 版被加入.

在 3.8 版的變更: Similar to *bytes.hex()*, *bytearray.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

Since bytearray objects are sequences of integers (akin to a list), for a bytearray object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytearray object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytearray objects uses the bytes literal format (`bytearray(b'...')`) since it is often more useful than e.g. `bytearray([46, 46, 46])`. You can always convert a bytearray object into a list of integers using `list(b)`.

4.9.3 Bytes and Bytearray Operations

Both bytes and bytearray objects support the *common* sequence operations. They interoperate not just with operands of the same type, but with any *bytes-like object*. Due to this flexibility, they can be freely mixed in operations without causing errors. However, the return type of the result may depend on the order of operands.

備🄵

The methods on bytes and bytearray objects don't accept strings as their arguments, just as the methods on strings don't accept bytes as their arguments. For example, you have to write:

```
a = "abc"
b = a.replace("a", "f")
```

和:

```
a = b"abc"
b = a.replace(b"a", b"f")
```

Some bytes and bytearray operations assume the use of ASCII compatible binary formats, and hence should be avoided when working with arbitrary binary data. These restrictions are covered below.

備🄵

Using these ASCII based operations to manipulate binary data that is not stored in an ASCII based format may lead to data corruption.

The following methods on bytes and bytearray objects can be used with arbitrary binary data.

`bytes.`**`count`**(*sub*[, *start*[, *end*]])

`bytearray.`**`count`**(*sub*[, *start*[, *end*]])

Return the number of non-overlapping occurrences of subsequence *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

If *sub* is empty, returns the number of empty slices between characters which is the length of the bytes object plus one.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**`removeprefix`**(*prefix*, /)

`bytearray.`**`removeprefix`**(*prefix*, /)

If the binary data starts with the *prefix* string, return `bytes[len(prefix):]`. Otherwise, return a copy of the original binary data:

```
>>> b'TestHook'.removeprefix(b'Test')
b'Hook'
>>> b'BaseTestCase'.removeprefix(b'Test')
b'BaseTestCase'
```

The *prefix* may be any *bytes-like object*.

> **備𝔽**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

在 3.9 版被加入.

`bytes.`**`removesuffix`**(*suffix*, */*)

`bytearray.`**`removesuffix`**(*suffix*, */*)

If the binary data ends with the *suffix* string and that *suffix* is not empty, return `bytes[:-len(suffix)]`. Otherwise, return a copy of the original binary data:

```
>>> b'MiscTests'.removesuffix(b'Tests')
b'Misc'
>>> b'TmpDirMixin'.removesuffix(b'Tests')
b'TmpDirMixin'
```

The *suffix* may be any *bytes-like object*.

> **備𝔽**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

在 3.9 版被加入.

`bytes.`**`decode`**(*encoding='utf-8'*, *errors='strict'*)

`bytearray.`**`decode`**(*encoding='utf-8'*, *errors='strict'*)

Return the bytes decoded to a *str*.

encoding defaults to `'utf-8'`; see *Standard Encodings* for possible values.

errors controls how decoding errors are handled. If `'strict'` (the default), a *UnicodeError* exception is raised. Other possible values are `'ignore'`, `'replace'`, and any other name registered via *codecs.register_error()*. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless a decoding error actually occurs, *Python 開發模式* is enabled or a debug build is used.

> **備𝔽**
>
> Passing the *encoding* argument to *str* allows decoding any *bytes-like object* directly, without needing to make a temporary `bytes` or `bytearray` object.

在 3.1 版的變更: 新增關鍵字引數的支援。

在 3.9 版的變更: The value of the *errors* argument is now checked in *Python 開發模式* and in debug mode.

`bytes.`**`endswith`**(*suffix*[, *start*[, *end*]])

`bytearray.`**`endswith`**(*suffix*[, *start*[, *end*]])

Return `True` if the binary data ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The suffix(es) to search for may be any *bytes-like object*.

`bytes.`**`find`**(*sub*[, *start*[, *end*]])

`bytearray.`**`find`**(*sub*[, *start*[, *end*]])

Return the lowest index in the data where the subsequence *sub* is found, such that *sub* is contained in the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

備🄵

The *`find()`* method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> b'Py' in b'Python'
True
```

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**`index`**(*sub*[, *start*[, *end*]])

`bytearray.`**`index`**(*sub*[, *start*[, *end*]])

Like *`find()`*, but raise *`ValueError`* when the subsequence is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.`**`join`**(*iterable*)

`bytearray.`**`join`**(*iterable*)

Return a bytes or bytearray object which is the concatenation of the binary data sequences in *iterable*. A *`TypeError`* will be raised if there are any values in *iterable* that are not *bytes-like objects*, including *`str`* objects. The separator between elements is the contents of the bytes or bytearray object providing this method.

`static` `bytes.`**`maketrans`**(*from*, *to*)

`static` `bytearray.`**`maketrans`**(*from*, *to*)

This static method returns a translation table usable for *`bytes.translate()`* that will map each character in *from* into the character at the same position in *to*; *from* and *to* must both be *bytes-like objects* and have the same length.

在 3.1 版被加入.

`bytes.`**`partition`**(*sep*)

`bytearray.`**`partition`**(*sep*)

Split the sequence at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing a copy of the original sequence, followed by two empty bytes or bytearray objects.

The separator to search for may be any *bytes-like object*.

`bytes.`**`replace`**(*old*, *new*[, *count*])

`bytearray.`**`replace`**(*old*, *new*[, *count*])

Return a copy of the sequence with all occurrences of subsequence *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

The subsequence to search for and its replacement may be any *bytes-like object*.

> **備F**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**rfind**(*sub*[, *start*[, *end*]])

bytearray.**rfind**(*sub*[, *start*[, *end*]])

Return the highest index in the sequence where the subsequence *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

bytes.**rindex**(*sub*[, *start*[, *end*]])

bytearray.**rindex**(*sub*[, *start*[, *end*]])

Like *rfind()* but raises *ValueError* when the subsequence *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

bytes.**rpartition**(*sep*)

bytearray.**rpartition**(*sep*)

Split the sequence at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty bytes or bytearray objects, followed by a copy of the original sequence.

The separator to search for may be any *bytes-like object*.

bytes.**startswith**(*prefix*[, *start*[, *end*]])

bytearray.**startswith**(*prefix*[, *start*[, *end*]])

Return `True` if the binary data starts with the specified *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The prefix(es) to search for may be any *bytes-like object*.

bytes.**translate**(*table*, */*, *delete=b''*)

bytearray.**translate**(*table*, */*, *delete=b''*)

Return a copy of the bytes or bytearray object where all bytes occurring in the optional argument *delete* are removed, and the remaining bytes have been mapped through the given translation table, which must be a bytes object of length 256.

You can use the *bytes.maketrans()* method to create a translation table.

Set the *table* argument to `None` for translations that only delete characters:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

在 3.6 版的變更: *delete* is now supported as a keyword argument.

The following methods on bytes and bytearray objects have default behaviours that assume the use of ASCII compatible binary formats, but can still be used with arbitrary binary data by passing appropriate arguments. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

bytes.**center**(*width*[, *fillbyte*])

bytearray.**center**(*width*[, *fillbyte*])

Return a copy of the object centered in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **備🄵**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**ljust**(*width*[, *fillbyte*])

bytearray.**ljust**(*width*[, *fillbyte*])

Return a copy of the object left justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **備🄵**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**lstrip**([*chars*])

bytearray.**lstrip**([*chars*])

Return a copy of the sequence with specified leading bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.lstrip()
b'spacious   '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See *removeprefix()* for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> b'Arthur: three!'.lstrip(b'Arthur: ')
b'ee!'
>>> b'Arthur: three!'.removeprefix(b'Arthur: ')
b'three!'
```

> **備🄵**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**rjust**(*width*[, *fillbyte*])

bytearray.**rjust**(*width*[, *fillbyte*])

Return a copy of the object right justified in a sequence of length *width*. Padding is done using the specified *fillbyte*

(default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

> **備🄵**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.`**`rsplit`**(*sep=None*, *maxsplit=-1*)

`bytearray.`**`rsplit`**(*sep=None*, *maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any subsequence consisting solely of ASCII whitespace is a separator. Except for splitting from the right, *rsplit()* behaves like *split()* which is described in detail below.

`bytes.`**`rstrip`**([*chars*])

`bytearray.`**`rstrip`**([*chars*])

Return a copy of the sequence with specified trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.rstrip()
b'   spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See *removesuffix()* for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> b'Monty Python'.rstrip(b' Python')
b'M'
>>> b'Monty Python'.removesuffix(b' Python')
b'Monty'
```

> **備🄵**
>
> The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.`**`split`**(*sep=None*, *maxsplit=-1*)

`bytearray.`**`split`**(*sep=None*, *maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given and non-negative, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or is `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty subsequences (for example, `b'1,,2'.split(b',')` returns `[b'1', b'', b'2']`). The *sep* argument may consist of a multibyte sequence as a single delimiter. Splitting an empty sequence with a specified separator returns `[b'']` or `[bytearray(b'')]` depending on the type of object being split. The *sep* argument may be any *bytes-like object*.

舉例來🄵:

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
>>> b'1,2,,3,'.split(b',')
[b'1', b'2', b'', b'3', b'']
>>> b'1<>2<>3<4'.split(b'<>')
[b'1', b'2', b'3<4']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive ASCII whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the sequence has leading or trailing whitespace. Consequently, splitting an empty sequence or a sequence consisting solely of ASCII whitespace without a specified separator returns `[]`.

舉例來🄵:

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b'   1   2   3   '.split()
[b'1', b'2', b'3']
```

`bytes.`**`strip`**`(`[*chars*]`)`

`bytearray.`**`strip`**`(`[*chars*]`)`

Return a copy of the sequence with specified leading and trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

The binary sequence of byte values to remove may be any *bytes-like object*.

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

The following methods on bytes and bytearray objects assume the use of ASCII compatible binary formats and should not be applied to arbitrary binary data. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

`bytes.`**`capitalize`**`()`

`bytearray.`**`capitalize`**`()`

Return a copy of the sequence with each byte interpreted as an ASCII character, and the first byte capitalized and the rest lowercased. Non-ASCII byte values are passed through unchanged.

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**expandtabs**(*tabsize=8*)

bytearray.**expandtabs**(*tabsize=8*)

Return a copy of the sequence where all ASCII tab characters are replaced by one or more ASCII spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* bytes (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the sequence, the current column is set to zero and the sequence is examined byte by byte. If the byte is an ASCII tab character (`b'\t'`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the current byte is an ASCII newline (`b'\n'`) or carriage return (`b'\r'`), it is copied and the current column is reset to zero. Any other byte value is copied unchanged and the current column is incremented by one regardless of how the byte value is represented when printed:

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012     0123    01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01  012 0123    01234'
```

備F

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**isalnum**()

bytearray.**isalnum**()

Return `True` if all bytes in the sequence are alphabetical ASCII characters or ASCII decimal digits and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

舉例來F:

```
>>> b'ABCabc1'.isalnum()
True
>>> b'ABC abc1'.isalnum()
False
```

bytes.**isalpha**()

bytearray.**isalpha**()

Return `True` if all bytes in the sequence are alphabetic ASCII characters and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

舉例來F:

```
>>> b'ABCabc'.isalpha()
True
>>> b'ABCabc1'.isalpha()
False
```

bytes.**isascii**()

bytearray.**isascii**()

Return `True` if the sequence is empty or all bytes in the sequence are ASCII, `False` otherwise. ASCII bytes are in the range 0-0x7F.

在 3.7 版被加入.

bytes.**isdigit**()

bytearray.**isdigit**()

Return `True` if all bytes in the sequence are ASCII decimal digits and the sequence is not empty, `False` otherwise. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

舉例來🄵:

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

bytes.**islower**()

bytearray.**islower**()

Return `True` if there is at least one lowercase ASCII character in the sequence and no uppercase ASCII characters, `False` otherwise.

舉例來🄵:

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

bytes.**isspace**()

bytearray.**isspace**()

Return `True` if all bytes in the sequence are ASCII whitespace and the sequence is not empty, `False` otherwise. ASCII whitespace characters are those byte values in the sequence `b' \t\n\r\x0b\f'` (space, tab, newline, carriage return, vertical tab, form feed).

bytes.**istitle**()

bytearray.**istitle**()

Return `True` if the sequence is ASCII titlecase and the sequence is not empty, `False` otherwise. See *bytes.title()* for more details on the definition of ”titlecase”.

舉例來🄵:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

bytes.**isupper**()

bytearray.**isupper**()

Return `True` if there is at least one uppercase alphabetic ASCII character in the sequence and no lowercase ASCII characters, `False` otherwise.

舉例來🄵:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.`**`lower`**`()`

`bytearray.`**`lower`**`()`

Return a copy of the sequence with all the uppercase ASCII characters converted to their corresponding lowercase counterpart.

舉例來𝔽:

```
>>> b'Hello World'.lower()
b'hello world'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

備𝔽

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.`**`splitlines`**`(`*keepends=False*`)`

`bytearray.`**`splitlines`**`(`*keepends=False*`)`

Return a list of the lines in the binary sequence, breaking at ASCII line boundaries. This method uses the *universal newlines* approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

舉例來𝔽:

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

Unlike *`split()`* when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([b''], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

`bytes.`**`swapcase`**`()`

`bytearray.`**`swapcase`**`()`

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart and vice-versa.

舉例來𝔽:

```
>>> b'Hello World'.swapcase()
b'hELLO wORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Unlike *str.swapcase()*, it is always the case that `bin.swapcase().swapcase() == bin` for the binary versions. Case conversions are symmetrical in ASCII, even though that is not generally true for arbitrary Unicode code points.

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**title**()

bytearray.**title**()

Return a titlecased version of the binary sequence where words start with an uppercase ASCII character and the remaining characters are lowercase. Uncased byte values are left unmodified.

舉例來🄵:

```
>>> b'Hello world'.title()
b'Hello World'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. All other byte values are uncased.

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> b"they're bill's friends from the UK".title()
b"They'Re Bill'S Friends From The Uk"
```

A workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(rb"[A-Za-z]+('[A-Za-z]+)?",
...                   lambda mo: mo.group(0)[0:1].upper() +
...                              mo.group(0)[1:].lower(),
...                   s)
...
>>> titlecase(b"they're bill's friends.")
b"They're Bill's Friends."
```

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**upper**()

bytearray.**upper**()

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart.

舉例來🄵:

```
>>> b'Hello World'.upper()
b'HELLO WORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

bytes.**zfill**(*width*)

bytearray.**zfill**(*width*)

Return a copy of the sequence left filled with ASCII `b'0'` digits to make a sequence of length *width*. A leading sign prefix (`b'+'`/`b'-'`) is handled by inserting the padding *after* the sign character rather than before. For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(seq)`.

舉例來🄵:

```
>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'
```

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

4.9.4 `printf`-style Bytes Formatting

備🄵

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). If the value being printed may be a tuple or dictionary, wrap it in a tuple.

Bytes objects (`bytes`/`bytearray`) have one unique built-in operation: the `%` operator (modulo). This is also known as the bytes *formatting* or *interpolation* operator. Given `format % values` (where *format* is a bytes object), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object.[Page 60, 5] Otherwise, *values* must be a tuple with exactly the number of items specified by the format bytes object, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the bytes object *must* include a parenthesised mapping key into that dictionary inserted immediately after the `'%'` character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print(b'%(language)s has %(number)03d quote types.' %
...       {b'language': b"Python", b"number": 2})
b'Python has 002 quote types.'
```

In this case no `*` specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

Flag	含義
`'#'`	The value conversion will use the ”alternate form” (where defined below).
`'0'`	The conversion will be zero padded for numeric values.
`'-'`	The converted value is left adjusted (overrides the `'0'` conversion if both are given).
`' '`	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
`'+'`	A sign character (`'+'` or `'-'`) will precede the conversion (overrides a ”space” flag).

A length modifier (`h`, `l`, or `L`) may be present, but is ignored as it is not necessary for Python -- so e.g. `%ld` is identical to `%d`.

The conversion types are:

Conversion	含義	🄵解
`'d'`	Signed integer decimal.	
`'i'`	Signed integer decimal.	
`'o'`	Signed octal value.	(1)
`'u'`	Obsolete type -- it is identical to `'d'`.	(8)
`'x'`	Signed hexadecimal (lowercase).	(2)
`'X'`	Signed hexadecimal (uppercase).	(2)
`'e'`	Floating-point exponential format (lowercase).	(3)
`'E'`	Floating-point exponential format (uppercase).	(3)
`'f'`	Floating-point decimal format.	(3)
`'F'`	Floating-point decimal format.	(3)
`'g'`	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'G'`	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
`'c'`	Single byte (accepts integer or single byte objects).	
`'b'`	Bytes (any object that follows the buffer protocol or has `__bytes__()`).	(5)
`'s'`	`'s'` is an alias for `'b'` and should only be used for Python2/3 code bases.	(6)
`'a'`	Bytes (converts any Python object using `repr(obj).encode('ascii', 'backslashreplace')`).	(5)
`'r'`	`'r'` is an alias for `'a'` and should only be used for Python2/3 code bases.	(7)
`'%'`	No argument is converted, results in a `'%'` character in the result.	

🄵解:

(1) The alternate form causes a leading octal specifier (`'0o'`) to be inserted before the first digit.

(2) The alternate form causes a leading `'0x'` or `'0X'` (depending on whether the `'x'` or `'X'` format was used) to be inserted before the first digit.

(3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.

The precision determines the number of digits after the decimal point and defaults to 6.

(4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.

The precision determines the number of significant digits before and after the decimal point and defaults to 6.

(5) If precision is `N`, the output is truncated to `N` characters.

(6) `b'%s'` is deprecated, but will not be removed during the 3.x series.

(7) `b'%r'` is deprecated, but will not be removed during the 3.x series.

(8) 參🄵 **PEP 237**。

備🄵

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

PEP 461 - Adding % formatting to bytes and bytearray

在 3.5 版被加入.

4.9.5 Memory Views

memoryview objects allow Python code to access the internal data of an object that supports the buffer protocol without copying.

class memoryview(*object*)

Create a *memoryview* that references *object*. *object* must support the buffer protocol. Built-in objects that support the buffer protocol include *bytes* and *bytearray*.

A *memoryview* has the notion of an *element*, which is the atomic memory unit handled by the originating *object*. For many simple types such as *bytes* and *bytearray*, an element is a single byte, but other types such as *array.array* may have bigger elements.

`len(view)` is equal to the length of *tolist*, which is the nested list representation of the view. If `view.ndim = 1`, this is equal to the number of elements in the view.

在 3.12 版的變更: If `view.ndim == 0`, `len(view)` now raises *TypeError* instead of returning 1.

The *itemsize* attribute will give you the number of bytes in a single element.

A *memoryview* supports slicing and indexing to expose its data. One-dimensional slicing will result in a subview:

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

If *format* is one of the native format specifiers from the *struct* module, indexing with an integer or a tuple of integers is also supported and returns a single *element* with the correct type. One-dimensional memoryviews can be indexed with an integer or a one-integer tuple. Multi-dimensional memoryviews can be indexed with tuples of exactly *ndim* integers where *ndim* is the number of dimensions. Zero-dimensional memoryviews can be indexed with the empty tuple.

Here is an example with a non-byte format:

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333, 44444444])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[::2].tolist()
[-11111111, -33333333]
```

If the underlying object is writable, the memoryview supports one-dimensional slice assignment. Resizing is not allowed:

```
>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue have different structures
>>> v[2:6] = b'spam'
>>> data
bytearray(b'z1spam')
```

One-dimensional memoryviews of *hashable* (read-only) types with formats 'B', 'b' or 'c' are also hashable. The hash is defined as `hash(m) == hash(m.tobytes())`:

```
>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
True
>>> hash(v[::-2]) == hash(b'abcefg'[::-2])
True
```

在 3.3 版的變更: One-dimensional memoryviews can now be sliced. One-dimensional memoryviews with formats 'B', 'b' or 'c' are now *hashable*.

在 3.4 版的變更: memoryview is now registered automatically with *collections.abc.Sequence*

在 3.5 版的變更: memoryviews can now be indexed with tuple of integers.

memoryview has several methods:

__eq__(*exporter*)

A memoryview and a **PEP 3118** exporter are equal if their shapes are equivalent and if all corresponding values are equal when the operands' respective format codes are interpreted using *struct* syntax.

For the subset of *struct* format strings currently supported by *tolist()*, `v` and `w` are equal if `v.tolist() == w.tolist()`:

```
>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
```

(繼續下一頁)

(繼續上一頁)

```
>>> z == c
True
>>> z.tolist() == c.tolist()
True
```

If either format string is not supported by the *struct* module, then the objects will always compare as unequal (even if the format strings and buffer contents are identical):

```
>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
>>> a == b
False
```

Note that, as with floating-point numbers, `v is w` does *not* imply `v == w` for memoryview objects.

在 3.3 版的變更: Previous versions compared the raw memory disregarding the item format and the logical array structure.

tobytes(*order='C'*)

Return the data in the buffer as a bytestring. This is equivalent to calling the *bytes* constructor on the memoryview.

```
>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'
```

For non-contiguous arrays the result is equal to the flattened list representation with all elements converted to bytes. *tobytes()* supports all format strings, including those that are not in *struct* module syntax.

在 3.8 版被加入: *order* can be {'C', 'F', 'A'}. When *order* is 'C' or 'F', the data of the original array is converted to C or Fortran order. For contiguous views, 'A' returns an exact copy of the physical memory. In particular, in-memory Fortran order is preserved. For non-contiguous views, the data is converted to C first. *order=None* is the same as *order='C'*.

hex(*[sep[, bytes_per_sep]]*)

Return a string object containing two hexadecimal digits for each byte in the buffer.

```
>>> m = memoryview(b"abc")
>>> m.hex()
'616263'
```

在 3.5 版被加入.

在 3.8 版的變更: Similar to *bytes.hex()*, *memoryview.hex()* now supports optional *sep* and *bytes_per_sep* parameters to insert separators between bytes in the hex output.

tolist()

Return the data in the buffer as a list of elements.

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

在 3.3 版的變更: *tolist()* now supports all single character native formats in *struct* module syntax as well as multi-dimensional representations.

toreadonly()

Return a readonly version of the memoryview object. The original memoryview object is unchanged.

```
>>> m = memoryview(bytearray(b'abc'))
>>> mm = m.toreadonly()
>>> mm.tolist()
[97, 98, 99]
>>> mm[0] = 42
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
>>> m[0] = 43
>>> mm.tolist()
[43, 98, 99]
```

在 3.8 版被加入.

release()

Release the underlying buffer exposed by the memoryview object. Many objects take special actions when a view is held on them (for example, a *bytearray* would temporarily forbid resizing); therefore, calling release() is handy to remove these restrictions (and free any dangling resources) as soon as possible.

After this method has been called, any further operation on the view raises a *ValueError* (except *release()* itself which can be called multiple times):

```
>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

The context management protocol can be used for a similar effect, using the `with` statement:

```
>>> with memoryview(b'abc') as m:
...     m[0]
...
97
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

在 3.2 版被加入.

cast(*format*[, *shape*])

Cast a memoryview to a new format or shape. *shape* defaults to `[byte_length//new_itemsize]`,

which means that the result view will be one-dimensional. The return value is a new memoryview, but the buffer itself is not copied. Supported casts are 1D -> C-*contiguous* and C-contiguous -> 1D.

The destination format is restricted to a single element native format in `struct` syntax. One of the formats must be a byte format ('B', 'b' or 'c'). The byte length of the result must be the same as the original length. Note that all byte lengths may depend on the operating system.

Cast 1D/long to 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1,2,3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24
```

Cast 1D/unsigned bytes to 1D/char:

```
>>> b = bytearray(b'zyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
  ...
TypeError: memoryview: invalid type for format 'B'
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')
```

Cast 1D/bytes to 3D/ints to 1D/signed char:

```
>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
```

(繼續下一頁)

(繼續上一頁)

```
48
>>> z = y.cast('b')
>>> z.format
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48
```

Cast 1D/unsigned long to 2D/unsigned long:

```
>>> buf = struct.pack("L"*6, *list(range(6)))
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]
```

在 3.3 版被加入.

在 3.5 版的變更: The source format is no longer restricted when casting to a byte view.

There are also several readonly attributes available:

obj

The underlying object of the memoryview:

```
>>> b  = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True
```

在 3.3 版被加入.

nbytes

`nbytes == product(shape) * itemsize == len(m.tobytes())`. This is the amount of space in bytes that the array would use in a contiguous representation. It is not necessarily equal to `len(m)`:

```
>>> import array
>>> a = array.array('i', [1,2,3,4,5])
>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes
20
>>> y = m[::2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12
```

Multi-dimensional arrays:

```
>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in range(12)])
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5], [12.0, 13.5, 15.0, 16.5]]
>>> len(y)
3
>>> y.nbytes
96
```

在 3.3 版被加入.

readonly

A bool indicating whether the memory is read only.

format

A string containing the format (in *struct* module style) for each element in the view. A memoryview can be created from exporters with arbitrary format strings, but some methods (e.g. *tolist()*) are restricted to native single element formats.

在 3.3 版的變更: format `'B'` is now handled according to the struct module syntax. This means that `memoryview(b'abc')[0] == b'abc'[0] == 97`.

itemsize

The size in bytes of each element of the memoryview:

```
>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32001, 32002]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True
```

ndim

An integer indicating how many dimensions of a multi-dimensional array the memory represents.

shape

A tuple of integers the length of *ndim* giving the shape of the memory as an N-dimensional array.

在 3.3 版的變更: An empty tuple instead of `None` when ndim = 0.

strides

A tuple of integers the length of *ndim* giving the size in bytes to access each element for each dimension of the array.

在 3.3 版的變更: An empty tuple instead of `None` when ndim = 0.

suboffsets

Used internally for PIL-style arrays. The value is informational only.

c_contiguous

A bool indicating whether the memory is C-*contiguous*.

在 3.3 版被加入.

f_contiguous

A bool indicating whether the memory is Fortran *contiguous*.

在 3.3 版被加入.

contiguous

A bool indicating whether the memory is *contiguous*.

在 3.3 版被加入.

4.10 Set Types --- set, frozenset

A *set* object is an unordered collection of distinct *hashable* objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built-in `dict`, `list`, and `tuple` classes, and the `collections` module.)

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

There are currently two built-in set types, `set` and `frozenset`. The `set` type is mutable --- the contents can be changed using methods like `add()` and `remove()`. Since it is mutable, it has no hash value and cannot be used as either a dictionary key or as an element of another set. The `frozenset` type is immutable and *hashable* --- its contents cannot be altered after it is created; it can therefore be used as a dictionary key or as an element of another set.

Non-empty sets (not frozensets) can be created by placing a comma-separated list of elements within braces, for example: `{'jack', 'sjoerd'}`, in addition to the `set` constructor.

The constructors for both classes work the same:

class set([*iterable*])

class frozenset([*iterable*])

Return a new set or frozenset object whose elements are taken from *iterable*. The elements of a set must be *hashable*. To represent sets of sets, the inner sets must be `frozenset` objects. If *iterable* is not specified, a new empty set is returned.

Sets can be created by several means:

- Use a comma-separated list of elements within braces: `{'jack', 'sjoerd'}`
- Use a set comprehension: `{c for c in 'abracadabra' if c not in 'abc'}`
- Use the type constructor: `set()`, `set('foobar')`, `set(['a', 'b', 'foo'])`

Instances of `set` and `frozenset` provide the following operations:

len(s)

Return the number of elements in set *s* (cardinality of *s*).

x in s

Test *x* for membership in *s*.

x not in s

Test *x* for non-membership in *s*.

isdisjoint(*other*)

Return `True` if the set has no elements in common with *other*. Sets are disjoint if and only if their intersection is the empty set.

issubset(*other*)

set <= other

Test whether every element in the set is in *other*.

set < other

Test whether the set is a proper subset of *other*, that is, `set <= other and set != other`.

issuperset(*other*)

set >= other

Test whether every element in *other* is in the set.

set > other

Test whether the set is a proper superset of *other*, that is, `set >= other and set != other`.

union(**others*)

set | other | ...

Return a new set with elements from the set and all others.

intersection(**others*)

set & other & ...

Return a new set with elements common to the set and all others.

difference(**others*)

set - other - ...

Return a new set with elements in the set that are not in the others.

symmetric_difference(*other*)

set ^ other

Return a new set with elements in either the set or *other* but not both.

copy()

Return a shallow copy of the set.

Note, the non-operator versions of *union()*, *intersection()*, *difference()*, *symmetric_difference()*, *issubset()*, and *issuperset()* methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Both *set* and *frozenset* support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

Instances of *set* are compared to instances of *frozenset* based on their members. For example, `set('abc') == frozenset('abc')` returns `True` and so does `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two nonempty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a<b`, `a==b`, or `a>b`.

Since sets only define partial ordering (subset relationships), the output of the *list.sort()* method is undefined for lists of sets.

Set elements, like dictionary keys, must be *hashable*.

Binary operations that mix *set* instances with *frozenset* return the type of the first operand. For example: `frozenset('ab') | set('bc')` returns an instance of *frozenset*.

The following table lists operations available for *set* that do not apply to immutable instances of *frozenset*:

update(**others*)

set |= other | ...

Update the set, adding elements from all others.

intersection_update(**others*)

set &= other & ...

Update the set, keeping only elements found in it and all others.

difference_update(**others*)

set -= other | ...

Update the set, removing elements found in others.

symmetric_difference_update(*other*)

set ^= other

Update the set, keeping only elements found in either set, but not in both.

add(*elem*)

Add element *elem* to the set.

remove(*elem*)

Remove element *elem* from the set. Raises *KeyError* if *elem* is not contained in the set.

discard(*elem*)

Remove element *elem* from the set if it is present.

pop()

Remove and return an arbitrary element from the set. Raises *KeyError* if the set is empty.

clear()

Remove all elements from the set.

Note, the non-operator versions of the *update()*, *intersection_update()*, *difference_update()*, and *symmetric_difference_update()* methods will accept any iterable as an argument.

Note, the *elem* argument to the `__contains__()`, *remove()*, and *discard()* methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

4.11 Mapping Types --- `dict`

A *mapping* object maps *hashable* values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built-in *list*, *set*, and *tuple* classes, and the *collections* module.)

A dictionary's keys are *almost* arbitrary values. Values that are not *hashable*, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Values that compare equal (such as `1`, `1.0`, and `True`) can be used interchangeably to index the same dictionary entry.

class dict(***kwargs*)

class dict(*mapping*, ***kwargs*)

class dict(*iterable*, ***kwargs*)

Return a new dictionary initialized from an optional positional argument and a possibly empty set of keyword arguments.

Dictionaries can be created by several means:

- Use a comma-separated list of `key: value` pairs within braces: `{'jack': 4098, 'sjoerd': 4127}` or `{4098: 'jack', 4127: 'sjoerd'}`
- Use a dict comprehension: `{}`, `{x: x ** 2 for x in range(10)}`
- Use the type constructor: `dict()`, `dict([('foo', 100), ('bar', 200)])`, `dict(foo=100, bar=200)`

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it is a mapping object, a dictionary is created with the same key-value pairs as the mapping object. Otherwise, the positional argument must be an *iterable* object. Each item in the iterable must itself be an iterable with exactly two objects. The first object of each item becomes a key in the new dictionary, and the second object the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

If keyword arguments are given, the keyword arguments and their values are added to the dictionary created from the positional argument. If a key being added is already present, the value from the keyword argument replaces the value from the positional argument.

To illustrate, the following examples all return a dictionary equal to `{"one": 1, "two": 2, "three": 3}`:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> f = dict({'one': 1, 'three': 3}, two=2)
>>> a == b == c == d == e == f
True
```

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

These are the operations that dictionaries support (and therefore, custom mapping types should support too):

list(d)

Return a list of all the keys used in the dictionary *d*.

len(d)

Return the number of items in the dictionary *d*.

d[key]

Return the item of *d* with key *key*. Raises a *KeyError* if *key* is not in the map.

If a subclass of dict defines a method `__missing__()` and *key* is not present, the `d[key]` operation calls that method with the key *key* as argument. The `d[key]` operation then returns or raises whatever is returned or raised by the `__missing__(key)` call. No other operations or methods invoke `__missing__()`. If `__missing__()` is not defined, *KeyError* is raised. `__missing__()` must be a method; it cannot be an instance variable:

```
>>> class Counter(dict):
...     def __missing__(self, key):
```

(繼續下一頁)

(繼續上一頁)

```
...         return 0
...
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

The example above shows part of the implementation of *collections.Counter*. A different __missing__ method is used by *collections.defaultdict*.

d[key] = value

Set `d[key]` to *value*.

del d[key]

Remove `d[key]` from *d*. Raises a *KeyError* if *key* is not in the map.

key in d

Return `True` if *d* has a key *key*, else `False`.

key not in d

Equivalent to `not key in d`.

iter(d)

Return an iterator over the keys of the dictionary. This is a shortcut for `iter(d.keys())`.

clear()

Remove all items from the dictionary.

copy()

Return a shallow copy of the dictionary.

classmethod fromkeys(*iterable*, *value=None*, /)

Create a new dictionary with keys from *iterable* and values set to *value*.

fromkeys() is a class method that returns a new dictionary. *value* defaults to `None`. All of the values refer to just a single instance, so it generally doesn't make sense for *value* to be a mutable object such as an empty list. To get distinct values, use a dict comprehension instead.

get(*key*, *default=None*)

Return the value for *key* if *key* is in the dictionary, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a *KeyError*.

items()

Return a new view of the dictionary's items (`(key, value)` pairs). See the *documentation of view objects*.

keys()

Return a new view of the dictionary's keys. See the *documentation of view objects*.

pop(*key*[, *default*])

If *key* is in the dictionary, remove it and return its value, else return *default*. If *default* is not given and *key* is not in the dictionary, a *KeyError* is raised.

popitem()

Remove and return a `(key, value)` pair from the dictionary. Pairs are returned in LIFO (last-in, first-out) order.

popitem() is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling *popitem()* raises a *KeyError*.

在 3.7 版的變更: LIFO order is now guaranteed. In prior versions, *popitem()* would return an arbitrary key/value pair.

reversed(d)

Return a reverse iterator over the keys of the dictionary. This is a shortcut for `reversed(d.keys())`.

在 3.8 版被加入.

setdefault(*key*, *default=None*)

If *key* is in the dictionary, return its value. If not, insert *key* with a value of *default* and return *default*. *default* defaults to `None`.

update([*other*])

Update the dictionary with the key/value pairs from *other*, overwriting existing keys. Return `None`.

update() accepts either another dictionary object or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

values()

Return a new view of the dictionary's values. See the *documentation of view objects*.

An equality comparison between one `dict.values()` view and another will always return `False`. This also applies when comparing `dict.values()` to itself:

```
>>> d = {'a': 1}
>>> d.values() == d.values()
False
```

d | other

Create a new dictionary with the merged keys and values of *d* and *other*, which must both be dictionaries. The values of *other* take priority when *d* and *other* share keys.

在 3.9 版被加入.

d |= other

Update the dictionary *d* with keys and values from *other*, which may be either a *mapping* or an *iterable* of key/value pairs. The values of *other* take priority when *d* and *other* share keys.

在 3.9 版被加入.

Dictionaries compare equal if and only if they have the same `(key, value)` pairs (regardless of ordering). Order comparisons ('<', '<=', '>=', '>') raise *TypeError*.

Dictionaries preserve insertion order. Note that updating a key does not affect the order. Keys added after deletion are inserted at the end.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(d)
['one', 'two', 'three', 'four']
>>> list(d.values())
[1, 2, 3, 4]
>>> d["one"] = 42
>>> d
{'one': 42, 'two': 2, 'three': 3, 'four': 4}
```

(繼續下一頁)

(繼續上一頁)

```
>>> del d["two"]
>>> d["two"] = None
>>> d
{'one': 42, 'three': 3, 'four': 4, 'two': None}
```

在 3.7 版的變更: Dictionary order is guaranteed to be insertion order. This behavior was an implementation detail of CPython from 3.6.

Dictionaries and dictionary views are reversible.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(reversed(d))
['four', 'three', 'two', 'one']
>>> list(reversed(d.values()))
[4, 3, 2, 1]
>>> list(reversed(d.items()))
[('four', 4), ('three', 3), ('two', 2), ('one', 1)]
```

在 3.8 版的變更: Dictionaries are now reversible.

也參考

types.MappingProxyType can be used to create a read-only view of a *dict*.

4.11.1 字典視圖物件

The objects returned by *dict.keys()*, *dict.values()* and *dict.items()* are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Dictionary views can be iterated over to yield their respective data, and support membership tests:

len(dictview)

Return the number of entries in the dictionary.

iter(dictview)

Return an iterator over the keys, values or items (represented as tuples of `(key, value)`) in the dictionary.

Keys and values are iterated over in insertion order. This allows the creation of `(value, key)` pairs using *zip()*: `pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

Iterating views while adding or deleting entries in the dictionary may raise a *RuntimeError* or fail to iterate over all entries.

在 3.7 版的變更: Dictionary order is guaranteed to be insertion order.

x in dictview

Return `True` if *x* is in the underlying dictionary's keys, values or items (in the latter case, *x* should be a `(key, value)` tuple).

reversed(dictview)

Return a reverse iterator over the keys, values or items of the dictionary. The view will be iterated in reverse order of the insertion.

在 3.8 版的變更: Dictionary views are now reversible.

dictview.mapping

Return a *types.MappingProxyType* that wraps the original dictionary to which the view refers.

在 3.10 版被加入.

Keys views are set-like since their entries are unique and *hashable*. Items views also have set-like operations since the (key, value) pairs are unique and the keys are hashable. If all values in an items view are hashable as well, then the items view can interoperate with other sets. (Values views are not treated as set-like since the entries are generally not unique.) For set-like views, all of the operations defined for the abstract base class *collections.abc.Set* are available (for example, ==, <, or ^). While using set operators, set-like views accept any iterable as the other operand, unlike sets which only accept sets as the input.

An example of dictionary view usage:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
...
>>> print(n)
504

>>> # keys and values are iterated over in the same order (insertion order)
>>> list(keys)
['eggs', 'sausage', 'bacon', 'spam']
>>> list(values)
[2, 1, 1, 500]

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['bacon', 'spam']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'} == {'juice', 'sausage', 'bacon', 'spam'}
True
>>> keys | ['juice', 'juice', 'juice'] == {'bacon', 'spam', 'juice'}
True

>>> # get back a read-only proxy for the original dictionary
>>> values.mapping
mappingproxy({'bacon': 1, 'spam': 500})
>>> values.mapping['spam']
500
```

4.12 Context Manager Types

Python's `with` statement supports the concept of a runtime context defined by a context manager. This is implemented using a pair of methods that allow user-defined classes to define a runtime context that is entered before the statement body is executed and exited when the statement ends:

`contextmanager.__enter__()`

Enter the runtime context and return either this object or another object related to the runtime context. The value returned by this method is bound to the identifier in the `as` clause of `with` statements using this context manager.

An example of a context manager that returns itself is a *file object*. File objects return themselves from __enter__() to allow *open()* to be used as the context expression in a `with` statement.

An example of a context manager that returns a related object is the one returned by *decimal.localcontext()*. These managers set the active decimal context to a copy of the original decimal context and then return the copy. This allows changes to be made to the current decimal context in the body of the `with` statement without affecting code outside the `with` statement.

`contextmanager.__exit__`(*exc_type*, *exc_val*, *exc_tb*)

Exit the runtime context and return a Boolean flag indicating if any exception that occurred should be suppressed. If an exception occurred while executing the body of the `with` statement, the arguments contain the exception type, value and traceback information. Otherwise, all three arguments are `None`.

Returning a true value from this method will cause the `with` statement to suppress the exception and continue execution with the statement immediately following the `with` statement. Otherwise the exception continues propagating after this method has finished executing. Exceptions that occur during execution of this method will replace any exception that occurred in the body of the `with` statement.

The exception passed in should never be reraised explicitly - instead, this method should return a false value to indicate that the method completed successfully and does not want to suppress the raised exception. This allows context management code to easily detect whether or not an `__exit__()` method has actually failed.

Python defines several context managers to support easy thread synchronisation, prompt closure of files or other objects, and simpler manipulation of the active decimal arithmetic context. The specific types are not treated specially beyond their implementation of the context management protocol. See the *contextlib* module for some examples.

Python's *generator*s and the *contextlib.contextmanager* decorator provide a convenient way to implement these protocols. If a generator function is decorated with the *contextlib.contextmanager* decorator, it will return a context manager implementing the necessary *__enter__()* and *__exit__()* methods, rather than the iterator produced by an undecorated generator function.

Note that there is no specific slot for any of these methods in the type structure for Python objects in the Python/C API. Extension types wanting to define these methods must provide them as a normal Python accessible method. Compared to the overhead of setting up the runtime context, the overhead of a single class dictionary lookup is negligible.

4.13 Type Annotation Types --- Generic Alias, Union

The core built-in types for *type annotations* are *Generic Alias* and *Union*.

4.13.1 Generic Alias Type

`GenericAlias` objects are generally created by subscripting a class. They are most often used with container classes, such as *`list`* or *`dict`*. For example, `list[int]` is a `GenericAlias` object created by subscripting the `list` class with the argument *`int`*. `GenericAlias` objects are intended primarily for use with *type annotations*.

> **備🄵**
>
> It is generally only possible to subscript a class if the class implements the special method `__class_getitem__()`.

A `GenericAlias` object acts as a proxy for a *generic type*, implementing *parameterized generics*.

For a container class, the argument(s) supplied to a subscription of the class may indicate the type(s) of the elements an object contains. For example, `set[bytes]` can be used in type annotations to signify a *`set`* in which all the elements are of type *`bytes`*.

For a class which defines `__class_getitem__()` but is not a container, the argument(s) supplied to a subscription of the class will often indicate the return type(s) of one or more methods defined on an object. For example, *`regular expressions`* can be used on both the *`str`* data type and the *`bytes`* data type:

- If `x = re.search('foo', 'foo')`, `x` will be a *re.Match* object where the return values of `x.group(0)` and `x[0]` will both be of type *`str`*. We can represent this kind of object in type annotations with the `GenericAlias` `re.Match[str]`.
- If `y = re.search(b'bar', b'bar')`, (note the `b` for *`bytes`*), `y` will also be an instance of `re.Match`, but the return values of `y.group(0)` and `y[0]` will both be of type *`bytes`*. In type annotations, we would represent this variety of *re.Match* objects with `re.Match[bytes]`.

`GenericAlias` objects are instances of the class *`types.GenericAlias`*, which can also be used to create `GenericAlias` objects directly.

`T[X, Y, ...]`

Creates a `GenericAlias` representing a type `T` parameterized by types *X*, *Y*, and more depending on the `T` used. For example, a function expecting a *`list`* containing *`float`* elements:

```
def average(values: list[float]) -> float:
    return sum(values) / len(values)
```

Another example for *mapping* objects, using a *`dict`*, which is a generic type expecting two type parameters representing the key type and the value type. In this example, the function expects a `dict` with keys of type *`str`* and values of type *`int`*:

```
def send_post_request(url: str, body: dict[str, int]) -> None:
    ...
```

The builtin functions *`isinstance()`* and *`issubclass()`* do not accept `GenericAlias` types for their second argument:

```
>>> isinstance([1, 2], list[str])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

The Python runtime does not enforce *type annotations*. This extends to generic types and their type parameters. When creating a container object from a `GenericAlias`, the elements in the container are not checked against their type. For example, the following code is discouraged, but will run without errors:

```
>>> t = list[str]
>>> t([1, 2, 3])
[1, 2, 3]
```

Furthermore, parameterized generics erase type parameters during object creation:

```
>>> t = list[str]
>>> type(t)
<class 'types.GenericAlias'>

>>> l = t()
>>> type(l)
<class 'list'>
```

Calling *repr()* or *str()* on a generic shows the parameterized type:

```
>>> repr(list[int])
'list[int]'

>>> str(list[int])
'list[int]'
```

The `__getitem__()` method of generic containers will raise an exception to disallow mistakes like `dict[str][str]`:

```
>>> dict[str][str]
Traceback (most recent call last):
  ...
TypeError: dict[str] is not a generic class
```

However, such expressions are valid when *type variables* are used. The index must have as many elements as there are type variable items in the `GenericAlias` object's *__args__*.

```
>>> from typing import TypeVar
>>> Y = TypeVar('Y')
>>> dict[str, Y][int]
dict[str, int]
```

Standard Generic Classes

The following standard library classes support parameterized generics. This list is non-exhaustive.

- *tuple*
- *list*
- *dict*
- *set*
- *frozenset*
- *type*
- *collections.deque*
- *collections.defaultdict*
- *collections.OrderedDict*

- *collections.Counter*
- *collections.ChainMap*
- *collections.abc.Awaitable*
- *collections.abc.Coroutine*
- *collections.abc.AsyncIterable*
- *collections.abc.AsyncIterator*
- *collections.abc.AsyncGenerator*
- *collections.abc.Iterable*
- *collections.abc.Iterator*
- *collections.abc.Generator*
- *collections.abc.Reversible*
- *collections.abc.Container*
- *collections.abc.Collection*
- *collections.abc.Callable*
- *collections.abc.Set*
- *collections.abc.MutableSet*
- *collections.abc.Mapping*
- *collections.abc.MutableMapping*
- *collections.abc.Sequence*
- *collections.abc.MutableSequence*
- *collections.abc.ByteString*
- *collections.abc.MappingView*
- *collections.abc.KeysView*
- *collections.abc.ItemsView*
- *collections.abc.ValuesView*
- *contextlib.AbstractContextManager*
- *contextlib.AbstractAsyncContextManager*
- *dataclasses.Field*
- *functools.cached_property*
- *functools.partialmethod*
- *os.PathLike*
- *queue.LifoQueue*
- *queue.Queue*
- *queue.PriorityQueue*
- *queue.SimpleQueue*
- *re.Pattern*

- *re.Match*
- *shelve.BsdDbShelf*
- *shelve.DbfilenameShelf*
- *shelve.Shelf*
- *types.MappingProxyType*
- *weakref.WeakKeyDictionary*
- *weakref.WeakMethod*

Special Attributes of `GenericAlias` objects

All parameterized generics implement special read-only attributes.

`genericalias.__origin__`

This attribute points at the non-parameterized generic class:

```
>>> list[int].__origin__
<class 'list'>
```

`genericalias.__args__`

This attribute is a *tuple* (possibly of length 1) of generic types passed to the original `__class_getitem__()` of the generic class:

```
>>> dict[str, list[int]].__args__
(<class 'str'>, list[int])
```

`genericalias.__parameters__`

This attribute is a lazily computed tuple (possibly empty) of unique type variables found in `__args__`:

```
>>> from typing import TypeVar

>>> T = TypeVar('T')
>>> list[T].__parameters__
(~T,)
```

備🄵

A `GenericAlias` object with *typing.ParamSpec* parameters may not have correct `__parameters__` after substitution because *typing.ParamSpec* is intended primarily for static type checking.

`genericalias.__unpacked__`

A boolean that is true if the alias has been unpacked using the `*` operator (see *TypeVarTuple*).

在 3.11 版被加入.

PEP 484 - Type Hints
Introducing Python's framework for type annotations.

PEP 585 - Type Hinting Generics In Standard Collections
Introducing the ability to natively parameterize standard-library classes, provided they implement the special class method `__class_getitem__()`.

泛型, *user-defined generics* and *typing.Generic*
Documentation on how to implement generic classes that can be parameterized at runtime and understood by static type-checkers.

在 3.9 版被加入.

4.13.2 Union Type

A union object holds the value of the `|` (bitwise or) operation on multiple *type objects*. These types are intended primarily for *type annotations*. The union type expression enables cleaner type hinting syntax compared to *typing.Union*.

X | Y | ...
Defines a union object which holds types *X*, *Y*, and so forth. `X | Y` means either X or Y. It is equivalent to `typing.Union[X, Y]`. For example, the following function expects an argument of type *int* or *float*:

```
def square(number: int | float) -> int | float:
    return number ** 2
```

備🄵

The `|` operand cannot be used at runtime to define unions where one or more members is a forward reference. For example, `int | "Foo"`, where `"Foo"` is a reference to a class not yet defined, will fail at runtime. For unions which include forward references, present the whole expression as a string, e.g. `"int | Foo"`.

union_object == other
Union objects can be tested for equality with other union objects. Details:

- Unions of unions are flattened:

```
(int | str) | float == int | str | float
```

- Redundant types are removed:

```
int | str | int == int | str
```

- When comparing unions, the order is ignored:

```
int | str == str | int
```

- It is compatible with *typing.Union*:

```
int | str == typing.Union[int, str]
```

- Optional types can be spelled as a union with `None`:

```
str | None == typing.Optional[str]
```

isinstance(obj, union_object)

issubclass(obj, union_object)

Calls to *isinstance()* and *issubclass()* are also supported with a union object:

```
>>> isinstance("", int | str)
True
```

However, *parameterized generics* in union objects cannot be checked:

```
>>> isinstance(1, int | list[int])  # short-circuit evaluation
True
>>> isinstance([1], int | list[int])
Traceback (most recent call last):
  ...
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

The user-exposed type for the union object can be accessed from *types.UnionType* and used for *isinstance()* checks. An object cannot be instantiated from the type:

```
>>> import types
>>> isinstance(int | str, types.UnionType)
True
>>> types.UnionType()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot create 'types.UnionType' instances
```

備F

The `__or__()` method for type objects was added to support the syntax `X | Y`. If a metaclass implements `__or__()`, the Union may override it:

```
>>> class M(type):
...     def __or__(self, other):
...         return "Hello"
...
>>> class C(metaclass=M):
...     pass
...
>>> C | int
'Hello'
>>> int | C
int | C
```

在 3.10 版被加入.

4.14 Other Built-in Types

The interpreter supports several other kinds of objects. Most of these support only one or two operations.

4.14.1 模組

The only special operation on a module is attribute access: `m.name`, where *m* is a module and *name* accesses a name defined in *m*'s symbol table. Module attributes can be assigned to. (Note that the `import` statement is not, strictly speaking, an operation on a module object; `import foo` does not require a module object named *foo* to exist, rather it requires an (external) *definition* for a module named *foo* somewhere.)

A special attribute of every module is *__dict__*. This is the dictionary containing the module's symbol table. Modifying this dictionary will actually change the module's symbol table, but direct assignment to the *__dict__* attribute is not possible (you can write `m.__dict__['a'] = 1`, which defines `m.a` to be `1`, but you can't write `m.__dict__ = {}`). Modifying *__dict__* directly is not recommended.

Modules built into the interpreter are written like this: `<module 'sys' (built-in)>`. If loaded from a file, they are written as `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

4.14.2 Classes and Class Instances

See objects and class for these.

4.14.3 函式

Function objects are created by function definitions. The only operation on a function object is to call it: `func(argument-list)`.

There are really two flavors of function objects: built-in functions and user-defined functions. Both support the same operation (to call the function), but the implementation is different, hence the different object types.

更多資訊請見 function。

4.14.4 Methods

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance method. Built-in methods are described with the types that support them.

If you access a method (a function defined in a class namespace) through an instance, you get a special object: a *bound method* (also called instance method) object. When called, it will add the `self` argument to the argument list. Bound methods have two special read-only attributes: `m.__self__` is the object on which the method operates, and `m.__func__` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`.

Like function objects, bound method objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`method.__func__`), setting method attributes on bound methods is disallowed. Attempting to set an attribute on a method results in an *AttributeError* being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```
>>> class C:
...     def method(self):
...         pass
```

(繼續下一頁)

(繼續上一頁)

```
...
>>> c = C()
>>> c.method.whoami = 'my name is method'  # can't set on the method
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

更多資訊請見 instance-methods。

4.14.5 Code Objects

Code objects are used by the implementation to represent "pseudo-compiled" executable Python code such as a function body. They differ from function objects because they don't contain a reference to their global execution environment. Code objects are returned by the built-in *compile()* function and can be extracted from function objects through their `__code__` attribute. See also the *code* module.

存取 `__code__` 會引發一個附帶引數 `obj` 與 `"__code__"` 的稽核事件 `object.__getattr__`。

A code object can be executed or evaluated by passing it (instead of a source string) to the *exec()* or *eval()* built-in functions.

更多資訊請見 types。

4.14.6 Type Objects

Type objects represent the various object types. An object's type is accessed by the built-in function *type()*. There are no special operations on types. The standard module *types* defines names for all standard built-in types.

Types are written like this: `<class 'int'>`.

4.14.7 The Null Object

This object is returned by functions that don't explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name). `type(None)()` produces the same singleton.

It is written as `None`.

4.14.8 The Ellipsis Object

This object is commonly used by slicing (see slicings). It supports no special operations. There is exactly one ellipsis object, named *Ellipsis* (a built-in name). `type(Ellipsis)()` produces the *Ellipsis* singleton.

It is written as `Ellipsis` or `...`.

4.14.9 The NotImplemented Object

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See comparisons for more information. There is exactly one *NotImplemented* object. `type(NotImplemented)()` produces the singleton instance.

It is written as `NotImplemented`.

4.14.10 Internal Objects

See types for this information. It describes stack frame objects, traceback objects, and slice objects.

4.15 Special Attributes

The implementation adds a few special read-only attributes to several object types, where they are relevant. Some of these are not reported by the *dir()* built-in function.

`object.`**`__dict__`**
: A dictionary or other mapping object used to store an object's (writable) attributes.

`instance.`**`__class__`**
: The class to which a class instance belongs.

`class.`**`__bases__`**
: The tuple of base classes of a class object.

`definition.`**`__name__`**
: The name of the class, function, method, descriptor, or generator instance.

`definition.`**`__qualname__`**
: The *qualified name* of the class, function, method, descriptor, or generator instance.

  在 3.3 版被加入.

`definition.`**`__type_params__`**
: The type parameters of generic classes, functions, and *type aliases*.

  在 3.12 版被加入.

`class.`**`__mro__`**
: This attribute is a tuple of classes that are considered when looking for base classes during method resolution.

`class.`**`mro`**`()`
: This method can be overridden by a metaclass to customize the method resolution order for its instances. It is called at class instantiation, and its result is stored in *__mro__*.

`class.`**`__subclasses__`**`()`
: Each class keeps a list of weak references to its immediate subclasses. This method returns a list of all those references still alive. The list is in definition order. Example:

```
>>> int.__subclasses__()
[<class 'bool'>, <enum 'IntEnum'>, <flag 'IntFlag'>, <class 're._constants._
↪NamedIntConstant'>]
```

4.16 Integer string conversion length limitation

CPython has a global limit for converting between *int* and *str* to mitigate denial of service attacks. This limit *only* applies to decimal or other non-power-of-two number bases. Hexadecimal, octal, and binary conversions are unlimited. The limit can be configured.

The *int* type in CPython is an arbitrary length number stored in binary form (commonly known as a "bignum"). There exists no algorithm that can convert a string to a binary integer or a binary integer to a string in linear time, *unless* the base is a power of 2. Even the best known algorithms for base 10 have sub-quadratic complexity. Converting a large value such as `int('1' * 500_000)` can take over a second on a fast CPU.

Limiting conversion size offers a practical way to avoid CVE-2020-10735.

The limit is applied to the number of digit characters in the input or output string when a non-linear conversion algorithm would be involved. Underscores and the sign are not counted towards the limit.

When an operation would exceed the limit, a *ValueError* is raised:

```
>>> import sys
>>> sys.set_int_max_str_digits(4300)  # Illustrative, this is the default.
>>> _ = int('2' * 5432)
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion: value has␣
↪5432 digits; use sys.set_int_max_str_digits() to increase the limit
>>> i = int('2' * 4300)
>>> len(str(i))
4300
>>> i_squared = i*i
>>> len(str(i_squared))
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion; use sys.
↪set_int_max_str_digits() to increase the limit
>>> len(hex(i_squared))
7144
>>> assert int(hex(i_squared), base=16) == i*i  # Hexadecimal is unlimited.
```

The default limit is 4300 digits as provided in *sys.int_info.default_max_str_digits*. The lowest limit that can be configured is 640 digits as provided in *sys.int_info.str_digits_check_threshold*.

Verification:

```
>>> import sys
>>> assert sys.int_info.default_max_str_digits == 4300, sys.int_info
>>> assert sys.int_info.str_digits_check_threshold == 640, sys.int_info
>>> msg = int('578966293710682886880994035146873798396722250538762761564'
...           '9252925514383915483333812743580549779436104706260696366600'
...           '571186405732').to_bytes(53, 'big')
...
```

在 3.11 版被加入.

4.16.1 Affected APIs

The limitation only applies to potentially slow conversions between *int* and *str* or *bytes*:

- `int(string)` with default base 10.
- `int(string, base)` for all bases that are not a power of 2.
- `str(integer)`。
- `repr(integer)`。
- any other string conversion to base 10, for example `f"{integer}"`, `"{}".format(integer)`, or `b"%d" % integer`.

The limitations do not apply to functions with a linear algorithm:

- `int(string, base)` with base 2, 4, 8, 16, or 32.
- *int.from_bytes()* and *int.to_bytes()*.
- *hex()*, *oct()*, *bin()*.
- 格式規格 *(Format Specification)* 迷你語言 for hex, octal, and binary numbers.
- *str* to *float*.
- *str* to *decimal.Decimal*.

4.16.2 Configuring the limit

Before Python starts up you can use an environment variable or an interpreter command line flag to configure the limit:

- `PYTHONINTMAXSTRDIGITS`, e.g. `PYTHONINTMAXSTRDIGITS=640 python3` to set the limit to 640 or `PYTHONINTMAXSTRDIGITS=0 python3` to disable the limitation.
- `-X int_max_str_digits`, e.g. `python3 -X int_max_str_digits=640`
- *sys.flags.int_max_str_digits* contains the value of `PYTHONINTMAXSTRDIGITS` or `-X int_max_str_digits`. If both the env var and the `-X` option are set, the `-X` option takes precedence. A value of *-1* indicates that both were unset, thus a value of *sys.int_info.default_max_str_digits* was used during initialization.

From code, you can inspect the current limit and set a new one using these *sys* APIs:

- *sys.get_int_max_str_digits()* and *sys.set_int_max_str_digits()* are a getter and setter for the interpreter-wide limit. Subinterpreters have their own limit.

Information about the default and minimum can be found in *sys.int_info*:

- *sys.int_info.default_max_str_digits* is the compiled-in default limit.
- *sys.int_info.str_digits_check_threshold* is the lowest accepted value for the limit (other than 0 which disables it).

在 3.11 版被加入.

警示

Setting a low limit *can* lead to problems. While rare, code exists that contains integer constants in decimal in their source that exceed the minimum threshold. A consequence of setting the limit is that Python source code containing decimal integer literals longer than the limit will encounter an error during parsing, usually at startup time or import

time or even at installation time - anytime an up to date `.pyc` does not already exist for the code. A workaround for source that contains such large constants is to convert them to `0x` hexadecimal form as it has no limit.

Test your application thoroughly if you use a low limit. Ensure your tests run with the limit set early via the environment or flag so that it applies during startup and even during any installation step that may invoke Python to precompile `.py` sources to `.pyc` files.

4.16.3 Recommended configuration

The default *sys.int_info.default_max_str_digits* is expected to be reasonable for most applications. If your application requires a different limit, set it from your main entry point using Python version agnostic code as these APIs were added in security patch releases in versions before 3.12.

範例:

```
>>> import sys
>>> if hasattr(sys, "set_int_max_str_digits"):
...     upper_bound = 68000
...     lower_bound = 4004
...     current_limit = sys.get_int_max_str_digits()
...     if current_limit == 0 or current_limit > upper_bound:
...         sys.set_int_max_str_digits(upper_bound)
...     elif current_limit < lower_bound:
...         sys.set_int_max_str_digits(lower_bound)
```

If you need to disable it entirely, set it to `0`.

🄵解

CHAPTER 5

內建的例外

在 Python 中，所有例外必須是從*BaseException*衍生的類別的實例。在陳述式 try 搭配 except 子句提到一個特定的類別時，那個子句也會處理任何從該類別衍生的例外類別（但不會處理該類別衍生自的例外類別）。兩個不是由子類別關係關聯起來的例外類別永遠不相等，就算它們有相同的名稱也是如此。

此章節列出的內建例外可以從直譯器或內建函式生。除了特別提到的地方之外，它們會有一個關聯值表示錯誤發生的詳細原因。這可能是一個字串，或者是一些資訊項目組成的元組（例如一個錯誤代碼及一個解釋該代碼的字串）。這個關聯值通常當作引數傳遞給例外類別的建構函式。

使用者的程式碼可以引發內建例外。這可以用來測試例外處理器或者用來回報一個錯誤條件，就像直譯器會引發相同例外的情形；但需要注意的是有任何方式可以避免使用者的程式碼引發不適當的錯誤。

可以從內建的例外類別定義新的例外子類別；程式設計師被鼓勵從*Exception*類別或其子類別衍生新的例外，而不是從*BaseException*來衍生。更多關於定義例外的資訊可以在 Python 教學中的 tut-userexceptions 取得。

5.1 例外的情境

三個例外物件上的屬性提供關於引發此例外的情境的資訊：

BaseException.**__context__**

BaseException.**__cause__**

BaseException.**__suppress_context__**

當引發一個新的例外而同時有另一個例外已經正在被處理時，這個新例外的 __context__ 屬性會自動被設成那個已處理的例外。當使用 except 或 finally 子句或 with 陳述式的時候例外會被處理。

這個隱含的例外情境可以透過使用 from 搭配 raise 來補充明確的原因：

```
raise new_exc from original_exc
```

在 from 後面的運算式必須是一個例外或 None。它將會被設定成所引發例外的 __cause__。設定 __cause__ 也隱含地設定 __suppress_context__ 屬性 True，因此使用 raise new_exc from None 實際上會以新的例外取代舊的例外以利於顯示（例如轉*KeyError*

🄵*AttributeError*），同時保持舊的例外可以透過 __context__ 取得以方便 debug 的時候檢查。

預設的回溯 (traceback) 顯示程式碼會顯示這些連鎖的例外 (chained exception) 加上例外本身的回溯。當存在的時候，在 __cause__ 中明確地連鎖的例外總是會被顯示。而在 __context__ 中隱含地連鎖的例外只有當 __cause__ 是*None* 且 __suppress_context__ 是 false 時才會顯示。

在任一種情🄵下，例外本身總是會顯示在任何連鎖例外的後面，因此回溯的最後一行總是顯示最後一個被引發的例外。

5.2 繼承自🄵建的例外

使用者的程式碼可以建立繼承自例外類型的子類🄵。建議一次只繼承一種例外類型以避免在基底類🄵之間如何處理 `args` 屬性的任何可能衝突，以及可能的記憶體🄵局 (memory layout) 不相容。

CPython 實作細節： 🄵了效率，大部分的🄵建例外使用 C 來實作，參考 Objects/exceptions.c。一些例外有客🄵化的記憶體🄵局，使其不可能建立一個繼承多種例外類型的子類🄵。類型的記憶體🄵局是實作細節且可能會在不同 Python 版本間改變，造成未來新的衝突。因此，總之建議避免繼承多種例外類型。

5.3 基底類🄵 (base classes)

以下的例外大部分被用在當作其他例外的基底類🄵。

exception BaseException

所有🄵建例外的基底類🄵。這不是🄵了讓使用者定義的類🄵直接繼承（可以使用*Exception*）。如果在這個類🄵的實例上呼叫*str()*，會回傳實例的引數的表示，或者🄵有引數的時候會回傳空字串。

args

提供給該例外建構函式的引數元組。一些🄵建的例外（像是*OSError*）預期接受特定數量的引數🄵賦予該元組的每一個元素一個特🄵的意義，其他例外則通常用一個提供錯誤訊息的單一字串來呼叫。

with_traceback(*tb*)

此方法設定 *tb* 🄵該例外的新的回溯🄵回傳該例外物件。在 **PEP 3134** 的例外連鎖功能變得可用之前，此方法曾被更普遍使用。下面的範例顯示我們如何將 `SomeException` 的實例轉🄵🄵 `OtherException` 的實例同時保留回溯。一旦被引發，目前的 frame 會被加進 `OtherException` 的回溯，就像原來 `SomeException` 的回溯會發生的一樣，我們允許它被傳遞給呼叫者：

```
try:
    ...
except SomeException:
    tb = sys.exception().__traceback__
    raise OtherException(...).with_traceback(tb)
```

__traceback__

可寫入的欄位，儲存關聯到該例外的回溯物件。也可以參考 raise。

add_note(*note*)

新增字串 `note` 到例外的備🄵，在標准的回溯🄵，備🄵出現在例外字串的後面。如果 `note` 不是字串則引發*TypeError*。

在 3.11 版被加入.

__notes__

該例外的備🄴串列，使用*add_note()* 來新增。此屬性在*add_note()* 被呼叫的時候建立。

在 3.11 版被加入.

exception Exception

所有🄴建、非系統退出 (non-system-exiting) 的例外都衍生自此類🄴。所有使用者定義的例外應該也要衍生自此類🄴。

exception ArithmeticError

各種運算錯誤所引發的那些🄴建例外：*OverflowError*、*ZeroDivisionError*、*FloatingPointError* 的基底類🄴。

exception BufferError

當緩衝 (buffer) 相關的操作無法被執行時會引發此例外。

exception LookupError

當使用在對映或序列上的鍵或索引是無效的時候所引發的例外：*IndexError*、*KeyError* 的基底類🄴。這可以被*codecs.lookup()* 直接引發。

5.4 實體例外

以下的例外是通常會被引發的例外。

exception AssertionError

當 `assert` 陳述式失敗的時候被引發。

exception AttributeError

當屬性參照（參考 attribute-references）或賦值失敗的時候被引發。（當物件根本不支援屬性參照或屬性賦值的時候，*TypeError* 會被引發。）

`name` 和 `obj` 屬性可以使用建構函式的僅限關鍵字 (keyword-only) 引數來設定。當被設定的時候，它們分🄴代表被嘗試存取的屬性名稱以及被以該屬性存取的物件。

在 3.10 版的變更: 新增 `name` 與 `obj` 屬性。

exception EOFError

當*input()* 函式在🄴有讀到任何資料而到達檔案結尾 (end-of-file, EOF) 條件的時候被引發。（注意: `io.IOBase.read()` 和*io.IOBase.readline()* 方法當達到 EOF 時會回傳空字串。）

exception FloatingPointError

目前🄴有被使用。

exception GeneratorExit

當*generator* 或*coroutine* 被關閉的時候被引發；參考 `generator.close()` 和 `coroutine.close()`。此例外直接繼承自*BaseException* 而不是*Exception*，因🄴技術上來🄴這不是一個錯誤。

exception ImportError

當 `import` 陳述式嘗試載入模組遇到問題的時候會被引發。當 `from …import` 🄴的 “from list” 包含找不到的名稱時也會被引發。

可選的僅限關鍵字引數 *name* 和 *path* 設定對應的屬性：

name

嘗試引入 (import) 的模組名稱。

path

觸發此例外的任何檔案的路徑。

在 3.3 版的變更: 新增*name* 與*path* 屬性。

exception ModuleNotFoundError

ImportError 的子類🄵，當模組不能被定位的時候會被 `import` 所引發。當在*sys.modules* 🄵找到 `None` 時也會被引發。

在 3.6 版被加入.

exception IndexError

當序列的索引超出範圍的時候會被引發。（切片索引 (slice indices) 會默默地被截短使其能落在允許的範圍🄵；如果索引不是整數，*TypeError* 會被引發。）

exception KeyError

當對映（字典）的鍵無法在已存在的鍵的集合中被找到時會被引發。

exception KeyboardInterrupt

當使用者輸入中斷鍵 (interrupt key)（一般來🄵是 `Control-C` 或 `Delete`）時會被引發。在執行過程中，會定期檢查是否🄵生中斷。此例外繼承自*BaseException* 以防止意外地被捕捉*Exception* 的程式碼所捕捉，而因此讓直譯器無法結束。

備🄵

捕捉*KeyboardInterrupt* 需要特殊的考量。因🄵它可以在無法預期的時間點被引發，可能在某些情🄵下讓正在跑的程式處在一個不一致的狀態。一般來🄵最好讓*KeyboardInterrupt* 越快結束程式越好，或者完全避免引發它。（參考*Note on Signal Handlers and Exceptions*。）

exception MemoryError

當一個操作用光了記憶體但情🄵還可能被修復 (rescued)（透過🄵除一些物件）的時候被引發。關聯的值是一個字串，表示什🄵類型的（🄵部）操作用光了記憶體。需注意的是因🄵底層的記憶體管理架構（C 的 `malloc()` 函式），直譯器可能無法總是完整地從該情🄵中修復；儘管如此，它還是引發例外以讓堆🄵回溯可以被印出，以防原因出在失控的程式。

exception NameError

當找不到本地或全域的名稱時會被引發。這只應用在不合格的名稱 (unqualified name) 上。關聯的值是一個錯誤訊息，包含那個無法被找到的名稱。

`name` 屬性可以使用僅限關鍵字引數來設定到建構函式。當被設定的時候它代表被嘗試存取的變數名稱。

在 3.10 版的變更: 新增 `name` 屬性。

exception NotImplementedError

This exception is derived from *RuntimeError*. In user defined base classes, abstract methods should raise this exception when they require derived classes to override the method, or while the class is being developed to indicate that the real implementation still needs to be added.

備🄵

It should not be used to indicate that an operator or method is not meant to be supported at all -- in that case either leave the operator / method undefined or, if a subclass, set it to *None*.

備F

NotImplementedError and *NotImplemented* are not interchangeable, even though they have similar names and purposes. See NotImplemented for details on when to use it.

exception OSError([*arg*])

exception OSError(*errno*, *strerror*[, *filename*[, *winerror*[, *filename2*]]])

This exception is raised when a system function returns a system-related error, including I/O failures such as "file not found" or "disk full" (not for illegal argument types or other incidental errors).

The second form of the constructor sets the corresponding attributes, described below. The attributes default to *None* if not specified. For backwards compatibility, if three arguments are passed, the *args* attribute contains only a 2-tuple of the first two constructor arguments.

The constructor often actually returns a subclass of *OSError*, as described in *OS exceptions* below. The particular subclass depends on the final *errno* value. This behaviour only occurs when constructing *OSError* directly or via an alias, and is not inherited when subclassing.

errno

A numeric error code from the C variable errno.

winerror

Under Windows, this gives you the native Windows error code. The *errno* attribute is then an approximate translation, in POSIX terms, of that native error code.

Under Windows, if the *winerror* constructor argument is an integer, the *errno* attribute is determined from the Windows error code, and the *errno* argument is ignored. On other platforms, the *winerror* argument is ignored, and the *winerror* attribute does not exist.

strerror

The corresponding error message, as provided by the operating system. It is formatted by the C functions perror() under POSIX, and FormatMessage() under Windows.

filename

filename2

For exceptions that involve a file system path (such as *open()* or *os.unlink()*), *filename* is the file name passed to the function. For functions that involve two file system paths (such as *os.rename()*), *filename2* corresponds to the second file name passed to the function.

在 3.3 版的變更: *EnvironmentError*, *IOError*, *WindowsError*, *socket.error*, *select.error* and mmap.error have been merged into *OSError*, and the constructor may return a subclass.

在 3.4 版的變更: The *filename* attribute is now the original file name passed to the function, instead of the name encoded to or decoded from the *filesystem encoding and error handler*. Also, the *filename2* constructor argument and attribute was added.

exception OverflowError

Raised when the result of an arithmetic operation is too large to be represented. This cannot occur for integers (which would rather raise *MemoryError* than give up). However, for historical reasons, OverflowError is sometimes raised for integers that are outside a required range. Because of the lack of standardization of floating-point exception handling in C, most floating-point operations are not checked.

exception RecursionError

This exception is derived from *RuntimeError*. It is raised when the interpreter detects that the maximum recursion depth (see *sys.getrecursionlimit()*) is exceeded.

在 3.5 版被加入: Previously, a plain *RuntimeError* was raised.

exception ReferenceError

This exception is raised when a weak reference proxy, created by the *weakref.proxy()* function, is used to access an attribute of the referent after it has been garbage collected. For more information on weak references, see the *weakref* module.

exception RuntimeError

Raised when an error is detected that doesn't fall in any of the other categories. The associated value is a string indicating what precisely went wrong.

exception StopIteration

Raised by built-in function *next()* and an *iterator*'s *__next__()* method to signal that there are no further items produced by the iterator.

value

The exception object has a single attribute `value`, which is given as an argument when constructing the exception, and defaults to *None*.

When a *generator* or *coroutine* function returns, a new *StopIteration* instance is raised, and the value returned by the function is used as the *value* parameter to the constructor of the exception.

If a generator code directly or indirectly raises *StopIteration*, it is converted into a *RuntimeError* (retaining the *StopIteration* as the new exception's cause).

在 3.3 版的變更: Added `value` attribute and the ability for generator functions to use it to return a value.

在 3.5 版的變更: Introduced the RuntimeError transformation via `from __future__ import generator_stop`, see **PEP 479**.

在 3.7 版的變更: Enable **PEP 479** for all code by default: a *StopIteration* error raised in a generator is transformed into a *RuntimeError*.

exception StopAsyncIteration

Must be raised by `__anext__()` method of an *asynchronous iterator* object to stop the iteration.

在 3.5 版被加入.

exception SyntaxError(*message*, *details*)

Raised when the parser encounters a syntax error. This may occur in an `import` statement, in a call to the built-in functions *compile()*, *exec()*, or *eval()*, or when reading the initial script or standard input (also interactively).

The *str()* of the exception instance returns only the error message. Details is a tuple whose members are also available as separate attributes.

filename

The name of the file the syntax error occurred in.

lineno

Which line number in the file the error occurred in. This is 1-indexed: the first line in the file has a `lineno` of 1.

offset

The column in the line where the error occurred. This is 1-indexed: the first character in the line has an `offset` of 1.

text

The source code text involved in the error.

end_lineno

Which line number in the file the error occurred ends in. This is 1-indexed: the first line in the file has a `lineno` of 1.

end_offset

The column in the end line where the error occurred finishes. This is 1-indexed: the first character in the line has an `offset` of 1.

For errors in f-string fields, the message is prefixed by "f-string: " and the offsets are offsets in a text constructed from the replacement expression. For example, compiling f'Bad {a b} field' results in this args attribute: ('f-string: ...', (", 1, 2, '(a b)n', 1, 5)).

在 3.10 版的變更: 新增*end_lineno* 與*end_offset* 屬性。

exception IndentationError

Base class for syntax errors related to incorrect indentation. This is a subclass of *SyntaxError*.

exception TabError

Raised when indentation contains an inconsistent use of tabs and spaces. This is a subclass of *IndentationError*.

exception SystemError

Raised when the interpreter finds an internal error, but the situation does not look so serious to cause it to abandon all hope. The associated value is a string indicating what went wrong (in low-level terms).

You should report this to the author or maintainer of your Python interpreter. Be sure to report the version of the Python interpreter (`sys.version`; it is also printed at the start of an interactive Python session), the exact error message (the exception's associated value) and if possible the source of the program that triggered the error.

exception SystemExit

This exception is raised by the *sys.exit()* function. It inherits from *BaseException* instead of *Exception* so that it is not accidentally caught by code that catches *Exception*. This allows the exception to properly propagate up and cause the interpreter to exit. When it is not handled, the Python interpreter exits; no stack traceback is printed. The constructor accepts the same optional argument passed to *sys.exit()*. If the value is an integer, it specifies the system exit status (passed to C's `exit()` function); if it is `None`, the exit status is zero; if it has another type (such as a string), the object's value is printed and the exit status is one.

A call to *sys.exit()* is translated into an exception so that clean-up handlers (`finally` clauses of `try` statements) can be executed, and so that a debugger can execute a script without running the risk of losing control. The *os._exit()* function can be used if it is absolutely positively necessary to exit immediately (for example, in the child process after a call to *os.fork()*).

code

The exit status or error message that is passed to the constructor. (Defaults to `None`.)

exception TypeError

Raised when an operation or function is applied to an object of inappropriate type. The associated value is a string giving details about the type mismatch.

This exception may be raised by user code to indicate that an attempted operation on an object is not supported, and is not meant to be. If an object is meant to support a given operation but has not yet provided an implementation, *NotImplementedError* is the proper exception to raise.

Passing arguments of the wrong type (e.g. passing a *list* when an *int* is expected) should result in a *TypeError*, but passing arguments with the wrong value (e.g. a number outside expected boundaries) should result in a *ValueError*.

exception UnboundLocalError

Raised when a reference is made to a local variable in a function or method, but no value has been bound to that variable. This is a subclass of *NameError*.

exception UnicodeError

Raised when a Unicode-related encoding or decoding error occurs. It is a subclass of *ValueError*.

UnicodeError has attributes that describe the encoding or decoding error. For example, `err.object[err.start:err.end]` gives the particular invalid input that the codec failed on.

encoding

The name of the encoding that raised the error.

reason

A string describing the specific codec error.

object

The object the codec was attempting to encode or decode.

start

The first index of invalid data in *object*.

end

The index after the last invalid data in *object*.

exception UnicodeEncodeError

Raised when a Unicode-related error occurs during encoding. It is a subclass of *UnicodeError*.

exception UnicodeDecodeError

Raised when a Unicode-related error occurs during decoding. It is a subclass of *UnicodeError*.

exception UnicodeTranslateError

Raised when a Unicode-related error occurs during translating. It is a subclass of *UnicodeError*.

exception ValueError

Raised when an operation or function receives an argument that has the right type but an inappropriate value, and the situation is not described by a more precise exception such as *IndexError*.

exception ZeroDivisionError

Raised when the second argument of a division or modulo operation is zero. The associated value is a string indicating the type of the operands and the operation.

The following exceptions are kept for compatibility with previous versions; starting from Python 3.3, they are aliases of *OSError*.

exception EnvironmentError

exception IOError

exception WindowsError

僅限於在 Windows 中使用。

5.4.1 OS exceptions

The following exceptions are subclasses of *OSError*, they get raised depending on the system error code.

exception BlockingIOError

Raised when an operation would block on an object (e.g. socket) set for non-blocking operation. Corresponds to errno *EAGAIN*, *EALREADY*, *EWOULDBLOCK* and *EINPROGRESS*.

In addition to those of *OSError*, *BlockingIOError* can have one more attribute:

characters_written

An integer containing the number of characters written to the stream before it blocked. This attribute is available when using the buffered I/O classes from the *io* module.

exception ChildProcessError

Raised when an operation on a child process failed. Corresponds to errno *ECHILD*.

exception ConnectionError

A base class for connection-related issues.

Subclasses are *BrokenPipeError*, *ConnectionAbortedError*, *ConnectionRefusedError* and *ConnectionResetError*.

exception BrokenPipeError

A subclass of *ConnectionError*, raised when trying to write on a pipe while the other end has been closed, or trying to write on a socket which has been shutdown for writing. Corresponds to errno *EPIPE* and *ESHUTDOWN*.

exception ConnectionAbortedError

A subclass of *ConnectionError*, raised when a connection attempt is aborted by the peer. Corresponds to errno *ECONNABORTED*.

exception ConnectionRefusedError

A subclass of *ConnectionError*, raised when a connection attempt is refused by the peer. Corresponds to errno *ECONNREFUSED*.

exception ConnectionResetError

A subclass of *ConnectionError*, raised when a connection is reset by the peer. Corresponds to errno *ECONNRESET*.

exception FileExistsError

Raised when trying to create a file or directory which already exists. Corresponds to errno *EEXIST*.

exception FileNotFoundError

Raised when a file or directory is requested but doesn't exist. Corresponds to errno *ENOENT*.

exception InterruptedError

Raised when a system call is interrupted by an incoming signal. Corresponds to errno *EINTR*.

在 3.5 版的變更: Python now retries system calls when a syscall is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

exception IsADirectoryError

Raised when a file operation (such as *os.remove()*) is requested on a directory. Corresponds to errno *EISDIR*.

exception NotADirectoryError

Raised when a directory operation (such as *os.listdir()*) is requested on something which is not a directory. On most POSIX platforms, it may also be raised if an operation attempts to open or traverse a non-directory file as if it were a directory. Corresponds to errno *ENOTDIR*.

exception PermissionError

Raised when trying to run an operation without the adequate access rights - for example filesystem permissions. Corresponds to `errno` *EACCES*, *EPERM*, and *ENOTCAPABLE*.

在 3.11.1 版的變更: WASI's *ENOTCAPABLE* is now mapped to *PermissionError*.

exception ProcessLookupError

Raised when a given process doesn't exist. Corresponds to `errno` *ESRCH*.

exception TimeoutError

Raised when a system function timed out at the system level. Corresponds to `errno` *ETIMEDOUT*.

在 3.3 版被加入: All the above *OSError* subclasses were added.

PEP 3151 - Reworking the OS and IO exception hierarchy

5.5 警告

The following exceptions are used as warning categories; see the *Warning Categories* documentation for more details.

exception Warning

Base class for warning categories.

exception UserWarning

Base class for warnings generated by user code.

exception DeprecationWarning

Base class for warnings about deprecated features when those warnings are intended for other Python developers.

Ignored by the default warning filters, except in the `__main__` module (**PEP 565**). Enabling the *Python Development Mode* shows this warning.

The deprecation policy is described in **PEP 387**.

exception PendingDeprecationWarning

Base class for warnings about features which are obsolete and expected to be deprecated in the future, but are not deprecated at the moment.

This class is rarely used as emitting a warning about a possible upcoming deprecation is unusual, and *DeprecationWarning* is preferred for already active deprecations.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

The deprecation policy is described in **PEP 387**.

exception SyntaxWarning

Base class for warnings about dubious syntax.

exception RuntimeWarning

Base class for warnings about dubious runtime behavior.

exception FutureWarning

Base class for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.

exception ImportWarning

Base class for warnings about probable mistakes in module imports.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

exception UnicodeWarning

Base class for warnings related to Unicode.

exception EncodingWarning

Base class for warnings related to encodings.

細節請見選擇性加入的編碼警告。

在 3.10 版被加入.

exception BytesWarning

Base class for warnings related to `bytes` and `bytearray`.

exception ResourceWarning

Base class for warnings related to resource usage.

Ignored by the default warning filters. Enabling the *Python Development Mode* shows this warning.

在 3.2 版被加入.

5.6 Exception groups

The following are used when it is necessary to raise multiple unrelated exceptions. They are part of the exception hierarchy so they can be handled with `except` like all other exceptions. In addition, they are recognised by `except*`, which matches their subgroups based on the types of the contained exceptions.

exception ExceptionGroup(*msg*, *excs*)

exception BaseExceptionGroup(*msg*, *excs*)

Both of these exception types wrap the exceptions in the sequence `excs`. The `msg` parameter must be a string. The difference between the two classes is that `BaseExceptionGroup` extends `BaseException` and it can wrap any exception, while `ExceptionGroup` extends `Exception` and it can only wrap subclasses of `Exception`. This design is so that `except Exception` catches an `ExceptionGroup` but not `BaseExceptionGroup`.

The `BaseExceptionGroup` constructor returns an `ExceptionGroup` rather than a `BaseExceptionGroup` if all contained exceptions are `Exception` instances, so it can be used to make the selection automatic. The `ExceptionGroup` constructor, on the other hand, raises a `TypeError` if any contained exception is not an `Exception` subclass.

message

The `msg` argument to the constructor. This is a read-only attribute.

exceptions

A tuple of the exceptions in the `excs` sequence given to the constructor. This is a read-only attribute.

subgroup(*condition*)

Returns an exception group that contains only the exceptions from the current group that match *condition*, or `None` if the result is empty.

The condition can be either a function that accepts an exception and returns true for those that should be in the subgroup, or it can be an exception type or a tuple of exception types, which is used to check for a match using the same check that is used in an `except` clause.

The nesting structure of the current exception is preserved in the result, as are the values of its *message*, *__traceback__*, *__cause__*, *__context__* and *__notes__* fields. Empty nested groups are omitted from the result.

The condition is checked for all exceptions in the nested exception group, including the top-level and any nested exception groups. If the condition is true for such an exception group, it is included in the result in full.

split(*condition*)

Like *subgroup()*, but returns the pair `(match, rest)` where `match` is `subgroup(condition)` and `rest` is the remaining non-matching part.

derive(*excs*)

Returns an exception group with the same *message*, but which wraps the exceptions in `excs`.

This method is used by *subgroup()* and *split()*, which are used in various contexts to break up an exception group. A subclass needs to override it in order to make *subgroup()* and *split()* return instances of the subclass rather than *ExceptionGroup*.

subgroup() and *split()* copy the *__traceback__*, *__cause__*, *__context__* and *__notes__* fields from the original exception group to the one returned by *derive()*, so these fields do not need to be updated by *derive()*.

```
>>> class MyGroup(ExceptionGroup):
...     def derive(self, excs):
...         return MyGroup(self.message, excs)
...
>>> e = MyGroup("eg", [ValueError(1), TypeError(2)])
>>> e.add_note("a note")
>>> e.__context__ = Exception("context")
>>> e.__cause__ = Exception("cause")
>>> try:
...     raise e
... except Exception as e:
...     exc = e
...
>>> match, rest = exc.split(ValueError)
>>> exc, exc.__context__, exc.__cause__, exc.__notes__
(MyGroup('eg', [ValueError(1), TypeError(2)]), Exception('context'),␣
↪Exception('cause'), ['a note'])
>>> match, match.__context__, match.__cause__, match.__notes__
(MyGroup('eg', [ValueError(1)]), Exception('context'), Exception('cause'), [
↪'a note'])
>>> rest, rest.__context__, rest.__cause__, rest.__notes__
(MyGroup('eg', [TypeError(2)]), Exception('context'), Exception('cause'), ['a␣
↪note'])
>>> exc.__traceback__ is match.__traceback__ is rest.__traceback__
True
```

Note that *BaseExceptionGroup* defines `__new__()`, so subclasses that need a different constructor signature need to override that rather than `__init__()`. For example, the following defines an exception group subclass which accepts an exit_code and and constructs the group's message from it.

```
class Errors(ExceptionGroup):
   def __new__(cls, errors, exit_code):
      self = super().__new__(Errors, f"exit code: {exit_code}", errors)
      self.exit_code = exit_code
      return self
```

(繼續下一頁)

(繼續上一頁)

```
  def derive(self, excs):
     return Errors(excs, self.exit_code)
```

Like *ExceptionGroup*, any subclass of *BaseExceptionGroup* which is also a subclass of *Exception* can only wrap instances of *Exception*.

CHAPTER 6

文本處理 (Text Processing) 服務

本章節介紹的模組 (module) 提供了廣泛的字串操作與其他文本處理服務。

在二進位資料服務 下所描述的*codecs* 模組也與文本處理高度相關。另外也請參🄵在*Text Sequence Type --- str* 中所描述的 Python 🄵建字串型🄵。

6.1 `string` --- 常見的字串操作

原始碼： Lib/string.py

也參考

Text Sequence Type --- str

String Methods

6.1.1 字串常數

此模組中定義的常數🄴：

`string.`**`ascii_letters`**

下文描述的*ascii_lowercase* 和*ascii_uppercase* 常數的串接，該值不依賴於區域設定。

`string.`**`ascii_lowercase`**

小寫字母 `'abcdefghijklmnopqrstuvwxyz'`。該值與地區設定無關且不會改變。

`string.`**`ascii_uppercase`**

大寫字母 ’ `ABCDEFGHIJKLMNOPQRSTUVWXYZ`’。此值與地區設定無關且不會改變。

string.**digits**
字串 '0123456789'。

string.**hexdigits**
字串 '0123456789abcdefABCDEF'。

string.**octdigits**
字串 '01234567'。

string.**punctuation**
在 C 語言中被視🄵標點符號的 ASCII 字元的字串：!"#$%&'()*+,-./:;<=>?@[\]^_`{|}~。

string.**printable**
ASCII 字元的字串是可被列印輸出的。這是*digits*、*ascii_letters*、*punctuation* 和 *whitespace* 的組合。

string.**whitespace**
包含所有 ASCII 字元的字串都視🄵空白字元 (whitespace)。包含空格 (space)、🄵表符號 (tab)、🄵行符號 (linefeed)、return、🄵頁符號 (formfeed) 和垂直🄵表符號 (vertical tab) 這些字元。

6.1.2 自訂字串格式

透過 **PEP 3101** 中描述的 *format()* 方法，🄵建字串類🄵提供了進行🄵雜變數替🄵和數值格式化的能力。*string* 模組中的 *Formatter* 類🄵模組可讓你使用與🄵建 *format()* 方法相同的實作來建立和自訂你自己的字串格式化行🄵。

class string.**Formatter**
Formatter 類🄵有以下的公開方法：

format(*format_string*, /, **args*, ***kwargs*)
主要的 API 方法。它接收一個格式字串及一組任意的位置引數與關鍵字引數，是呼叫 *vformat()* 的包裝器 (wrapper)。

在 3.7 版的變更: 現在格式字串引數是僅限位置參數。

vformat(*format_string*, *args*, *kwargs*)
This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the `*args` and `**kwargs` syntax. *vformat()* does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the *Formatter* defines a number of methods that are intended to be replaced by subclasses:

parse(*format_string*)
將 format_string 放入🄵圈，🄵回傳一個可🄵代物件，其元素🄵 (*literal_text*, *field_name*, *format_spec*, *conversion*)。這會被 *vformat()* 用於將字串裁切🄵字面文本或替🄵欄位。

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then *literal_text* will be a zero-length string. If there is no replacement field, then the values of *field_name*, *format_spec* and *conversion* will be `None`.

get_field(*field_name*, *args*, *kwargs*)
Given *field_name* as returned by *parse()* (see above), convert it to an object to be formatted. Returns a tuple (obj, used_key). The default version takes strings of the form defined in **PEP 3101**, such as "0[name]" or "label.title". *args* and *kwargs* are as passed in to *vformat()*. The return value *used_key* has the same meaning as the *key* parameter to *get_value()*.

get_value(*key*, *args*, *kwargs*)

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to *vformat()*, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression '0.name' would cause *get_value()* to be called with a *key* argument of 0. The `name` attribute will be looked up after *get_value()* returns by calling the built-in *getattr()* function.

If the index or keyword refers to an item that does not exist, then an *IndexError* or *KeyError* should be raised.

check_unused_args(*used_args*, *args*, *kwargs*)

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to vformat. The set of unused args can be calculated from these parameters. *check_unused_args()* is assumed to raise an exception if the check fails.

format_field(*value*, *format_spec*)

format_field() simply calls the global *format()* built-in. The method is provided so that subclasses can override it.

convert_field(*value*, *conversion*)

Converts the value (returned by *get_field()*) given a conversion type (as in the tuple returned by the *parse()* method). The default version understands 's' (str), 'r' (repr) and 'a' (ascii) conversion types.

6.1.3 格式化文字語法

The *str.format()* method and the *Formatter* class share the same syntax for format strings (although in the case of *Formatter*, subclasses can define their own format string syntax). The syntax is related to that of formatted string literals, but it is less sophisticated and, in particular, does not support arbitrary expressions.

Format strings contain "replacement fields" surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field  ::=   "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name         ::=   arg_name ("." attribute_name | "[" element_index "]")*
arg_name           ::=   [identifier | digit+]
attribute_name     ::=   identifier
element_index      ::=   digit+ | index_string
index_string       ::=   <any source character except "]"> +
conversion         ::=   "r" | "s" | "a"
format_spec        ::=   format-spec:format_spec
```

In less formal terms, the replacement field can start with a *field_name* that specifies the object whose value is to be

formatted and inserted into the output instead of the replacement field. The *field_name* is optionally followed by a *conversion* field, which is preceded by an exclamation point `'!'`, and a *format_spec*, which is preceded by a colon `':'`. These specify a non-default format for the replacement value.

另請參🄵格式規格 *(Format Specification)* 迷你語言 部份。

The *field_name* itself begins with an *arg_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. An *arg_name* is treated as a number if a call to *str.isdecimal()* on the string would return true. If the numerical arg_names in a format string are 0, 1, 2, ... in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, ... will be automatically inserted in that order. Because *arg_name* is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings `'10'` or `':-]'`) within a format string. The *arg_name* can be followed by any number of index or attribute expressions. An expression of the form `'.name'` selects the named attribute using *getattr()*, while an expression of the form `'[index]'` does an index lookup using `__getitem__()`.

在 3.1 版的變更: The positional argument specifiers can be omitted for *str.format()*, so `'{} {}'.format(a, b)` is equivalent to `'{0} {1}'.format(a, b)`.

在 3.4 版的變更: The positional argument specifiers can be omitted for *Formatter*.

Some simple format string examples:

```
"First, thou shalt count to {0}"  # References first positional argument
"Bring me a {}"                   # Implicitly references the first positional␣
↪argument
"From {} to {}"                   # Same as "From {0} to {1}"
"My quest is {name}"              # References keyword argument 'name'
"Weight in tons {0.weight}"       # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}"   # First element of keyword argument 'players'.
```

The *conversion* field causes a type coercion before formatting. Normally, the job of formatting a value is done by the `__format__()` method of the value itself. However, in some cases it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling `__format__()`, the normal formatting logic is bypassed.

目前支援三種轉🄵旗標: `'!s'` 會對該值呼叫*str()*, `'!r'` 會對該值呼叫*repr()*, 而 `'!a'` 則會對該值呼叫*ascii()*。

一些範例:

```
"Harold's a clever {0!s}"         # Calls str() on the argument first
"Bring out the holy {name!r}"     # Calls repr() on the argument first
"More {!a}"                       # Calls ascii() on the argument first
```

format_spec 欄位描述了值的呈現規格，例如欄位寬度、對齊、填充 (padding)、小數精度等細節資訊。每種值類型都可以定義自己的「格式化迷你語言 (formatting mini-language)」或對 *format_spec* 的解釋。

大多數🄵建型🄵都支援常見的格式化迷你語言，下一節將會詳細🄴明。

format_spec 欄位還可以在其🄴部包含巢狀的替🄵欄位。這些巢狀的替🄵欄位可能包含欄位名稱、轉🄵旗標、格式規格描述，但是不允許再更深層的巢狀結構。format_spec 內部的替🄵欄位會在 *format_spec* 字串被直譯前被替🄵。這讓數值的格式能🄵被動態地指定。

範例請見格式範例。

格式規格 (Format Specification) 迷你語言

「格式規格」在格式字串 (format string) 中包含的替🄴欄位中使用，以定義各個值如何被呈現（請參考格式化文字語法 和 f-strings）。它們也能🄴直接傳遞給🄴建的*format()* 函式。每個可格式化型🄴 (formattable type) 可以定義格式規格如何被直譯。

大部分🄴建型🄴🄴了格式規格實作了下列選項，不過有些選項只被數值型🄴支援。

一般來🄴，輸入空格式規格會🄴生和對值呼叫*str()* 函式相同的結果，非空的格式規格才會修改結果。

標準格式🄴明符號 *(standard format specifier)* 的一般型式如下：

```
format_spec      ::=  [[fill]align][sign]["z"]["#"]["0"][width][grouping_option]["." preci
fill             ::=  <any character>
align            ::=  "<" | ">" | "=" | "^"
sign             ::=  "+" | "-" | " "
width            ::=  digit+
grouping_option  ::=  "_" | ","
precision        ::=  digit+
type             ::=  "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s
```

如果給定了一個有效的 *align* 值，則可以在它之前加一個 *fill* 字元，且該字元可🄴任意字元，若不加的話預設🄴空格。使用格式字串或*str.format()* 時是無法在其中使用大括號（"{" 或"}"）作🄴 *fill* 字元的，但仍可透過巢狀替🄴欄位的方式插入大括號。此限制不影響*format()* 函式。

The meaning of the various alignment options is as follows:

選項	Meaning
`'<'`	🄴制欄位在可用空間🄴靠左對齊（這是大多數物件的預設值）。
`'>'`	🄴制欄位在可用空間🄴靠右對齊（這是數字的預設值）。
`'='`	Forces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form '+000000120'. This alignment option is only valid for numeric types. It becomes the default for numbers when '0' immediately precedes the field width.
`'^'`	🄴制欄位在可用空間🄴置中。

請注意，除非有定義了最小欄位寬度，否則欄位寬度將始終與填充它的資料大小相同，故在該情🄴下的對齊選項是🄴有意義的。

sign 選項只適用於數字型🄴，🄴可🄴以下之一：

選項	Meaning
`'+'`	表示正數與負數均需使用符號。
`'-'`	indicates that a sign should be used only for negative numbers (this is the default behavior).
space	表示正數應使用前導空格，負數應使用🄴號。

The `'z'` option coerces negative zero floating-point values to positive zero after rounding to the format precision. This option is only valid for floating-point presentation types.

在 3.11 版的變更: 新增 `'z'` 選項（請見 **PEP 682**）。

The `'#'` option causes the "alternate form" to be used for the conversion. The alternate form is defined differently for different types. This option is only valid for integer, float and complex types. For integers, when binary, octal, or hexadecimal output is used, this option adds the respective prefix `'0b'`, `'0o'`, `'0x'`, or `'0X'` to the output value. For

float and complex the alternate form causes the result of the conversion to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for `'g'` and `'G'` conversions, trailing zeros are not removed from the result.

The `','` option signals the use of a comma for a thousands separator. For a locale aware separator, use the `'n'` integer presentation type instead.

在 3.1 版的變更: 新增 `','` 選項（請見 **PEP 378**）。

The `'_'` option signals the use of an underscore for a thousands separator for floating-point presentation types and for integer presentation type `'d'`. For integer presentation types `'b'`, `'o'`, `'x'`, and `'X'`, underscores will be inserted every 4 digits. For other presentation types, specifying this option is an error.

在 3.6 版的變更: 新增 `'_'` 選項（請見 **PEP 515**）。

width 是一個十進位整數，定義了最小總欄位寬度，包括任何前綴、分隔符號和其他格式字元。如果未指定，則欄位寬度將由🄵容🄴定。

當未給予明確的對齊指示，在 *width* 欄位前面填入零 (`'0'`) 字元將會🄵數值型🄵🄵用有符號察覺的零填充 (sign-aware zero-padding)。這相當於使用 `'0'` 🄵 *fill* 字元且對齊類型🄵 `'='`。

在 3.10 版的變更: 在 *width* 欄位前面加上 `'0'` 不再影響字串的預設對齊方式。

precision 是一個十進位整數，指定表示類型 `'f'` 和 `'F'` 的小數點後應顯示多少位，或表示類型 `'g'` 或 `'G'` 的小數點前後應顯示多少位。對於字串表示類型，該欄位指定最大欄位大小 - 🄵言之，將使用欄位中的多少字元。整數表示類型不允許使用 *precision*。

最終，型🄵🄵定了資料將會如何呈現

可用的字串表示型🄵有：

型🄵	Meaning
`'s'`	String format. This is the default type for strings and may be omitted.
None	The same as `'s'`.

The available integer presentation types are:

型🄵	Meaning
`'b'`	Binary format. Outputs the number in base 2.
`'c'`	Character. Converts the integer to the corresponding unicode character before printing.
`'d'`	Decimal Integer. Outputs the number in base 10.
`'o'`	Octal format. Outputs the number in base 8.
`'x'`	十六進位格式。輸出以 16 🄵基數的數字，9 以上的數字使用小寫字母。
`'X'`	十六進位格式。輸出以 16 🄵基數的數字，9 以上的數字使用大寫字母。如果指定了 `'#'`，則前綴 `'0x'` 也會被轉成大寫的 `'0X'`。
`'n'`	Number. This is the same as `'d'`, except that it uses the current locale setting to insert the appropriate number separator characters.
None	The same as `'d'`.

In addition to the above presentation types, integers can be formatted with the floating-point presentation types listed below (except `'n'` and `None`). When doing so, *`float()`* is used to convert the integer to a floating-point number before formatting.

The available presentation types for *`float`* and *`Decimal`* values are:

型 F	Meaning
`'e'`	Scientific notation. For a given precision `p`, formats the number in scientific notation with the letter 'e' separating the coefficient from the exponent. The coefficient has one digit before and `p` digits after the decimal point, for a total of `p + 1` significant digits. With no precision given, uses a precision of `6` digits after the decimal point for *`float`*, and shows all coefficient digits for *`Decimal`*. If no digits follow the decimal point, the decimal point is also removed unless the `#` option is used.
`'E'`	Scientific notation. Same as `'e'` except it uses an upper case 'E' as the separator character.
`'f'`	Fixed-point notation. For a given precision `p`, formats the number as a decimal number with exactly `p` digits following the decimal point. With no precision given, uses a precision of `6` digits after the decimal point for *`float`*, and uses a precision large enough to show all coefficient digits for *`Decimal`*. If no digits follow the decimal point, the decimal point is also removed unless the `#` option is used.
`'F'`	Fixed-point notation. Same as `'f'`, but converts `nan` to `NAN` and `inf` to `INF`.
`'g'`	General format. For a given precision `p >= 1`, this rounds the number to `p` significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. A precision of `0` is treated as equivalent to a precision of `1`. The precise rules are as follows: suppose that the result formatted with presentation type `'e'` and precision `p-1` would have exponent `exp`. Then, if `m <= exp < p`, where `m` is -4 for floats and -6 for *`Decimals`*, the number is formatted with presentation type `'f'` and precision `p-1-exp`. Otherwise, the number is formatted with presentation type `'e'` and precision `p-1`. In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it, unless the `'#'` option is used. With no precision given, uses a precision of `6` significant digits for *`float`*. For *`Decimal`*, the coefficient of the result is formed from the coefficient digits of the value; scientific notation is used for values smaller than `1e-6` in absolute value and values where the place value of the least significant digit is larger than 1, and fixed-point notation is used otherwise. Positive and negative infinity, positive and negative zero, and nans, are formatted as `inf`, `-inf`, `0`, `-0` and `nan` respectively, regardless of the precision.
`'G'`	General format. Same as `'g'` except switches to `'E'` if the number gets too large. The representations of infinity and NaN are uppercased, too.
`'n'`	Number. This is the same as `'g'`, except that it uses the current locale setting to insert the appropriate number separator characters.
`'%'`	Percentage. Multiplies the number by 100 and displays in fixed (`'f'`) format, followed by a percent sign.
None	For *`float`* this is the same as `'g'`, except that when fixed-point notation is used to format the result, it always includes at least one digit past the decimal point. The precision used is as large as needed to represent the given value faithfully. For *`Decimal`*, this is the same as either `'g'` or `'G'` depending on the value of `context.capitals` for the current decimal context. The overall effect is to match the output of *`str()`* as altered by the other format modifiers.

格式范例

本節包含*str.format()* 語法以及與舊式 `%` 格式的比較。

此語法在大多情🄴下與舊式的 `%` 格式類似，只是增加了 `{}` 和 `:` 來取代 `%`。例如，`'%03.2f'` 可以改寫🄵 `'{:03.2f}'`。

新的語法還支援新的選項，將在以下的範例中🄴明。

按位置存取引數：

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c')  # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc')      # unpacking argument sequence
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad')   # arguments' indices can be repeated
'abracadabra'
```

按名稱存取引數：

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.
↪81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

存取引數的屬性：

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
...  'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.
↪0.'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

存取引數的🄴容：

```
>>> coord = (3, 5)
>>> 'X: {0[0]};  Y: {0[1]}'.format(coord)
'X: 3;  Y: 5'
```

替🄵 `%s` 和 `%r`：

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
"repr() shows quotes: 'test1'; str() doesn't: test2"
```

對齊文字以及指定寬度：

```
>>> '{:<30}'.format('left aligned')
'left aligned                  '
>>> '{:>30}'.format('right aligned')
'                 right aligned'
>>> '{:^30}'.format('centered')
'           centered           '
>>> '{:*^30}'.format('centered')  # use '*' as a fill char
'***********centered***********'
```

替🄵 `%+f`、`%-f` 和 `% f` 以及指定正負號:

```
>>> '{:+f}; {:+f}'.format(3.14, -3.14)  # show it always
'+3.140000; -3.140000'
>>> '{: f}; {: f}'.format(3.14, -3.14)  # show a space for positive numbers
' 3.140000; -3.140000'
>>> '{:-f}; {:-f}'.format(3.14, -3.14)  # show only the minus -- same as '{:f}; {:f}'
'3.140000; -3.140000'
```

替🄵 `%x` 和 `%o` 🄵將其值轉🄵🄵不同的進位制:

```
>>> # format also supports binary numbers
>>> "int: {0:d};  hex: {0:x};  oct: {0:o};  bin: {0:b}".format(42)
'int: 42;  hex: 2a;  oct: 52;  bin: 101010'
>>> # with 0x, 0o, or 0b as prefix:
>>> "int: {0:d};  hex: {0:#x};  oct: {0:#o};  bin: {0:#b}".format(42)
'int: 42;  hex: 0x2a;  oct: 0o52;  bin: 0b101010'
```

使用逗號作🄵千位分隔符:

```
>>> '{:,}'.format(1234567890)
'1,234,567,890'
```

表示🄵百分比:

```
>>> points = 19
>>> total = 22
>>> 'Correct answers: {:.2%}'.format(points/total)
'Correct answers: 86.36%'
```

作🄵特定型🄵格式:

```
>>> import datetime
>>> d = datetime.datetime(2010, 7, 4, 12, 15, 58)
>>> '{:%Y-%m-%d %H:%M:%S}'.format(d)
'2010-07-04 12:15:58'
```

巢狀引數及更多🄵雜範例:

```
>>> for align, text in zip('<^>', ['left', 'center', 'right']):
...     '{0:{fill}{align}16}'.format(text, fill=align, align=align)
...
'left<<<<<<<<<<<<'
'^^^^^center^^^^^'
'>>>>>>>>>>>right'
>>>
>>> octets = [192, 168, 0, 1]
>>> '{:02X}{:02X}{:02X}{:02X}'.format(*octets)
```

(繼續下一頁)

(繼續上一頁)

```
'C0A80001'
>>> int(_, 16)
3232235521
>>>
>>> width = 5
>>> for num in range(5,12):
...     for base in 'dXob':
...         print('{0:{width}{base}}'.format(num, base=base, width=width), end=' ')
...     print()
...
    5     5     5   101
    6     6     6   110
    7     7     7   111
    8     8    10  1000
    9     9    11  1001
   10     A    12  1010
   11     B    13  1011
```

6.1.4 模板字串

模板字串提供如 **PEP 292** 所述更簡單的字串替🄴。模板字串的主要用例是國際化 (i18n)，因🄵在這種情🄵下，更簡單的語法和功能使得它比其他 Python 🄵建字串格式化工具更容易翻譯。基於模板字串建構的 i18n 函式庫範例，請參🄵 flufl.i18n 套件。

Template strings support `$`-based substitutions, using the following rules:

- `$$` is an escape; it is replaced with a single `$`.
- `$identifier` names a substitution placeholder matching a mapping key of `"identifier"`. By default, `"identifier"` is restricted to any case-insensitive ASCII alphanumeric string (including underscores) that starts with an underscore or ASCII letter. The first non-identifier character after the `$` character terminates this placeholder specification.
- `${identifier}` is equivalent to `$identifier`. It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as `"${noun}ification"`.

Any other appearance of `$` in the string will result in a *`ValueError`* being raised.

The *`string`* module provides a *`Template`* class that implements these rules. The methods of *`Template`* are:

class `string.`**Template**(*template*)

The constructor takes a single argument which is the template string.

substitute(*mapping={}*, */*, ***kwds*)

進行模板替🄴，🄵回傳一個新的字串。*mapping* 是任何有金鑰🄵符合模板🄵🄵位符號的字典型物件。或者如果關鍵字就是🄵位符號時，你也可以改提供關鍵字引數。當 *mapping* 跟 *kwds* 同時給定🄵存在重🄵時，*kwds* 的🄵位符號會被優先使用。

safe_substitute(*mapping={}*, */*, ***kwds*)

類似於*`substitute()`*，但如果 *mapping* 與 *kwds* 中缺少🄵位符號的話，原始的🄵位符號會完整地出現在結果字串🄵，而不會引發*`KeyError`* 例外。此外，與*`substitute()`* 不同的是，任何包含 `$` 的字句會直接回傳 `$` 而非引發*`ValueError`*。

雖然仍可能發生其他例外，但這個方法被認🄵是「安全」的，因🄵它總是試圖回傳一個有用的字串而不是引發例外。從另一個角度來看，*`safe_substitute()`* 可能🄵非完全安全，因🄵它會默默忽略格式錯誤的模板，這些模板包含了多余的左右定界符、不匹配的括號，或者不是有效的 Python 識🄵字的🄵位符號。

is_valid()

如果模板有將導致*substitute()*引發*ValueError*的無效🄵位符號，就會回傳 false。

在 3.11 版被加入.

get_identifiers()

回傳模板中有效識🄵字的串列，按照它們首次出現的順序，🄵忽略任何無效的識🄵字。

在 3.11 版被加入.

*Template*實例也提供一個公開的資料屬性：

template

這是傳遞給建構函式 *template* 引數的物件。一般來🄵，你不應該改變它，但🄵🄵有🄵制設定成唯讀。

以下是如何使用 Template 的一個範例：

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

進階用法：你可以衍生*Template*類🄵來自定義🄵位符號語法、左右定界符字元，或者用於剖析模板字串的正則表達式。你可以透過覆寫這些類🄵屬性來達成：

- *delimiter* -- 這是描述引入左右定界符的文字字串。預設值是 `$`。請注意這不是正規表示式，因🄵實作會在需要時對這個字串呼叫*re.escape()*。也請注意你不能在建立類🄵後修改左右定界符。（意即在子類🄵的命名空間中必須設置不同的左右定界符）
- *idpattern* -- This is the regular expression describing the pattern for non-braced placeholders. The default value is the regular expression `(?a:[_a-z][_a-z0-9]*)`. If this is given and *braceidpattern* is `None` this pattern will also apply to braced placeholders.

  備🄵

  Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use the local `a` flag here.

  在 3.7 版的變更: *braceidpattern* can be used to define separate patterns used inside and outside the braces.

- *braceidpattern* -- This is like *idpattern* but describes the pattern for braced placeholders. Defaults to `None` which means to fall back to *idpattern* (i.e. the same pattern is used both inside and outside braces). If given, this allows you to define different patterns for braced and unbraced placeholders.

  在 3.7 版被加入.

- *flags* -- The regular expression flags that will be applied when compiling the regular expression used for recognizing substitutions. The default value is `re.IGNORECASE`. Note that `re.VERBOSE` will always be added to the flags, so custom *idpattern*s must follow conventions for verbose regular expressions.

  在 3.2 版被加入.

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* -- 此群組與跳🄵序列匹配，例如在預設模式下🄵 `$$`。
- *named* -- 此群組與不帶大括號的🄵位符號名稱匹配；它不應包含🄵取群組中的左右定界符號。
- *braced* -- 此群組與大括號括起來的🄵位符號名稱匹配；它不應在🄵取群組中包含左右定界符或大括號。
- *invalid* -- 此群組與任何其他左右定界符模式（通常是單一左右定界符）匹配，且它應該出現在正規表示式的最後。

當此模式有匹配於模板但這些命名組中🄵有任一個不匹配，此類🄵的方法將引發*`ValueError`*。

6.1.5 輔助函式

`string.`**`capwords`**(*s*, *sep=None*)

使用*`str.split()`* 將引數分割🄵字詞，使用*`str.capitalize()`* 將每個單字大寫，🄵使用*`str.join()`* 將大寫字詞連接起來。如果可選的第二引數 *sep* 不存在或🄵 `None`，則連續的空白字元將替🄵🄵單一空格，🄵且🄵除前導和尾隨空白；在其他情🄵下則使用 *sep* 來分割和連接單字。

6.2 `re` --- 正規表示式 (regular expression) 操作

原始碼： Lib/re/

此模組提供類似於 Perl 中正規表示式的配對操作。

被搜尋的模式 (pattern) 與字串可以是 Unicode 字串 (*`str`*)，也可以是 8-bit 字串 (*`bytes`*)。然而，Unicode 字串和 8-bit 字串不能混用：也就是，你不能用 byte 模式配對 Unicode 字串，反之亦然；同樣地，替🄵時，用來替🄵的字串必須與模式和搜尋字串是相同的型🄵 (type)。

正規表示式使用反斜🄵字元 (`'\'`) 表示特🄵的形式，或是使用特殊字元而不調用它們的特殊意義。這與 Python 在字串文本 (literal) 中，🄵了一樣的目的使用同一個字元的目的相衝突；舉例來🄵，🄵了配對一個反斜🄵文字，一個人可能需要寫 `'\\\\'` 當作模式字串，因🄵正規表示式必須是 `\\`，而且每個反斜🄵在一個普通的 Python 字串文本中必須表示🄵 `\\`。另外，請注意在 Python 的字串文本中使用反斜🄵的任何無效跳🄵序列目前會🄵生一個*`SyntaxWarning`*，而在未來這會變成一個*`SyntaxError`*。🄵管它對正規表示式是一個有效的跳🄵序列，這種行🄵也會發生。

解🄵方法是對正規表示式模式使用 Python 的原始字串符號；反斜🄵在一個以 `'r'` 🄵前綴的字串文本中不會被用任何特🄵的方式處理。所以 `r"\n"` 是一個兩個字元的字串，包含 `'\'` 和 `'n'`，同時 `"\n"` 是一個單個字元的字串，包含一個🄵行符號。通常模式在 Python 程式中會使用這個原始字串符號表示。

請務必注意到大部分的正規表示式操作是可以在模組層級的函式和*compiled regular expressions* 中的方法使用的。這些函式是個捷徑且讓你不需要先編譯一個正規表示式物件，但是會缺少一些微調參數。

也參考

第三方的 regex 模組，有著和標准函式庫 *re* 模組相容的 API，但是提供額外的功能以及更完整的 Unicode 支援。

6.2.1 正規表示式語法

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match AB. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book [Frie09], or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the regex-howto.

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like `'A'`, `'a'`, or `'0'`, are the simplest regular expressions; they simply match themselves. You can concatenate ordinary characters, so `last` matches the string `'last'`. (In the rest of this section, we'll write RE's in `this special style`, usually without quotes, and strings to be matched `'in single quotes'`.)

Some characters, like `'|'` or `'('`, are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted.

Repetition operators or quantifiers (`*`, `+`, `?`, `{m,n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six `'a'` characters.

The special characters are:

.
(Dot.) In the default mode, this matches any character except a newline. If the *DOTALL* flag has been specified, this matches any character including a newline. `(?s:.)` matches any character regardless of flags.

^
(Caret.) Matches the start of the string, and in *MULTILINE* mode also matches immediately after each newline.

$
Matches the end of the string or just before the newline at the end of the string, and in *MULTILINE* mode also matches before a newline. `foo` matches both 'foo' and 'foobar', while the regular expression `foo$` matches only 'foo'. More interestingly, searching for `foo.$` in `'foo1\nfoo2\n'` matches 'foo2' normally, but 'foo1' in *MULTILINE* mode; searching for a single `$` in `'foo\n'` will find two (empty) matches: one just before the newline, and one at the end of the string.

*****
Causes the resulting RE to match 0 or more repetitions of the preceding RE, as many repetitions as are possible. `ab*` will match 'a', 'ab', or 'a' followed by any number of 'b's.

+
Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match 'a' followed by any non-zero number of 'b's; it will not match just 'a'.

?

Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either 'a' or 'ab'.

***?, +?, ??**

The `'*'`, `'+'`, and `'?'` quantifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against `'<a> b <c>'`, it will match the entire string, and not just `'<a>'`. Adding `?` after the quantifier makes it perform the match in *non-greedy* or *minimal* fashion; as *few* characters as possible will be matched. Using the RE `<.*?>` will match only `'<a>'`.

***+, ++, ?+**

Like the `'*'`, `'+'`, and `'?'` quantifiers, those where `'+'` is appended also match as many times as possible. However, unlike the true greedy quantifiers, these do not allow back-tracking when the expression following it fails to match. These are known as *possessive* quantifiers. For example, `a*a` will match `'aaaa'` because the `a*` will match all 4 `'a'`s, but, when the final `'a'` is encountered, the expression is backtracked so that in the end the `a*` ends up matching 3 `'a'`s total, and the fourth `'a'` is matched by the final `'a'`. However, when `a*+a` is used to match `'aaaa'`, the `a*+` will match all 4 `'a'`, but when the final `'a'` fails to find any more characters to match, the expression cannot be backtracked and will thus fail to match. `x*+`, `x++` and `x?+` are equivalent to `(?>x*)`, `(?>x+)` and `(?>x?)` correspondingly.

在 3.11 版被加入.

{m}

Specifies that exactly *m* copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six `'a'` characters, but not five.

{m,n}

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3,5}` will match from 3 to 5 `'a'` characters. Omitting *m* specifies a lower bound of zero, and omitting *n* specifies an infinite upper bound. As an example, `a{4,}b` will match `'aaaab'` or a thousand `'a'` characters followed by a `'b'`, but not `'aaab'`. The comma may not be omitted or the modifier would be confused with the previously described form.

{m,n}?

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as *few* repetitions as possible. This is the non-greedy version of the previous quantifier. For example, on the 6-character string `'aaaaaa'`, `a{3,5}` will match 5 `'a'` characters, while `a{3,5}?` will only match 3 characters.

{m,n}+

Causes the resulting RE to match from *m* to *n* repetitions of the preceding RE, attempting to match as many repetitions as possible *without* establishing any backtracking points. This is the possessive version of the quantifier above. For example, on the 6-character string `'aaaaaa'`, `a{3,5}+aa` attempt to match 5 `'a'` characters, then, requiring 2 more `'a'`s, will need more characters than available and thus fail, while `a{3,5}aa` will match with `a{3,5}` capturing 5, then 4 `'a'`s by backtracking and then the final 2 `'a'`s are matched by the final `aa` in the pattern. `x{m,n}+` is equivalent to `(?>x{m,n})`.

在 3.11 版被加入.

****

Either escapes special characters (permitting you to match characters like `'*'`, `'?'`, and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[]

Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match `'a'`, `'m'`, or `'k'`.
- Ranges of characters can be indicated by giving two characters and separating them by a `'-'`, for example `[a-z]` will match any lowercase ASCII letter, `[0-5][0-9]` will match all the two-digits numbers from `00` to `59`, and `[0-9A-Fa-f]` will match any hexadecimal digit. If `-` is escaped (e.g. `[a\-z]`) or if it's placed as the first or last character (e.g. `[-a]` or `[a-]`), it will match a literal `'-'`.
- Special characters lose their special meaning inside sets. For example, `[(+*)]` will match any of the literal characters `'('`, `'+'`, `'*'`, or `')'`.
- Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depend on the *flags* used.
- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is `'^'`, all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except `'5'`, and `[^^]` will match any character except `'^'`. `^` has no special meaning if it's not the first character in the set.
- To match a literal `']'` inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[()[\]{}]` and `[]()[{}]` will match a right bracket, as well as left bracket, braces, and parentheses.
- Support of nested sets and set operations as in Unicode Technical Standard #18 might be added in the future. This would change the syntax, so to facilitate this change a *FutureWarning* will be raised in ambiguous cases for the time being. That includes sets starting with a literal `'['` or containing literal character sequences `'--'`, `'&&'`, `'~~'`, and `'||'`. To avoid a warning escape them with a backslash.

在 3.7 版的變更: *FutureWarning* is raised if a character set contains constructs that will change semantically in the future.

|

`A|B`, where *A* and *B* can be arbitrary REs, creates a regular expression that will match either *A* or *B*. An arbitrary number of REs can be separated by the `'|'` in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by `'|'` are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once *A* matches, *B* will not be tested further, even if it would produce a longer overall match. In other words, the `'|'` operator is never greedy. To match a literal `'|'`, use `\|`, or enclose it inside a character class, as in `[|]`.

(...)

Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string with the `\number` special sequence, described below. To match the literals `'('` or `')'`, use `\(` or `\)`, or enclose them inside a character class: `[(]`, `[)]`.

(?...)

This is an extension notation (a `'?'` following a `'('` is not meaningful otherwise). The first character after the `'?'` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; `(?P<name>...)` is the only exception to this rule. Following are the currently supported extensions.

(?aiLmsux)

(One or more letters from the set `'a'`, `'i'`, `'L'`, `'m'`, `'s'`, `'u'`, `'x'`.) The group matches the empty string; the letters set the corresponding flags for the entire regular expression:

- *re.A* (ASCII-only matching)
- *re.I* (ignore case)
- *re.L* (locale dependent)
- *re.M* (multi-line)
- *re.S* (dot matches all)

- *re.U* (Unicode matching)
- *re.X* (verbose)

(The flags are described in 模組𝔽容.) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the *re.compile()* function. Flags should be used first in the expression string.

在 3.11 版的變更: This construction can only be used at the start of the expression.

(?:...)
A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

(?aiLmsux-imsx:...)
(Zero or more letters from the set `'a'`, `'i'`, `'L'`, `'m'`, `'s'`, `'u'`, `'x'`, optionally followed by `'-'` followed by one or more letters from the `'i'`, `'m'`, `'s'`, `'x'`.) The letters set or remove the corresponding flags for the part of the expression:

- *re.A* (ASCII-only matching)
- *re.I* (ignore case)
- *re.L* (locale dependent)
- *re.M* (multi-line)
- *re.S* (dot matches all)
- *re.U* (Unicode matching)
- *re.X* (verbose)

(The flags are described in 模組𝔽容.)

The letters `'a'`, `'L'` and `'u'` are mutually exclusive when used as inline flags, so they can't be combined or follow `'-'`. Instead, when one of them appears in an inline group, it overrides the matching mode in the enclosing group. In Unicode patterns `(?a:...)` switches to ASCII-only matching, and `(?u:...)` switches to Unicode matching (default). In bytes patterns `(?L:...)` switches to locale dependent matching, and `(?a:...)` switches to ASCII-only matching (default). This override is only in effect for the narrow inline group, and the original matching mode is restored outside of the group.

在 3.6 版被加入.

在 3.7 版的變更: The letters `'a'`, `'L'` and `'u'` also can be used in a group.

(?>...)
Attempts to match `...` as if it was a separate regular expression, and if successful, continues to match the rest of the pattern following it. If the subsequent pattern fails to match, the stack can only be unwound to a point *before* the `(?>...)` because once exited, the expression, known as an *atomic group*, has thrown away all stack points within itself. Thus, `(?>.*).` would never match anything because first the `.*` would match all characters possible, then, having nothing left to match, the final `.` would fail to match. Since there are no stack points saved in the Atomic Group, and there is no stack point before it, the entire expression would thus fail to match.

在 3.11 版被加入.

(?P<name>...)
Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and in *bytes* patterns they can only contain bytes in the ASCII range. Each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is `(?P<quote>['"]).*?(?P=quote)` (i.e. matching a string quoted with either single or double quotes):

Context of reference to group "quote"	Ways to reference it
in the same pattern itself	• `(?P=quote)` (as shown) • `\1`
when processing match object *m*	• `m.group('quote')` • `m.end('quote')` (etc.)
in a string passed to the *repl* argument of `re.sub()`	• `\g<quote>` • `\g<1>` • `\1`

在 3.12 版的變更: In *bytes* patterns, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

(?P=name)
A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

(?#...)
A comment; the contents of the parentheses are simply ignored.

(?=...)
Matches if `...` matches next, but doesn't consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match `'Isaac '` only if it's followed by `'Asimov'`.

(?!...)
Matches if `...` doesn't match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match `'Isaac '` only if it's *not* followed by `'Asimov'`.

(?<=...)
Matches if the current position in the string is preceded by a match for `...` that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in `'abcdef'`, since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the *search()* function rather than the *match()* function:

```
>>> import re
>>> m = re.search('(?<=abc)def', 'abcdef')
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search(r'(?<=-)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

在 3.5 版的變更: Added support for group references of fixed length.

(?<!...)
Matches if the current position in the string is not preceded by a match for `...`. This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

(?(id/name)yes-pattern|no-pattern)
Will try to match with `yes-pattern` if the group with given *id* or *name* exists, and with `no-pattern` if it doesn't. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@\w+(?:\.\w+)+)(?(1)>|$)` is a poor email matching pattern, which will match with `'<user@host.com>'` as well as `'user@host.com'`, but not with `'<user@host.com'` nor `'user@host.com>'`.

在 3.12 版的變更: Group *id* can only contain ASCII digits. In *bytes* patterns, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not an ASCII digit or an ASCII letter, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

\number
Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+) \1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'['` and `']'` of a character class, all numeric escapes are treated as characters.

\A
Matches only at the start of the string.

\b
Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of word characters. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning or end of the string. This means that `r'\bat\b'` matches `'at'`, `'at.'`, `'(at)'`, and `'as at ay'` but not `'attempt'` or `'atlas'`.

The default word characters in Unicode (str) patterns are Unicode alphanumerics and the underscore, but this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

> **備🄵**
>
> Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

\B
Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'at\B'` matches `'athens'`, `'atom'`, `'attorney'`, but not `'at'`, `'at.'`, or `'at!'`. `\B` is the opposite of `\b`, so word characters in Unicode (str) patterns are Unicode alphanumerics or the underscore, although this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

\d

For Unicode (str) patterns:
Matches any Unicode decimal digit (that is, any character in Unicode character category [Nd]). This includes `[0-9]`, and also many other digit characters.

Matches `[0-9]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:
Matches any decimal digit in the ASCII character set; this is equivalent to `[0-9]`.

\D
Matches any character which is not a decimal digit. This is the opposite of `\d`.

Matches `[^0-9]` if the *ASCII* flag is used.

\s

For Unicode (str) patterns:
Matches Unicode whitespace characters (which includes `[ \t\n\r\f\v]`, and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages).

Matches `[ \t\n\r\f\v]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:
Matches characters considered whitespace in the ASCII character set; this is equivalent to `[ \t\n\r\f\v]`.

\S

Matches any character which is not a whitespace character. This is the opposite of `\s`.

Matches `[^ \t\n\r\f\v]` if the *ASCII* flag is used.

\w

For Unicode (str) patterns:
Matches Unicode word characters; this includes all Unicode alphanumeric characters (as defined by *str.isalnum()*), as well as the underscore (_).

Matches `[a-zA-Z0-9_]` if the *ASCII* flag is used.

For 8-bit (bytes) patterns:
Matches characters considered alphanumeric in the ASCII character set; this is equivalent to `[a-zA-Z0-9_]`. If the *LOCALE* flag is used, matches characters considered alphanumeric in the current locale and the underscore.

\W

Matches any character which is not a word character. This is the opposite of `\w`. By default, matches non-underscore (_) characters for which *str.isalnum()* returns `False`.

Matches `[^a-zA-Z0-9_]` if the *ASCII* flag is used.

If the *LOCALE* flag is used, matches characters which are neither alphanumeric in the current locale nor the underscore.

\Z

Matches only at the end of the string.

Most of the escape sequences supported by Python string literals are also accepted by the regular expression parser:

```
\a      \b      \f      \n
\N      \r      \t      \u
\U      \v      \x      \\
```

(Note that `\b` is used to represent word boundaries, and means ”backspace” only inside character classes.)

`'\u'`, `'\U'`, and `'\N'` escape sequences are only recognized in Unicode (str) patterns. In bytes patterns they are errors. Unknown escapes of ASCII letters are reserved for future use and treated as errors.

Octal escapes are included in a limited form. If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

在 3.3 版的變更: The `'\u'` and `'\U'` escape sequences have been added.

在 3.6 版的變更: Unknown escapes consisting of `'\'` and an ASCII letter now are errors.

在 3.8 版的變更: The `'\N{name}'` escape sequence has been added. As in string literals, it expands to the named Unicode character (e.g. `'\N{EM DASH}'`).

6.2.2 模組🄵容

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

Flags

在 3.6 版的變更: Flag constants are now instances of *RegexFlag*, which is a subclass of *enum.IntFlag*.

class re.**RegexFlag**

An *enum.IntFlag* class containing the regex options listed below.

在 3.11 版被加入: - added to __all__

re.**A**

re.**ASCII**

Make \w, \W, \b, \B, \d, \D, \s and \S perform ASCII-only matching instead of full Unicode matching. This is only meaningful for Unicode (str) patterns, and is ignored for bytes patterns.

Corresponds to the inline flag (?a).

> **備🄵**
>
> The *U* flag still exists for backward compatibility, but is redundant in Python 3 since matches are Unicode by default for str patterns, and Unicode matching isn't allowed for bytes patterns. *UNICODE* and the inline flag (?u) are similarly redundant.

re.**DEBUG**

Display debug information about compiled expression.

No corresponding inline flag.

re.**I**

re.**IGNORECASE**

Perform case-insensitive matching; expressions like [A-Z] will also match lowercase letters. Full Unicode matching (such as Ü matching ü) also works unless the *ASCII* flag is used to disable non-ASCII matches. The current locale does not change the effect of this flag unless the *LOCALE* flag is also used.

Corresponds to the inline flag (?i).

Note that when the Unicode patterns [a-z] or [A-Z] are used in combination with the *IGNORECASE* flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: 'İ' (U+0130, Latin capital letter I with dot above), 'ı' (U+0131, Latin small letter dotless i), 'ſ' (U+017F, Latin small letter long s) and 'K' (U+212A, Kelvin sign). If the *ASCII* flag is used, only letters 'a' to 'z' and 'A' to 'Z' are matched.

re.**L**

re.**LOCALE**

Make \w, \W, \b, \B and case-insensitive matching dependent on the current locale. This flag can be used only with bytes patterns.

Corresponds to the inline flag (?L).

警告

This flag is discouraged; consider Unicode matching instead. The locale mechanism is very unreliable as it only handles one "culture" at a time and only works with 8-bit locales. Unicode matching is enabled by default for Unicode (str) patterns and it is able to handle different locales and languages.

在 3.6 版的變更: *LOCALE* can be used only with bytes patterns and is not compatible with *ASCII*.

在 3.7 版的變更: Compiled regular expression objects with the *LOCALE* flag no longer depend on the locale at compile time. Only the locale at matching time affects the result of matching.

re.**M**

re.**MULTILINE**

When specified, the pattern character `'^'` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `'$'` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `'^'` matches only at the beginning of the string, and `'$'` only at the end of the string and immediately before the newline (if any) at the end of the string.

Corresponds to the inline flag `(?m)`.

re.**NOFLAG**

Indicates no flag being applied, the value is `0`. This flag may be used as a default value for a function keyword argument or as a base value that will be conditionally ORed with other flags. Example of use as a default value:

```
def myfunc(text, flag=re.NOFLAG):
    return re.match(text, flag)
```

在 3.11 版被加入.

re.**S**

re.**DOTALL**

Make the `'.'` special character match any character at all, including a newline; without this flag, `'.'` will match anything *except* a newline.

Corresponds to the inline flag `(?s)`.

re.**U**

re.**UNICODE**

In Python 3, Unicode characters are matched by default for `str` patterns. This flag is therefore redundant with **no effect** and is only kept for backward compatibility.

See *ASCII* to restrict matching to ASCII characters instead.

re.**X**

re.**VERBOSE**

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored, except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. For example, `(? :` and `* ?` are not allowed. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d +  # the integral part
                   \.    # the decimal point
```

(繼續下一頁)

(繼續上一頁)

```
                    \d *  # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

Corresponds to the inline flag `(?x)`.

Functions

`re.`**`compile`**(*pattern*, *flags=0*)

Compile a regular expression pattern into a *regular expression object*, which can be used for matching using its `match()`, `search()` and other methods, described below.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

The sequence

```
prog = re.compile(pattern)
result = prog.match(string)
```

等價於:

```
result = re.match(pattern, string)
```

but using `re.compile()` and saving the resulting regular expression object for reuse is more efficient when the expression will be used several times in a single program.

備🄵

The compiled versions of the most recent patterns passed to `re.compile()` and the module-level matching functions are cached, so programs that use only a few regular expressions at a time needn't worry about compiling regular expressions.

`re.`**`search`**(*pattern*, *string*, *flags=0*)

Scan through *string* looking for the first location where the regular expression *pattern* produces a match, and return a corresponding `Match`. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

`re.`**`match`**(*pattern*, *string*, *flags=0*)

If zero or more characters at the beginning of *string* match the regular expression *pattern*, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

Note that even in `MULTILINE` mode, `re.match()` will only match at the beginning of the string and not at the beginning of each line.

If you want to locate a match anywhere in *string*, use `search()` instead (see also *search() vs. match()*).

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

re.**fullmatch**(*pattern*, *string*, *flags=0*)

If the whole *string* matches the regular expression *pattern*, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

在 3.4 版被加入.

re.**split**(*pattern*, *string*, *maxsplit=0*, *flags=0*)

Split *string* by the occurrences of *pattern*. If capturing parentheses are used in *pattern*, then the text of all groups in the pattern are also returned as part of the resulting list. If *maxsplit* is nonzero, at most *maxsplit* splits occur, and the remainder of the string is returned as the final element of the list.

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', ', ', 'words', ', ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', 1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

If there are capturing groups in the separator and it matches at the start of the string, the result will start with an empty string. The same holds for the end of the string:

```
>>> re.split(r'(\W+)', '...words, words...')
['', '...', 'words', ', ', 'words', '...', '']
```

That way, separator components are always found at the same relative indices within the result list.

Empty matches for the pattern split the string only when not adjacent to a previous empty match.

```
>>> re.split(r'\b', 'Words, words, words.')
['', 'Words', ', ', 'words', ', ', 'words', '.']
>>> re.split(r'\W*', '...words...')
['', '', 'w', 'o', 'r', 'd', 's', '', '']
>>> re.split(r'(\W*)', '...words...')
['', '...', '', '', 'w', '', 'o', '', 'r', '', 'd', '', 's', '...', '', '', '']
```

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

在 3.1 版的變更: 新增可選的旗標引數。

在 3.7 版的變更: Added support of splitting on a pattern that could match an empty string.

re.**findall**(*pattern*, *string*, *flags=0*)

Return all non-overlapping matches of *pattern* in *string*, as a list of strings or tuples. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The result depends on the number of capturing groups in the pattern. If there are no groups, return a list of strings matching the whole pattern. If there is exactly one group, return a list of strings matching that group. If multiple groups are present, return a list of tuples of strings matching the groups. Non-capturing groups do not affect the form of the result.

```
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
```

(繼續下一頁)

(繼續上一頁)

```
>>> re.findall(r'(\w+)=(\d+)', 'set width=20 and height=10')
[('width', '20'), ('height', '10')]
```

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

在 3.7 版的變更: Non-empty matches can now start just after a previous empty match.

`re.`**`finditer`**(*pattern*, *string*, *flags=0*)

Return an *iterator* yielding `Match` objects over all non-overlapping matches for the RE *pattern* in *string*. The *string* is scanned left-to-right, and matches are returned in the order found. Empty matches are included in the result.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

在 3.7 版的變更: Non-empty matches can now start just after a previous empty match.

`re.`**`sub`**(*pattern*, *repl*, *string*, *count=0*, *flags=0*)

Return the string obtained by replacing the leftmost non-overlapping occurrences of *pattern* in *string* by the replacement *repl*. If the pattern isn't found, *string* is returned unchanged. *repl* can be a string or a function; if it is a string, any backslash escapes in it are processed. That is, `\n` is converted to a single newline character, `\r` is converted to a carriage return, and so forth. Unknown escapes of ASCII letters are reserved for future use and treated as errors. Other unknown escapes such as `\&` are left alone. Backreferences, such as `\6`, are replaced with the substring matched by group 6 in the pattern. For example:

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*\(\s*\):',
...        r'static PyObject*\npy_\1(void)\n{',
...        'def myfunc():')
'static PyObject*\npy_myfunc(void)\n{'
```

If *repl* is a function, it is called for every non-overlapping occurrence of *pattern*. The function takes a single `Match` argument, and returns the replacement string. For example:

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
...
>>> re.sub('-{1,2}', dashrepl, 'pro----gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

The pattern may be a string or a `Pattern`.

The optional argument *count* is the maximum number of pattern occurrences to be replaced; *count* must be a non-negative integer. If omitted or zero, all occurrences will be replaced. Empty matches for the pattern are replaced only when not adjacent to a previous empty match, so `sub('x*', '-', 'abxd')` returns `'-a-b--d-'`.

In string-type *repl* arguments, in addition to the character escapes and backreferences described above, `\g<name>` will use the substring matched by the group named `name`, as defined by the `(?P<name>...)` syntax. `\g<number>` uses the corresponding group number; `\g<2>` is therefore equivalent to `\2`, but isn't ambiguous in a replacement such as `\g<2>0`. `\20` would be interpreted as a reference to group 20, not a reference to group 2 followed by the literal character `'0'`. The backreference `\g<0>` substitutes in the entire substring matched by the RE.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

在 3.1 版的變更: 新增可選的旗標引數。

在 3.5 版的變更: Unmatched groups are replaced with an empty string.

在 3.6 版的變更: Unknown escapes in *pattern* consisting of `'\'` and an ASCII letter now are errors.

在 3.7 版的變更: Unknown escapes in *repl* consisting of `'\'` and an ASCII letter now are errors.

在 3.7 版的變更: Empty matches for the pattern are replaced when adjacent to a previous non-empty match.

在 3.12 版的變更: Group *id* can only contain ASCII digits. In *bytes* replacement strings, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

`re.`**`subn`**(*pattern*, *repl*, *string*, *count=0*, *flags=0*)

Perform the same operation as *sub()*, but return a tuple `(new_string, number_of_subs_made)`.

在 3.1 版的變更: 新增可選的旗標引數。

在 3.5 版的變更: Unmatched groups are replaced with an empty string.

The expression's behaviour can be modified by specifying a *flags* value. Values can be any of the *flags* variables, combined using bitwise OR (the `|` operator).

`re.`**`escape`**(*pattern*)

Escape special characters in *pattern*. This is useful if you want to match an arbitrary literal string that may have regular expression metacharacters in it. For example:

```
>>> print(re.escape('https://www.python.org'))
https://www\.python\.org

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789!\#\$%\&'\*\+\-\.\^_`\|\~:]+

>>> operators = ['+', '-', '*', '/', '**']
>>> print('|'.join(map(re.escape, sorted(operators, reverse=True))))
/|\-|\+|\*\*|\*
```

This function must not be used for the replacement string in *sub()* and *subn()*, only backslashes should be escaped. For example:

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\\', r'\\'), sample))
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

在 3.3 版的變更: The `'_'` character is no longer escaped.

在 3.7 版的變更: Only characters that can have special meaning in a regular expression are escaped. As a result, `'!'`, `'"'`, `'%'`, `"'"`, `','`, `'/'`, `':'`, `';'`, `'<'`, `'='`, `'>'`, `'@'`, and `"`" are no longer escaped.

`re.`**`purge`**()

Clear the regular expression cache.

Exceptions

exception re.**error**(*msg*, *pattern=None*, *pos=None*)

Exception raised when a string passed to one of the functions here is not a valid regular expression (for example, it might contain unmatched parentheses) or when some other error occurs during compilation or matching. It is never an error if a string contains no match for a pattern. The error instance has the following additional attributes:

msg

The unformatted error message.

pattern

The regular expression pattern.

pos

The index in *pattern* where compilation failed (may be `None`).

lineno

The line corresponding to *pos* (may be `None`).

colno

The column corresponding to *pos* (may be `None`).

在 3.5 版的變更: 新增額外屬性。

6.2.3 Regular Expression Objects

class re.**Pattern**

Compiled regular expression object returned by *re.compile()*.

在 3.9 版的變更: *re.Pattern* supports `[]` to indicate a Unicode (str) or bytes pattern. See *Generic Alias Type*.

Pattern.**search**(*string*[, *pos*[, *endpos*]])

Scan through *string* looking for the first location where this regular expression produces a match, and return a corresponding *Match*. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter *pos* gives an index in the string where the search is to start; it defaults to `0`. This is not completely equivalent to slicing the string; the `'^'` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter *endpos* limits how far the string will be searched; it will be as if the string is *endpos* characters long, so only the characters from *pos* to `endpos - 1` will be searched for a match. If *endpos* is less than *pos*, no match will be found; otherwise, if *rx* is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")     # Match at index 0
<re.Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)  # No match; search doesn't include the "d"
```

Pattern.**match**(*string*[, *pos*[, *endpos*]])

If zero or more characters at the *beginning* of *string* match this regular expression, return a corresponding *Match*. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the *search()* method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")      # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)   # Match as "o" is the 2nd character of "dog".
<re.Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in *string*, use `search()` instead (see also *search() vs. match()*).

`Pattern.`**`fullmatch`**(*string*[, *pos*[, *endpos*]])

If the whole *string* matches this regular expression, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional *pos* and *endpos* parameters have the same meaning as for the `search()` method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")      # No match as "o" is not at the start of "dog".
>>> pattern.fullmatch("ogre")     # No match as not the full string matches.
>>> pattern.fullmatch("doggie", 1, 3)   # Matches within given limits.
<re.Match object; span=(1, 3), match='og'>
```

在 3.4 版被加入.

`Pattern.`**`split`**(*string*, *maxsplit=0*)

Identical to the `split()` function, using the compiled pattern.

`Pattern.`**`findall`**(*string*[, *pos*[, *endpos*]])

Similar to the `findall()` function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for `search()`.

`Pattern.`**`finditer`**(*string*[, *pos*[, *endpos*]])

Similar to the `finditer()` function, using the compiled pattern, but also accepts optional *pos* and *endpos* parameters that limit the search region like for `search()`.

`Pattern.`**`sub`**(*repl*, *string*, *count=0*)

Identical to the `sub()` function, using the compiled pattern.

`Pattern.`**`subn`**(*repl*, *string*, *count=0*)

Identical to the `subn()` function, using the compiled pattern.

`Pattern.`**`flags`**

The regex matching flags. This is a combination of the flags given to `compile()`, any `(?...)` inline flags in the pattern, and implicit flags such as `UNICODE` if the pattern is a Unicode string.

`Pattern.`**`groups`**

The number of capturing groups in the pattern.

`Pattern.`**`groupindex`**

A dictionary mapping any symbolic group names defined by `(?P<id>)` to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

`Pattern.`**`pattern`**

The pattern string from which the pattern object was compiled.

在 3.7 版的變更: Added support of `copy.copy()` and `copy.deepcopy()`. Compiled regular expression objects are considered atomic.

6.2.4 Match Objects

Match objects always have a boolean value of `True`. Since *match()* and *search()* return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

class re.**Match**

Match object returned by successful `match`es and `search`es.

在 3.9 版的變更: *re.Match* supports `[]` to indicate a Unicode (str) or bytes match. See *Generic Alias Type*.

Match.**expand**(*template*)

Return the string obtained by doing backslash substitution on the template string *template*, as done by the *sub()* method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group. The backreference `\g<0>` will be replaced by the entire match.

在 3.5 版的變更: Unmatched groups are replaced with an empty string.

Match.**group**([*group1*, ...])

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, *group1* defaults to zero (the whole match is returned). If a *groupN* argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range [1..99], it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an *IndexError* exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)       # The entire match
'Isaac Newton'
>>> m.group(1)       # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)       # The second parenthesized subgroup.
'Newton'
>>> m.group(1, 2)    # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the *groupN* arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an *IndexError* exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
```

(繼續下一頁)

(繼續上一頁)

```
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(..)+", "a1b2c3")  # Matches 3 times.
>>> m.group(1)                        # Returns only the last match.
'c3'
```

`Match.__getitem__`(*g*)

This is identical to `m.group(g)`. This allows easier access to an individual group from a match:

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]       # The entire match
'Isaac Newton'
>>> m[1]       # The first parenthesized subgroup.
'Isaac'
>>> m[2]       # The second parenthesized subgroup.
'Newton'
```

Named groups are supported as well:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Isaac Newton")
>>> m['first_name']
'Isaac'
>>> m['last_name']
'Newton'
```

在 3.6 版被加入.

`Match.groups`(*default=None*)

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to `None`.

舉例來🄵:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to `None` unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(\d+)?", "24")
>>> m.groups()      # Second group defaults to None.
('24', None)
>>> m.groups('0')   # Now, the second group defaults to '0'.
('24', '0')
```

`Match.groupdict`(*default=None*)

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it defaults to `None`. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

Match.**start**([*group*])

Match.**end**([*group*])

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return `-1` if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to `m.group(g)`) is

```
m.string[m.start(g):m.end(g)]
```

Note that `m.start(group)` will equal `m.end(group)` if *group* matched a null string. For example, after `m = re.search('b(c?)', 'cba')`, `m.start(0)` is 1, `m.end(0)` is 2, `m.start(1)` and `m.end(1)` are both 2, and `m.start(2)` raises an *IndexError* exception.

An example that will remove *remove_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

Match.**span**([*group*])

For a match *m*, return the 2-tuple `(m.start(group), m.end(group))`. Note that if *group* did not contribute to the match, this is `(-1, -1)`. *group* defaults to zero, the entire match.

Match.**pos**

The value of *pos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string at which the RE engine started looking for a match.

Match.**endpos**

The value of *endpos* which was passed to the *search()* or *match()* method of a *regex object*. This is the index into the string beyond which the RE engine will not go.

Match.**lastindex**

The integer index of the last matched capturing group, or `None` if no group was matched at all. For example, the expressions `(a)b`, `((a)(b))`, and `((ab))` will have `lastindex == 1` if applied to the string `'ab'`, while the expression `(a)(b)` will have `lastindex == 2`, if applied to the same string.

Match.**lastgroup**

The name of the last matched capturing group, or `None` if the group didn't have a name, or if no group was matched at all.

Match.**re**

The *regular expression object* whose *match()* or *search()* method produced this match instance.

Match.**string**

The string passed to *match()* or *search()*.

在 3.7 版的變更: Added support of *copy.copy()* and *copy.deepcopy()*. Match objects are considered atomic.

6.2.5 Regular Expression Examples

Checking for a Pair

In this example, we'll use the following helper function to display match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, "a" for ace, "k" for king, "q" for queen, "j" for jack, "t" for 10, and "2" through "9" representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q"))  # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e"))  # Invalid.
>>> displaymatch(valid.match("akt"))    # Invalid.
>>> displaymatch(valid.match("727ak"))  # Valid.
"<Match: '727ak', groups=()>"
```

That last hand, `"727ak"`, contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r".*(.).*\1")
>>> displaymatch(pair.match("717ak"))     # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak"))     # No pairs.
>>> displaymatch(pair.match("354aa"))     # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the *group()* method of the match object in the following manner:

```
>>> pair = re.compile(r".*(.).*\1")
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    re.match(r".*(.).*\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

Simulating scanf()

Python does not currently have an equivalent to `scanf()`. Regular expressions are generally more powerful, though also more verbose, than `scanf()` format strings. The table below offers some more-or-less equivalent mappings between `scanf()` format tokens and regular expressions.

`scanf()` Token	Regular Expression
`%c`	`.`
`%5c`	`.{5}`
`%d`	`[-+]?\d+`
`%e, %E, %f, %g`	`[-+]?(\d+(\.\d*)?|\.\d+)([eE][-+]?\d+)?`
`%i`	`[-+]?(0[xX][\dA-Fa-f]+|0[0-7]*|\d+)`
`%o`	`[-+]?[0-7]+`
`%s`	`\S+`
`%u`	`\d+`
`%x、%X`	`[-+]?(0[xX])?[\dA-Fa-f]+`

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a `scanf()` format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

search() vs. match()

Python offers different primitive operations based on regular expressions:

- *re.match()* checks for a match only at the beginning of the string
- *re.search()* checks for a match anywhere in the string (this is what Perl does by default)
- *re.fullmatch()* checks for entire string to be a match

舉例來🄵:

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("c", "abcdef")   # Match
<re.Match object; span=(2, 3), match='c'>
>>> re.fullmatch("p.*n", "python") # Match
<re.Match object; span=(0, 6), match='python'>
>>> re.fullmatch("r.*n", "python") # No match
```

Regular expressions beginning with `'^'` can be used with *search()* to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef")    # No match
>>> re.search("^c", "abcdef")  # No match
>>> re.search("^a", "abcdef")  # Match
<re.Match object; span=(0, 1), match='a'>
```

Note however that in *MULTILINE* mode *match()* only matches at the beginning of the string, whereas using *search()* with a regular expression beginning with `'^'` will match at the beginning of each line.

```
>>> re.match("X", "A\nB\nX", re.MULTILINE)  # No match
>>> re.search("^X", "A\nB\nX", re.MULTILINE)  # Match
<re.Match object; span=(4, 5), match='X'>
```

Making a Phonebook

split() splits a string into a list delimited by the passed pattern. The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
'Frank Burger: 925.541.7625 662 South Dogwood Way',
'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of *split()* because the address has spaces, our splitting pattern, in it:

```
>>> [re.split(":? ", entry, 3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `:?` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of `4`, we could separate the house number from the street name:

```
>>> [re.split(":? ", entry, 4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

Text Munging

sub() replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using *sub()* with a function to ”munge” text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
...
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlobdk, pslaee reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reoprt yuor asnebces potlmrpy.'
```

Finding all Adverbs

findall() matches *all* occurrences of a pattern, not just the first one as *search()* does. For example, if a writer wanted to find all of the adverbs in some text, they might use *findall()* in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly\b", text)
['carefully', 'quickly']
```

Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, *finditer()* is useful as it provides *Match* objects instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use *finditer()* in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly\b", text):
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group(0)))
07-16: carefully
40-47: quickly
```

Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
>>> re.match("\\W(.)\\1\\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\\"`. Without raw string notation, one must use `"\\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
>>> re.match("\\\\", r"\\")
<re.Match object; span=(0, 1), match='\\'>
```

Writing a Tokenizer

A tokenizer or scanner analyzes a string to categorize groups of characters. This is a useful first step in writing a compiler or interpreter.

The text categories are specified with regular expressions. The technique is to combine those into a single master regular expression and to loop over successive matches:

```
from typing import NamedTuple
import re

class Token(NamedTuple):
    type: str
    value: str
    line: int
    column: int

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOSUB', 'RETURN'}
    token_specification = [
        ('NUMBER',   r'\d+(\.\d*)?'),  # Integer or decimal number
        ('ASSIGN',   r':='),           # Assignment operator
        ('END',      r';'),            # Statement terminator
        ('ID',       r'[A-Za-z]+'),    # Identifiers
        ('OP',       r'[+\-*/]'),      # Arithmetic operators
        ('NEWLINE',  r'\n'),           # Line endings
        ('SKIP',     r'[ \t]+'),       # Skip over spaces and tabs
        ('MISMATCH', r'.'),            # Any other character
    ]
    tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
    line_num = 1
    line_start = 0
    for mo in re.finditer(tok_regex, code):
        kind = mo.lastgroup
        value = mo.group()
        column = mo.start() - line_start
        if kind == 'NUMBER':
            value = float(value) if '.' in value else int(value)
        elif kind == 'ID' and value in keywords:
            kind = value
        elif kind == 'NEWLINE':
            line_start = mo.end()
            line_num += 1
            continue
        elif kind == 'SKIP':
            continue
        elif kind == 'MISMATCH':
            raise RuntimeError(f'{value!r} unexpected on line {line_num}')
        yield Token(kind, value, line_num, column)

statements = '''
```

(繼續下一頁)

(繼續上一頁)

```
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)
```

The tokenizer produces the following output:

```
Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=', line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=', line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)
```

6.3 difflib --- 計算差🄵的輔助工具

原始碼： Lib/difflib.py

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce information about file differences in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the *filecmp* module.

class difflib.**SequenceMatcher**

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name "gestalt pattern matching." The idea is to find the longest contiguous matching subsequence that contains no "junk" elements; these "junk" elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that "look right" to people.

Timing: The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. *SequenceMatcher* is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

Automatic junk heuristic: `SequenceMatcher` supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as "popular" and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the `SequenceMatcher`.

在 3.2 版的變更: 新增 *autojunk* 參數。

class difflib.**Differ**

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. Differ uses `SequenceMatcher` both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a `Differ` delta begins with a two-letter code:

Code	Meaning
`'- '`	line unique to sequence 1
`'+ '`	line unique to sequence 2
`'  '`	line common to both sequences
`'? '`	line not present in either input sequence

Lines beginning with '?' attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain whitespace characters, such as spaces, tabs or line breaks.

class difflib.**HtmlDiff**

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

__init__(*tabsize=8*, *wrapcolumn=None*, *linejunk=None*, *charjunk=IS_CHARACTER_JUNK*)

Initializes instance of `HtmlDiff`.

tabsize is an optional keyword argument to specify tab stop spacing and defaults to `8`.

wrapcolumn is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

linejunk and *charjunk* are optional keyword arguments passed into `ndiff()` (used by `HtmlDiff` to generate the side by side HTML differences). See `ndiff()` documentation for argument default values and descriptions.

The following methods are public:

make_file(*fromlines*, *tolines*, *fromdesc=''*, *todesc=''*, *context=False*, *numlines=5*, ***, *charset='utf-8'*)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

fromdesc and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

context and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to `5`. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using

the ”next” hyperlinks (setting to zero would cause the ”next” hyperlinks to place the next difference highlight at the top of the browser without any leading context).

備🄵

fromdesc and *todesc* are interpreted as unescaped HTML and should be properly escaped while receiving input from untrusted sources.

在 3.5 版的變更: *charset* keyword-only argument was added. The default charset of HTML document changed from `'ISO-8859-1'` to `'utf-8'`.

make_table(*fromlines*, *tolines*, *fromdesc=”*, *todesc=”*, *context=False*, *numlines=5*)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the *make_file()* method.

difflib.**context_diff**(*a*, *b*, *fromfile=”*, *tofile=”*, *fromfiledate=”*, *tofiledate=”*, *n=3*, *lineterm='\n'*)

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from *io.IOBase.readlines()* result in diffs that are suitable for use with *io.IOBase.writelines()* since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `""` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> import sys
>>> from difflib import *
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py',
...                       tofile='after.py'))
*** before.py
--- after.py
***************
*** 1,4 ****
! bacon
! eggs
! ham
  guido
--- 1,4 ----
! python
! eggy
! hamster
  guido
```

一個更詳盡的範例請見*A command-line interface to difflib*。

difflib.**get_close_matches**(*word*, *possibilities*, *n=3*, *cutoff=0.6*)

Return a list of the best "good enough" matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default `3`) is the maximum number of close matches to return; *n* must be greater than `0`.

Optional argument *cutoff* (default `0.6`) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```
>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']
```

difflib.**ndiff**(*a*, *b*, *linejunk=None*, *charjunk=IS_CHARACTER_JUNK*)

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or `None`):

linejunk: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is `None`. There is also a module-level function *IS_LINE_JUNK()*, which filters out lines without visible characters, except for at most one pound character (`'#'`) -- however the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

charjunk: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function *IS_CHARACTER_JUNK()*, which filters out whitespace characters (a blank or tab; it's a bad idea to include newline in this!).

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> print(''.join(diff), end="")
- one
?  ^
+ ore
?  ^
- two
- three
?  -
+ tree
+ emu
```

difflib.**restore**(*sequence*, *which*)

Return one of the two sequences that generated a delta.

Given a *sequence* produced by *Differ.compare()* or *ndiff()*, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

範例:

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...              'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print(''.join(restore(diff, 1)), end="")
one
two
three
>>> print(''.join(restore(diff, 2)), end="")
ore
tree
emu
```

difflib.**unified_diff**(*a*, *b*, *fromfile=''*, *tofile=''*, *fromfiledate=''*, *tofiledate=''*, *n=3*, *lineterm='\n'*)

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `---`, `+++`, or `@@`) are created with a trailing newline. This is helpful so that inputs created from *io.IOBase.readlines()* result in diffs that are suitable for use with *io.IOBase.writelines()* since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `""` so that the output will be uniformly newline free.

The unified diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile=
↪'after.py'))
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon

 guido
```

一個更詳盡的範例請見*A command-line interface to difflib*。

difflib.**diff_bytes**(*dfunc*, *a*, *b*, *fromfile=b''*, *tofile=b''*, *fromfiledate=b''*, *tofiledate=b''*, *n=3*, *lineterm=b'\n'*)

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either *unified_diff()* or *context_diff()*.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile, tofile, fromfiledate, tofiledate, n, lineterm)`. The output of *dfunc* is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as *a* and *b*.

在 3.5 版被加入.

difflib.**IS_LINE_JUNK**(*line*)

Return `True` for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single `'#'`, otherwise it is not ignorable. Used as a default for parameter *linejunk* in *ndiff()* in older versions.

difflib.**IS_CHARACTER_JUNK**(*ch*)

Return `True` for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in *ndiff()*.

也參考

Pattern Matching: The Gestalt Approach
Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in Dr. Dobb's Journal in July, 1988.

6.3.1 SequenceMatcher 物件

The *SequenceMatcher* class has this constructor:

class difflib.**SequenceMatcher**(*isjunk=None*, *a=''*, *b=''*, *autojunk=True*)

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is "junk" and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: False`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

在 3.2 版的變更: 新增 *autojunk* 參數。

SequenceMatcher objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is `True`; *bpopular* is the set of non-junk elements considered popular by the heuristic (if it is not disabled); *b2j* is a dict mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with *set_seqs()* or *set_seq2()*.

在 3.2 版被加入: The *bjunk* and *bpopular* attributes.

SequenceMatcher objects have the following methods:

set_seqs(*a*, *b*)

Set the two sequences to be compared.

SequenceMatcher computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use *set_seq2()* to set the commonly used sequence once and call *set_seq1()* repeatedly, once for each of the other sequences.

set_seq1(*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

set_seq2(*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

find_longest_match(*alo=0*, *ahi=None*, *blo=0*, *bhi=None*)

Find longest matching block in `a[alo:ahi]` and `b[blo:bhi]`.

If *isjunk* was omitted or `None`, *find_longest_match()* returns `(i, j, k)` such that `a[i:i+k]` is equal to `b[j:j+k]`, where `alo <= i <= i+k <= ahi` and `blo <= j <= j+k <= bhi`. For all `(i', j', k')` meeting those conditions, the additional conditions `k >= k'`, `i <= i'`, and if `i == i'`, `j <= j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents `' abcd'` from matching the `' abcd'` at the tail end of the second sequence directly. Instead only the `'abcd'` can match, and matches the leftmost `'abcd'` in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", " abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns `(alo, blo, 0)`.

This method returns a *named tuple* `Match(a, b, size)`.

在 3.9 版的變更: 新增預設引數。

get_matching_blocks()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form `(i, j, n)`, and means that `a[i:i+n] == b[j:j+n]`. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value `(len(a), len(b), 0)`. It is the only triple with `n == 0`. If `(i, j, n)` and `(i', j', n')` are adjacent triples in the list, and the second is not the last triple in the list, then `i+n < i'` or `j+n < j'`; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

get_opcodes()

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form `(tag, i1, i2, j1, j2)`. The first tuple has `i1 == j1 == 0`, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings:

Value	Meaning
`'replace'`	`a[i1:i2]` should be replaced by `b[j1:j2]`.
`'delete'`	`a[i1:i2]` should be deleted. Note that `j1 == j2` in this case.
`'insert'`	`b[j1:j2]` should be inserted at `a[i1:i1]`. Note that `i1 == i2` in this case.
`'equal'`	`a[i1:i2] == b[j1:j2]` (the sub-sequences are equal).

舉例來🄵:

```
>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}   a[{}:{}] --> b[{}:{}] {!r:>8} --> {!r}'.format(
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete    a[0:1] --> b[0:0]      'q' --> ''
equal     a[1:3] --> b[0:2]     'ab' --> 'ab'
replace   a[3:4] --> b[2:3]      'x' --> 'y'
equal     a[4:6] --> b[3:5]     'cd' --> 'cd'
insert    a[6:6] --> b[5:6]       '' --> 'f'
```

get_grouped_opcodes(*n=3*)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by *get_opcodes()*, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as *get_opcodes()*.

ratio()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is 2.0*M / T. Note that this is `1.0` if the sequences are identical, and `0.0` if they have nothing in common.

This is expensive to compute if *get_matching_blocks()* or *get_opcodes()* hasn't already been called, in which case you may want to try *quick_ratio()* or *real_quick_ratio()* first to get an upper bound.

備🄵

Caution: The result of a *ratio()* call may depend on the order of the arguments. For instance:

```
>>> SequenceMatcher(None, 'tide', 'diet').ratio()
0.25
>>> SequenceMatcher(None, 'diet', 'tide').ratio()
0.5
```

quick_ratio()

Return an upper bound on *ratio()* relatively quickly.

real_quick_ratio()

Return an upper bound on *ratio()* very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although *quick_ratio()* and *real_quick_ratio()* are always at least as large as *ratio()*:

```
>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0
```

6.3.2 SequenceMatcher 范例

This example compares two strings, considering blanks to be "junk":

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                     "private Thread currentThread;",
...                     "private volatile Thread currentThread;")
```

ratio() returns a float in [0, 1], measuring the similarity of the sequences. As a rule of thumb, a *ratio()* value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you're only interested in where the sequences match, *get_matching_blocks()* is handy:

```
>>> for block in s.get_matching_blocks():
...     print("a[%d] and b[%d] match for %d elements" % block)
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by *get_matching_blocks()* is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is `0`.

If you want to know how to change the first sequence into the second, use *get_opcodes()*:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
 equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
 equal a[8:29] b[17:38]
```

6.3.3 Differ Objects

Note that *Differ*-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The *Differ* class has this constructor:

class difflib.**Differ**(*linejunk=None*, *charjunk=None*)

Optional keyword parameters *linejunk* and *charjunk* are for filter functions (or `None`):

linejunk: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

charjunk: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the *find_longest_match()* method's *isjunk* parameter for an explanation.

Differ objects are used (deltas generated) via a single method:

compare(*a*, *b*)

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the *readlines()* method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the *writelines()* method of a file-like object.

6.3.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the *readlines()* method of file-like objects):

```
>>> text1 = '''  1. Beautiful is better than ugly.
...   2. Explicit is better than implicit.
...   3. Simple is better than complex.
...   4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = '''  1. Beautiful is better than ugly.
...   3.   Simple is better than complex.
...   4. Complicated is better than complex.
...   5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a Differ object:

```
>>> d = Differ()
```

Note that when instantiating a *Differ* object we may pass functions to filter out line and character "junk." See the *Differ()* constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let's pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
['    1. Beautiful is better than ugly.\n',
 '-   2. Explicit is better than implicit.\n',
 '-   3. Simple is better than complex.\n',
 '+   3.   Simple is better than complex.\n',
 '?     ++\n',
 '-   4. Complex is better than complicated.\n',
 '?            ^                     ---- ^\n',
 '+   4. Complicated is better than complex.\n',
 '?           ++++ ^                     ^\n',
 '+   5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
    1. Beautiful is better than ugly.
-   2. Explicit is better than implicit.
-   3. Simple is better than complex.
+   3.   Simple is better than complex.
?     ++
-   4. Complex is better than complicated.
?           ^                     ---- ^
+   4. Complicated is better than complex.
?          ++++ ^                      ^
+   5. Flat is better than nested.
```

6.3.5 A command-line interface to difflib

This example shows how to use difflib to create a `diff`-like utility.

```
""" Command line interface to difflib.py providing diffs in four formats:

* ndiff:    lists every line and highlights interline changes.
* context:  highlights clusters of changes in a before/after format.
* unified:  highlights clusters of changes in an inline format.
* html:     generates side by side comparison with change highlights.

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                               timezone.utc)
    return t.astimezone().isoformat()

def main():

    parser = argparse.ArgumentParser()
    parser.add_argument('-c', action='store_true', default=False,
                        help='Produce a context format diff (default)')
    parser.add_argument('-u', action='store_true', default=False,
                        help='Produce a unified format diff')
    parser.add_argument('-m', action='store_true', default=False,
                        help='Produce HTML side by side diff '
                             '(can use -c and -l in conjunction)')
    parser.add_argument('-n', action='store_true', default=False,
                        help='Produce a ndiff format diff')
    parser.add_argument('-l', '--lines', type=int, default=3,
                        help='Set number of context lines (default 3)')

↪todate, n=n)

    sys.stdout.writelines(diff)

if __name__ == '__main__':
    main()
```

6.3.6 ndiff 范例:

This example shows how to use *difflib.ndiff()*.

```
"""ndiff [-q] file1 file2
    or
ndiff (-r1 | -r2) < ndiff_output > file1_or_file2

Print a human-friendly file difference report to stdout.  Both inter-
and intra-line differences are noted.  In the second form, recreate file1
(-r1) or file2 (-r2) on stdout, from an ndiff report on stdin.

In the first form, if -q ("quiet") is not specified, the first two lines
of output are

-: file1
+: file2

Each remaining line begins with a two-letter code:

    "- "    line unique to file1
    "+ "    line unique to file2
    "  "    line common to both files
    "? "    line not present in either input file

Lines beginning with "? " attempt to guide the eye to intraline
differences, and were not present in either input file.  These lines can be
confusing if the source files contain tab characters.
```

(繼續下一頁)

(繼續上一頁)

```
The first file can be recovered by retaining only lines that begin with
"  " or "- ", and deleting those 2-character prefixes; use ndiff with -r1.

The second file can be recovered similarly, but by retaining only "  " and
"+ " lines; use ndiff with -r2; or, on Unix, the second file can be
recovered by piping the output through

    sed -n '/^[+ ] /s/^..//p'
"""

6.4 textwrap --- 文字包裝與填充

原始碼： Lib/textwrap.py

The *textwrap* module provides some convenience functions, as well as *TextWrapper*, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of *TextWrapper* for efficiency.

textwrap.**wrap**(*text*, *width=70*, ***, *initial_indent=''*, *subsequent_indent=''*, *expand_tabs=True*, *replace_whitespace=True*, *fix_sentence_endings=False*, *break_long_words=True*, *drop_whitespace=True*, *break_on_hyphens=True*, *tabsize=8*, *max_lines=None*, *placeholder=' [...]'*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of *TextWrapper*, documented below.

See the *TextWrapper.wrap()* method for additional details on how *wrap()* behaves.

textwrap.**fill**(*text*, *width=70*, ***, *initial_indent=''*, *subsequent_indent=''*, *expand_tabs=True*, *replace_whitespace=True*, *fix_sentence_endings=False*, *break_long_words=True*, *drop_whitespace=True*, *break_on_hyphens=True*, *tabsize=8*, *max_lines=None*, *placeholder=' [...]'*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph. `fill()` is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

textwrap.**shorten**(*text*, *width*, *, *fix_sentence_endings=False*, *break_long_words=True*, *break_on_hyphens=True*, *placeholder='[...]'*)

Collapse and truncate the given *text* to fit in the given *width*.

First the whitespace in *text* is collapsed (all whitespace is replaced by single spaces). If the result fits in the *width*, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the *placeholder* fit within *width*:

```
>>> textwrap.shorten("Hello  world!", width=12)
'Hello world!'
>>> textwrap.shorten("Hello  world!", width=11)
'Hello [...]'
>>> textwrap.shorten("Hello world", width=10, placeholder="...")
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below. Note that the whitespace is collapsed before the text is passed to the `TextWrapper` `fill()` function, so changing the value of `tabsize`, `expand_tabs`, `drop_whitespace`, and `replace_whitespace` will have no effect.

在 3.4 版被加入.

textwrap.**dedent**(*text*)

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines `"  hello"` and `"\thello"` are considered to have no common leading whitespace.

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

舉例來🄵:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
    hello
      world
    '''
    print(repr(s))          # prints '    hello\n      world\n    '
    print(repr(dedent(s)))  # prints 'hello\n  world\n'
```

textwrap.**indent**(*text*, *prefix*, *predicate=None*)

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

舉例來🄵:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, '  ')
'  hello\n\n \n  world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
+ world
```

在 3.3 版被加入.

wrap(), *fill()* and *shorten()* work by creating a *TextWrapper* instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using *wrap()* and/or *fill()*, it may be more efficient to create your own *TextWrapper* object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless *TextWrapper.break_long_words* is set to false.

class textwrap.**TextWrapper**(***kwargs*)

The *TextWrapper* constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can reuse the same *TextWrapper* object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The *TextWrapper* instance attributes (and keyword arguments to the constructor) are as follows:

width

(default: `70`) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than *width*, *TextWrapper* guarantees that no output line will be longer than *width* characters.

expand_tabs

(default: `True`) If true, then all tab characters in *text* will be expanded to spaces using the *expandtabs()* method of *text*.

tabsize

(default: `8`) If *expand_tabs* is true, then all tab characters in *text* will be expanded to zero or more spaces, depending on the current column and the given tab size.

在 3.3 版被加入.

replace_whitespace

(default: `True`) If true, after tab expansion but before wrapping, the *wrap()* method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

備🄵

If *expand_tabs* is false and *replace_whitespace* is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

備🄵

If *replace_whitespace* is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using *str.splitlines()* or similar) which are wrapped separately.

drop_whitespace

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

initial_indent

(default: `''`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

subsequent_indent

(default: `''`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

fix_sentence_endings

(default: `False`) If true, *TextWrapper* attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `'!'`, or `'?'`, possibly followed by one of `'"'` or `"'"`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between "Dr." in

```
[...] Dr. Frankenstein's monster [...]
```

and "Spot." in

```
[...] See Spot. See Spot run [...]
```

fix_sentence_endings is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of "lowercase letter", and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

break_long_words

(default: `True`) If true, then words longer than *width* will be broken in order to ensure that no lines are longer than *width*. If it is false, long words will not be broken, and some lines may be longer than *width*. (Long words will be put on a line by themselves, in order to minimize the amount by which *width* is exceeded.)

break_on_hyphens

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set *break_long_words* to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

max_lines

(default: `None`) If not `None`, then the output will contain at most *max_lines* lines, with *placeholder* appearing at the end of the output.

在 3.4 版被加入.

placeholder

(default: `' [...]'`) String that will appear at the end of the output text if it has been truncated.

在 3.4 版被加入.

TextWrapper also provides some public methods, analogous to the module-level convenience functions:

wrap(*text*)

Wraps the single paragraph in *text* (a string) so every line is at most *width* characters long. All wrapping options are taken from instance attributes of the *TextWrapper* instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

fill(*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

6.5 unicodedata --- Unicode 資料庫

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the UCD version 15.0.0.

The module uses the same names and symbols as defined by Unicode Standard Annex #44, "Unicode Character Database". It defines the following functions:

unicodedata.**lookup**(*name*)

Look up character by name. If a character with the given name is found, return the corresponding character. If not found, *KeyError* is raised.

在 3.3 版的變更: Support for name aliases[1] and named sequences[2] has been added.

unicodedata.**name**(*chr*[, *default*])

Returns the name assigned to the character *chr* as a string. If no name is defined, *default* is returned, or, if not given, *ValueError* is raised.

unicodedata.**decimal**(*chr*[, *default*])

Returns the decimal value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

unicodedata.**digit**(*chr*[, *default*])

Returns the digit value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

unicodedata.**numeric**(*chr*[, *default*])

Returns the numeric value assigned to the character *chr* as float. If no such value is defined, *default* is returned, or, if not given, *ValueError* is raised.

[1] https://www.unicode.org/Public/15.0.0/ucd/NameAliases.txt
[2] https://www.unicode.org/Public/15.0.0/ucd/NamedSequences.txt

unicodedata.**category**(*chr*)

Returns the general category assigned to the character *chr* as string.

unicodedata.**bidirectional**(*chr*)

Returns the bidirectional class assigned to the character *chr* as string. If no such value is defined, an empty string is returned.

unicodedata.**combining**(*chr*)

Returns the canonical combining class assigned to the character *chr* as integer. Returns `0` if no combining class is defined.

unicodedata.**east_asian_width**(*chr*)

Returns the east asian width assigned to the character *chr* as string.

unicodedata.**mirrored**(*chr*)

Returns the mirrored property assigned to the character *chr* as integer. Returns `1` if the character has been identified as a "mirrored" character in bidirectional text, `0` otherwise.

unicodedata.**decomposition**(*chr*)

Returns the character decomposition mapping assigned to the character *chr* as string. An empty string is returned in case no such mapping is defined.

unicodedata.**normalize**(*form*, *unistr*)

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U+00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U+0043 (LATIN CAPITAL LETTER C) U+0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U+2160 (ROMAN NUMERAL ONE) is really the same thing as U+0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

unicodedata.**is_normalized**(*form*, *unistr*)

Return whether the Unicode string *unistr* is in the normal form *form*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

在 3.8 版被加入.

In addition, the module exposes the following constant:

unicodedata.**unidata_version**

The version of the Unicode database used in this module.

unicodedata.**ucd_3_2_0**

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

範例:

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A')  # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umber
'AN'
```

🄵解

6.6 stringprep --- 網際網路字串準備

原始碼: Lib/stringprep.py

When identifying things (such as host names) in the internet, it is often necessary to compare such identifications for ”equality”. Exactly how this comparison is executed may depend on the application domain, e.g. whether it should be case-insensitive or not. It may be also necessary to restrict the possible identifications, to allow only identifications consisting of ”printable” characters.

RFC 3454 defines a procedure for ”preparing” Unicode strings in internet protocols. Before passing strings onto the wire, they are processed with the preparation procedure, after which they have a certain normalized form. The RFC defines a set of tables, which can be combined into profiles. Each profile must define which tables it uses, and what other optional parts of the stringprep procedure are part of the profile. One example of a stringprep profile is nameprep, which is used for internationalized domain names.

The module *stringprep* only exposes the tables from RFC 3454. As these tables would be very large to represent as dictionaries or lists, the module uses the Unicode character database internally. The module source code itself was generated using the mkstringprep.py utility.

As a result, these tables are exposed as functions, not as data structures. There are two kinds of tables in the RFC: sets and mappings. For a set, *stringprep* provides the ”characteristic function”, i.e. a function that returns True if the parameter is part of the set. For mappings, it provides the mapping function: given the key, it returns the associated value. Below is a list of all functions available in the module.

stringprep.**in_table_a1**(*code*)

Determine whether *code* is in tableA.1 (Unassigned code points in Unicode 3.2).

stringprep.**in_table_b1**(*code*)

Determine whether *code* is in tableB.1 (Commonly mapped to nothing).

stringprep.**map_table_b2**(*code*)
Return the mapped value for *code* according to tableB.2 (Mapping for case-folding used with NFKC).

stringprep.**map_table_b3**(*code*)
Return the mapped value for *code* according to tableB.3 (Mapping for case-folding used with no normalization).

stringprep.**in_table_c11**(*code*)
Determine whether *code* is in tableC.1.1 (ASCII space characters).

stringprep.**in_table_c12**(*code*)
Determine whether *code* is in tableC.1.2 (Non-ASCII space characters).

stringprep.**in_table_c11_c12**(*code*)
Determine whether *code* is in tableC.1 (Space characters, union of C.1.1 and C.1.2).

stringprep.**in_table_c21**(*code*)
Determine whether *code* is in tableC.2.1 (ASCII control characters).

stringprep.**in_table_c22**(*code*)
Determine whether *code* is in tableC.2.2 (Non-ASCII control characters).

stringprep.**in_table_c21_c22**(*code*)
Determine whether *code* is in tableC.2 (Control characters, union of C.2.1 and C.2.2).

stringprep.**in_table_c3**(*code*)
Determine whether *code* is in tableC.3 (Private use).

stringprep.**in_table_c4**(*code*)
Determine whether *code* is in tableC.4 (Non-character code points).

stringprep.**in_table_c5**(*code*)
Determine whether *code* is in tableC.5 (Surrogate codes).

stringprep.**in_table_c6**(*code*)
Determine whether *code* is in tableC.6 (Inappropriate for plain text).

stringprep.**in_table_c7**(*code*)
Determine whether *code* is in tableC.7 (Inappropriate for canonical representation).

stringprep.**in_table_c8**(*code*)
Determine whether *code* is in tableC.8 (Change display properties or are deprecated).

stringprep.**in_table_c9**(*code*)
Determine whether *code* is in tableC.9 (Tagging characters).

stringprep.**in_table_d1**(*code*)
Determine whether *code* is in tableD.1 (Characters with bidirectional property ”R” or ”AL”).

stringprep.**in_table_d2**(*code*)
Determine whether *code* is in tableD.2 (Characters with bidirectional property ”L”).

6.7 readline --- GNU readline 介面

The *readline* module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the *rlcompleter* module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the built-in *input()* function.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See Readline Init File in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

備🄵

The underlying Readline library API may be implemented by the `libedit` library instead of GNU readline. On macOS the *readline* module detects which library is being used at run time.

The configuration file for `libedit` is different from that of GNU readline. If you programmatically load configuration strings you can check for the text "libedit" in `readline.__doc__` to differentiate between GNU readline and libedit.

If you use *editline*/`libedit` readline emulation on macOS, the initialization file located in your home directory is named `.editrc`. For example, the following content in `~/.editrc` will turn ON *vi* keybindings and TAB completion:

```
python:bind -v
python:bind ^I rl_complete
```

Also note that different libraries may use different history file formats. When switching the underlying library, existing history files may become unusable.

6.7.1 Init file

The following functions relate to the init file and user configuration:

`readline.`**`parse_and_bind`**(*string*)

Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.`**`read_init_file`**([*filename*])

Execute a readline initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

6.7.2 Line buffer

The following functions operate on the line buffer:

`readline.`**`get_line_buffer`**()

Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.`**`insert_text`**(*string*)

Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

readline.**redisplay**()

Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

6.7.3 History file

The following functions operate on a history file:

readline.**read_history_file**([*filename*])

Load a readline history file, and append it to the history list. The default filename is `~/.history`. This calls `read_history()` in the underlying library.

readline.**write_history_file**([*filename*])

Save the history list to a readline history file, overwriting any existing file. The default filename is `~/.history`. This calls `write_history()` in the underlying library.

readline.**append_history_file**(*nelements*[, *filename*])

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls `append_history()` in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

在 3.5 版被加入.

readline.**get_history_length**()

readline.**set_history_length**(*length*)

Set or return the desired number of lines to save in the history file. The *write_history_file()* function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

6.7.4 History list

The following functions operate on a global history list:

readline.**clear_history**()

Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

readline.**get_current_history_length**()

Return the number of items currently in the history. (This is different from *get_history_length()*, which returns the maximum number of lines that will be written to a history file.)

readline.**get_history_item**(*index*)

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

readline.**remove_history_item**(*pos*)

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

readline.**replace_history_item**(*pos*, *line*)

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

readline.**add_history**(*line*)

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

readline.**set_auto_history**(*enabled*)

Enable or disable automatic calls to `add_history()` when reading input via readline. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

在 3.6 版被加入.

CPython 實作細節： Auto history is enabled by default, and changes to this do not persist across multiple sessions.

6.7.5 Startup hooks

readline.**set_startup_hook**([*function*])

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before readline prints the first prompt.

readline.**set_pre_input_hook**([*function*])

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before readline starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

6.7.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, Readline is set up to be used by *rlcompleter* to complete Python identifiers for the interactive interpreter. If the *readline* module is to be used with a custom completer, a different set of word delimiters should be set.

readline.**set_completer**([*function*])

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in `0`, `1`, `2`, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the *entry_func* callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

readline.**get_completer**()

Get the completer function, or `None` if no completer function has been set.

readline.**get_completion_type**()

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

readline.**get_begidx**()

readline.**get_endidx**()

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library. The values may be different in the same input editing scenario based on the underlying C readline implementation. Ex: libedit is known to behave differently than libreadline.

readline.**set_completer_delims**(*string*)

readline.**get_completer_delims**()

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

readline.**set_completion_display_matches_hook**([*function*])

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

6.7.7 范例

The following example demonstrates how to use the *readline* module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
    readline.read_history_file(histfile)
    # default history len is -1 (infinite), which may grow unruly
    readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)
```

This code is actually automatically run when Python is run in interactive mode (see *Readline configuration*).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```
import atexit
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)
```

The following example extends the *code.InteractiveConsole* class to support history save/restore.

```
import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/.console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except FileNotFoundError:
                pass
            atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
        readline.set_history_length(1000)
        readline.write_history_file(histfile)
```

6.8 `rlcompleter` --- GNU readline 的補全函式

原始碼： Lib/rlcompleter.py

The `rlcompleter` module defines a completion function suitable to be passed to *set_completer()* in the *readline* module.

When this module is imported on a Unix platform with the *readline* module available, an instance of the *Completer* class is automatically created and its *complete()* method is set as the *readline completer*. The method provides completion of valid Python identifiers and keywords.

範例：

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__         readline.insert_text(      readline.set_completer(
readline.__name__         readline.parse_and_bind(
>>> readline.
```

The `rlcompleter` module is designed for use with Python's interactive mode. Unless Python is run with the `-S` option, the module is automatically imported and configured (see *Readline configuration*).

On platforms without *readline*, the *Completer* class defined by this module can still be used for custom purposes.

class rlcompleter.**Completer**

Completer objects have the following method:

complete(*text*, *state*)

Return the next possible completion for *text*.

When called by the *readline* module, this method is called successively with `state == 0, 1, 2, ...` until the method returns `None`.

If called for *text* that doesn't include a period character (`'.'`), it will complete from names currently defined in *__main__*, *builtins* and keywords (as defined by the *keyword* module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()`) up to the last part, and find matches for the rest via the *dir()* function. Any exception raised during the evaluation of the expression is caught, silenced and *None* is returned.

CHAPTER 7

二進位資料服務

本章所描述的模組提供了一些基本的二進位資料操作服務。而針對二進位資料的其他操作 —— 尤其是關於檔案格式和網路協定的部分 —— 則會在相關章節中詳細描述。

一些在*文本處理 (Text Processing) 服務* 中提及的函式庫也可處理 ASCII 相容的二進位格式（例如，`re`）及所有的二進位資料（例如，`difflib`）。

此外，請參🄵 Python 🄵建的二進位資料類型的文件，詳情請參考*Binary Sequence Types --- bytes, bytearray, memoryview*。

7.1 `struct` --- 將位元組直譯🄵打包起來的二進位資料

原始碼： Lib/struct.py

This module converts between Python values and C structs represented as Python `bytes` objects. Compact *format strings* describe the intended conversions to/from Python values. The module's functions and objects can be used for two largely distinct applications, data exchange with external sources (files or network connections), or data transfer between the Python application and the C layer.

備🄵

When no prefix character is given, native mode is the default. It packs or unpacks data based on the platform and compiler on which the Python interpreter was built. The result of packing a given C struct includes pad bytes which maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. In contrast, when communicating data between external sources, the programmer is responsible for defining byte ordering and padding between elements. See *Byte Order, Size, and Alignment* for details.

Several `struct` functions (and methods of `Struct`) take a *buffer* argument. This refers to objects that implement the bufferobjects and provide either a readable or read-writable buffer. The most common types used for that purpose are `bytes` and `bytearray`, but many other types that can be viewed as an array of bytes implement the buffer protocol, so that they can be read/filled without additional copying from a `bytes` object.

7.1.1 函式與例外

The module defines the following exception and functions:

exception `struct.`**error**

Exception raised on various occasions; argument is a string describing what is wrong.

`struct.`**pack**(*format*, *v1*, *v2*, ...)

Return a bytes object containing the values *v1*, *v2*, ... packed according to the format string *format*. The arguments must match the values required by the format exactly.

`struct.`**pack_into**(*format*, *buffer*, *offset*, *v1*, *v2*, ...)

Pack the values *v1*, *v2*, ... according to the format string *format* and write the packed bytes into the writable buffer *buffer* starting at position *offset*. Note that *offset* is a required argument.

`struct.`**unpack**(*format*, *buffer*)

Unpack from the buffer *buffer* (presumably packed by `pack(format, ...)`) according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes must match the size required by the format, as reflected by *calcsize()*.

`struct.`**unpack_from**(*format*, */*, *buffer*, *offset=0*)

Unpack from *buffer* starting at position *offset*, according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes, starting at position *offset*, must be at least the size required by the format, as reflected by *calcsize()*.

`struct.`**iter_unpack**(*format*, *buffer*)

Iteratively unpack from the buffer *buffer* according to the format string *format*. This function returns an iterator which will read equally sized chunks from the buffer until all its contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by *calcsize()*.

Each iteration yields a tuple as specified by the format string.

在 3.4 版被加入.

`struct.`**calcsize**(*format*)

Return the size of the struct (and hence of the bytes object produced by `pack(format, ...)`) corresponding to the format string *format*.

7.1.2 Format Strings

Format strings describe the data layout when packing and unpacking data. They are built up from *format characters*, which specify the type of data being packed/unpacked. In addition, special characters control the *byte order, size and alignment*. Each format string consists of an optional prefix character which describes the overall properties of the data and one or more format characters which describe the actual data values and padding.

Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler). This behavior is chosen so that the bytes of a packed struct correspond exactly to the memory layout of the corresponding C struct. Whether to use native byte ordering and padding or standard formats depends on the application.

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table:

Character	Byte order	Size	Alignment
`@`	native	native	native
=	native	standard	none
<	little-endian	standard	none
>	big-endian	standard	none
!	network (= big-endian)	standard	none

If the first character is not one of these, `'@'` is assumed.

備🄵

The number 1023 (`0x3ff` in hexadecimal) has the following byte representations:

- `03 ff` in big-endian (>)
- `ff 03` in little-endian (<)

Python example:

```
>>> import struct
>>> struct.pack('>h', 1023)
b'\x03\xff'
>>> struct.pack('<h', 1023)
b'\xff\x03'
```

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86, AMD64 (x86-64), and Apple M1 are little-endian; IBM z and many legacy architectures are big-endian. Use *`sys.byteorder`* to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the *Format Characters* section.

Note the difference between `'@'` and `'='`: both use native byte order, but the size and alignment of the latter is standardized.

The form `'!'` represents the network byte order which is always big-endian as defined in IETF RFC 1700.

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of `'<'` or `'>'`.

🄵解:

(1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.

(2) No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.

(3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See 範例.

Format Characters

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The 'Standard size' column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of `'<'`, `'>'`, `'!'` or `'='`. When using native size, the size of the packed value is platform-dependent.

Format	C Type	Python type	Standard size	🄵解
`x`	pad byte	no value		(7)
`c`	`char`	bytes of length 1	1	
`b`	`signed char`	integer	1	(1), (2)
`B`	`unsigned char`	integer	1	(2)
`?`	`_Bool`	bool	1	(1)
`h`	`short`	integer	2	(2)
`H`	`unsigned short`	integer	2	(2)
`i`	`int`	integer	4	(2)
`I`	`unsigned int`	integer	4	(2)
`l`	`long`	integer	4	(2)
`L`	`unsigned long`	integer	4	(2)
`q`	`long long`	integer	8	(2)
`Q`	`unsigned long long`	integer	8	(2)
`n`	`ssize_t`	integer		(3)
`N`	`size_t`	integer		(3)
`e`	(6)	float	2	(4)
`f`	`float`	float	4	(4)
`d`	`double`	float	8	(4)
`s`	`char[]`	bytes		(9)
`p`	`char[]`	bytes		(8)
`P`	`void*`	integer		(5)

在 3.3 版的變更: 新增 `'n'` 與 `'N'` 格式的支援。

在 3.6 版的變更: 新增 `'e'` 格式的支援。

🄵解:

(1) The `'?'` conversion code corresponds to the `_Bool` type defined by C99. If this type is not available, it is simulated using a `char`. In standard mode, it is always represented by one byte.

(2) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing.

在 3.2 版的變更: Added use of the `__index__()` method for non-integers.

(3) The `'n'` and `'N'` conversion codes are only available for the native size (selected as the default or with the `'@'` byte order character). For the standard size, you can use whichever of the other integer formats fits your application.

(4) For the `'f'`, `'d'` and `'e'` conversion codes, the packed representation uses the IEEE 754 binary32, binary64 or binary16 format (for `'f'`, `'d'` or `'e'` respectively), regardless of the floating-point format used by the platform.

(5) The `'P'` format character is only available for the native byte ordering (selected as the default or with the `'@'` byte order character). The byte order character `'='` chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the `'P'` format is not available.

(6) The IEEE 754 binary16 "half precision" type was introduced in the 2008 revision of the IEEE 754 standard. It has a sign bit, a 5-bit exponent and 11-bit precision (with 10 bits explicitly stored), and can represent numbers between approximately `6.1e-05` and `6.5e+04` at full precision. This type is not widely supported by C compilers: on a

typical machine, an unsigned short can be used for storage, but not for math operations. See the Wikipedia page on the half-precision floating-point format for more information.

(7) When packing, `'x'` inserts one NUL byte.

(8) The `'p'` format character encodes a "Pascal string", meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to *`pack()`* is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it is padded with null bytes so that exactly count bytes in all are used. Note that for *`unpack()`*, the `'p'` format character consumes `count` bytes, but that the string returned can never contain more than 255 bytes.

(9) For the `'s'` format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, `'10s'` means a single 10-byte string mapping to or from a single Python byte string, while `'10c'` means 10 separate one byte character elements (e.g., `cccccccccc`) mapping to or from ten different Python byte objects. (See 範例 for a concrete demonstration of the difference.) If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, `'0s'` means a single, empty string (while `'0c'` means 0 characters).

A format character may be preceded by an integral repeat count. For example, the format string `'4h'` means exactly the same as `'hhhh'`.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

When packing a value `x` using one of the integer formats (`'b'`, `'B'`, `'h'`, `'H'`, `'i'`, `'I'`, `'l'`, `'L'`, `'q'`, `'Q'`), if `x` is outside the valid range for that format then *`struct.error`* is raised.

在 3.1 版的變更: Previously, some of the integer formats wrapped out-of-range values and raised *`DeprecationWarning`* instead of *`struct.error`*.

For the `'?'` format character, the return value is either *`True`* or *`False`*. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be `True` when unpacking.

范例

備🄵

Native byte order examples (designated by the `'@'` format prefix or lack of any prefix character) may not match what the reader's machine produces as that depends on the platform and compiler.

Pack and unpack integers of three different sizes, using big endian ordering:

```
>>> from struct import *
>>> pack(">bhl", 1, 2, 3)
b'\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('>bhl', b'\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('>bhl')
7
```

Attempt to pack an integer which is too large for the defined field:

```
>>> pack(">h", 99999)
Traceback (most recent call last):
```

(繼續下一頁)

(繼續上一頁)

```
  File "<stdin>", line 1, in <module>
struct.error: 'h' format requires -32768 <= number <= 32767
```

Demonstrate the difference between `'s'` and `'c'` format characters:

```
>>> pack("@ccc", b'1', b'2', b'3')
b'123'
>>> pack("@3s", b'123')
b'123'
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = b'raymond   \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)

>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond   ', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size in native mode since padding is implicit. In standard mode, the user is responsible for inserting any desired padding. Note in the first `pack` call below that three NUL bytes were added after the packed `'#'` to align the following integer on a four-byte boundary. In this example, the output was produced on a little endian machine:

```
>>> pack('@ci', b'#', 0x12131415)
b'#\x00\x00\x00\x15\x14\x13\x12'
>>> pack('@ic', 0x12131415, b'#')
b'\x15\x14\x13\x12#'
>>> calcsize('@ci')
8
>>> calcsize('@ic')
5
```

The following format `'llh0l'` results in two pad bytes being added at the end, assuming the platform's longs are aligned on 4-byte boundaries:

```
>>> pack('@llh0l', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

7.1.3 Applications

Two main applications for the `struct` module exist, data interchange between Python and C code within an application or another application compiled using the same compiler (*native formats*), and data interchange between applications using agreed upon data layout (*standard formats*). Generally speaking, the format strings constructed for these two domains are distinct.

Native Formats

When constructing format strings which mimic native layouts, the compiler and machine architecture determine byte ordering and padding. In such cases, the `@` format character should be used to specify native byte ordering and data sizes. Internal pad bytes are normally inserted automatically. It is possible that a zero-repeat format code will be needed at the end of a format string to round up to the correct byte boundary for proper alignment of consecutive chunks of data.

Consider these two simple examples (on a 64-bit, little-endian machine):

```
>>> calcsize('@lhl')
24
>>> calcsize('@llh')
18
```

Data is not padded to an 8-byte boundary at the end of the second format string without the use of extra padding. A zero-repeat format code solves that problem:

```
>>> calcsize('@llh0l')
24
```

The `'x'` format code can be used to specify the repeat, but for native formats it is better to use a zero-repeat format like `'0l'`.

By default, native byte ordering and alignment is used, but it is better to be explicit and use the `'@'` prefix character.

Standard Formats

When exchanging data beyond your process such as networking or storage, be precise. Specify the exact byte order, size, and alignment. Do not assume they match the native order of a particular machine. For example, network byte order is big-endian, while many popular CPUs are little-endian. By defining this explicitly, the user need not care about the specifics of the platform their code is running on. The first character should typically be < or > (or `!`). Padding is the responsibility of the programmer. The zero-repeat format character won't work. Instead, the user must explicitly add `'x'` pad bytes where needed. Revisiting the examples from the previous section, we have:

```
>>> calcsize('<qh6xq')
24
>>> pack('<qh6xq', 1, 2, 3) == pack('@lhl', 1, 2, 3)
True
>>> calcsize('@llh')
18
>>> pack('@llh', 1, 2, 3) == pack('<qqh', 1, 2, 3)
True
>>> calcsize('<qqh6x')
24
>>> calcsize('@llh0l')
24
>>> pack('@llh0l', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
True
```

The above results (executed on a 64-bit machine) aren't guaranteed to match when executed on different machines. For example, the examples below were executed on a 32-bit machine:

```
>>> calcsize('<qqh6x')
24
>>> calcsize('@llh0l')
12
>>> pack('@llh0l', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
False
```

7.1.4 Classes

The *struct* module also defines the following type:

class struct.**Struct**(*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling module-level functions with the same format since the format string is only compiled once.

> **備🄵**
>
> The compiled versions of the most recent format strings passed to the module-level functions are cached, so programs that use only a few format strings needn't worry about reusing a single *Struct* instance.

Compiled Struct objects support the following methods and attributes:

pack(*v1*, *v2*, ...)

Identical to the *pack()* function, using the compiled format. (len(result) will equal *size*.)

pack_into(*buffer*, *offset*, *v1*, *v2*, ...)

Identical to the *pack_into()* function, using the compiled format.

unpack(*buffer*)

Identical to the *unpack()* function, using the compiled format. The buffer's size in bytes must equal *size*.

unpack_from(*buffer*, *offset=0*)

Identical to the *unpack_from()* function, using the compiled format. The buffer's size in bytes, starting at position *offset*, must be at least *size*.

iter_unpack(*buffer*)

Identical to the *iter_unpack()* function, using the compiled format. The buffer's size in bytes must be a multiple of *size*.

在 3.4 版被加入.

format

The format string used to construct this Struct object.

在 3.7 版的變更: The format string type is now *str* instead of *bytes*.

size

The calculated size of the struct (and hence of the bytes object produced by the *pack()* method) corresponding to *format*.

7.2 codecs --- 編解碼器FF表和基底類F

原始碼： Lib/codecs.py

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are *text encodings*, which encode text to bytes (and decode bytes to text), but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to be used specifically with *text encodings* or with codecs that encode to `bytes`.

The module defines the following functions for encoding and decoding with any codec:

codecs.**encode**(*obj*, *encoding='utf-8'*, *errors='strict'*)

Encodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is `'strict'` meaning that encoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeEncodeError`). Refer to *Codec Base Classes* for more information on codec error handling.

codecs.**decode**(*obj*, *encoding='utf-8'*, *errors='strict'*)

Decodes *obj* using the codec registered for *encoding*.

Errors may be given to set the desired error handling scheme. The default error handler is `'strict'` meaning that decoding errors raise `ValueError` (or a more codec specific subclass, such as `UnicodeDecodeError`). Refer to *Codec Base Classes* for more information on codec error handling.

The full details for each codec can also be looked up directly:

codecs.**lookup**(*encoding*)

Looks up the codec info in the Python codec registry and returns a `CodecInfo` object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no `CodecInfo` object is found, a `LookupError` is raised. Otherwise, the `CodecInfo` object is stored in the cache and returned to the caller.

class codecs.**CodecInfo**(*encode*, *decode*, *streamreader=None*, *streamwriter=None*, *incrementalencoder=None*, *incrementaldecoder=None*, *name=None*)

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

name

The name of the encoding.

encode

decode

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the `encode()` and `decode()` methods of Codec instances (see *Codec Interface*). The functions or methods are expected to work in a stateless mode.

incrementalencoder

incrementaldecoder

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes `IncrementalEncoder` and `IncrementalDecoder`, respectively. Incremental codecs can maintain state.

streamwriter

streamreader

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes *StreamWriter* and *StreamReader*, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use *lookup()* for the codec lookup:

codecs.**getencoder**(*encoding*)

Look up the codec for the given encoding and return its encoder function.

Raises a *LookupError* in case the encoding cannot be found.

codecs.**getdecoder**(*encoding*)

Look up the codec for the given encoding and return its decoder function.

Raises a *LookupError* in case the encoding cannot be found.

codecs.**getincrementalencoder**(*encoding*)

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental encoder.

codecs.**getincrementaldecoder**(*encoding*)

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental decoder.

codecs.**getreader**(*encoding*)

Look up the codec for the given encoding and return its *StreamReader* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

codecs.**getwriter**(*encoding*)

Look up the codec for the given encoding and return its *StreamWriter* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

codecs.**register**(*search_function*)

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters with hyphens and spaces converted to underscores, and return a *CodecInfo* object. In case a search function cannot find a given encoding, it should return `None`.

在 3.9 版的變更: Hyphens and spaces are converted to underscore.

codecs.**unregister**(*search_function*)

Unregister a codec search function and clear the registry's cache. If the search function is not registered, do nothing.

在 3.10 版被加入.

While the builtin *open()* and the associated *io* module are the recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

codecs.**open**(*filename*, *mode='r'*, *encoding=None*, *errors='strict'*, *buffering=-1*)

Open an encoded file using the given *mode* and return an instance of *StreamReaderWriter*, providing transparent encoding/decoding. The default file mode is `'r'`, meaning to open the file in read mode.

備F

If *encoding* is not `None`, then the underlying encoded files are always opened in binary mode. No automatic conversion of `'\n'` is done on reading and writing. The *mode* argument may be any binary mode acceptable to the built-in *open()* function; the `'b'` is automatically added.

encoding specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

errors may be given to define the error handling. It defaults to `'strict'` which causes a *ValueError* to be raised in case an encoding error occurs.

buffering has the same meaning as for the built-in *open()* function. It defaults to -1 which means that the default buffer size will be used.

在 3.11 版的變更: The `'U'` mode has been removed.

codecs.**EncodedFile**(*file*, *data_encoding*, *file_encoding=None*, *errors='strict'*)

Return a *StreamRecoder* instance, a wrapped version of *file* which provides transparent transcoding. The original file is closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given *data_encoding* and then written to the original file as bytes using *file_encoding*. Bytes read from the original file are decoded according to *file_encoding*, and the result is encoded using *data_encoding*.

If *file_encoding* is not given, it defaults to *data_encoding*.

errors may be given to define the error handling. It defaults to `'strict'`, which causes *ValueError* to be raised in case an encoding error occurs.

codecs.**iterencode**(*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental encoder to iteratively encode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text *str* objects to encode. Therefore it does not support bytes-to-bytes encoders such as `base64_codec`.

codecs.**iterdecode**(*iterator*, *encoding*, *errors='strict'*, ***kwargs*)

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept *bytes* objects to decode. Therefore it does not support text-to-text encoders such as `rot_13`, although `rot_13` may be used equivalently with *iterencode()*.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

codecs.**BOM**

codecs.**BOM_BE**

codecs.**BOM_LE**

codecs.**BOM_UTF8**

codecs.**BOM_UTF16**

codecs.**BOM_UTF16_BE**

codecs.**BOM_UTF16_LE**

codecs.**BOM_UTF32**

codecs.**BOM_UTF32_BE**

codecs.**BOM_UTF32_LE**

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature. *BOM_UTF16* is either *BOM_UTF16_BE* or *BOM_UTF16_LE* depending on the platform's native byte order, *BOM* is an alias for *BOM_UTF16*, *BOM_LE* for *BOM_UTF16_LE* and *BOM_BE* for *BOM_UTF16_BE*. The others represent the BOM in UTF-8 and UTF-32 encodings.

7.2.1 Codec Base Classes

The *codecs* module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument:

```
>>> 'German ß, ♬'.encode(encoding='ascii', errors='backslashreplace')
b'German \\xdf, \\u266c'
>>> 'German ß, ♬'.encode(encoding='ascii', errors='xmlcharrefreplace')
b'German &#223;, &#9836;'
```

The following error handlers can be used with all Python *Standard Encodings* codecs:

Value	Meaning
`'strict'`	Raise *UnicodeError* (or a subclass), this is the default. Implemented in *strict_errors()*.
`'ignore'`	Ignore the malformed data and continue without further notice. Implemented in *ignore_errors()*.
`'replace'`	Replace with a replacement marker. On encoding, use `?` (ASCII character). On decoding, use `�` (U+FFFD, the official REPLACEMENT CHARACTER). Implemented in *replace_errors()*.
`'backslashreplace'`	Replace with backslashed escape sequences. On encoding, use hexadecimal form of Unicode code point with formats `\xhh` `\uxxxx` `\Uxxxxxxxx`. On decoding, use hexadecimal form of byte value with format `\xhh`. Implemented in *backslashreplace_errors()*.
`'surrogateescape'`	On decoding, replace byte with individual surrogate code ranging from `U+DC80` to `U+DCFF`. This code will then be turned back into the same byte when the `'surrogateescape'` error handler is used when encoding the data. (See **PEP 383** for more.)

The following error handlers are only applicable to encoding (within *text encodings*):

Value	Meaning
`'xmlcharref`	Replace with XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;`. Implemented in *xmlcharrefreplace_errors()*.
`'namereplac`	Replace with `\N{...}` escape sequences, what appears in the braces is the Name property from Unicode Character Database. Implemented in *namereplace_errors()*.

In addition, the following error handler is specific to the given codecs:

Value	Codecs	Meaning
`'surrog`	utf-8, utf-16, utf-32, utf-16-be, utf-16-le, utf-32-be, utf-32-le	Allow encoding and decoding surrogate code point (`U+D800` - `U+DFFF`) as normal code point. Otherwise these codecs treat the presence of surrogate code point in *str* as an error.

在 3.1 版被加入: The `'surrogateescape'` and `'surrogatepass'` error handlers.

在 3.4 版的變更: The `'surrogatepass'` error handler now works with utf-16* and utf-32* codecs.

在 3.5 版被加入: The `'namereplace'` error handler.

在 3.5 版的變更: The `'backslashreplace'` error handler now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.`**`register_error`**(*name*, *error_handler*)

Register the error handling function *error_handler* under the name *name*. The *error_handler* argument will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding, *error_handler* will be called with a *UnicodeEncodeError* instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either *str* or *bytes*. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an *IndexError* will be raised.

Decoding and translating works similarly, except *UnicodeDecodeError* or *UnicodeTranslateError* will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

`codecs.`**`lookup_error`**(*name*)

Return the error handler previously registered under the name *name*.

Raises a *LookupError* in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

`codecs.`**`strict_errors`**(*exception*)

Implements the `'strict'` error handling.

Each encoding or decoding error raises a *UnicodeError*.

`codecs.`**`ignore_errors`**(*exception*)

Implements the `'ignore'` error handling.

Malformed data is ignored; encoding or decoding is continued without further notice.

codecs.**replace_errors**(*exception*)

Implements the `'replace'` error handling.

Substitutes `?` (ASCII character) for encoding errors or `\ufffd` (U+FFFD, the official REPLACEMENT CHARACTER) for decoding errors.

codecs.**backslashreplace_errors**(*exception*)

Implements the `'backslashreplace'` error handling.

Malformed data is replaced by a backslashed escape sequence. On encoding, use the hexadecimal form of Unicode code point with formats `\x`*hh* `\u`*xxxx* `\U`*xxxxxxxx*. On decoding, use the hexadecimal form of byte value with format `\x`*hh*.

在 3.5 版的變更: Works with decoding and translating.

codecs.**xmlcharrefreplace_errors**(*exception*)

Implements the `'xmlcharrefreplace'` error handling (for encoding within *text encoding* only).

The unencodable character is replaced by an appropriate XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#`*num*`;` .

codecs.**namereplace_errors**(*exception*)

Implements the `'namereplace'` error handling (for encoding within *text encoding* only).

The unencodable character is replaced by a `\N{...}` escape sequence. The set of characters that appear in the braces is the Name property from Unicode Character Database. For example, the German lowercase letter `'ß'` will be converted to byte sequence `\N{LATIN SMALL LETTER SHARP S}`.

在 3.5 版被加入.

Stateless Encoding and Decoding

The base `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder:

class codecs.**Codec**

encode(*input*, *errors='strict'*)

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, *text encoding* converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to `'strict'` handling.

The method may not store state in the `Codec` instance. Use `StreamWriter` for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

decode(*input*, *errors='strict'*)

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a *text encoding*, decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface -- for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to `'strict'` handling.

The method may not store state in the `Codec` instance. Use `StreamReader` for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

Incremental Encoding and Decoding

The *IncrementalEncoder* and *IncrementalDecoder* classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the *encode()*/*decode()* method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the *encode()*/*decode()* method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

IncrementalEncoder 物件

The *IncrementalEncoder* class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalEncoder**(*errors='strict'*)

Constructor for an *IncrementalEncoder* instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalEncoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalEncoder* object.

encode(*object*, *final=False*)

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to *encode()* *final* must be true (the default is false).

reset()

Reset the encoder to the initial state. The output is discarded: call `.encode(object, final=True)`, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

getstate()

Return the current state of the encoder which must be an integer. The implementation should make sure that `0` is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer.)

setstate(*state*)

Set the state of the encoder to *state*. *state* must be an encoder state returned by *getstate()*.

IncrementalDecoder 物件

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

class codecs.**IncrementalDecoder**(*errors='strict'*)

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

decode(*object*, *final=False*)

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

reset()

Reset the decoder to the initial state.

getstate()

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that `0` is the most common additional state info.) If this additional state info is `0` it must be possible to set the decoder to the state which has no input buffered and `0` as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

setstate(*state*)

Set the state of the decoder to *state*. *state* must be a decoder state returned by *getstate()*.

Stream Encoding and Decoding

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

StreamWriter 物件

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

class codecs.**StreamWriter**(*stream*, *errors='strict'*)

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The `StreamWriter` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamWriter` object.

write(*object*)

Writes the object's contents encoded to the stream.

writelines(*list*)

Writes the concatenated iterable of strings to the stream (possibly by reusing the `write()` method). Infinite or very large iterables are not supported. The standard bytes-to-bytes codecs do not support this method.

reset()

Resets the codec buffers used for keeping internal state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the `StreamWriter` must also inherit all other methods and attributes from the underlying stream.

StreamReader 物件

The `StreamReader` class is a subclass of `Codec` and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

class codecs.**StreamReader**(*stream*, *errors='strict'*)

Constructor for a `StreamReader` instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The `StreamReader` may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the `StreamReader` object.

The set of allowed values for the *errors* argument can be extended with `register_error()`.

read(*size=-1*, *chars=-1*, *firstline=False*)

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The `read()` method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

readline(*size=None*, *keepends=True*)

Read one line from the input stream and return the decoded data.

size, if given, is passed as size argument to the stream's `read()` method.

If *keepends* is false line-endings will be stripped from the lines returned.

readlines(*sizehint=None*, *keepends=True*)

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's `decode()` method and are included in the list entries if *keepends* is true.

sizehint, if given, is passed as the *size* argument to the stream's `read()` method.

reset()

Resets the codec buffers used for keeping internal state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the `StreamReader` must also inherit all other methods and attributes from the underlying stream.

StreamReaderWriter 物件

The `StreamReaderWriter` is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

class codecs.**StreamReaderWriter**(*stream*, *Reader*, *Writer*, *errors='strict'*)

Creates a `StreamReaderWriter` instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the `StreamReader` and `StreamWriter` interface resp. Error handling is done in the same way as defined for the stream readers and writers.

`StreamReaderWriter` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

StreamRecoder 物件

The `StreamRecoder` translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the `lookup()` function to construct the instance.

class codecs.**StreamRecoder**(*stream*, *encode*, *decode*, *Reader*, *Writer*, *errors='strict'*)

Creates a `StreamRecoder` instance which implements a two-way conversion: *encode* and *decode* work on the frontend —the data visible to code calling `read()` and `write()`, while *Reader* and *Writer* work on the backend —the data in *stream*.

You can use these objects to do transparent transcodings, e.g., from Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the `Codec` interface. *Reader* and *Writer* must be factory functions or classes providing objects of the `StreamReader` and `StreamWriter` interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

`StreamRecoder` instances define the combined interfaces of `StreamReader` and `StreamWriter` classes. They inherit all other methods and attributes from the underlying stream.

7.2.2 Encodings and Unicode

Strings are stored internally as sequences of code points in range `U+0000--U+10FFFF`. (See **PEP 393** for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes is known as *encoding*, and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectivity referred to as *text encodings*.

The simplest text encoding (called `'latin-1'` or `'iso-8859-1'`) maps the code points 0--255 to the bytes `0x0--0xff`, which means that a string object that contains code points above `U+00FF` can't be encoded with this codec. Doing so will raise a `UnicodeEncodeError` that looks like the following (although the details of the error message may differ): `UnicodeEncodeError: 'latin-1' codec can't encode character '\u1234' in position 3: ordinal not in range(256).`

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes `0x0--0xff`. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called `UTF-32-BE` and `UTF-32-LE` respectively. Their disadvantage is that if e.g. you use `UTF-32-BE` on a little endian machine you will always have to swap bytes on encoding and decoding. `UTF-32` avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a `UTF-16` or `UTF-32` byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character `U+FEFF`. This character can be prepended to every `UTF-16` or `UTF-32` byte sequence. The byte swapped version of this character (`0xFFFE`) is an illegal character that may not appear in a Unicode text. So when the first character in a `UTF-16` or `UTF-32` byte sequence appears to be a `U+FFFE` the bytes have to be swapped on decoding. Unfortunately the character `U+FEFF` had a second purpose as a `ZERO WIDTH NO-BREAK SPACE`: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using `U+FEFF` as a `ZERO WIDTH NO-BREAK SPACE` has been deprecated (with `U+2060` (`WORD JOINER`) assuming this role). Nevertheless Unicode software still must be able to handle `U+FEFF` in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a `ZERO WIDTH NO-BREAK SPACE` it's a normal character that will be decoded like any other.

There's another encoding that is able to encode the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four `1` bits followed by a `0` bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

Range	Encoding
U-00000000 ... U-0000007F	0xxxxxxx
U-00000080 ... U-000007FF	110xxxxx 10xxxxxx
U-00000800 ... U-0000FFFF	1110xxxx 10xxxxxx 10xxxxxx
U-00010000 ... U-0010FFFF	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

> LATIN SMALL LETTER I WITH DIAERESIS
> RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK
> INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a utf-8-sig encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the utf-8-sig codec will write 0xef, 0xbb, 0xbf as the first three bytes to the file. On decoding utf-8-sig will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

7.2.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. 'utf-8' is a valid alias for the 'utf_8' codec.

CPython 實作細節： Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: utf-8, utf8, latin-1, latin1, iso-8859-1, iso8859-1, mbcs (Windows only), ascii, us-ascii, utf-16, utf16, utf-32, utf32, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

在 3.6 版的變更: Optimization opportunity recognized for us-ascii.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

在 3.4 版的變更: The utf-16* and utf-32* encoders no longer allow surrogate code points (`U+D800--U+DFFF`) to be encoded. The utf-32* decoders no longer decode byte sequences that correspond to surrogate code points.

在 3.8 版的變更: `cp65001` is now an alias to `utf_8`.

7.2.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated meaning describes the encoding direction.

Text Encodings

The following codecs provide `str` to `bytes` encoding and *bytes-like object* to `str` decoding, similar to the Unicode text encodings.

Codec	Aliases	Meaning
idna		Implement **RFC 3490**, see also *encodings.idna*. Only `errors='strict'` is supported.
mbcs	ansi, dbcs	Windows only: Encode the operand according to the ANSI codepage (CP_ACP).
oem		Windows only: Encode the operand according to the OEM codepage (CP_OEMCP). 在 3.6 版被加入.
palmos		Encoding of PalmOS 3.5.
punycode		Implement **RFC 3492**. Stateful codecs are not supported.
raw_unicode_escape		Latin-1 encoding with `\u`*XXXX* and `\U`*XXXXXXXX* for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol.
undefined		Raise an exception for all conversions, even empty strings. The error handler is ignored.
unicode_escape		Encoding suitable as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decode from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default.

在 3.8 版的變更: "unicode_internal" codec is removed.

Binary Transforms

The following codecs provide binary transforms: *bytes-like object* to `bytes` mappings. They are not supported by `bytes.decode()` (which only produces `str` output).

Codec	Aliases	Meaning	Encoder / decoder
base64_codec[1]	base64, base_64	Convert the operand to multiline MIME base64 (the result always includes a trailing `'\n'`). 在 3.4 版的變更: accepts any *bytes-like object* as input for encoding and decoding	*base64.encodebytes()* / *base64.decodebytes()*
bz2_codec	bz2	Compress the operand using bz2.	*bz2.compress()* / *bz2.decompress()*
hex_codec	hex	Convert the operand to hexadecimal representation, with two digits per byte.	*binascii.b2a_hex()* / *binascii.a2b_hex()*
quopri_codec	quopri, quotedprintable, quoted_printab	Convert the operand to MIME quoted printable.	*quopri.encode()* with `quotetabs=True` / *quopri.decode()*
uu_codec	uu	Convert the operand using uuencode.	`uu.encode()` / `uu.decode()` (Note: *uu* is deprecated.)
zlib_codec	zip, zlib	Compress the operand using gzip.	*zlib.compress()* / *zlib.decompress()*

在 3.2 版被加入: Restoration of the binary transforms.

在 3.4 版的變更: Restoration of the aliases for the binary transforms.

Text Transforms

The following codec provides a text transform: a *str* to *str* mapping. It is not supported by *str.encode()* (which only produces *bytes* output).

Codec	Aliases	Meaning
rot_13	rot13	Return the Caesar-cypher encryption of the operand.

在 3.2 版被加入: Restoration of the `rot_13` text transform.

在 3.4 版的變更: Restoration of the `rot13` alias.

[1] In addition to *bytes-like objects*, `'base64_codec'` also accepts ASCII-only instances of *str* for decoding

7.2.5 encodings.idna --- Internationalized Domain Names in Applications

This module implements **RFC 3490** (Internationalized Domain Names in Applications) and **RFC 3492** (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and *stringprep*.

If you need the IDNA 2008 standard from **RFC 5891** and **RFC 5895**, use the third-party idna module.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in **section 3.1 of RFC 3490** and converting each label to ACE as required, and conversely separating an input byte string into labels based on the `.` separator and converting any ACE labels found into unicode. Furthermore, the *socket* module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as *http.client* and *ftplib*, accept Unicode host names (*http.client* then also transparently sends an IDNA hostname in the *Host* field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: applications wishing to present such host names to the user should decode them to Unicode.

The module *encodings.idna* also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.`**`nameprep`**(*label*)

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is true.

`encodings.idna.`**`ToASCII`**(*label*)

Convert a label to ASCII, as specified in **RFC 3490**. `UseSTD3ASCIIRules` is assumed to be false.

`encodings.idna.`**`ToUnicode`**(*label*)

Convert a label to Unicode, as specified in **RFC 3490**.

7.2.6 encodings.mbcs --- Windows ANSI codepage

This module implements the ANSI codepage (CP_ACP).

適用： Windows。

在 3.2 版的變更: Before 3.2, the *errors* argument was ignored; `'replace'` was always used to encode, and `'ignore'` to decode.

在 3.3 版的變更: Support any error handler.

7.2.7 `encodings.utf_8_sig` --- UTF-8 codec with BOM signature

This module implements a variant of the UTF-8 codec. On encoding, a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). On decoding, an optional UTF-8 encoded BOM at the start of the data will be skipped.

CHAPTER 8

資料型🄵

本章節所描述的模組 (module) 提供了多樣的專門資料型🄵，例如日期與時間、固定型🄵陣列 (fixed-type arrays)、堆積🄵列 (heap queues)、雙端🄵列 (double-ended queues) 與列舉 (enumerations)。

Python 也有提供一些🄵建資料型🄵，特🄵是*dict*、*list*、*set* 與*frozenset* 和*tuple*。*str* 類🄵是用來儲存 Unicode 字串，*bytes* 與*bytearray* 類🄵則是用來儲存二進位制資料。

本章節包含下列模組的文件：

8.1 datetime --- 日期與時間的基本型🄵

原始碼： Lib/datetime.py

`datetime` 模組提供操作日期與時間的類🄵。

While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation.

小訣竅

跳轉至格式碼 *(format codes)*。

***time* 模組**
Time access and conversions.

zoneinfo 模組
: Concrete time zones representing the IANA time zone database.

Package dateutil
: 帶有時區與剖析擴充支援的第三方函式庫。

DateType 套件
: Third-party library that introduces distinct static types to e.g. allow *static type checkers* to differentiate between naive and aware datetimes.

8.1.1 Aware and Naive Objects

Date and time objects may be categorized as ”aware” or ”naive” depending on whether or not they include time zone information.

With sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, an **aware** object can locate itself relative to other aware objects. An aware object represents a specific moment in time that is not open to interpretation.[1]

A **naive** object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other time zone is purely up to the program, just like it is up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, *datetime* and *time* objects have an optional time zone information attribute, `tzinfo`, that can be set to an instance of a subclass of the abstract *tzinfo* class. These *tzinfo* objects capture information about the offset from UTC time, the time zone name, and whether daylight saving time is in effect.

Only one concrete *tzinfo* class, the *timezone* class, is supplied by the `datetime` module. The `timezone` class can represent simple time zones with fixed offsets from UTC, such as UTC itself or North American EST and EDT time zones. Supporting time zones at deeper levels of detail is up to the application. The rules for time adjustment across the world are more political than rational, change frequently, and there is no standard suitable for every application aside from UTC.

8.1.2 常數

`datetime` 模組匯出以下常數：

`datetime.`**`MINYEAR`**
: The smallest year number allowed in a *date* or *datetime* object. *MINYEAR* is 1.

`datetime.`**`MAXYEAR`**
: The largest year number allowed in a *date* or *datetime* object. *MAXYEAR* is 9999.

`datetime.`**`UTC`**
: Alias for the UTC time zone singleton *datetime.timezone.utc*.

  在 3.11 版被加入.

[1] 也就是🄴，我們會忽略相對論的效應

8.1.3 Available Types

class datetime.**date**

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: *year*, *month*, and *day*.

class datetime.**time**

An idealized time, independent of any particular day, assuming that every day has exactly 24*60*60 seconds. (There is no notion of "leap seconds" here.) Attributes: *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

class datetime.**datetime**

A combination of a date and a time. Attributes: *year*, *month*, *day*, *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

class datetime.**timedelta**

表示兩個*datetime* 或*date* 實例之間時間的差🄴，以微秒🄴解析度。

class datetime.**tzinfo**

An abstract base class for time zone information objects. These are used by the *datetime* and *time* classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

class datetime.**timezone**

A class that implements the *tzinfo* abstract base class as a fixed offset from the UTC.

在 3.2 版被加入.

Objects of these types are immutable.

Subclass relationships:

```
object
    timedelta
    tzinfo
        timezone
    time
    date
        datetime
```

常見屬性

The *date*, *datetime*, *time*, and *timezone* types share these common features:

- Objects of these types are immutable.
- Objects of these types are *hashable*, meaning that they can be used as dictionary keys.
- Objects of these types support efficient pickling via the *pickle* module.

Determining if an Object is Aware or Naive

Objects of the *date* type are always naive.

An object of type *time* or *datetime* may be aware or naive.

A *datetime* object *d* is aware if both of the following hold:

1. `d.tzinfo` 不是 `None`
2. `d.tzinfo.utcoffset(d)` 不會回傳 `None`

否則 *d* 會是 naive 的。

A *time* object *t* is aware if both of the following hold:

1. `t.tzinfo` 不是 `None`
2. `t.tzinfo.utcoffset(None)` 🄵有回傳 `None`。

Otherwise, *t* is naive.

The distinction between aware and naive doesn't apply to *timedelta* objects.

8.1.4 `timedelta` 物件

一個*timedelta* 物件代表著一段持續時間，即兩個*datetime* 或*date* 之間的差🄵。

class datetime.**timedelta**(*days=0*, *seconds=0*, *microseconds=0*, *milliseconds=0*, *minutes=0*, *hours=0*, *weeks=0*)

All arguments are optional and default to 0. Arguments may be integers or floats, and may be positive or negative.

Only *days*, *seconds* and *microseconds* are stored internally. Arguments are converted to those units:

- 一毫秒會被轉🄵🄵 1000 微秒。
- 一分鐘會被轉🄵🄵 60 秒。
- 一小時會被轉🄵🄵 3600 秒。
- 一🄵會被轉🄵🄵 7 天。

and days, seconds and microseconds are then normalized so that the representation is unique, with

- `0 <= microseconds < 1000000`
- `0 <= seconds < 3600*24` (the number of seconds in one day)
- `-999999999 <= days <= 999999999`

The following example illustrates how any arguments besides *days*, *seconds* and *microseconds* are "merged" and normalized into those three resulting attributes:

```
>>> from datetime import timedelta
>>> delta = timedelta(
...     days=50,
...     seconds=27,
...     microseconds=10,
...     milliseconds=29000,
...     minutes=5,
...     hours=8,
...     weeks=2
... )
```

(繼續下一頁)

(繼續上一頁)

```
>>> # Only days, seconds, and microseconds remain
>>> delta
datetime.timedelta(days=64, seconds=29156, microseconds=10)
```

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond using round-half-to-even tiebreaker. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of days lies outside the indicated range, *OverflowError* is raised.

Note that normalization of negative values may be surprising at first. For example:

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

類🄵屬性:

`timedelta.`**`min`**

The most negative *timedelta* object, `timedelta(-999999999)`.

`timedelta.`**`max`**

The most positive *timedelta* object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.`**`resolution`**

The smallest possible difference between non-equal *timedelta* objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max` is greater than `-timedelta.min`. `-timedelta.max` is not representable as a *timedelta* object.

Instance attributes (read-only):

屬性	Value
`days`	Between -999999999 and 999999999 inclusive
`seconds`	在 0 到 86399 （含）之間
`microseconds`	在 0 到 999999 （含）之間

Supported operations:

Operation	Result
`t1 = t2 + t3`	Sum of `t2` and `t3`. Afterwards `t1 - t2 == t3` and `t1 - t3 == t2` are true. (1)
`t1 = t2 - t3`	Difference of `t2` and `t3`. Afterwards `t1 == t2 - t3` and `t2 == t1 + t3` are true. (1)(6)
`t1 = t2 * i or t1 = i * t2`	Delta multiplied by an integer. Afterwards `t1 // i == t2` is true, provided `i != 0`.
	In general, `t1 * i == t1 * (i-1) + t1` is true. (1)
`t1 = t2 * f or t1 = f * t2`	Delta multiplied by a float. The result is rounded to the nearest multiple of timedelta.resolution using round-half-to-even.
`f = t2 / t3`	Division (3) of overall duration `t2` by interval unit `t3`. Returns a *float* object.
`t1 = t2 / f or t1 = t2 / i`	Delta divided by a float or an int. The result is rounded to the nearest multiple of timedelta.resolution using round-half-to-even.
`t1 = t2 // i or t1 = t2 // t3`	The floor is computed and the remainder (if any) is thrown away. In the second case, an integer is returned. (3)
`t1 = t2 % t3`	The remainder is computed as a *timedelta* object. (3)
`q, r = divmod(t1, t2)`	Computes the quotient and the remainder: `q = t1 // t2` (3) and `r = t1 % t2`. q is an integer and r is a *timedelta* object.
`+t1`	Returns a *timedelta* object with the same value. (2)
`-t1`	Equivalent to `timedelta(-t1.days, -t1.seconds*, -t1.microseconds)`, and to `t1 * -1`. (1)(4)
`abs(t)`	Equivalent to `+t` when `t.days >= 0`, and to `-t` when `t.days < 0`. (2)
`str(t)`	Returns a string in the form `[D day[s], ][H]H:MM:SS[.UUUUUU]`, where D is negative for negative `t`. (5)
`repr(t)`	Returns a string representation of the *timedelta* object as a constructor call with canonical attribute values.

F解:

(1) 這是精確的，但可能會溢位。

(2) 這是精確的，且不會溢位。

(3) Division by zero raises *ZeroDivisionError*.

(4) `-timedelta.max` is not representable as a *timedelta* object.

(5) String representations of *timedelta* objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(days=-1, seconds=68400)
>>> print(_)
-1 day, 19:00:00
```

(6) The expression `t2 - t3` will always be equal to the expression `t2 + (-t3)` except when t3 is equal to `timedelta.max`; in that case the former will produce a result while the latter will overflow.

In addition to the operations listed above, *timedelta* objects support certain additions and subtractions with *date* and *datetime* objects (see below).

在 3.2 版的變更: Floor division and true division of a *timedelta* object by another *timedelta* object are now supported, as are remainder operations and the *divmod()* function. True division and multiplication of a *timedelta* object by a *float* object are now supported.

timedelta objects support equality and order comparisons.

In Boolean contexts, a *timedelta* object is considered to be true if and only if it isn't equal to `timedelta(0)`.

實例方法:

`timedelta.`**`total_seconds`**`()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`. For interval units other than seconds, use the division form directly (e.g. `td / timedelta(microseconds=1)`).

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

在 3.2 版被加入.

用法范例: `timedelta`

An additional example of normalization:

```
>>> # Components of another_year add up to exactly 365 days
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                          minutes=50, seconds=600)
>>> year == another_year
True
>>> year.total_seconds()
31536000.0
```

Examples of *timedelta* arithmetic:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> ten_years = 10 * year
>>> ten_years
datetime.timedelta(days=3650)
>>> ten_years.days // 365
10
>>> nine_years = ten_years - year
>>> nine_years
datetime.timedelta(days=3285)
>>> three_years = nine_years // 3
>>> three_years, three_years.days // 365
(datetime.timedelta(days=1095), 3)
```

8.1.5 `date` 物件

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions.

January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on.[2]

`class` `datetime.`**`date`**`(`*year*, *month*, *day*`)`

All arguments are required. Arguments must be integers, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`

[2] This matches the definition of the "proleptic Gregorian" calendar in Dershowitz and Reingold's book *Calendrical Calculations*, where it's the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, *`ValueError`* is raised.

Other constructors, all class methods:

classmethod `date.`**today**`()`

回傳目前的本地日期。

這等同於 `date.fromtimestamp(time.time())`。

classmethod `date.`**fromtimestamp**(*timestamp*)

Return the local date corresponding to the POSIX timestamp, such as is returned by *`time.time()`*.

This may raise *`OverflowError`*, if the timestamp is out of the range of values supported by the platform C `localtime()` function, and *`OSError`* on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by *`fromtimestamp()`*.

在 3.3 版的變更: Raise *`OverflowError`* instead of *`ValueError`* if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise *`OSError`* instead of *`ValueError`* on `localtime()` failure.

classmethod `date.`**fromordinal**(*ordinal*)

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1.

`ValueError` is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date *d*, `date.fromordinal(d.toordinal()) == d`.

classmethod `date.`**fromisoformat**(*date_string*)

Return a *`date`* corresponding to a *date_string* given in any valid ISO 8601 format, with the following exceptions:

1. Reduced precision dates are not currently supported (`YYYY-MM`, `YYYY`).
2. Extended date representations are not currently supported (`±YYYYYY-MM-DD`).
3. Ordinal dates are not currently supported (`YYYY-OOO`).

範例:

```
>>> from datetime import date
>>> date.fromisoformat('2019-12-04')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('20191204')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('2021-W01-1')
datetime.date(2021, 1, 4)
```

在 3.7 版被加入.

在 3.11 版的變更: Previously, this method only supported the format `YYYY-MM-DD`.

classmethod `date.`**fromisocalendar**(*year*, *week*, *day*)

Return a *`date`* corresponding to the ISO calendar date specified by year, week and day. This is the inverse of the function *`date.isocalendar()`*.

在 3.8 版被加入.

類🄵屬性:

`date.`**`min`**
The earliest representable date, `date(MINYEAR, 1, 1)`.

`date.`**`max`**
The latest representable date, `date(MAXYEAR, 12, 31)`.

`date.`**`resolution`**
The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

`date.`**`year`**
Between *MINYEAR* and *MAXYEAR* inclusive.

`date.`**`month`**
在 1 到 12（含）之間。

`date.`**`day`**
Between 1 and the number of days in the given month of the given year.

Supported operations:

Operation	Result
`date2 = date1 + timedelta`	`date2` will be `timedelta.days` days after `date1`. (1)
`date2 = date1 - timedelta`	Computes `date2` such that `date2 + timedelta == date1`. (2)
`timedelta = date1 - date2`	(3)
`date1 == date2` `date1 != date2`	Equality comparison. (4)

`date1 < date2`
`date1 > date2`
`date1 <= date2`
`date1 >= date2`
	Order comparison. (5)

🄵解:

(1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days`. `timedelta.seconds` and `timedelta.microseconds` are ignored. *OverflowError* is raised if `date2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*.

(2) `timedelta.seconds` 和 `timedelta.microseconds` 被忽略。

(3) This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.

(4) *date* objects are equal if they represent the same date.

(5) *date1* is considered less than *date2* when *date1* precedes *date2* in time. In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`.

In Boolean contexts, all *date* objects are considered to be true.

實例方法:

date.**replace**(*year=self.year*, *month=self.month*, *day=self.day*)

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified.

範例:

```
>>> from datetime import date
>>> d = date(2002, 12, 31)
>>> d.replace(day=26)
datetime.date(2002, 12, 26)
```

date.**timetuple**()

回傳一個*time.struct_time*, 如同*time.localtime()* 所回傳。

The hours, minutes and seconds are 0, and the DST flag is -1.

`d.timetuple()` 等價於:

```
time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

date.**toordinal**()

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any *date* object *d*, `date.fromordinal(d.toordinal()) == d`.

date.**weekday**()

回傳一個代表星期幾的整數, 星期一🄵 0、星期日🄵 6。例如 `date(2002, 12, 4).weekday() == 2` 🄵星期三。也請參考*isoweekday()*。

date.**isoweekday**()

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also *weekday()*, *isocalendar()*.

date.**isocalendar**()

Return a *named tuple* object with three components: `year`, `week` and `weekday`.

The ISO calendar is a widely used variant of the Gregorian calendar.[3]

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004:

```
>>> from datetime import date
>>> date(2003, 12, 29).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=1)
>>> date(2004, 1, 4).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=7)
```

在 3.9 版的變更: Result changed from a tuple to a *named tuple*.

[3] See R. H. van Gent's guide to the mathematics of the ISO 8601 calendar for a good explanation.

date.**isoformat**()

回傳一以 ISO 8601 格式 YYYY-MM-DD 表示的日期字串:

```
>>> from datetime import date
>>> date(2002, 12, 4).isoformat()
'2002-12-04'
```

date.**__str__**()

For a date *d*, str(d) is equivalent to d.isoformat().

date.**ctime**()

Return a string representing the date:

```
>>> from datetime import date
>>> date(2002, 12, 4).ctime()
'Wed Dec  4 00:00:00 2002'
```

d.ctime() 等價於:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C ctime() function (which *time.ctime()* invokes, but which *date.ctime()* does not invoke) conforms to the C standard.

date.**strftime**(*format*)

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. See also *strftime() 與 strptime() 的行🄵* and *date.isoformat()*.

date.**__format__**(*format*)

Same as *date.strftime()*. This makes it possible to specify a format string for a *date* object in formatted string literals and when using *str.format()*. See also *strftime() 與 strptime() 的行🄵* and *date.isoformat()*.

用法范例: date

計算一個事件的天數的範例:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
...
>>> my_birthday
datetime.date(2008, 6, 24)
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

更多*date*的用法範例:

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)

>>> # Methods related to formatting string output
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> d.ctime()
'Mon Mar 11 00:00:00 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'

>>> # Methods for to extracting 'components' under different calendars
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002                # year
3                   # month
11                  # day
0
0
0
0                   # weekday (0 = Monday)
70                  # 70th day in the year
-1
>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002                # ISO year
11                  # ISO week number
1                   # ISO day number ( 1 = Monday )

>>> # A date object is immutable; all operations produce a new object
>>> d.replace(year=2005)
datetime.date(2005, 3, 11)
```

8.1.6 datetime 物件

A *datetime* object is a single object containing all the information from a *date* object and a *time* object.

Like a *date* object, *datetime* assumes the current Gregorian calendar extended in both directions; like a *time* object, *datetime* assumes there are exactly 3600*24 seconds in every day.

Constructor:

class datetime.**datetime**(*year*, *month*, *day*, *hour=0*, *minute=0*, *second=0*, *microsecond=0*, *tzinfo=None*, ***, *fold=0*)

The *year*, *month* and *day* arguments are required. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments must be integers in the following ranges:

- `MINYEAR <= year <= MAXYEAR`,

- `1 <= month <= 12`,
- `1 <= day <= number of days in the given month and year`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold in [0, 1]`.

If an argument outside those ranges is given, *ValueError* is raised.

在 3.6 版的變更: 新增 *fold* 參數。

Other constructors, all class methods:

classmethod datetime.**today**()

回傳目前的本地日期與時間，且*tzinfo* 🄵 None。

等價於:

```
datetime.fromtimestamp(time.time())
```

也請見*now()*、*fromtimestamp()*。

This method is functionally equivalent to *now()*, but without a `tz` parameter.

classmethod datetime.**now**(*tz=None*)

Return the current local date and time.

如果選用的引數 *tz* 🄵 None 或未指定，則會像是*today()*，但盡可能提供比透過*time.time()* 取得的時間戳記更多位數的資訊（例如，這在有提供 C `gettimeofday()` 函式的平台上可能可行）。

If *tz* is not None, it must be an instance of a *tzinfo* subclass, and the current date and time are converted to *tz*'s time zone.

This function is preferred over *today()* and *utcnow()*.

classmethod datetime.**utcnow**()

Return the current UTC date and time, with *tzinfo* None.

This is like *now()*, but returns the current UTC date and time, as a naive *datetime* object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also *now()*.

警告

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing the current time in UTC is by calling `datetime.now(timezone.utc)`.

在 3.12 版之後被🄵用: Use *datetime.now()* with *UTC* instead.

classmethod datetime.**fromtimestamp**(*timestamp*, *tz=None*)

Return the local date and time corresponding to the POSIX timestamp, such as is returned by *time.time()*. If optional argument *tz* is None or not specified, the timestamp is converted to the platform's local date and time, and the returned *datetime* object is naive.

If *tz* is not None, it must be an instance of a *tzinfo* subclass, and the timestamp is converted to *tz*'s time zone.

fromtimestamp() may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions, and *OSError* on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by *fromtimestamp()*, and then it's possible to have two timestamps differing by a second that yield identical *datetime* objects. This method is preferred over *utcfromtimestamp()*.

在 3.3 版的變更: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise *OSError* instead of *ValueError* on `localtime()` or `gmtime()` failure.

在 3.6 版的變更: *fromtimestamp()* may return instances with *fold* set to 1.

classmethod datetime.**utcfromtimestamp**(*timestamp*)

Return the UTC *datetime* corresponding to the POSIX timestamp, with *tzinfo* `None`. (The resulting object is naive.)

This may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and *OSError* on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware *datetime* object, call *fromtimestamp()*:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta(seconds=timestamp)
```

except the latter formula always supports the full years range: between *MINYEAR* and *MAXYEAR* inclusive.

警告

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing a specific timestamp in UTC is by calling `datetime.fromtimestamp(timestamp, tz=timezone.utc)`.

在 3.3 版的變更: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise *OSError* instead of *ValueError* on `gmtime()` failure.

在 3.12 版之後被🄵用: Use *datetime.fromtimestamp()* with *UTC* instead.

classmethod datetime.**fromordinal**(*ordinal*)

Return the *datetime* corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. *ValueError* is raised unless `1 <= ordinal <= datetime.max.toordinal()`. The hour, minute, second and microsecond of the result are all 0, and *tzinfo* is `None`.

classmethod datetime.**combine**(*date*, *time*, *tzinfo=time.tzinfo*)

Return a new *datetime* object whose date components are equal to the given *date* object's, and whose time components are equal to the given *time* object's. If the *tzinfo* argument is provided, its value is used to set the *tzinfo* attribute of the result, otherwise the *tzinfo* attribute of the *time* argument is used. If the *date* argument is a *datetime* object, its time components and *tzinfo* attributes are ignored.

For any *datetime* object *d*, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`.

在 3.6 版的變更: 新增 *tzinfo* 引數。

classmethod datetime.**fromisoformat**(*date_string*)

Return a *datetime* corresponding to a *date_string* in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The `T` separator may be replaced by any single unicode character.
3. Fractional hours and minutes are not supported.
4. Reduced precision dates are not currently supported (`YYYY-MM`, `YYYY`).
5. Extended date representations are not currently supported (`±YYYYYY-MM-DD`).
6. Ordinal dates are not currently supported (`YYYY-OOO`).

範例:

```
>>> from datetime import datetime
>>> datetime.fromisoformat('2011-11-04')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('20111104')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('2011-11-04T00:05:23')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-11-04T00:05:23Z')
datetime.datetime(2011, 11, 4, 0, 5, 23, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('20111104T000523')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-W01-2T00:05:23.283')
datetime.datetime(2011, 1, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283+00:00')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('2011-11-04T00:05:23+04:00')
datetime.datetime(2011, 11, 4, 0, 5, 23,
    tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
```

在 3.7 版被加入.

在 3.11 版的變更: Previously, this method only supported formats that could be emitted by *date.isoformat()* or *datetime.isoformat()*.

classmethod datetime.**fromisocalendar**(*year*, *week*, *day*)

Return a *datetime* corresponding to the ISO calendar date specified by year, week and day. The non-date components of the datetime are populated with their normal default values. This is the inverse of the function *datetime.isocalendar()*.

在 3.8 版被加入.

classmethod datetime.**strptime**(*date_string*, *format*)

Return a *datetime* corresponding to *date_string*, parsed according to *format*.

If *format* does not contain microseconds or time zone information, this is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

ValueError is raised if the date_string and format can't be parsed by *time.strptime()* or if it returns a value which isn't a time tuple. See also *strftime() 與 strptime() 的行🄵* and *datetime.fromisoformat()*.

類🄴屬性:

datetime.**min**

The earliest representable *datetime*, datetime(MINYEAR, 1, 1, tzinfo=None).

datetime.**max**

The latest representable *datetime*, datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None).

datetime.**resolution**

The smallest possible difference between non-equal *datetime* objects, timedelta(microseconds=1).

Instance attributes (read-only):

datetime.**year**

Between *MINYEAR* and *MAXYEAR* inclusive.

datetime.**month**

在 1 到 12 （含）之間。

datetime.**day**

Between 1 and the number of days in the given month of the given year.

datetime.**hour**

In range(24).

datetime.**minute**

In range(60).

datetime.**second**

In range(60).

datetime.**microsecond**

In range(1000000).

datetime.**tzinfo**

The object passed as the *tzinfo* argument to the *datetime* constructor, or None if none was passed.

datetime.**fold**

In [0, 1]. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

在 3.6 版被加入.

Supported operations:

Operation	Result
`datetime2 = datetime1 + timedelta`	(1)
`datetime2 = datetime1 - timedelta`	(2)
`timedelta = datetime1 - datetime2`	(3)
`datetime1 == datetime2` `datetime1 != datetime2`	Equality comparison. (4)

`datetime1 < datetime2`
`datetime1 > datetime2`
`datetime1 <= datetime2`
`datetime1 >= datetime2`
	Order comparison. (5)

(1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same *`tzinfo`* attribute as the input datetime, and `datetime2 - datetime1 == timedelta` after. *`OverflowError`* is raised if `datetime2.year` would be smaller than *`MINYEAR`* or larger than *`MAXYEAR`*. Note that no time zone adjustments are done even if the input is an aware object.

(2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same *`tzinfo`* attribute as the input datetime, and no time zone adjustments are done even if the input is aware.

(3) Subtraction of a *`datetime`* from a *`datetime`* is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, *`TypeError`* is raised.

If both are naive, or both are aware and have the same *`tzinfo`* attribute, the *`tzinfo`* attributes are ignored, and the result is a *`timedelta`* object *t* such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different *`tzinfo`* attributes, `a-b` acts as if *a* and *b* were first converted to naive UTC datetimes. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

(4) *`datetime`* objects are equal if they represent the same date and time, taking into account the time zone.

Naive and aware `datetime` objects are never equal. `datetime` objects are never equal to *`date`* objects that are not also `datetime` instances, even if they represent the same date.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and *`fold`* attributes are ignored and the base datetimes are compared. If both comparands are aware and have different *`tzinfo`* attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows. `datetime` instances in a repeated interval are never equal to `datetime` instances in other time zone.

(5) *datetime1* is considered less than *datetime2* when *datetime1* precedes *datetime2* in time, taking into account the time zone.

Order comparison between naive and aware *`datetime`* objects, as well as a `datetime` object and a `date` object that is not also a `datetime` instance, raises *`TypeError`*.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and *`fold`* attributes are ignored and the base datetimes are compared. If both comparands are aware and have different *`tzinfo`* attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows.

在 3.3 版的變更: Equality comparisons between aware and naive *datetime* instances don't raise *TypeError*.

實例方法:

datetime.**date**()

Return *date* object with same year, month and day.

datetime.**time**()

Return *time* object with same hour, minute, second, microsecond and fold. *tzinfo* is None. See also method *timetz()*.

在 3.6 版的變更: The fold value is copied to the returned *time* object.

datetime.**timetz**()

Return *time* object with same hour, minute, second, microsecond, fold, and tzinfo attributes. See also method *time()*.

在 3.6 版的變更: The fold value is copied to the returned *time* object.

datetime.**replace**(*year=self.year*, *month=self.month*, *day=self.day*, *hour=self.hour*, *minute=self.minute*, *second=self.second*, *microsecond=self.microsecond*, *tzinfo=self.tzinfo*, *, *fold=0*)

Return a datetime with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that tzinfo=None can be specified to create a naive datetime from an aware datetime with no conversion of date and time data.

在 3.6 版的變更: 新增 *fold* 參數。

datetime.**astimezone**(*tz=None*)

Return a *datetime* object with new *tzinfo* attribute *tz*, adjusting the date and time data so the result is the same UTC time as *self*, but in *tz*'s local time.

If provided, *tz* must be an instance of a *tzinfo* subclass, and its *utcoffset()* and *dst()* methods must not return None. If *self* is naive, it is presumed to represent time in the system time zone.

If called without arguments (or with tz=None) the system local time zone is assumed for the target time zone. The .tzinfo attribute of the converted datetime instance will be set to an instance of *timezone* with the zone name and offset obtained from the OS.

If self.tzinfo is *tz*, self.astimezone(tz) is equal to *self*: no adjustment of date or time data is performed. Else the result is local time in the time zone *tz*, representing the same UTC time as *self*: after astz = dt.astimezone(tz), astz - astz.utcoffset() will have the same date and time data as dt - dt.utcoffset().

If you merely want to attach a *timezone* object *tz* to a datetime *dt* without adjustment of date and time data, use dt.replace(tzinfo=tz). If you merely want to remove the timezone object from an aware datetime *dt* without conversion of date and time data, use dt.replace(tzinfo=None).

Note that the default *tzinfo.fromutc()* method can be overridden in a *tzinfo* subclass to affect the result returned by *astimezone()*. Ignoring error cases, *astimezone()* acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new timezone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

在 3.3 版的變更: *tz* now can be omitted.

在 3.6 版的變更: The *astimezone()* method can now be called on naive instances that are presumed to represent system local time.

datetime.**utcoffset**()

If *tzinfo* is None, returns None, else returns self.tzinfo.utcoffset(self), and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

datetime.**dst**()

If *tzinfo* is None, returns None, else returns self.tzinfo.dst(self), and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

datetime.**tzname**()

If *tzinfo* is None, returns None, else returns self.tzinfo.tzname(self), raises an exception if the latter doesn't return None or a string object,

datetime.**timetuple**()

回傳一個*time.struct_time*，如同*time.localtime()* 所回傳。

d.timetuple() 等價於:

```
time.struct_time((d.year, d.month, d.day,
                  d.hour, d.minute, d.second,
                  d.weekday(), yday, dst))
```

where yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1 is the day number within the current year starting with 1 for January 1st. The *tm_isdst* flag of the result is set according to the *dst()* method: *tzinfo* is None or *dst()* returns None, tm_isdst is set to −1; else if *dst()* returns a non-zero value, tm_isdst is set to 1; else tm_isdst is set to 0.

datetime.**utctimetuple**()

If *datetime* instance *d* is naive, this is the same as d.timetuple() except that *tm_isdst* is forced to 0 regardless of what d.dst() returns. DST is never in effect for a UTC time.

If *d* is aware, *d* is normalized to UTC time, by subtracting d.utcoffset(), and a *time.struct_time* for the normalized time is returned. tm_isdst is forced to 0. Note that an *OverflowError* may be raised if d.year was MINYEAR or MAXYEAR and UTC adjustment spills over a year boundary.

警告

Because naive datetime objects are treated by many datetime methods as local times, it is preferred to use aware datetimes to represent times in UTC; as a result, using *datetime.utctimetuple()* may give misleading results. If you have a naive datetime representing UTC, use datetime.replace(tzinfo=timezone.utc) to make it aware, at which point you can use *datetime.timetuple()*.

datetime.**toordinal**()

Return the proleptic Gregorian ordinal of the date. The same as self.date().toordinal().

datetime.**timestamp**()

Return POSIX timestamp corresponding to the *datetime* instance. The return value is a *float* similar to that returned by *time.time()*.

Naive *datetime* instances are assumed to represent local time and this method relies on the platform C `mktime()` function to perform the conversion. Since *datetime* supports wider range of values than `mktime()` on many platforms, this method may raise *OverflowError* or *OSError* for times far in the past or far in the future.

For aware *datetime* instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).total_seconds()
```

在 3.3 版被加入.

在 3.6 版的變更: The *timestamp()* method uses the *fold* attribute to disambiguate the times during a repeated interval.

備🄵

There is no method to obtain the POSIX timestamp directly from a naive *datetime* instance representing UTC time. If your application uses this convention and your system time zone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:

```
timestamp = dt.replace(tzinfo=timezone.utc).timestamp()
```

or by calculating the timestamp directly:

```
timestamp = (dt - datetime(1970, 1, 1)) / timedelta(seconds=1)
```

`datetime.`**`weekday`**`()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also *isoweekday()*.

`datetime.`**`isoweekday`**`()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also *weekday()*, *isocalendar()*.

`datetime.`**`isocalendar`**`()`

Return a *named tuple* with three components: `year`, `week` and `weekday`. The same as `self.date().isocalendar()`.

`datetime.`**`isoformat`**`(`*sep='T'*, *timespec='auto'*`)`

Return a string representing the date and time in ISO 8601 format:

- `YYYY-MM-DDTHH:MM:SS.ffffff`，如果*microsecond* 不是 0
- `YYYY-MM-DDTHH:MM:SS`，如果*microsecond* 是 0

如果*utcoffset()* 没有回傳 `None`，則會附加一个字串，給出 UTC 偏移：

- `YYYY-MM-DDTHH:MM:SS.ffffff+HH:MM[:SS[.ffffff]]`，如果*microsecond* 不是 0
- `YYYY-MM-DDTHH:MM:SS+HH:MM[:SS[.ffffff]]`，如果*microsecond* 是 0

範例：

```
>>> from datetime import datetime, timezone
>>> datetime(2019, 5, 18, 15, 17, 8, 132263).isoformat()
'2019-05-18T15:17:08.132263'
>>> datetime(2019, 5, 18, 15, 17, tzinfo=timezone.utc).isoformat()
'2019-05-18T15:17:00+00:00'
```

The optional argument *sep* (default `'T'`) is a one-character separator, placed between the date and time portions of the result. For example:

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     """A time zone with an arbitrary, constant -06:39 offset."""
...     def utcoffset(self, dt):
...         return timedelta(hours=-6, minutes=-39)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
'2002-12-25 00:00:00-06:39'
>>> datetime(2009, 11, 27, microsecond=100, tzinfo=TZ()).isoformat()
'2009-11-27T00:00:00.000100-06:39'
```

The optional argument *timespec* specifies the number of additional components of the time to include (the default is `'auto'`). It can be one of the following:

- `'auto'`: Same as `'seconds'` if *microsecond* is 0, same as `'microseconds'` otherwise.
- `'hours'`: Include the *hour* in the two-digit `HH` format.
- `'minutes'`: Include *hour* and *minute* in `HH:MM` format.
- `'seconds'`: Include *hour*, *minute*, and *second* in `HH:MM:SS` format.
- `'milliseconds'`: Include full time, but truncate fractional second part to milliseconds. `HH:MM:SS.sss` format.
- `'microseconds'`: Include full time in `HH:MM:SS.ffffff` format.

備🄵

Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument:

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

在 3.6 版的變更: 新增 *timespec* 參數。

`datetime.__str__()`

For a *datetime* instance *d*, `str(d)` is equivalent to `d.isoformat(' ')`.

`datetime.ctime()`

Return a string representing the date and time:

```
>>> from datetime import datetime
>>> datetime(2002, 12, 4, 20, 30, 40).ctime()
'Wed Dec  4 20:30:40 2002'
```

The output string will *not* include time zone information, regardless of whether the input is aware or naive.

`d.ctime()` 等價於:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which *time.ctime()* invokes, but which *datetime.ctime()* does not invoke) conforms to the C standard.

`datetime.`**`strftime`**(*format*)

Return a string representing the date and time, controlled by an explicit format string. See also *strftime() 與 strptime() 的行🄵* and *datetime.isoformat()*.

`datetime.`**`__format__`**(*format*)

Same as *datetime.strftime()*. This makes it possible to specify a format string for a *datetime* object in formatted string literals and when using *str.format()*. See also *strftime() 與 strptime() 的行🄵* and *datetime.isoformat()*.

用法范例：datetime

更多*datetime* 的用法範例：

```
>>> from datetime import datetime, date, time, timezone

>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)

>>> # Using datetime.now()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043)   # GMT +1
>>> datetime.now(timezone.utc)
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060, tzinfo=datetime.timezone.utc)

>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print(it)
...
2006    # year
11      # month
21      # day
16      # hour
30      # minute
0       # second
1       # weekday (0 = Monday)
325     # number of days since 1st January
-1      # dst - method tzinfo.dst() returned None

>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print(it)
```

(繼續下一頁)

(繼續上一頁)

```
...
2006    # ISO year
47      # ISO week
2       # ISO weekday

>>> # Formatting a datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day",
↪"month", "time")
'The day is 21, the month is November, the time is 04:30PM.'
```

The example below defines a *tzinfo* subclass capturing time zone information for Kabul, Afghanistan, which used +4 UTC until 1945 and then +4:30 UTC thereafter:

```
from datetime import timedelta, datetime, tzinfo, timezone

class KabulTz(tzinfo):
    # Kabul used +4 until 1945, when they moved to +4:30
    UTC_MOVE_DATE = datetime(1944, 12, 31, 20, tzinfo=timezone.utc)

    def utcoffset(self, dt):
        if dt.year < 1945:
            return timedelta(hours=4)
        elif (1945, 1, 1, 0, 0) <= dt.timetuple()[:5] < (1945, 1, 1, 0, 30):
            # An ambiguous ("imaginary") half-hour range representing
            # a 'fold' in time due to the shift from +4 to +4:30.
            # If dt falls in the imaginary range, use fold to decide how
            # to resolve. See PEP495.
            return timedelta(hours=4, minutes=(30 if dt.fold else 0))
        else:
            return timedelta(hours=4, minutes=30)

    def fromutc(self, dt):
        # Follow same validations as in datetime.tzinfo
        if not isinstance(dt, datetime):
            raise TypeError("fromutc() requires a datetime argument")
        if dt.tzinfo is not self:
            raise ValueError("dt.tzinfo is not self")

        # A custom implementation is required for fromutc as
        # the input to this function is a datetime with utc values
        # but with a tzinfo set to self.
        # See datetime.astimezone or fromtimestamp.
        if dt.replace(tzinfo=timezone.utc) >= self.UTC_MOVE_DATE:
            return dt + timedelta(hours=4, minutes=30)
        else:
            return dt + timedelta(hours=4)

    def dst(self, dt):
        # Kabul does not observe daylight saving time.
        return timedelta(0)

    def tzname(self, dt):
        if dt >= self.UTC_MOVE_DATE:
            return "+04:30"
        return "+04"
```

Usage of `KabulTz` from above:

```
>>> tz1 = KabulTz()

>>> # Datetime before the change
>>> dt1 = datetime(1900, 11, 21, 16, 30, tzinfo=tz1)
>>> print(dt1.utcoffset())
4:00:00

>>> # Datetime after the change
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=tz1)
>>> print(dt2.utcoffset())
4:30:00

>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(timezone.utc)
>>> dt3
datetime.datetime(2006, 6, 14, 8, 30, tzinfo=datetime.timezone.utc)
>>> dt2
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=KabulTz())
>>> dt2 == dt3
True
```

8.1.7 `time` 物件

A *time* object represents a (local) time of day, independent of any particular day, and subject to adjustment via a *tzinfo* object.

class datetime.**time**(*hour=0*, *minute=0*, *second=0*, *microsecond=0*, *tzinfo=None*, *, *fold=0*)

All arguments are optional. *tzinfo* may be `None`, or an instance of a *tzinfo* subclass. The remaining arguments must be integers in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold in [0, 1]`.

If an argument outside those ranges is given, *ValueError* is raised. All default to 0 except *tzinfo*, which defaults to `None`.

類🄵屬性:

time.**min**

The earliest representable *time*, `time(0, 0, 0, 0)`.

time.**max**

The latest representable *time*, `time(23, 59, 59, 999999)`.

time.**resolution**

The smallest possible difference between non-equal *time* objects, `timedelta(microseconds=1)`, although note that arithmetic on *time* objects is not supported.

Instance attributes (read-only):

`time.`**hour**

In `range(24)`.

`time.`**minute**

In `range(60)`.

`time.`**second**

In `range(60)`.

`time.`**microsecond**

In `range(1000000)`.

`time.`**tzinfo**

The object passed as the tzinfo argument to the *time* constructor, or `None` if none was passed.

`time.`**fold**

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

在 3.6 版被加入.

time objects support equality and order comparisons, where *a* is considered less than *b* when *a* precedes *b* in time.

Naive and aware `time` objects are never equal. Order comparison between naive and aware `time` objects raises *TypeError*.

If both comparands are aware, and have the same *tzinfo* attribute, the `tzinfo` and `fold` attributes are ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

在 3.3 版的變更: Equality comparisons between aware and naive *time* instances don't raise *TypeError*.

In Boolean contexts, a *time* object is always considered to be true.

在 3.5 版的變更: Before Python 3.5, a *time* object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See bpo-13936 for full details.

Other constructor:

classmethod `time.`**fromisoformat**(*time_string*)

Return a *time* corresponding to a *time_string* in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The leading `T`, normally required in cases where there may be ambiguity between a date and a time, is not required.
3. Fractional seconds may have any number of digits (anything beyond 6 will be truncated).
4. Fractional hours and minutes are not supported.

範例:

```
>>> from datetime import time
>>> time.fromisoformat('04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T042301')
datetime.time(4, 23, 1)
```

(繼續下一頁)

(繼續上一頁)

```
>>> time.fromisoformat('04:23:01.000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01,000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01+04:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone(datetime.
↪timedelta(seconds=14400)))
>>> time.fromisoformat('04:23:01Z')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
>>> time.fromisoformat('04:23:01+00:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
```

在 3.7 版被加入.

在 3.11 版的變更: Previously, this method only supported formats that could be emitted by *time.isoformat()*.

實例方法:

time.**replace**(*hour=self.hour*, *minute=self.minute*, *second=self.second*, *microsecond=self.microsecond*, *tzinfo=self.tzinfo*, ***, *fold=0*)

Return a *time* with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive *time* from an aware *time*, without conversion of the time data.

在 3.6 版的變更: 新增 *fold* 參數。

time.**isoformat**(*timespec='auto'*)

Return a string representing the time in ISO 8601 format, one of:

- `HH:MM:SS.ffffff`, if *microsecond* is not 0
- `HH:MM:SS`, if *microsecond* is 0
- `HH:MM:SS.ffffff+HH:MM[:SS[.ffffff]]`, if *utcoffset()* does not return `None`
- `HH:MM:SS+HH:MM[:SS[.ffffff]]`, if *microsecond* is 0 and *utcoffset()* does not return `None`

The optional argument *timespec* specifies the number of additional components of the time to include (the default is `'auto'`). It can be one of the following:

- `'auto'`: Same as `'seconds'` if *microsecond* is 0, same as `'microseconds'` otherwise.
- `'hours'`: Include the *hour* in the two-digit `HH` format.
- `'minutes'`: Include *hour* and *minute* in `HH:MM` format.
- `'seconds'`: Include *hour*, *minute*, and *second* in `HH:MM:SS` format.
- `'milliseconds'`: Include full time, but truncate fractional second part to milliseconds. `HH:MM:SS.sss` format.
- `'microseconds'`: Include full time in `HH:MM:SS.ffffff` format.

備F

Excluded time components are truncated, not rounded.

ValueError will be raised on an invalid *timespec* argument.

範例：

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=123456).isoformat(timespec=
↪'minutes')
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

在 3.6 版的變更: 新增 *timespec* 參數。

time.**__str__**()

For a time *t*, `str(t)` is equivalent to `t.isoformat()`.

time.**strftime**(*format*)

Return a string representing the time, controlled by an explicit format string. See also *strftime() 與 strptime() 的行為* and *time.isoformat()*.

time.**__format__**(*format*)

Same as *time.strftime()*. This makes it possible to specify a format string for a *time* object in formatted string literals and when using *str.format()*. See also *strftime() 與 strptime() 的行為* and *time.isoformat()*.

time.**utcoffset**()

If *tzinfo* is `None`, returns `None`, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return `None` or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

time.**dst**()

If *tzinfo* is `None`, returns `None`, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return `None`, or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

time.**tzname**()

If *tzinfo* is `None`, returns `None`, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return `None` or a string object.

用法范例：time

Examples of working with a *time* object:

```
>>> from datetime import time, tzinfo, timedelta
>>> class TZ1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self,dt):
...         return "+01:00"
...     def  __repr__(self):
...         return f"{self.__class__.__name__}()"
...
```

(繼續上一頁)

```
>>> t = time(12, 10, 30, tzinfo=TZ1())
>>> t
datetime.time(12, 10, 30, tzinfo=TZ1())
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'+01:00'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 +01:00'
>>> 'The {} is {:%H:%M}.'.format("time", t)
'The time is 12:10.'
```

8.1.8 tzinfo 物件

class datetime.**tzinfo**

This is an abstract base class, meaning that this class should not be instantiated directly. Define a subclass of *tzinfo* to capture information about a particular time zone.

An instance of (a concrete subclass of) *tzinfo* can be passed to the constructors for *datetime* and *time* objects. The latter objects view their attributes as being in local time, and the *tzinfo* object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

You need to derive a concrete subclass, and (at least) supply implementations of the standard *tzinfo* methods needed by the *datetime* methods you use. The `datetime` module provides *timezone*, a simple concrete subclass of *tzinfo* which can represent time zones with fixed offset from UTC such as UTC itself or North American EST and EDT.

Special requirement for pickling: A *tzinfo* subclass must have an `__init__()` method that can be called with no arguments, otherwise it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of *tzinfo* may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

tzinfo.**utcoffset**(*dt*)

Return offset of local time from UTC, as a *timedelta* object that is positive east of UTC. If local time is west of UTC, this should be negative.

This represents the *total* offset from UTC; for example, if a *tzinfo* object represents both time zone and DST adjustments, *utcoffset()* should return their sum. If the UTC offset isn't known, return `None`. Else the value returned must be a *timedelta* object strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` (the magnitude of the offset must be less than one day). Most implementations of *utcoffset()* will probably look like one of these two:

```
return CONSTANT                 # fixed-offset class
return CONSTANT + self.dst(dt)  # daylight-aware class
```

If *utcoffset()* does not return `None`, *dst()* should not return `None` either.

The default implementation of *utcoffset()* raises *NotImplementedError*.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

tzinfo.**dst**(*dt*)

Return the daylight saving time (DST) adjustment, as a *timedelta* object or None if DST information isn't known.

Return timedelta(0) if DST is not in effect. If DST is in effect, return the offset as a *timedelta* object (see *utcoffset()* for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by *utcoffset()*, so there's no need to consult *dst()* unless you're interested in obtaining DST info separately. For example, *datetime.timetuple()* calls its *tzinfo* attribute's *dst()* method to determine how the *tm_isdst* flag should be set, and *tzinfo.fromutc()* calls *dst()* to account for DST changes when crossing time zones.

An instance *tz* of a *tzinfo* subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every *datetime* *dt* with dt.tzinfo == tz. For sane *tzinfo* subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of *datetime.astimezone()* relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a *tzinfo* subclass cannot guarantee this, it may be able to override the default implementation of *tzinfo.fromutc()* to work correctly with *astimezone()* regardless.

Most implementations of *dst()* will probably look like one of these two:

```
def dst(self, dt):
    # a fixed-offset class:  doesn't account for DST
    return timedelta(0)
```

或是:

```
def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time.

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)
```

The default implementation of *dst()* raises *NotImplementedError*.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

tzinfo.**tzname**(*dt*)

Return the time zone name corresponding to the *datetime* object *dt*, as a string. Nothing about string names is defined by the datetime module, and there's no requirement that it mean anything in particular. For example, "GMT", "UTC", "-500", "-5:00", "EDT", "US/Eastern", "America/New York" are all valid replies. Return None if a string name isn't known. Note that this is a method rather than a fixed string primarily because some *tzinfo* subclasses will wish to return different names depending on the specific value of *dt* passed, especially if the *tzinfo* class is accounting for daylight time.

The default implementation of *tzname()* raises *NotImplementedError*.

These methods are called by a *datetime* or *time* object, in response to their methods of the same names. A *datetime* object passes itself as the argument, and a *time* object passes None as the argument. A *tzinfo* subclass's methods should therefore be prepared to accept a *dt* argument of None, or of class *datetime*.

When None is passed, it's up to the class designer to decide the best response. For example, returning None is appropriate if the class wishes to say that time objects don't participate in the *tzinfo* protocols. It may be more useful for

`utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a *datetime* object is passed in response to a *datetime* method, `dt.tzinfo` is the same object as *self*. *tzinfo* methods can rely on this, unless user code calls *tzinfo* methods directly. The intent is that the *tzinfo* methods interpret *dt* as being in local time, and not need worry about objects in other time zones.

There is one more *tzinfo* method that a subclass may wish to override:

`tzinfo.`**`fromutc`**`(`*dt*`)`

This is called from the default *datetime.astimezone()* implementation. When called from that, `dt.tzinfo` is *self*, and *dt*'s date and time data are to be viewed as expressing a UTC time. The purpose of *fromutc()* is to adjust the date and time data, returning an equivalent datetime in *self*'s local time.

Most *tzinfo* subclasses should be able to inherit the default *fromutc()* implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default *fromutc()* implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of *astimezone()* and *fromutc()* may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default *fromutc()* implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst  # this is self's standard offset
    if delta:
        dt += delta   # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

In the following `tzinfo_examples.py` file there are some examples of *tzinfo* classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
#  timezones where UTC offset and/or the DST rules had
#  changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
    DSTOFFSET = STDOFFSET
```

        # DST is off.
        return ZERO

    def fromutc(self, dt):
        assert dt.tzinfo is self
        start, end = us_dst_range(dt.year)
        start = start.replace(tzinfo=self)
        end = end.replace(tzinfo=self)
        std_time = dt + self.stdoffset
        dst_time = std_time + HOUR
        if end <= dst_time < end + HOUR:
            # Repeated hour
            return std_time.replace(fold=1)
        if std_time < start or dst_time >= end:
            # Standard time
            return std_time
        if start <= std_time < end - HOUR:
            # Daylight saving time
            return dst_time

Eastern  = USTimeZone(-5, "Eastern",  "EST", "EDT")
Central  = USTimeZone(-6, "Central",  "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific  = USTimeZone(-8, "Pacific",  "PST", "PDT")
```

Note that there are unavoidable subtleties twice per year in a *tzinfo* subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

```
  UTC   3:MM  4:MM  5:MM  6:MM  7:MM  8:MM
  EST  22:MM 23:MM  0:MM  1:MM  2:MM  3:MM
  EDT  23:MM  0:MM  1:MM  2:MM  3:MM  4:MM

start  22:MM 23:MM  0:MM  1:MM  3:MM  4:MM

  end  23:MM  0:MM  1:MM  1:MM  2:MM  3:MM
```

When DST starts (the "start" line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn't really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get:

```
>>> from datetime import datetime, timezone
>>> from tzinfo_examples import HOUR, Eastern
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
08:00:00 UTC = 04:00:00 EDT
```

When DST ends (the "end" line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. *`astimezone()`* mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the *`fold`* attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get:

```
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

Note that the *`datetime`* instances that differ only by the value of the *`fold`* attribute are considered equal in comparisons.

Applications that can't bear wall-time ambiguities should explicitly check the value of the *`fold`* attribute or avoid using hybrid *`tzinfo`* subclasses; there are no ambiguities when using *`timezone`*, or any other fixed-offset *`tzinfo`* subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

也參考

zoneinfo
: The `datetime` module has a basic *`timezone`* class (for handling arbitrary fixed offsets from UTC) and its *`timezone.utc`* attribute (a UTC `timezone` instance).

  `zoneinfo` brings the *IANA time zone database* (also known as the Olson database) to Python, and its usage is recommended.

IANA 時區資料庫
: The Time Zone Database (often called tz, tzdata or zoneinfo) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

8.1.9 timezone 物件

The *timezone* class is a subclass of *tzinfo*, each instance of which represents a time zone defined by a fixed offset from UTC.

Objects of this class cannot be used to represent time zone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

class datetime.**timezone**(*offset*, *name=None*)

The *offset* argument must be specified as a *timedelta* object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)`, otherwise *ValueError* is raised.

The *name* argument is optional. If specified it must be a string that will be used as the value returned by the *datetime.tzname()* method.

在 3.2 版被加入.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

timezone.**utcoffset**(*dt*)

Return the fixed value specified when the *timezone* instance is constructed.

The *dt* argument is ignored. The return value is a *timedelta* instance equal to the difference between the local time and UTC.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

timezone.**tzname**(*dt*)

Return the fixed value specified when the *timezone* instance is constructed.

If *name* is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the `offset` as follows. If *offset* is `timedelta(0)`, the name is "UTC", otherwise it is a string in the format `UTC±HH:MM`, where ± is the sign of `offset`, HH and MM are two digits of `offset.hours` and `offset.minutes` respectively.

在 3.6 版的變更: Name generated from `offset=timedelta(0)` is now plain `'UTC'`, not `'UTC+00:00'`.

timezone.**dst**(*dt*)

總是回傳 `None`。

timezone.**fromutc**(*dt*)

Return `dt + offset`. The *dt* argument must be an aware *datetime* instance, with `tzinfo` set to `self`.

類🄵屬性:

timezone.**utc**

UTC 時區, `timezone(timedelta(0))`。

8.1.10 strftime() 與 strptime() 的行🄵

date, *datetime*, and *time* objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string.

Conversely, the *datetime.strptime()* class method creates a *datetime* object from a string representing a date and time and a corresponding format string.

The table below provides a high-level comparison of *strftime()* versus *strptime()*:

	strftime	strptime
用法	Convert object to a string according to a given format	Parse a string into a *datetime* object given a corresponding format
Type of method	實例方法	類🄵方法
Method of	*date*; *datetime*; *time*	*datetime*
Signature	strftime(format)	strptime(date_string, format)

strftime() 與 strptime() 格式碼

These methods accept format codes that can be used to parse and format dates:

```
>>> datetime.strptime('31/01/22 23:59:59.999999',
...                   '%d/%m/%y %H:%M:%S.%f')
datetime.datetime(2022, 1, 31, 23, 59, 59, 999999)
>>> _.strftime('%a %d %b %Y, %I:%M%p')
'Mon 31 Jan 2022, 11:59PM'
```

The following is a list of all the format codes that the 1989 C standard requires, and these work on all platforms with a standard C implementation.

Directive	Meaning	範例	F解
%a	Weekday as locale's abbreviated name.	Sun, Mon, ..., Sat (en_US); So, Mo, ..., Sa (de_DE)	(1)
%A	Weekday as locale's full name.	Sunday, Monday, ..., Saturday (en_US); Sonntag, Montag, ..., Samstag (de_DE)	(1)
%w	Weekday as a decimal number, where 0 is Sunday and 6 is Saturday.	0, 1, ..., 6	
%d	Day of the month as a zero-padded decimal number.	01, 02, ..., 31	(9)
%b	Month as locale's abbreviated name.	Jan, Feb, ..., Dec (en_US); Jan, Feb, ..., Dez (de_DE)	(1)
%B	Month as locale's full name.	January, February, ..., December (en_US); Januar, Februar, ..., Dezember (de_DE)	(1)
%m	以零填充的F以十進位數字表示的月份。	01, 02, ..., 12	(9)
%y	Year without century as a zero-padded decimal number.	00, 01, ..., 99	(9)
%Y	Year with century as a decimal number.	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(2)
%H	Hour (24-hour clock) as a zero-padded decimal number.	00, 01, ..., 23	(9)
%I	Hour (12-hour clock) as a zero-padded decimal number.	01, 02, ..., 12	(9)
%p	Locale's equivalent of either AM or PM.	AM, PM (en_US); am, pm (de_DE)	(1), (3)
%M	Minute as a zero-padded decimal number.	00, 01, ..., 59	(9)
%S	Second as a zero-padded decimal number.	00, 01, ..., 59	(4), (9)
%f	Microsecond as a decimal number, zero-padded to 6 digits.	000000, 000001, ..., 999999	(5)
%z	UTC offset in the form ±HHMM[SS[.ffffff]] (empty string if the object is naive).	(empty), +0000, -0400, +1030, +063415, -030712.345216	(6)

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values.

Directive	Meaning	範例	🄵解
`%G`	ISO 8601 year with century representing the year that contains the greater part of the ISO week (`%V`).	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(8)
`%u`	ISO 8601 weekday as a decimal number where 1 is Monday.	1, 2, ..., 7	
`%V`	ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4.	01, 02, ..., 53	(8), (9)
`%:z`	UTC offset in the form `±HH:MM[:SS[.ffffff]]` (empty string if the object is naive).	(empty), +00:00, -04:00, +10:30, +06:34:15, -03:07:12.345216	(6)

These may not be available on all platforms when used with the *`strftime()`* method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling *`strptime()`* with incomplete or ambiguous ISO 8601 directives will raise a *`ValueError`*.

The full set of format codes supported varies across platforms, because Python calls the platform C library's `strftime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the *`strftime(3)`* documentation. There are also differences between platforms in handling of unsupported format specifiers.

在 3.6 版被加入: 新增 `%G`、`%u` 與 `%V`。

在 3.12 版被加入: 新增 `%:z`。

技術細節

Broadly speaking, `d.strftime(fmt)` acts like the *`time`* module's `time.strftime(fmt, d.timetuple())` although not all objects support a *`timetuple()`* method.

For the *`datetime.strptime()`* class method, the default value is `1900-01-01T00:00:00.000`: any components not specified in the format string will be pulled from the default value.[4]

Using `datetime.strptime(date_string, format)` is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

except when the format includes sub-second components or time zone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

對*`time`* 物件來🄵，不應該使用年、月、日的格式碼，因🄵 `time` 物件🄵🄵有這些值。如果使用這些格式碼，年份會以 1900 代替、月及日會以 1 代替。

對*`date`* 物件來🄵，不應該使用時、分、秒、微秒的格式碼，因🄵*`date`* 物件🄵🄵有這些值。如果使用這些格式碼，這些值都會以 0 代替。

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strftime` may raise *`UnicodeError`* or return an empty string instead.

🄵解:

[4] Passing `datetime.strptime('Feb 29', '%b %d')` will fail since 1900 is not a leap year.

(1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, "month/day/year" versus "day/month/year"), and the output may contain non-ASCII characters.

(2) The *strptime()* method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.

在 3.2 版的變更: In previous versions, *strftime()* method was restricted to years >= 1900.

在 3.3 版的變更: In version 3.2, *strftime()* method was restricted to years >= 1000.

(3) When used with the *strptime()* method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

(4) Unlike the *time* module, the `datetime` module does not support leap seconds.

(5) When used with the *strptime()* method, the `%f` directive accepts from one to six digits and zero pads on the right. `%f` is an extension to the set of format characters in the C standard (but implemented separately in datetime objects, and therefore always available).

(6) For a naive object, the `%z`, `%:z` and `%Z` format codes are replaced by empty strings.

For an aware object:

%z

utcoffset() is transformed into a string of the form `±HHMM[SS[.ffffff]]`, where `HH` is a 2-digit string giving the number of UTC offset hours, `MM` is a 2-digit string giving the number of UTC offset minutes, `SS` is a 2-digit string giving the number of UTC offset seconds and `ffffff` is a 6-digit string giving the number of UTC offset microseconds. The `ffffff` part is omitted when the offset is a whole number of seconds and both the `ffffff` and the `SS` part is omitted when the offset is a whole number of minutes. For example, if *utcoffset()* returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

在 3.7 版的變更: When the `%z` directive is provided to the *strptime()* method, the UTC offsets can have a colon as a separator between hours, minutes and seconds. For example, `'+01:00:00'` will be parsed as an offset of one hour. In addition, providing `'Z'` is identical to `'+00:00'`.

%:z

Behaves exactly as `%z`, but has a colon separator added between hours, minutes and seconds.

%Z

In *strftime()*, `%Z` is replaced by an empty string if *tzname()* returns `None`; otherwise `%Z` is replaced by the returned value, which must be a string.

strptime() only accepts certain values for `%Z`:

1. any value in `time.tzname` for your machine's locale
2. the hard-coded values `UTC` and `GMT`

So someone living in Japan may have `JST`, `UTC`, and `GMT` as valid values, but probably not `EST`. It will raise `ValueError` for invalid values.

在 3.2 版的變更: When the `%z` directive is provided to the *strptime()* method, an aware *datetime* object will be produced. The `tzinfo` of the result will be set to a *timezone* instance.

(7) When used with the *strptime()* method, `%U` and `%W` are only used in calculations when the day of the week and the calendar year (`%Y`) are specified.

(8) Similar to `%U` and `%W`, `%V` is only used in calculations when the day of the week and the ISO year (`%G`) are specified in a *strptime()* format string. Also note that `%G` and `%Y` are not interchangeable.

(9) When used with the *strptime()* method, the leading zero is optional for formats %d, %m, %H, %I, %M, %S, %j, %U, %W, and %V. Format %y does require a leading zero.

🄵解

8.2 zoneinfo --- IANA 時區支援

在 3.9 版被加入.

原始碼： Lib/zoneinfo

The *zoneinfo* module provides a concrete time zone implementation to support the IANA time zone database as originally specified in **PEP 615**. By default, *zoneinfo* uses the system's time zone data if available; if no system time zone data is available, the library will fall back to using the first-party tzdata package available on PyPI.

也參考

***datetime* 模組**
Provides the *time* and *datetime* types with which the *ZoneInfo* class is designed to be used.

Package tzdata
First-party package maintained by the CPython core developers to supply time zone data via PyPI.

Availability: not Emscripten, not WASI.

此模組在 WebAssembly 平台 wasm32-emscripten 和 wasm32-wasi 上無法作用或無法使用。有關更多資訊，請參🄵*WebAssembly 平台*。

8.2.1 Using ZoneInfo

ZoneInfo is a concrete implementation of the *datetime.tzinfo* abstract base class, and is intended to be attached to tzinfo, either via the constructor, the *datetime.replace* method or *datetime.astimezone*:

```
>>> from zoneinfo import ZoneInfo
>>> from datetime import datetime, timedelta

>>> dt = datetime(2020, 10, 31, 12, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-10-31 12:00:00-07:00

>>> dt.tzname()
'PDT'
```

Datetimes constructed in this way are compatible with datetime arithmetic and handle daylight saving time transitions with no further intervention:

```
>>> dt_add = dt + timedelta(days=1)

>>> print(dt_add)
2020-11-01 12:00:00-08:00
```

(繼續下一頁)

(繼續上一頁)

```
>>> dt_add.tzname()
'PST'
```

These time zones also support the *fold* attribute introduced in **PEP 495**. During offset transitions which induce ambiguous times (such as a daylight saving time to standard time transition), the offset from *before* the transition is used when `fold=0`, and the offset *after* the transition is used when `fold=1`, for example:

```
>>> dt = datetime(2020, 11, 1, 1, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-11-01 01:00:00-07:00

>>> print(dt.replace(fold=1))
2020-11-01 01:00:00-08:00
```

When converting from another time zone, the fold will be set to the correct value:

```
>>> from datetime import timezone
>>> LOS_ANGELES = ZoneInfo("America/Los_Angeles")
>>> dt_utc = datetime(2020, 11, 1, 8, tzinfo=timezone.utc)

>>> # Before the PDT -> PST transition
>>> print(dt_utc.astimezone(LOS_ANGELES))
2020-11-01 01:00:00-07:00

>>> # After the PDT -> PST transition
>>> print((dt_utc + timedelta(hours=1)).astimezone(LOS_ANGELES))
2020-11-01 01:00:00-08:00
```

8.2.2 Data sources

The `zoneinfo` module does not directly provide time zone data, and instead pulls time zone information from the system time zone database or the first-party PyPI package tzdata, if available. Some systems, including notably Windows systems, do not have an IANA database available, and so for projects targeting cross-platform compatibility that require time zone data, it is recommended to declare a dependency on tzdata. If neither system data nor tzdata are available, all calls to *ZoneInfo* will raise *ZoneInfoNotFoundError*.

Configuring the data sources

When `ZoneInfo(key)` is called, the constructor first searches the directories specified in *TZPATH* for a file matching `key`, and on failure looks for a match in the tzdata package. This behavior can be configured in three ways:

1. The default *TZPATH* when not otherwise specified can be configured at *compile time*.
2. *TZPATH* can be configured using *an environment variable*.
3. At *runtime*, the search path can be manipulated using the *reset_tzpath()* function.

Compile-time configuration

The default *TZPATH* includes several common deployment locations for the time zone database (except on Windows, where there are no "well-known" locations for time zone data). On POSIX systems, downstream distributors and those building Python from source who know where their system time zone data is deployed may change the default time zone path by specifying the compile-time option `TZPATH` (or, more likely, the `configure flag --with-tzpath`), which should be a string delimited by *os.pathsep*.

On all platforms, the configured value is available as the `TZPATH` key in *sysconfig.get_config_var()*.

Environment configuration

When initializing *TZPATH* (either at import time or whenever *reset_tzpath()* is called with no arguments), the `zoneinfo` module will use the environment variable `PYTHONTZPATH`, if it exists, to set the search path.

PYTHONTZPATH

This is an *os.pathsep*-separated string containing the time zone search path to use. It must consist of only absolute rather than relative paths. Relative components specified in `PYTHONTZPATH` will not be used, but otherwise the behavior when a relative path is specified is implementation-defined; CPython will raise *InvalidTZPathWarning*, but other implementations are free to silently ignore the erroneous component or raise an exception.

To set the system to ignore the system data and use the tzdata package instead, set `PYTHONTZPATH=""`.

Runtime configuration

The TZ search path can also be configured at runtime using the *reset_tzpath()* function. This is generally not an advisable operation, though it is reasonable to use it in test functions that require the use of a specific time zone path (or require disabling access to the system time zones).

8.2.3 The `ZoneInfo` class

class zoneinfo.**ZoneInfo**(*key*)

A concrete *datetime.tzinfo* subclass that represents an IANA time zone specified by the string `key`. Calls to the primary constructor will always return objects that compare identically; put another way, barring cache invalidation via *ZoneInfo.clear_cache()*, for all values of `key`, the following assertion will always be true:

```
a = ZoneInfo(key)
b = ZoneInfo(key)
assert a is b
```

`key` must be in the form of a relative, normalized POSIX path, with no up-level references. The constructor will raise *ValueError* if a non-conforming key is passed.

If no file matching `key` is found, the constructor will raise *ZoneInfoNotFoundError*.

The `ZoneInfo` class has two alternate constructors:

classmethod ZoneInfo.**from_file**(*fobj*, */*, *key=None*)

Constructs a `ZoneInfo` object from a file-like object returning bytes (e.g. a file opened in binary mode or an *io.BytesIO* object). Unlike the primary constructor, this always constructs a new object.

The `key` parameter sets the name of the zone for the purposes of `__str__()` and `__repr__()`.

Objects created via this constructor cannot be pickled (see *pickling*).

classmethod ZoneInfo.**no_cache**(*key*)

An alternate constructor that bypasses the constructor's cache. It is identical to the primary constructor, but returns a new object on each call. This is most likely to be useful for testing or demonstration purposes, but it can also be used to create a system with a different cache invalidation strategy.

Objects created via this constructor will also bypass the cache of a deserializing process when unpickled.

警示

Using this constructor may change the semantics of your datetimes in surprising ways, only use it if you know that you need to.

The following class methods are also available:

classmethod ZoneInfo.**clear_cache**(*, *only_keys=None*)

A method for invalidating the cache on the `ZoneInfo` class. If no arguments are passed, all caches are invalidated and the next call to the primary constructor for each key will return a new instance.

If an iterable of key names is passed to the `only_keys` parameter, only the specified keys will be removed from the cache. Keys passed to `only_keys` but not found in the cache are ignored.

警告

Invoking this function may change the semantics of datetimes using `ZoneInfo` in surprising ways; this modifies module state and thus may have wide-ranging effects. Only use it if you know that you need to.

The class has one attribute:

ZoneInfo.**key**

This is a read-only *attribute* that returns the value of `key` passed to the constructor, which should be a lookup key in the IANA time zone database (e.g. `America/New_York`, `Europe/Paris` or `Asia/Tokyo`).

For zones constructed from file without specifying a `key` parameter, this will be set to `None`.

備🄵

Although it is a somewhat common practice to expose these to end users, these values are designed to be primary keys for representing the relevant zones and not necessarily user-facing elements. Projects like CLDR (the Unicode Common Locale Data Repository) can be used to get more user-friendly strings from these keys.

String representations

The string representation returned when calling *str* on a *ZoneInfo* object defaults to using the *ZoneInfo.key* attribute (see the note on usage in the attribute documentation):

```
>>> zone = ZoneInfo("Pacific/Kwajalein")
>>> str(zone)
'Pacific/Kwajalein'

>>> dt = datetime(2020, 4, 1, 3, 15, tzinfo=zone)
```

(繼續下一頁)

(繼續上一頁)

```
>>> f"{dt.isoformat()} [{dt.tzinfo}]"
'2020-04-01T03:15:00+12:00 [Pacific/Kwajalein]'
```

For objects constructed from a file without specifying a `key` parameter, `str` falls back to calling *`repr()`*. `ZoneInfo`'s `repr` is implementation-defined and not necessarily stable between versions, but it is guaranteed not to be a valid `ZoneInfo` key.

Pickle serialization

Rather than serializing all transition data, `ZoneInfo` objects are serialized by key, and `ZoneInfo` objects constructed from files (even those with a value for `key` specified) cannot be pickled.

The behavior of a `ZoneInfo` file depends on how it was constructed:

1. `ZoneInfo(key)`: When constructed with the primary constructor, a `ZoneInfo` object is serialized by key, and when deserialized, the deserializing process uses the primary and thus it is expected that these are expected to be the same object as other references to the same time zone. For example, if `europe_berlin_pkl` is a string containing a pickle constructed from `ZoneInfo("Europe/Berlin")`, one would expect the following behavior:

   ```
   >>> a = ZoneInfo("Europe/Berlin")
   >>> b = pickle.loads(europe_berlin_pkl)
   >>> a is b
   True
   ```

2. `ZoneInfo.no_cache(key)`: When constructed from the cache-bypassing constructor, the `ZoneInfo` object is also serialized by key, but when deserialized, the deserializing process uses the cache bypassing constructor. If `europe_berlin_pkl_nc` is a string containing a pickle constructed from `ZoneInfo.no_cache("Europe/Berlin")`, one would expect the following behavior:

   ```
   >>> a = ZoneInfo("Europe/Berlin")
   >>> b = pickle.loads(europe_berlin_pkl_nc)
   >>> a is b
   False
   ```

3. `ZoneInfo.from_file(fobj, /, key=None)`: When constructed from a file, the `ZoneInfo` object raises an exception on pickling. If an end user wants to pickle a `ZoneInfo` constructed from a file, it is recommended that they use a wrapper type or a custom serialization function: either serializing by key or storing the contents of the file object and serializing that.

This method of serialization requires that the time zone data for the required key be available on both the serializing and deserializing side, similar to the way that references to classes and functions are expected to exist in both the serializing and deserializing environments. It also means that no guarantees are made about the consistency of results when unpickling a `ZoneInfo` pickled in an environment with a different version of the time zone data.

8.2.4 函式

zoneinfo.**available_timezones**()

Get a set containing all the valid keys for IANA time zones available anywhere on the time zone path. This is recalculated on every call to the function.

This function only includes canonical zone names and does not include "special" zones such as those under the `posix/` and `right/` directories, or the `posixrules` zone.

警示

This function may open a large number of files, as the best way to determine if a file on the time zone path is a valid time zone is to read the "magic string" at the beginning.

備🄵

These values are not designed to be exposed to end-users; for user facing elements, applications should use something like CLDR (the Unicode Common Locale Data Repository) to get more user-friendly strings. See also the cautionary note on *ZoneInfo.key*.

zoneinfo.**reset_tzpath**(*to=None*)

Sets or resets the time zone search path (*TZPATH*) for the module. When called with no arguments, *TZPATH* is set to the default value.

Calling `reset_tzpath` will not invalidate the *ZoneInfo* cache, and so calls to the primary `ZoneInfo` constructor will only use the new `TZPATH` in the case of a cache miss.

The `to` parameter must be a *sequence* of strings or *os.PathLike* and not a string, all of which must be absolute paths. *ValueError* will be raised if something other than an absolute path is passed.

8.2.5 Globals

zoneinfo.**TZPATH**

A read-only sequence representing the time zone search path -- when constructing a `ZoneInfo` from a key, the key is joined to each entry in the `TZPATH`, and the first file found is used.

`TZPATH` may contain only absolute paths, never relative paths, regardless of how it is configured.

The object that `zoneinfo.TZPATH` points to may change in response to a call to *reset_tzpath()*, so it is recommended to use `zoneinfo.TZPATH` rather than importing `TZPATH` from `zoneinfo` or assigning a long-lived variable to `zoneinfo.TZPATH`.

For more information on configuring the time zone search path, see *Configuring the data sources*.

8.2.6 Exceptions and warnings

exception zoneinfo.**ZoneInfoNotFoundError**

Raised when construction of a *ZoneInfo* object fails because the specified key could not be found on the system. This is a subclass of *KeyError*.

exception zoneinfo.**InvalidTZPathWarning**

Raised when *PYTHONTZPATH* contains an invalid component that will be filtered out, such as a relative path.

8.3 calendar --- 日🄵相關函式

原始碼： Lib/calendar.py

這個模組讓你可以像 Unix 的 **cal** 程式一樣輸出日🄵，🄵額外提供有用的日🄵相關函式。這些日🄵預設把🄵一當作一🄵的第一天，而🄵日當作最後一天（歐洲的慣例）。可以使用*setfirstweekday()* 設定一🄵的第一天🄵🄵日 (6) 或一🄵的其它任一天，其中指定日期的參數是整數。相關功能參考*datetime* 和*time* 模組。

這個模組定義的函式和類🄵使用理想化的日🄵，也就是公🄵 (Gregorian calendar) 無限往前後兩個方向延伸。這符合 Dershowitz 和 Reingold 在「Calendrical Calculations」這本書定義的「逆推公🄵」(proleptic Gregorian)，是做所有計算的基礎日🄵。0 及負數年份的解讀跟 ISO 8601 標準🄵規定的一樣，0 年是公元前 1 年，-1 年是公元前 2 年依此類推。

class calendar.**Calendar**(*firstweekday=0*)

建立*Calendar* 物件。*firstweekday* 是一個指定一🄵第一天的整數，*MONDAY* 是 0（預設值），*SUNDAY* 是 6。

Calendar 物件提供一些方法來🄵日🄵資料的格式化做准備。這個類🄵本身不做任何格式化，這是子類🄵的工作。

Calendar 實例有以下方法：

iterweekdays()

回傳一個以數字代表一🄵的每一天的🄵代器 (iterator)。🄵代器的第一個值和*firstweekday* 屬性的值一樣。

itermonthdates(*year*, *month*)

回傳一個在 *year* 年 *month* (1--12) 月的🄵代器。這個🄵代器會回傳該月的所有日期（*datetime.date* 物件）以及在該月之前及之後用來組成完整一🄵的日期。

itermonthdays(*year*, *month*)

類似*itermonthdates()*，回傳一個在 *year* 年 *month* 月的🄵代器，但不受限於*datetime.date* 的範圍。回傳的日期單純是該月當日的數字，對於該月之外的日期數字會是 0。

itermonthdays2(*year*, *month*)

類似*itermonthdates()*，回傳一個在 *year* 年 *month* 月的🄵代器，但不受限於*datetime.date* 的範圍。回傳的日期是一個由該月當日的數字及代表🄵幾的數字組成的元組。

itermonthdays3(*year*, *month*)

類似*itermonthdates()*，回傳一個在 *year* 年 *month* 月的🄵代器，但不受限於*datetime.date* 的範圍。回傳的日期是一個由年、月、日的數字組成的元組。

在 3.7 版被加入.

itermonthdays4(*year*, *month*)

類似*itermonthdates()*，回傳一個在 *year* 年 *month* 月的🄵代器，但不受限於*datetime.date*的範圍。回傳的日期是一個由年、月、日及代表🄵幾的數字組成的元組。

在 3.7 版被加入.

monthdatescalendar(*year*, *month*)

回傳一個在 *year* 年 *month* 月每一🄵組成的串列。每一🄵是一個串列，包含七個*datetime.date*物件。

monthdays2calendar(*year*, *month*)

回傳一個在 *year* 年 *month* 月每一🄵組成的串列。每一🄵是一個串列，包含七個該月當日的數字及代表🄵幾的數字組成的元組。

monthdayscalendar(*year*, *month*)

回傳一個在 *year* 年 *month* 月每一🄵組成的串列。每一🄵是一個串列，包含七個該月當日的數字。

yeardatescalendar(*year*, *width=3*)

回傳用來格式化的指定年份的資料。回傳值是月份列的串列，每個月份列最多由 *width* 個月份組成（預設🄵 3）。每個月份包含四到六🄵，每一🄵包含一到七天，每一天則是一個*datetime.date*物件。

yeardays2calendar(*year*, *width=3*)

回傳用來格式化的指定年份的資料（類似*yeardatescalendar()*）。每一天是一個該月當日的數字及代表🄵幾的數字組成的元組，該月外的日期的該月當日數字🄵 0。

yeardayscalendar(*year*, *width=3*)

回傳用來格式化的指定年份的資料（類似*yeardatescalendar()*）。每一天是一個該月當日的數字，該月外的日期的該月當日數字🄵 0。

class calendar.**TextCalendar**(*firstweekday=0*)

這個類🄵用來🄵生純文字的日🄵。

TextCalendar 實例有以下方法：

formatmonth(*theyear*, *themonth*, *w=0*, *l=0*)

以多行字串的形式回傳一個月份的日🄵。如果給定 *w*，它會指定置中的日期欄的寬度。如果給定 *l*，它會指定每一🄵使用的行數。這個日🄵會依據在建構函式中指定或者透過*setfirstweekday()*方法設定的一🄵的第一天來輸出。

prmonth(*theyear*, *themonth*, *w=0*, *l=0*)

印出一個月份的日🄵，🄵容和*formatmonth()* 回傳的一樣。

formatyear(*theyear*, *w=2*, *l=1*, *c=6*, *m=3*)

以多行字串的形式回傳有 *m* 欄的一整年的日🄵。可選的參數 *w*、*l* 及 *c* 分🄵是日期欄寬度、每🄵行數及月份欄中間的空白數。這個日🄵會依據在建構函式中指定或者透過*setfirstweekday()*方法設定的一🄵的第一天來輸出。最早可以🄵生日🄵的年份會依據平台而不同。

pryear(*theyear*, *w=2*, *l=1*, *c=6*, *m=3*)

印出一整年的日🄵，🄵容和*formatyear()* 回傳的一樣。

class calendar.**HTMLCalendar**(*firstweekday=0*)

這個類🄵用來🄵生 HTML 日🄵。

HTMLCalendar 實例有以下方法：

formatmonth(*theyear*, *themonth*, *withyear=True*)

以 HTML 表格的形式回傳一個月份的日🄵。如果 *withyear* 是 true 則標題會包含年份，否則只會有月份名稱。

formatyear(*theyear*, *width=3*)

以 HTML 表格的形式回傳一整年的日□。*width*（預設□ 3）指定一列有幾個月。

formatyearpage(*theyear*, *width=3*, *css='calendar.css'*, *encoding=None*)

以完整 HTML 頁面的形式回傳一整年的日□。*width*（預設□ 3）指定一列有幾個月。*css* 是要使用的 CSS (cascading style sheet) 名稱，可以給*None* 表示不使用任何 CSS。*encoding* 指定輸出使用的編碼（預設使用系統預設編碼）。

formatmonthname(*theyear*, *themonth*, *withyear=True*)

以 HTML 表列的形式回傳一個月份的名稱。如果 *withyear* 是 true 則該列會包含年份，否則只會有月份名稱。

HTMLCalendar 可以覆寫以下屬性來客□日□所使用的 CSS 類□:

cssclasses

對應一□每一天 CSS 類□的串列。預設的串列□容□:

```
cssclasses = ["mon", "tue", "wed", "thu", "fri", "sat", "sun"]
```

可以針對每一天增加更多樣式:

```
cssclasses = ["mon text-bold", "tue", "wed", "thu", "fri", "sat", "sun red"]
```

注意這個串列的長度必須是七個項目。

cssclass_noday

跟當月□同一□且屬於前一個或下一個月份的日期使用的 CSS 類□。

在 3.7 版被加入.

cssclasses_weekday_head

在標題列中一□每一天名稱的 CSS 類□的串列。預設□容和*cssclasses* 相同。

在 3.7 版被加入.

cssclass_month_head

月份標題的 CSS 類□（由*formatmonthname()* 所使用），預設值是 "month"。

在 3.7 版被加入.

cssclass_month

整個月份表格的 CSS 類□（由*formatmonth()* 所使用），預設值是 "month"。

在 3.7 版被加入.

cssclass_year

整年表格的 CSS 類□（由*formatyear()* 所使用），預設值是 "year"。

在 3.7 版被加入.

cssclass_year_head

整年表格標題的 CSS 類□（由*formatyear()* 所使用），預設值是 "year"。

在 3.7 版被加入.

注意雖然上面提到的 CSS 屬性名稱是單數（例如 cssclass_month、cssclass_noday），你可以使用多個以空格隔開的 CSS 類□取代單一 CSS 類□，例如:

```
"text-bold text-red"
```

以下是客□化 HTMLCalendar 的範例:

```
class CustomHTMLCal(calendar.HTMLCalendar):
    cssclasses = [style + " text-nowrap" for style in
                  calendar.HTMLCalendar.cssclasses]
    cssclass_month_head = "text-center month-head"
    cssclass_month = "text-center month"
    cssclass_year = "text-italic lead"
```

class calendar.**LocaleTextCalendar**(*firstweekday=0*, *locale=None*)

TextCalendar 的子類🄵，可以在建構函式傳入語系名稱，它會回傳指定語系的月份及一🄵每一天的名稱。

class calendar.**LocaleHTMLCalendar**(*firstweekday=0*, *locale=None*)

HTMLCalendar 的子類🄵，可以在建構函式傳入語系名稱，它會回傳指定語系的月份及一🄵每一天的名稱。

備🄵

這兩個類🄵的建構函式、`formatweekday()` 及 `formatmonthname()` 方法會把 `LC_TIME` 語系暫時改成給定的 *locale*。因🄵目前的語系是屬於整個行程 (process-wide) 的設定，它們不是執行緒安全的。

這個模組提供以下函式給單純的文字日🄵使用。

calendar.**setfirstweekday**(*weekday*)

設定一🄵的第一天（`0` 是🄵一、`6` 是🄵日）。提供*MONDAY*、*TUESDAY*、*WEDNESDAY*、*THURSDAY*、*FRIDAY*、*SATURDAY* 及*SUNDAY* 可以方便設定。例如設定一🄵的第一天🄵🄵日：

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

calendar.**firstweekday**()

回傳目前設定的一🄵的第一天。

calendar.**isleap**(*year*)

如果 *year* 是閏年回傳*True*，否則回傳*False*。

calendar.**leapdays**(*y1*, *y2*)

回傳從 *y1* 到 *y2*（不包含）間有幾個閏年，其中 *y1* 和 *y2* 是年份。

這個函式也適用在跨越世紀的時間範圍。

calendar.**weekday**(*year*, *month*, *day*)

回傳 *year* 年 (`1970`--...) *month* 月 (`1`--`12`) *day* 日 (`1`--`31`) 是🄵幾（`0` 是星期一）。

calendar.**weekheader**(*n*)

回傳包含一🄵每一天的名稱縮寫的標題。*n* 指定每一天的字元寬度。

calendar.**monthrange**(*year*, *month*)

回傳指定 *year* 年 *month* 月該月第一天代表🄵幾的數字及該月有多少天。

calendar.**monthcalendar**(*year*, *month*)

回傳代表一個月份日🄵的矩陣。每一列🄵一🄵；該月以外的日期以 0 表示。每一🄵以🄵一開始，除非有使用*setfirstweekday()* 改變設定。

calendar.**prmonth**(*theyear*, *themonth*, *w=0*, *l=0*)

印出一個月份的日🄵，跟*month()* 回傳的🄵容一樣。

calendar.**month**(*theyear*, *themonth*, *w=0*, *l=0*)

以多行字串的形式回傳一個月的日F，使用*TextCalendar* 類F的*formatmonth()*。

calendar.**prcal**(*year*, *w=0*, *l=0*, *c=6*, *m=3*)

印出一整年的日F，跟*calendar()* 回傳的F容一樣。

calendar.**calendar**(*year*, *w=2*, *l=1*, *c=6*, *m=3*)

以多行字串回傳三欄形式的一整年日F，使用*TextCalendar* 類F的*formatyear()*。

calendar.**timegm**(*tuple*)

一個跟日F無關但方便的函式，它接受一個像*time* 模組F的*gmtime()* 函式回傳的元組，F回傳對應的 Unix 時間戳，假設從 1970 開始及 POSIX 編碼。事實上，*time.gmtime()* 和*timegm()* 是彼此相反的。

calendar 模組匯出以下資料屬性：

calendar.**day_name**

以目前語系來表示的一F每一天名稱的陣列。

calendar.**day_abbr**

以目前語系來表示的一F每一天縮寫名稱的陣列。

calendar.**MONDAY**

calendar.**TUESDAY**

calendar.**WEDNESDAY**

calendar.**THURSDAY**

calendar.**FRIDAY**

calendar.**SATURDAY**

calendar.**SUNDAY**

一F每一天的F名，其中 MONDAY 是 0 而 SUNDAY 是 6。

在 3.12 版被加入.

class calendar.**Day**

將一F中的幾天定義F整數常數的列舉。此列舉的成員將作F*MONDAY* 到*SUNDAY* 匯出到模組作用域。

在 3.12 版被加入.

calendar.**month_name**

以目前語系來表示的一年每個月份名稱的陣列。它按照一般慣例以數字 1 代表一月，因此它的長度F 13，而 month_name[0] 是空字串。

calendar.**month_abbr**

以目前語系來表示的一年每個月份縮寫名稱的陣列。它按照一般慣例以數字 1 代表一月，因此它的長度F 13，而 month_abbr[0] 是空字串。

calendar.**JANUARY**

calendar.**FEBRUARY**

calendar.**MARCH**

calendar.**APRIL**

calendar.**MAY**

calendar.**JUNE**

calendar.**JULY**

calendar.**AUGUST**

calendar.**SEPTEMBER**

calendar.**OCTOBER**

calendar.**NOVEMBER**

calendar.**DECEMBER**

一年🄵每個月的🄵名，其中 JANUARY 是 ㄅ而 DECEMBER 是 12。

在 3.12 版被加入.

class calendar.**Month**

將一年中的月份定義🄵整數常數的列舉。此列舉的成員將作🄵*JANUARY* 到*DECEMBER* 匯出到模組作用域。

在 3.12 版被加入.

calendar 模組定義了以下例外：

exception calendar.**IllegalMonthError**(*month*)

ValueError 的子類🄵，當給定的月份數字超出 1-12 範圍（含）時引發。

month

無效的月份號。

exception calendar.**IllegalWeekdayError**(*weekday*)

ValueError 的子類🄵，當給定的🄵幾的數字超出 0-6（含）範圍時引發。

weekday

無效的🄵幾編號。

也參考

***datetime* 模組**
日期與時間的物件導向介面，和*time* 模組有相似的功能。

***time* 模組**
底層的時間相關函式。

8.3.1 命令列用法

在 2.5 版被加入.

calendar 模組可以作🄵🄵本從命令列執行，🄵以互動方式列印日🄵。

```
python -m calendar [-h] [-L LOCALE] [-e ENCODING] [-t {text,html}]
                   [-w WIDTH] [-l LINES] [-s SPACING] [-m MONTHS] [-c CSS]
                   [year] [month]
```

例如，要列印 2000 年的日🄵：

```
$ python -m calendar 2000
                                  2000

      January                   February                  March
Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su
                1  2          1  2  3  4  5  6            1  2  3  4  5
 3  4  5  6  7  8  9       7  8  9 10 11 12 13       6  7  8  9 10 11 12
10 11 12 13 14 15 16      14 15 16 17 18 19 20      13 14 15 16 17 18 19
```

(繼續下一頁)

(繼續上一頁)

```
17 18 19 20 21 22 23      21 22 23 24 25 26 27      20 21 22 23 24 25 26
24 25 26 27 28 29 30      28 29                     27 28 29 30 31
31

       April                     May                       June
Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su
                1  2       1  2  3  4  5  6  7                1  2  3  4
 3  4  5  6  7  8  9       8  9 10 11 12 13 14       5  6  7  8  9 10 11
10 11 12 13 14 15 16      15 16 17 18 19 20 21      12 13 14 15 16 17 18
17 18 19 20 21 22 23      22 23 24 25 26 27 28      19 20 21 22 23 24 25
24 25 26 27 28 29 30      29 30 31                  26 27 28 29 30
31

24 25 26 27 28 29 30      28 29 30 31               25 26 27 28 29 30
31

      October                   November                  December
Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su      Mo Tu We Th Fr Sa Su
                   1             1  2  3  4  5                   1  2  3
 2  3  4  5  6  7  8       6  7  8  9 10 11 12       4  5  6  7  8  9 10
 9 10 11 12 13 14 15      13 14 15 16 17 18 19      11 12 13 14 15 16 17
16 17 18 19 20 21 22      20 21 22 23 24 25 26      18 19 20 21 22 23 24
23 24 25 26 27 28 29      27 28 29 30               25 26 27 28 29 30 31
30 31
```

接受以下選項:

--help, -h

顯示幫助訊息F退出。

--locale LOCALE, **-L** LOCALE

用於月份和F幾名稱的語系。預設F英語。

--encoding ENCODING, **-e** ENCODING

用於輸出的編碼。如有設定*--locale*則必須給定*--encoding*。

--type {text,html}, **-t** {text,html}

將日F以文字或 HTML 文件的形式印出到終端機。

year

印出日F的年份。必須是 1 到 9999 之間的數字。預設F當前年份。

month

要列印日F的指定*year*的月份。必須是 1 到 12 之間的數字，F且只能在文字模式下使用。預設列印全年日F。

文字模式選項:

--width WIDTH, **-w** WIDTH

終端機行中日期行的寬度。日期印出在行的中央。任何小於 2 的值都會被忽略。預設F 2。

--lines LINES, **-l** LINES

終端機列中每F的列數。日期印出時頂部會對齊。任何小於 1 的值都會被忽略。預設F 1。

--spacing SPACING, **-s** SPACING
: 行中月份之間的間距。任何小於 2 的值都會被忽略。預設🄴 6。

--months MONTHS, **-m** MONTHS
: 每列印出的月份數量。預設🄴 3。

HTML 模式選項：

--css CSS, **-c** CSS
: 用於日🄴的 CSS 樣式表路徑。這必須是相對於🄴生之 HTML 的，或者🄴🄴對的 HTTP 或 `file:///` URL。

8.4 collections --- 容器資料型態

原始碼： Lib/collections/__init__.py

這個模組實作了一些特🄴的容器資料型態，用來替代 Python 一般🄴建的容器，例如*dict*（字典）、*list*（串列）、*set*（集合）和*tuple*（元組）。

namedtuple()	用來建立具名欄位的 tuple 子類🄴的工廠函式
deque	一個類似 list 的容器，可以快速的在頭尾加入 (append) 元素與移除 (pop) 元素
ChainMap	一個類似 dict 的類🄴，用來🄴多個對映 (mapping) 建立單一的視圖 (view)
Counter	dict 的子類🄴，用來計算可雜🄴物件的數量
OrderedDict	dict 的子類🄴，會記🄴物件被加入的順序
defaultdict	dict 的子類🄴，當值不存在 dict 中時會呼叫一個提供預設值的工廠函式
UserDict	dict 物件的包裝器 (wrapper)，簡化了 dict 的子類🄴化過程
UserList	list 物件的包裝器，簡化了 list 的子類🄴化過程
UserString	字串物件的包裝器，簡化了字串的子類🄴化過程

8.4.1 ChainMap 物件

在 3.3 版被加入.

ChainMap（對映鏈結）類🄴的目的是快速將數個對映連結在一起，讓它們可以被當作一個單元來處理。它通常會比建立一個新的字典🄴多次呼叫*update()* 來得更快。

這個類🄴可用於模擬巢狀作用域 (nested scopes)，且在模板化 (templating) 時能派上用場。

class collections.**ChainMap**(**maps*)
: 一個*ChainMap* 將多個 dict 或其他對映組合在一起，建立一個獨立、可更新的視圖。如果🄴有指定 *maps*，預設會提供一個空字典讓每個新鏈結都至少有一個對映。

  底層的對映儲存於一個 list 中，這個 list 是公開的且可透過 *maps* 屬性存取或更新，🄴有其他狀態 (state)。

  檢索 (lookup) 陸續查詢底層對映，直到鍵被找到，然而讀取、更新和🄴除就只會對第一個對映操作。

  ChainMap 透過參照將底層對映合🄴，所以當一個底層對映被更新，這些改變也會反映到*ChainMap*。

  所有常見的字典方法都有支援。此外，還有一個 *maps* 屬性 (attribute)、一個建立子上下文 (subcontext) 的方法、和一個能🄴存取除了第一個以外其他所有對映的特性 (property)：

maps

一個可被更新的對映列表，這個列表是按照被搜索的順序來排列，在 ChainMap 中它是唯一被儲存的狀態，可被修改來變🄵搜索順序。回傳的列表都至少包含一個對映。

new_child(*m=None*, ***kwargs*)

回傳包含一個新對映的*ChainMap*，新對映後面接著當前實例的所有現存對映。如果有給定 `m`，`m` 會成🄵那個最前面的新對映；若🄵有指定，則會加上一個空 dict，如此一來呼叫 `d.new_child()` 就等同於 `ChainMap({}, *d.maps)`。這個方法用於建立子上下文，而保持父對映的不變。

在 3.4 版的變更: 加入可選參數 `m`。

在 3.10 版的變更: 增加了對關鍵字引數的支援。

parents

回傳一個包含除了第一個以外所有其他對映的新*ChainMap*的特性，可用於需要跳過第一個對映的搜索。使用情境類似於在巢狀作用域當中使用 `nonlocal` 關鍵字，也可與🄵建函式*super()*做類比。引用 `d.parents` 等同於 `ChainMap(*d.maps[1:])`。

注意，一個*ChainMap*的🄵代順序是透過由後往前掃描對映而定:

```
>>> baseline = {'music': 'bach', 'art': 'rembrandt'}
>>> adjustments = {'art': 'van gogh', 'opera': 'carmen'}
>>> list(ChainMap(adjustments, baseline))
['music', 'art', 'opera']
```

這和呼叫*dict.update()*結果的順序一樣是從最後一個對映開始:

```
>>> combined = baseline.copy()
>>> combined.update(adjustments)
>>> list(combined)
['music', 'art', 'opera']
```

在 3.9 版的變更: 支援 `|` 和 `|=` 運算子，詳見 **PEP 584**。

也參考

- Enthought CodeTools package 中的 MultiContext class 支援在鏈中選定任意對映寫入。
- Django 中用於模板的 Context class 是唯讀的對映鏈，也具有加入 (push) 和移除 (pop) 上下文的功能，與*new_child()*方法和*parents*特性類似。
- Nested Contexts recipe 提供了控制是否只對鏈中第一個或其他對映做寫入或其他操作的選項。
- 一個極度簡化、維讀版本的 Chainmap。

ChainMap 范例和用法

此章節提供了多種操作 ChainMap 的案例。

模擬 Python 🄵部檢索鏈結的例子:

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

讓使用者指定的命令列引數優先於環境變數、再優先於預設值的範例:

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k: v for k, v in vars(namespace).items() if v is not None}

combined = ChainMap(command_line_args, os.environ, defaults)
print(combined['color'])
print(combined['user'])
```

用*ChainMap*類🄵模擬巢狀上下文的範例模式：

```
c = ChainMap()          # Create root context
d = c.new_child()       # Create nested child context
e = c.new_child()       # Child of c, independent from d
e.maps[0]               # Current context dictionary -- like Python's locals()
e.maps[-1]              # Root context -- like Python's globals()
e.parents               # Enclosing context chain -- like Python's nonlocals

d['x'] = 1              # Set value in current context
d['x']                  # Get first key in the chain of contexts
del d['x']              # Delete from current context
list(d)                 # All nested values
k in d                  # Check all nested values
len(d)                  # Number of nested values
d.items()               # All nested items
dict(d)                 # Flatten into a regular dictionary
```

*ChainMap*類🄵只對鏈結中第一個對映來做寫入或🄵除，但檢索則會掃過整個鏈結。但如果需要對更深層的鍵寫入或🄵除，透過定義一個子類🄵來實作也不困難：

```
class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to inner scopes'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
                return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'blue'}, {'lion': 'yellow'})
>>> d['lion'] = 'orange'         # update an existing key two levels down
>>> d['snake'] = 'red'           # new keys get added to the topmost dict
>>> del d['elephant']            # remove an existing key one level down
>>> d                            # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})
```

8.4.2 Counter 物件

提供一個支援方便且快速計數的計數器工具，例如：

```
>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
...
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554),  ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

class collections.**Counter**([*iterable-or-mapping*])

Counter 是*dict* 的子類𠀀，用來計算可雜𠀀物件的數量。它是將物件與其計數作𠀀字典的鍵值對儲存的集合容器。計數可以是包含 0 與負數的任何整數值。*Counter* 類𠀀類似其他程式語言中的 bags 或 multisets。

被計數的元素來自一個 *iterable* 或是被其他的 *mapping*（或 Counter）初始化：

```
>>> c = Counter()                           # a new, empty counter
>>> c = Counter('gallahad')                 # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2})      # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)             # a new counter from keyword args
```

Counter 物件擁有一個字典的使用介面，除了遇到 Counter 中𠀀有的值時會回傳計數 0 取代*KeyError* 這點不同：

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon']                              # count of a missing element is zero
0
```

將一個值的計數設𠀀 0 𠀀不會真的從 Counter 中𠀀除這個元素，要使用 `del` 來將其𠀀除：

```
>>> c['sausage'] = 0                        # counter entry with a zero count
>>> del c['sausage']                        # del actually removes the entry
```

在 3.1 版被加入.

在 3.7 版的變更: 作𠀀*dict* 的子類𠀀，*Counter* 繼承了記憶插入順序的功能。對 *Counter* 做數學運算後同樣保留順序性，其結果是依照各個元素在運算元左邊出現的時間先後、再按照運算元右邊出現的時間先後來排列。

除了字典原本就有的方法外，Counter 物件額外支援數個新方法：

elements()

回傳每個元素都重𠀀出現計算次數的 iterator（𠀀代器）物件，其中元素的回傳順序是依照各元素首次出現的時間先後。如果元素的出現次數小於 1，*elements()* 方法會忽略這些元素。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

most_common([*n*])

回傳一個 list，包含出現最多次的 *n* 個元素及其出現次數，F按照出現次數排序。如果 *n* 被省略或者F None，*most_common()* 會回傳所有 counter 中的元素。出現次數相同的元素會按照首次出現的時間先後來排列：

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('b', 2), ('r', 2)]
```

subtract([*iterable-or-mapping*])

F去自一個 *iterable* 或另一個對映（或 Counter）中的計數元素，行F類似*dict.update()* 但是是F了F去計數而非取代其值。輸入和輸出都可以是 0 或是負數。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

在 3.2 版被加入.

total()

計算總計數值。

```
>>> c = Counter(a=10, b=5, c=0)
>>> c.total()
15
```

在 3.10 版被加入.

通常來F字典方法也可以用於*Counter* 物件，除了以下兩個作用方式與計數器不同。

fromkeys(*iterable*)

此類F方法F有被實作於*Counter* 物件中。

update([*iterable-or-mapping*])

加上自一個 *iterable* 計算出的計數或加上另一個 *mapping*（或 Counter）中的計數，行F類似*dict.update()* 但是是F了加上計數而非取代其值。另外，*iterable* 需要是一串將被計算個數元素的序列，而非元素F (key, value) 形式的序列。

Counter 支援相等性、子集和超集關F的 rich comparison 運算子：==、!=、<、<=、>、>=。這些檢測會將不存在的元素之計數值當作零，因此 Counter(a=1) == Counter(a=1, b=0) 將回傳真值。

在 3.10 版的變更: 增加了 rich comparison 運算。

在 3.10 版的變更: 在相等性運算中，不存在的元素之計數值會被當作零。在此之前，Counter(a=3) 和 Counter(a=3, b=0) 被視F不同。

使用*Counter* 物件的常見使用模式：

```
c.total()                       # total of all counts
c.clear()                       # reset all counts
list(c)                         # list unique elements
set(c)                          # convert to a set
dict(c)                         # convert to a regular dictionary
c.items()                       # convert to a list of (elem, cnt) pairs
Counter(dict(list_of_pairs))    # convert from a list of (elem, cnt) pairs
c.most_common()[:-n-1:-1]       # n least common elements
+c                              # remove zero and negative counts
```

𝔽結合多個*Counter* 物件以𝔽生 multiset（多重集合，擁有大於 0 計數元素的計數器），有提供了幾種數學操作。加法和𝔽法是根據各個對應元素分𝔽將 Counter 加上和𝔽去計數，交集和聯集分𝔽回傳各個元素最小和最大計數，相等性與包含性運算則會比較對應的計數。每一個操作都可以接受輸入帶有正負號的計數，但輸出的 Counter 則會將擁有小於或等於 0 計數的元素剔除。

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d                       # add two counters together:  c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d                       # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d                       # intersection:  min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d                       # union:  max(c[x], d[x])
Counter({'a': 3, 'b': 2})
>>> c == d                      # equality:  c[x] == d[x]
False
>>> c <= d                      # inclusion:  c[x] <= d[x]
False
```

加𝔽法的一元運算子分𝔽是加上空的 Counter 和從空 Counter 𝔽去的簡寫。

```
>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})
```

在 3.3 版被加入: 開始支援加𝔽一元運算子和 multiset 的原地 (in-place) 操作。

備𝔽

Counter 主要是被設計來操作正整數以當作使用中的計數，但𝔽了某些會用到計數之值𝔽負數或𝔽其他型𝔽的案例中，Counter 也小心地被設計成不會預先排除這些特殊元素。𝔽了輔助使用於上述案例，這一小節記𝔽了最小範圍和型𝔽限制。

- *Counter* 類𝔽本身是字典的子類𝔽，且不限制其鍵與值。值被用來表示計數，但實際上你可以儲存任何值。
- 使用*most_common()* 方法的唯一條件是其值要是可被排序的。
- 像是 `c[key] += 1` 的原地操作中，其值之型𝔽只必須支援加𝔽，所以分數、浮點數、十進位數與其負值都可以使用。同理，*update()* 和*subtract()* 也都允許 0 或負值𝔽輸入或輸出。
- Multiset 相關方法只𝔽了處理正值而設計，其輸入允許是 0 或負值但只有正值會被輸出。𝔽無型𝔽限制，但其值的型𝔽須支援加、𝔽及比較運算。
- *elements()* 方法需要其計數𝔽正值，如𝔽 0 或負值則忽略。

也參考

- Smalltalk 中的 Bag class。
- 維基百科上的多重集合條目。
- C++ multisets 教學與範例。

- Multiset 的數學運算及其使用時機，參考 *Knuth, Donald. The Art of Computer Programming Volume II, Section 4.6.3, Exercise 19*。
- 若要根據給定的元素集合來列舉出所有不重🄵且擁有指定元素數量的 multiset，請見*itertools.combinations_with_replacement()*：

```
map(Counter, combinations_with_replacement('ABC', 2)) # --> AA AB AC BB BC CC
```

8.4.3 deque 物件

class collections.**deque**([*iterable*[, *maxlen*]])

回傳一個新的 deque（雙端🄵列）物件，將 *iterable* 中的資料由左至右（使用*append()*）加入來做初始化。如果 *iterable* 🄵未給定，回傳的則是一個空的 deque。

Deque（發音🄵"deck"，🄵"double-ended queue" 的簡稱）🄵 stack 和 queue 的一般化。deque 支援執行緒安全 (thread-safe)，且能🄵有效率地節省記憶體在頭和尾加入和移除元素，兩個方向的表現都大致🄵 *O*(1) 🄵雜度。

雖然*list* 物件也支援類似操作，但 list 優化了長度固定時的操作，而會改變底層資料的長度及位置的 `pop(0)` 和 `insert(0, v)` 操作，記憶體移動則🄵 *O*(*n*) 🄵雜度。

如果 *maxlen* 🄵有給定或者🄵 `None`，deque 可以增長到任意長度；但若有給定的話，deque 的最大長度就會被限制。一個被限制長度的 deque 一但滿了，若在一端加入數個新元素，則同時會在另一端移除相同數量的元素。限定長度的 deque 提供了和 Unix `tail` filter 類似的功能，可用於追🄵使用者在意的那些最新執行事項或數據源。

Deque 物件支援以下方法：

append(*x*)

將 *x* 自 deque 的右側加入。

appendleft(*x*)

將 *x* 自 deque 的左側加入。

clear()

將所有元素從 deque 中移除，使其長度🄵 0。

copy()

建立一個 deque 的淺🄵🄵 (shallow copy)。

在 3.5 版被加入.

count(*x*)

計算 deque 🄵元素🄵 *x* 的個數。

在 3.2 版被加入.

extend(*iterable*)

將 iterable 引數加入 deque 的右側。

extendleft(*iterable*)

將 iterable 引數加入 deque 的左側。要注意的是，加入後的元素順序和 iterable 參數是相反的。

index(*x*[, *start*[, *stop*]])

回傳 deque 中 *x* 的位置（或在索引 *start* 之後、索引 *stop* 之前的位置）。回傳第一個匹配的位置，如果🄵找到就引發*ValueError*。

在 3.5 版被加入.

insert(*i*, *x*)

在 deque 位置 *i* 中插入 *x*。

如果此插入操作導致 deque 超過其長度上限 *maxlen* 的話，會引發*IndexError* 例外。

在 3.5 版被加入.

pop()

移除🄵回傳 deque 的最右側元素，若本來就🄵有任何元素，則會引發*IndexError*。

popleft()

移除🄵回傳 deque 的最左側元素，若本來就🄵有任何元素，則會引發*IndexError*。

remove(*value*)

移除第一個出現的 *value*，如果🄵找到的話就引發一個*ValueError*。

reverse()

將 deque 中的元素原地 (in-place) 倒序排列🄵回傳 `None`。

在 3.2 版被加入.

rotate(*n=1*)

將 deque 向右輪轉 *n* 步。若 *n* 🄵負值則向左輪轉。

當 deque 不是空的，向右輪轉一步和 `d.appendleft(d.pop())` 有相同意義，而向左輪轉亦等價於 `d.append(d.popleft())`。

Deque 物件也提供了一個唯讀屬性：

maxlen

Deque 的最大長度，如果不限制長度的話則🄵 `None`。

在 3.1 版被加入.

除了以上使用方式，deque 亦支援了🄵代、pickle、`len(d)`、`reversed(d)`、`copy.copy(d)`、`copy.deepcopy(d)`、用 `in` 運算子來作隸屬資格檢測以及像是 `d[0]` 的標號引用來取得第一個元素。在兩端做索引存取的🄵雜度🄵 *O*(1) 但越靠近中間則🄵慢至 *O*(*n*)。若想要隨機而快速的存取，使用 list 會較🄵合適。

自從 3.5 版本起，deque 開始支援 `__add__()`、`__mul__()` 和 `__imul__()`。

範例：

```
>>> from collections import deque
>>> d = deque('ghi')                 # make a new deque with three items
>>> for elem in d:                   # iterate over the deque's elements
...     print(elem.upper())
G
H
I

>>> d.append('j')                    # add a new entry to the right side
>>> d.appendleft('f')                # add a new entry to the left side
>>> d                                # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])

>>> d.pop()                          # return and remove the rightmost item
'j'
>>> d.popleft()                      # return and remove the leftmost item
'f'
>>> list(d)                          # list the contents of the deque
['g', 'h', 'i']
```

(繼續下一頁)

(繼續上一頁)

```
>>> d[0]                            # peek at leftmost item
'g'
>>> d[-1]                           # peek at rightmost item
'i'

>>> list(reversed(d))               # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d                        # search the deque
True
>>> d.extend('jkl')                 # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1)                     # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1)                    # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d))              # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear()                       # empty the deque
>>> d.pop()                         # cannot pop from an empty deque
Traceback (most recent call last):
    File "<pyshell#6>", line 1, in -toplevel-
        d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc')             # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])
```

deque 用法

這一章節提供了多種操作 deque 的案例。

被限制長度的 deque 功能類似 Unix 中的 `tail` filter：

```
def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)
```

另一用法是透過從右邊加入、從左邊移除來維護最近加入元素的 list：

```
def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # https://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)
        yield s / n
```

一個輪詢調度器可以透過在*deque* 中放入 iterator 來實現，值自當前 iterator 的位置 0 取出，如果 iterator 已經消耗完畢就用*popleft()* 將其從🄵列中移除，否則利用*rotate()* 來將其移至🄵列尾端：

```
def roundrobin(*iterables):
    "roundrobin('ABC', 'D', 'EF') --> A D E B F C"
    iterators = deque(map(iter, iterables))
    while iterators:
        try:
            while True:
                yield next(iterators[0])
                iterators.rotate(-1)
        except StopIteration:
            # Remove an exhausted iterator.
            iterators.popleft()
```

rotate() 提供了可以用來實作*deque* 切片和🄵除的方法。舉例來🄵，用純 Python 實作 `del d[n]` 需要用 `rotate()` 來定位要被移除的元素：

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

要實現*deque* 切片，可使用近似以下方法：使用*rotate()* 來將目標元素移動到 deque 最左側，用*popleft()* 移除舊元素🄵用*extend()* 加入新元素，最後再反向 rotate。在這個方法上做小小的更動就能簡單地實現 Forth 風格的 stack 操作，例如 `dup`、`drop`、`swap`、`over`、`pick`、`rot` 和 `roll`。

8.4.4 defaultdict 物件

class collections.**defaultdict**(*default_factory=None*, /[, ...])

回傳一個新的類似字典的物件。*defaultdict* 是🄵建類🄵*dict* 的子類🄵。它覆蓋掉了一個方法🄵添加了一個可寫入的實例變數。其余功能與*dict* 相同，此文件不再🄵述。

第一個引數🄵*default_factory* 屬性提供了初始值，他被預設🄵 `None`，所有其他的引數（包括關鍵字引數）都會被傳遞給*dict* 的建構函式 (constructor)。

defaultdict 物件支援以下*dict* 所🄵有的方法：

__missing__(*key*)

如果*default_factory* 屬性🄵 `None`，呼叫此方法會引發一個附帶引數 *key* 的*KeyError* 例外。

如果*default_factory* 不🄵 `None`，它會不帶引數地被呼叫來🄵給定的 *key* 提供一個預設值，這個值和 *key* 被作🄵鍵值對來插入到字典中，🄵且被此方法所回傳。

如果呼叫*default_factory* 時發生例外，則該例外將會保持不變地向外傳遞。

在無法找到所要求的鍵時，此方法會被*dict* 類🄵的 `__getitem__()` 方法呼叫。無論此方法回傳了值還是引發了例外，都會被 `__getitem__()` 所傳遞。

注意，*__missing__()* 不會被 `__getitem__()` 以外的其他方法呼叫，這意味著 `get()` 會像一般的 dict 那樣回傳 `None` 做🄵預設值，而非使用*default_factory*。

defaultdict 物件支援以下實例變數：

default_factory

此屬性🄵*__missing__()* 方法所使用。如果有引數被傳入建構函式，則此屬性會被初始化成第一個引數，如未提供引數則被初始化🄵 `None`。

在 3.9 版的變更: 新增合🄵 (|) 和更新 (|=) 運算子，請見 **PEP 584**。

defaultdict 范例

使用*list* 作🄵*default_factory* 可以很輕松地將鍵值對序列轉🄵🄵包含 list 之字典：

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

當每個鍵第一次被存取時，它還🄴有存在於對映中，所以會自動呼叫*default_factory* 方法來回傳一個空的*list* 以建立一個條目，`list.append()` 操作後續會再新增值到這個新的列表🄴。當再次存取該鍵時，就如普通字典般操作（回傳該鍵所對應到的 list），`list.append()` 也會新增另一個值到 list 中。和使用與其等價的*dict.setdefault()* 相比，這個技巧更加快速和簡單：

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

設定*default_factory* 🄵*int* 使得*defaultdict* 可被用於計數（類似其他語言中的 bag 或 multiset）：

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

當一個字母首次被存取時，它🄵不存在於對映中，則*default_factory* 函式會呼叫*int()* 來提供一個整數 0 作🄵預設值。後續的增加操作繼續對每個字母做計數。

函式*int()* 總是回傳 0，這是常數函式的特殊情🄵。一個更快、更有彈性的方法是使用 lambda 函式來提供任何常數值（不用一定要是 0）：

```
>>> def constant_factory(value):
...     return lambda: value
...
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

將*default_factory* 設🄵*set* 使*defaultdict* 可用於構建一個值🄵 set 的字典：

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

8.4.5 `namedtuple()` 擁有具名欄位之 tuple 的工廠函式

Named tuple（具名元組）賦予 tuple 中各個位置意義，使程式碼更有可讀性與自我文件性。它們可以用於任何普通 tuple 可使用的場合，賦予其透過名稱（而非位置索引）來存取欄位的能力。

`collections.`**`namedtuple`**(*typename*, *field_names*, *, *rename=False*, *defaults=None*, *module=None*)

回傳一個名🄵 *typename* 的新 tuple 子類🄵。這個新的子類🄵被用於建立類似 tuple 的物件，可以透過屬性名稱來存取欄位，它同時也是可索引 (indexable) 和可🄵代的 (iterable)。子類🄵實例同樣有文件字串 (docstring)（有類🄵名 typename 和欄位名 field_names）和一個好用的 `__repr__()` 方法，可將 tuple 🄵容以 `name=value` 格式列出。

field_names 是一個像 `['x', 'y']` 一樣的字串序列。*field_names* 也可以是一個用空白或逗號分隔各個欄位名稱的字串，比如 `'x y'` 或者 `'x, y'`。

除了底🄵開頭以外的其他任何有效 Python 識🄵字 (identifier) 都可以作🄵欄位名稱，有效識🄵字由字母、數字、底🄵所組成，但不能是數字或底🄵開頭，也不能是關鍵詞*keyword*，例如 *class*、*for*、*return*、*global*、*pass* 或 *raise*。

如果 *rename* 🄵真值，無效的欄位名稱會自動被位置名稱取代。比如 `['abc', 'def', 'ghi', 'abc']` 會被轉🄵成 `['abc', '_1', 'ghi', '_3']`，移除了關鍵字 `def` 和重🄵欄位名 `abc`。

defaults 可以🄵 `None` 或者是一個預設值的*iterable*。因🄵有預設值的欄位必須出現在那些🄵有預設值的欄位之後，*defaults* 是被應用在右側的引數。例如 fieldnames 🄵 `['x', 'y', 'z']` 且 defaults 🄵 `(1, 2)`，那🄵 `x` 就必須被給定一個引數，`y` 被預設🄵 `1`，`z` 則被預設🄵 `2`。

如果 *module* 值有被定義，named tuple 的 `__module__` 屬性就被設定🄵該值。

Named tuple 實例中🄵有字典，所以它們更加輕量，且和一般 tuple 相比🄵用更少記憶體。

要支援 pickle，應將 named tuple 類🄵賦值給一個符合 *typename* 的變數。

在 3.1 版的變更: 新增對於 *rename* 的支援。

在 3.6 版的變更: *verbose* 和 *rename* 參數成🄵僅限關鍵字引數。

在 3.6 版的變更: 新增 *module* 參數。

在 3.7 版的變更: 移除 *verbose* 參數和 `_source` 屬性。

在 3.7 版的變更: 新增 *defaults* 參數和 `_field_defaults` 屬性。

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)     # instantiate with positional or keyword arguments
>>> p[0] + p[1]             # indexable like the plain tuple (11, 22)
33
>>> x, y = p                # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y               # fields also accessible by name
33
>>> p                       # readable __repr__ with a name=value style
Point(x=11, y=22)
```

Named tuple 在賦予欄位名稱於*csv* 或*sqlite3* 模組回傳之 tuple 時相當有用：

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade
↪')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
```

(繼續下一頁)

(繼續上一頁)

```
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

除了繼承自 tuple 的方法，named tuple 還支援三個額外的方法和兩個屬性。F了防止欄位名稱有衝突，方法和屬性的名稱以底F開頭。

classmethod somenamedtuple.**_make**(*iterable*)

從已存在的序列或可F代物件建立一個新實例的類F方法。

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

somenamedtuple.**_asdict**()

回傳一個將欄位名稱對映至對應值的*dict*：

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
{'x': 11, 'y': 22}
```

在 3.1 版的變更: 回傳一個*OrderedDict* 而非*dict*。

在 3.8 版的變更: 回傳一個常規*dict* 而非*OrderedDict*，自從 Python 3.7 開始，dict 已經保證有順序性，如果需要*OrderedDict* 所專屬的特性，推薦的解法是將結果專F成所需的類型：`OrderedDict(nt._asdict())`。

somenamedtuple.**_replace**(***kwargs*)

回傳一個新的 named tuple 實例，F將指定欄位替FF新的值：

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum],␣
↪timestamp=time.now())
```

somenamedtuple.**_fields**

列出 tuple 欄位名稱的字串，用於自我檢查或是從現有 named tuple 建立一個新的 named tuple 型F。

```
>>> p._fields            # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

somenamedtuple.**_field_defaults**

將欄位名稱對映至預設值的字典。

```
>>> Account = namedtuple('Account', ['type', 'balance'], defaults=[0])
>>> Account._field_defaults
{'balance': 0}
>>> Account('premium')
Account(type='premium', balance=0)
```

要取得這個名稱存於字串的欄位，要使用*getattr()* 函式：

```
>>> getattr(p, 'x')
11
```

（如 tut-unpacking-arguments 所述）將一個字典轉🄵成 named tuple，要使用 ** 雙星號運算子：

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

因🄵一個 named tuple 是一個常規的 Python 類🄵，我們可以很容易的透過子類🄵來新增或更改功能，以下是如何新增一個計算得到的欄位和固定寬度的輸出列印格式：

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f  y=%6.3f  hypot=%6.3f' % (self.x, self.y, self.
↪hypot)

>>> for p in Point(3, 4), Point(14, 5/7):
...     print(p)
Point: x= 3.000  y= 4.000  hypot= 5.000
Point: x=14.000  y= 0.714  hypot=14.018
```

上面的子類🄵將 `__slots__` 設定🄵空 tuple，這樣一來就防止了字典實例被建立，因而保持了較低的記憶體用量。

子類🄵化無法用於增加新的、已被儲存的欄位，應當透過*_fields* 屬性以建立一個新的 named tuple 來實現：

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

透過直接賦值給 `__doc__`，可以自訂🄵明文件字串：

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

在 3.5 版的變更: 文件字串屬性變成可寫入。

也參考

- 關於🄵 named tuple 新增型🄵提示的方法，請參🄵*typing.NamedTuple*，它運用 `class` 關鍵字以提供了一個簡潔的表示法：

```
class Component(NamedTuple):
    part_number: int
    weight: float
    description: Optional[str] = None
```

- 關於以 dict 而非 tuple F底層的可變命名空間，請參考*types.SimpleNamespace()*。
- *dataclasses* 模組提供了一個裝飾器和一些函式，用於自動將被生成的特殊方法新增到使用者定義的類F中。

8.4.6 OrderedDict 物件

Ordered dictionary（有序字典）就像常規字典一樣，但有一些與排序操作相關的額外功能，但由於F建的*dict*類F現在已經有記憶插入順序的能力（Python 3.7 中確保了這種新行F），它們變得不那F重要了。

仍存在一些與*dict* 的不同之處：

- 常規的*dict* 被設計成非常擅長於對映相關操作，追F插入的順序F次要目標。
- *OrderedDict* 則被設計成擅長於重新排序相關的操作，空間效率、F代速度和更新操作的效能則F次要設計目標。
- *OrderedDict* 比起*dict* 更適合處理頻繁的重新排序操作，如在下方用法中所示，這讓它適合用於多種 LRU cache 的實作中。
- *OrderedDict* 之相等性運算會檢查順序是否相同。

  一個一般的*dict* 可以用 `p == q and all(k1 == k2 for k1, k2 in zip(p, q))` 來效仿有檢查順序的相等性運算。
- *OrderedDict* 類F的 `popitem()` 方法有不同的函式簽名 (signature)，它接受傳入一個選擇性引數來指定要移除哪個元素。

  一個一般的*dict* 可以用 `d.popitem()` 來效仿 OrderedDict 的 `od.popitem(last=True)`，這保證會移除最右邊（最後一個）的元素。

  一個一般的*dict* 可以用 `(k := next(iter(d)), d.pop(k))` 來效仿 OrderedDict 的 `od.popitem(last=False)`，若最左邊（第一個）的元素存在，則將其回傳F移除。
- *OrderedDict* 有個 `move_to_end()` 方法可有效率地將一個元素重新排列到任一端。

  一個一般的*dict* 可以用 `d[k] = d.pop(k)` 來效仿 OrderedDict 的 `od.move_to_end(k, last=True)`，這會將該鍵與其對應到的值移動至最右（最後面）的位置。

  一個一般的*dict* F有和 OrderedDict 的 `od.move_to_end(k, last=False)` 等價的有效方式，這是將鍵與其對應到的值移動至最左（最前面）位置的方法。
- 在 Python 3.8 之前，*dict* FF有 `__reversed__()` 方法。

class collections.**OrderedDict**([*items*])

回傳一個*dict* 子類F的實例，它具有專門用於重新排列字典順序的方法。

在 3.1 版被加入.

popitem(*last=True*)

Ordered dictionary 的*popitem()* 方法移除F回傳一個鍵值 (key, value) 對。如果 *last* F真值，則按 LIFO 後進先出的順序回傳鍵值對，否則就按 FIFO (first-in, first-out) 先進先出的順序回傳鍵值對。

move_to_end(*key*, *last=True*)

將現有的 *key* 移動到 ordered dictionary 的任一端。如果 *last* 🄴真值（此🄴預設值）則將元素移至右端；如果 *last* 🄴假值則將元素移至左端。如果 *key* 不存在則會引發*KeyError*：

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d)
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d)
'bacde'
```

在 3.2 版被加入.

除了普通的對映方法，ordered dictionary 還支援了透過*reversed()* 來做倒序🄴代。

OrderedDict 物件之間的相等性運算是會檢查順序是否相同的，是透過 `list(od1.items())==list(od2.items())` 來實現。*OrderedDict* 物件和其他*Mapping* 物件間的相等性運算則像普通字典一樣不考慮順序性，這使得*OrderedDict* 可於任何字典可使用的時機中被替🄵掉。

在 3.5 版的變更: *OrderedDict* 的項 (item)、鍵與值之視圖現在可透過*reversed()* 來倒序🄴代。

在 3.6 版的變更: 隨著 **PEP 468** 被核可，被傳入給*OrderedDict* 建構函式與其 `update()` 方法的關鍵字引數之順序被保留了下來。

在 3.9 版的變更: 新增合🄴 (`|`) 和更新 (`|=`) 運算子，請見 **PEP 584**。

OrderedDict 范例與用法

建立一個能🄵記住鍵最後插入順序的 ordered dictionary 變體很簡單。如果新條目覆蓋了現有條目，則原本插入位置會被更改🄵移動至末端：

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        super().__setitem__(key, value)
        self.move_to_end(key)
```

OrderedDict 在實現一個*functools.lru_cache()* 的變形版本時也非常有用：

```
from collections import OrderedDict
from time import time

class TimeBoundedLRU:
    "LRU Cache that invalidates and refreshes old entries."

    def __init__(self, func, maxsize=128, maxage=30):
        self.cache = OrderedDict()      # { args : (timestamp, result)}
        self.func = func
        self.maxsize = maxsize
        self.maxage = maxage

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            timestamp, result = self.cache[args]
            if time() - timestamp <= self.maxage:
```

(繼續下一頁)

(繼續上一頁)

```
                return result
        result = self.func(*args)
        self.cache[args] = time(), result
        if len(self.cache) > self.maxsize:
            self.cache.popitem(0)
        return result
```

```
class MultiHitLRUCache:
    """ LRU cache that defers caching a result until
        it has been requested multiple times.

        To avoid flushing the LRU cache with one-time requests,
        we don't cache until a request has been made more than once.

    """

    def __init__(self, func, maxsize=128, maxrequests=4096, cache_after=1):
        self.requests = OrderedDict()   # { uncached_key : request_count }
        self.cache = OrderedDict()      # { cached_key : function_result }
        self.func = func
        self.maxrequests = maxrequests  # max number of uncached requests
        self.maxsize = maxsize          # max number of stored return values
        self.cache_after = cache_after

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            return self.cache[args]
        result = self.func(*args)
        self.requests[args] = self.requests.get(args, 0) + 1
        if self.requests[args] <= self.cache_after:
            self.requests.move_to_end(args)
            if len(self.requests) > self.maxrequests:
                self.requests.popitem(0)
        else:
            self.requests.pop(args, None)
            self.cache[args] = result
            if len(self.cache) > self.maxsize:
                self.cache.popitem(0)
        return result
```

8.4.7 UserDict 物件

UserDict 類🄵是作🄵 dict 物件的包裝器。因🄵已經可以直接自*dict* 建立子類🄵，這個類🄵的需求已部分被滿足，不過這個類🄵使用起來更方便，因🄵被包裝的字典可以作🄵其屬性來存取。

class collections.**UserDict**([*initialdata*])

模擬字典的類🄵。實例的🄵容被存於一個字典，可透過*UserDict* 的*data* 屬性來做存取。如果有提供 *initialdata*，*data* 屬性會被初始化🄵其值；要注意指到 *initialdata* 的參照不會被保留，使其可被用於其他目的。

除了支援作🄵對映所需的方法與操作，*UserDict* 實例提供了以下屬性：

data

一個真實的字典，用於儲存*UserDict* 類🄵的資料🄵容。

8.4.8 UserList 物件

此類𝔽是 list 物件的包裝器。它是個方便的基礎類𝔽，可繼承它𝔽覆寫現有方法或加入新方法來定義你所需的一個類似於 list 的類𝔽。如此一來，我們可以𝔽 list 加入新的特性。

因𝔽已經可以直接自 *list* 建立子類𝔽，這個類𝔽的需求已部分被滿足，不過這個類𝔽使用起來更方便，因𝔽被包裝的 list 可以作𝔽其屬性來存取。

class collections.**UserList**([*list*])

模擬 list 的類𝔽。實例的𝔽容被存於一個 list，可透過 *UserList* 的 *data* 屬性來做存取。實例𝔽容被初始化𝔽 *list* 的𝔽𝔽，預設𝔽一個空的 list `[]`。*list* 可以是任何 iterable，例如一個真實的 Python list 或是一個 *UserList* 物件。

除了支援可變序列的方法與操作，*UserList* 實例提供了以下屬性：

data

一個真實的 *list* 物件，用於儲存 *UserList* 類𝔽的資料𝔽容。

子類𝔽化的條件： *UserList* 的子類𝔽應該要提供一個不需要引數或一個引數的建構函式。回傳一個新序列的 list 操作會從那些實作出來的類𝔽建立一個實例，𝔽了達成上述目的，它假設建構函式可傳入單一參數來呼叫，該參數即是做𝔽數據來源的一個序列物件。

如果希望一個自此獲得的子類𝔽不遵從上述要求，那所有該類𝔽支援的特殊方法則必須被覆寫；請參考原始碼來理解在這情𝔽下哪些方法是必須提供的。

8.4.9 UserString 物件

UserString 類𝔽是字串物件的包裝器，因𝔽已經可以從 *str* 直接建立子類𝔽，這個類𝔽的需求已經部分被滿足，不過這個類𝔽使用起來更方便，因𝔽被包裝的字串可以作𝔽其屬性來存取。

class collections.**UserString**(*seq*)

模擬字串物件的類𝔽。實例的𝔽容被存於一個字串物件，可透過 *UserString* 的 *data* 屬性來做存取。實例𝔽容被初始化𝔽 *seq* 的𝔽𝔽，*seq* 引數可以是任何可被𝔽建函式 *str()* 轉𝔽成字串的物件。

除了支援字串的方法和操作以外，*UserString* 實例也提供了以下屬性：

data

一個真實的 *str* 物件，用來儲存 *UserString* 類𝔽的資料𝔽容。

在 3.5 版的變更: 新增方法 `__getnewargs__`、`__rmod__`、`casefold`、`format_map`、`isprintable` 以及 `maketrans`。

8.5 collections.abc --- 容器的抽象基底類𝔽

在 3.3 版被加入: Formerly, this module was part of the *collections* module.

原始碼： Lib/_collections_abc.py

This module provides *abstract base classes* that can be used to test whether a class provides a particular interface; for example, whether it is *hashable* or whether it is a *mapping*.

An *issubclass()* or *isinstance()* test for an interface works in one of three ways.

1) A newly written class can inherit directly from one of the abstract base classes. The class must supply the required abstract methods. The remaining mixin methods come from inheritance and can be overridden if desired. Other methods may be added as needed:

```
class C(Sequence):                          # Direct inheritance
    def __init__(self): ...                 # Extra method not required by the ABC
    def __getitem__(self, index):  ...      # Required abstract method
    def __len__(self):  ...                 # Required abstract method
    def count(self, value): ...             # Optionally override a mixin method
```

```
>>> issubclass(C, Sequence)
True
>>> isinstance(C(), Sequence)
True
```

2) Existing classes and built-in classes can be registered as "virtual subclasses" of the ABCs. Those classes should define the full API including all of the abstract methods and all of the mixin methods. This lets users rely on *issubclass()* or *isinstance()* tests to determine whether the full interface is supported. The exception to this rule is for methods that are automatically inferred from the rest of the API:

```
class D:                                    # No inheritance
    def __init__(self): ...                 # Extra method not required by the ABC
    def __getitem__(self, index):  ...      # Abstract method
    def __len__(self):  ...                 # Abstract method
    def count(self, value): ...             # Mixin method
    def index(self, value): ...             # Mixin method

Sequence.register(D)                        # Register instead of inherit
```

```
>>> issubclass(D, Sequence)
True
>>> isinstance(D(), Sequence)
True
```

In this example, class `D` does not need to define `__contains__`, `__iter__`, and `__reversed__` because the in-operator, the *iteration* logic, and the *reversed()* function automatically fall back to using `__getitem__` and `__len__`.

3) Some simple interfaces are directly recognizable by the presence of the required methods (unless those methods have been set to *None*):

```
class E:
    def __iter__(self): ...
    def __next__(self): ...
```

```
>>> issubclass(E, Iterable)
True
>>> isinstance(E(), Iterable)
True
```

Complex interfaces do not support this last technique because an interface is more than just the presence of method names. Interfaces specify semantics and relationships between methods that cannot be inferred solely from the presence of specific method names. For example, knowing that a class supplies `__getitem__`, `__len__`, and `__iter__` is insufficient for distinguishing a *Sequence* from a *Mapping*.

在 3.9 版被加入: These abstract classes now support `[]`. See *Generic Alias Type* and **PEP 585**.

8.5.1 Collections Abstract Base Classes

The collections module offers the following *ABCs*:

ABC	Inherits from	Abstract Methods	Mixin Methods
Container[1]		`__contains__`	
Hashable[Page 284, 1]		`__hash__`	
Iterable[Page 284, 12]		`__iter__`	
Iterator[Page 284, 1]	*Iterable*	`__next__`	`__iter__`
Reversible[Page 284, 1]	*Iterable*	`__reversed__`	
Generator[Page 284, 1]	*Iterator*	`send`、`throw`	`close`、`__iter__`、`__next__`
Sized[Page 284, 1]		`__len__`	
Callable[Page 284, 1]		`__call__`	
Collection[Page 284, 1]	*Sized*、*Iterable*、*Container*	`__contains__`、`__iter__`、`__len__`	
Sequence	*Reversibl* *Collectio*	`__getitem__`、`__len__`	`__contains__`、`__iter__`、`__reversed__`、`index` 和 `count`
MutableSequence	*Sequence*	`__getitem__`、`__setitem__`、`__delitem__`、`__len__`、`insert`	Inherited *Sequence* methods and `append`, `clear`, `reverse`, `extend`, `pop`, `remove`, and `__iadd__`
ByteString	*Sequence*	`__getitem__`、`__len__`	Inherited *Sequence* methods
Set	*Collectio*	`__contains__`、`__iter__`、`__len__`	`__le__`、`__lt__`、`__eq__`、`__ne__`、`__gt__`、`__ge__`、`__and__`、`__or__`、`__sub__`、`__xor__` 與 `isdisjoint`
MutableSet	*Set*	`__contains__`、`__iter__`、`__len__`、`add`、`discard`	Inherited *Set* methods and `clear`, `pop`, `remove`, `__ior__`, `__iand__`, `__ixor__`, and `__isub__`
Mapping	*Collectio*	`__getitem__`、`__iter__`、`__len__`	`__contains__`、`keys`、`items`、`values`、`get`、`__eq__` 和 `__ne__`
MutableMapping	*Mapping*	`__getitem__`、`__setitem__`、`__delitem__`、`__iter__`、`__len__`	Inherited *Mapping* methods and `pop`, `popitem`, `clear`, `update`, and `setdefault`
MappingView	*Sized*		`__len__`
ItemsView	*MappingVi* *Set*		`__contains__`、`__iter__`
KeysView	*MappingVi* *Set*		`__contains__`、`__iter__`
ValuesView	*MappingVi* *Collectio*		`__contains__`、`__iter__`
Awaitable[Page 284, 1]		`__await__`	
Coroutine[Page 284, 1]	*Awaitable*	`send`、`throw`	`close`
AsyncIterable[Page 284, 1]		`__aiter__`	
AsyncIterator[Page 284, 1]	*AsyncIter*	`__anext__`	`__aiter__`
AsyncGenerator[Page 284, 1]	*AsyncIter*	`asend`、`athrow`	`aclose`、`__aiter__`、`__anext__`
Buffer[Page 284, 1]		`__buffer__`	

F解

8.5.2 Collections Abstract Base Classes -- Detailed Descriptions

class collections.abc.**Container**

ABC for classes that provide the __contains__() method.

class collections.abc.**Hashable**

ABC for classes that provide the __hash__() method.

class collections.abc.**Sized**

ABC for classes that provide the __len__() method.

class collections.abc.**Callable**

ABC for classes that provide the __call__() method.

class collections.abc.**Iterable**

ABC for classes that provide the *__iter__()* method.

Checking isinstance(obj, Iterable) detects classes that are registered as *Iterable* or that have an *__iter__()* method, but it does not detect classes that iterate with the __getitem__() method. The only reliable way to determine whether an object is *iterable* is to call iter(obj).

class collections.abc.**Collection**

ABC for sized iterable container classes.

在 3.6 版被加入.

class collections.abc.**Iterator**

ABC for classes that provide the *__iter__()* and *__next__()* methods. See also the definition of *iterator*.

class collections.abc.**Reversible**

ABC for iterable classes that also provide the __reversed__() method.

在 3.6 版被加入.

class collections.abc.**Generator**

ABC for *generator* classes that implement the protocol defined in **PEP 342** that extends *iterators* with the send(), throw() and close() methods.

在 3.5 版被加入.

class collections.abc.**Sequence**

class collections.abc.**MutableSequence**

class collections.abc.**ByteString**

ABCs for read-only and mutable *sequences*.

Implementation note: Some of the mixin methods, such as *__iter__()*, __reversed__() and index(), make repeated calls to the underlying __getitem__() method. Consequently, if __getitem__() is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

在 3.5 版的變更: The index() method added support for *stop* and *start* arguments.

[1] These ABCs override *__subclasshook__()* to support testing an interface by verifying the required methods are present and have not been set to *None*. This only works for simple interfaces. More complex interfaces require registration or direct subclassing.

[2] Checking isinstance(obj, Iterable) detects classes that are registered as *Iterable* or that have an *__iter__()* method, but it does not detect classes that iterate with the __getitem__() method. The only reliable way to determine whether an object is *iterable* is to call iter(obj).

Deprecated since version 3.12, will be removed in version 3.14: The *ByteString* ABC has been deprecated. For use in typing, prefer a union, like `bytes | bytearray`, or *collections.abc.Buffer*. For use as an ABC, prefer *Sequence* or *collections.abc.Buffer*.

class collections.abc.**Set**

class collections.abc.**MutableSet**

ABCs for read-only and mutable *sets*.

class collections.abc.**Mapping**

class collections.abc.**MutableMapping**

ABCs for read-only and mutable *mappings*.

class collections.abc.**MappingView**

class collections.abc.**ItemsView**

class collections.abc.**KeysView**

class collections.abc.**ValuesView**

ABCs for mapping, items, keys, and values *views*.

class collections.abc.**Awaitable**

ABC for *awaitable* objects, which can be used in `await` expressions. Custom implementations must provide the `__await__()` method.

Coroutine objects and instances of the *Coroutine* ABC are all instances of this ABC.

> **備🄵**
>
> In CPython, generator-based coroutines (*generators* decorated with *@types.coroutine*) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Awaitable)` for them will return `False`. Use *inspect.isawaitable()* to detect them.

在 3.5 版被加入.

class collections.abc.**Coroutine**

ABC for *coroutine* compatible classes. These implement the following methods, defined in coroutine-objects: `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All *Coroutine* instances are also instances of *Awaitable*.

> **備🄵**
>
> In CPython, generator-based coroutines (*generators* decorated with *@types.coroutine*) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use *inspect.isawaitable()* to detect them.

在 3.5 版被加入.

class collections.abc.**AsyncIterable**

ABC for classes that provide an `__aiter__` method. See also the definition of *asynchronous iterable*.

在 3.5 版被加入.

class collections.abc.**AsyncIterator**

ABC for classes that provide `__aiter__` and `__anext__` methods. See also the definition of *asynchronous iterator*.

在 3.5 版被加入.

class collections.abc.**AsyncGenerator**

ABC for *asynchronous generator* classes that implement the protocol defined in **PEP 525** and **PEP 492**.

在 3.6 版被加入.

class collections.abc.**Buffer**

ABC for classes that provide the `__buffer__()` method, implementing the buffer protocol. See **PEP 688**.

在 3.12 版被加入.

8.5.3 Examples and Recipes

ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full *Set* API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, *__iter__()*, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and *isdisjoint()*:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2            # The __and__() method is supported automatically
```

Notes on using *Set* and *MutableSet* as a mixin:

(1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an *iterable*. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal *classmethod* called `_from_iterable()` which calls `cls(iterable)` to produce a new set. If the *Set* mixin is being used in a class with a different constructor signature, you will need to override `_from_iterable()` with a classmethod or regular method that can construct new instances from an iterable argument.

(2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.

(3) The *Set* mixin provides a `_hash()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are *hashable* or immutable. To add set hashability using mixins, inherit from both *Set()* and *Hashable()*, then define `__hash__ = Set._hash`.

8.6 heapq --- 堆積🄵列 (heap queue) 演算法

原始碼： Lib/heapq.py

這個模組實作了堆積🄵列 (heap queue) 演算法，亦被稱🄵優先🄵列 (priority queue) 演算法。

Heap（堆積）是一顆二元樹，樹上所有父節點的值都小於等於他的子節點的值，我們將這種情🄵稱🄵堆積的性質不變。

使用陣列實作，對於所有從 0 開始的 *k* 都滿足 `heap[k] <= heap[2*k+1]` 和 `heap[k] <= heap[2*k+2]`。🄵了比較節點的值，不存在的元素被視🄵無限大。heap 存在一個有趣的性質：樹上最小的元素永遠會在根節點 `heap[0]` 上。

下方的 API 跟一般教科書的 heap queue 演算法有兩個方面不同：第一，我們的索引從 0 開始計算，這會父節點與子節點之間的關🄴🄵生很微小的差🄵，但更符合 Python 從 0 開始索引的設計。第二，我們的 pop 方法會回傳最小的元素而不是最大的元素（在教科書中被稱作"min heap"，而"max heap" 因🄵他很適合做原地排序，所以更常出現在教科書中）。

這兩個特性使得把 heap 當作一個標準的 Python list 檢視時不會出現意外：`heap[0]` 是最小的物件，`heap.sort()` 能保持 heap 的性質不變！

建立一個 heap 可以使用 list 初始化🄵 `[]`，或者使用函式*heapify()* 將一個已經有元素的 list 轉成一個 heap。

此模組提供下面的函式

`heapq.`**`heappush`**`(`*heap*, *item*`)`

把 *item* 放進 *heap*，🄵保持 heap 性質不變。

`heapq.`**`heappop`**`(`*heap*`)`

從 *heap* 取出🄵回傳最小的元素，同時保持 heap 性質不變。如果 heap 是空的會🄵生*IndexError* 錯誤。只存取最小元素但不取出可以使用 `heap[0]`。

`heapq.`**`heappushpop`**`(`*heap*, *item*`)`

將 *item* 放入 heap，接著從 *heap* 取出🄵回傳最小的元素。這個組合函式比呼叫*heappush()* 之後呼叫*heappop()* 更有效率。

`heapq.`**`heapify`**`(`*x*`)`

在🄵性時間🄵將 list *x* 轉🄵 heap，且過程不會申請額外記憶體。

`heapq.`**`heapreplace`**`(`*heap*, *item*`)`

從 *heap* 取出🄴回傳最小的元素，接著將新的 *item* 放進 heap。heap 的大小不會改變。如果 heap 是空的會🄵生*IndexError* 錯誤。

這個一次完成的操作會比呼叫*heappop()* 之後呼叫*heappush()* 更有效率，🄵在維護 heap 的大小不變時更🄵適當，取出/放入的組合函式一定會從 heap 回傳一個元素🄴用 *item* 取代他。

函式的回傳值可能會大於被加入的 *item* 。如果這不是你期望發生的，可以考慮使用`heappushpop()`替代，他會回傳 heap 的最小值和 *item* 兩個當中比較小的那個，🄵將大的留在 heap 🄵。

這個模組也提供三個利用 heap 實作的一般用途函式

`heapq.`**`merge`**(**iterables*, *key=None*, *reverse=False*)

合🄵多個已排序的輸入🄵🄵生單一且已排序的輸出（舉例：合🄵來自多個 log 檔中有時間戳記的項目）。回傳一個*iterator* 包含已經排序的值。

和 `sorted(itertools.chain(*iterables))` 類似但回傳值是一個 iterable ，不會一次把所有資料都放進記憶體中，🄵且假設每一個輸入都已經（由小到大）排序過了。

有兩個選用參數，指定時必須被當作關鍵字參數指定。

key 參數指定了一個*key function* 引數，用來從每一個輸入的元素中🄵定一個比較的依據。預設的值是 `None` （直接比較元素）。

reverse 是一個布林值，如果設定🄵 `True` ，則輸入的元素將以相反的比較順序進行合🄵。🄵了達成類似 `sorted(itertools.chain(*iterables), reverse=True)` 的行🄵，所有 iterables 必須由大到小排序。

在 3.5 版的變更: 加入選用參數 *key* 和 *reverse* 。

`heapq.`**`nlargest`**(*n*, *iterable*, *key=None*)

回傳一個包含資料 *iterable* 中前 *n* 大元素的 list 。如果有指定 *key* 引數，*key* 會是只有一個引數的函式，用來從每一個在 *iterable* 中的元素提取一個比較的依據（例如 `key=str.lower` ）。效果相當於 `sorted(iterable, key=key, reverse=True)[:n]` 。

`heapq.`**`nsmallest`**(*n*, *iterable*, *key=None*)

回傳一個包含資料 *iterable* 中前 *n* 小元素的 list 。如果有指定 *key* 引數，*key* 會是只有一個引數的函式，用來從每一個在 *iterable* 中的元素提取一個比較的依據（例如 `key=str.lower` ）。效果相當於 `sorted(iterable, key=key)[:n]` 。

後兩個函式在 *n* 值比較小時有最好的表現。對於較大的 *n* 值，只用`sorted()` 函式會更有效率。同樣地，當 `n==1` 時，使用🄵建函式`min()` 和`max()` 會有更好的效率。如果需要重🄵使用這些函式，可以考慮將 iterable 轉成真正的 heap 。

8.6.1 基礎范例

堆積排序 (heapsort) 可以透過將所有的值推入一個 heap，🄵且從 heap 中一個接一個彈出最小元素來實作：

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

雖然類似 `sorted(iterable)` ，但跟`sorted()` 不同的是，這個實作不是 stable 的排序。

Heap 中的元素可以是 tuple 。這有利於將要比較的值（例如一個 task 的優先度）和主要資料放在一起排序：

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
```

(繼續下一頁)

(繼續上一頁)

```
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

8.6.2 優先🄵列實作細節

優先🄵列 (priority queue) 是 heap 的常見用途之一，實作優先🄵列伴隨著下列挑戰：

- 排序的穩定性：如何將兩個擁有相同優先次序 (priority) 的 task 按照他們被加入的順序回傳?
- Tuple 的排序在某些情🄵下會壞掉，例如當 Tuple (priority, task) 的 priorities 相等且 tasks 🄵有一個預設的排序時。
- 當一個 heap 中 task 的 priority 改變時，如何將它移到 heap 正確的位置上?
- 或者一個還🄵被解🄵的 task 需要被🄵除時，要如何從🄵列中找到🄵🄵除指定的 task?

一個針對前兩個問題的解法是：儲存一個包含 priority 、entry count 和 task 三個元素的 tuple 。兩個 task 有相同 priority 時，entry count 會讓兩個 task 能根據加入的順序排序。因🄵🄵有任何兩個 task 擁有相同的 entry count ，所以永遠不會直接使用 task 做比較。

task 無法比較的另一個解🄵方案是建立一個包裝器類🄵，該類🄵忽略 task 項目，只比較優先等級：

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

剩下的問題可以藉由找到要🄵除的 task 🄵更改它的 priority 或者直接將它移除。尋找一個 task 可以使用一個 dictionary 指向🄵列當中的 entry 。

移除 entry 或更改它的 priority 更🄵困難，因🄵這會破壞 heap 的性質。所以一個可行的方案是將原本的 entry 做一個標記表示它已經被🄵除，🄵新增一個擁有新的 priority 的 entry：

```
pq = []                         # list of entries arranged in a heap
entry_finder = {}               # mapping of tasks to entries
REMOVED = '<removed-task>'      # placeholder for a removed task
counter = itertools.count()     # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED.  Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
```

(繼續下一頁)

(繼續上一頁)

```
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')
```

8.6.3 原理

Heap 是一個陣列對於所有從 0 開始的 index *k* 都存在性質 `a[k] <= a[2*k+1]` 和 `a[k] <= a[2*k+2]`。F了方便比較，不存在的元素被視F無限大。Heap 的一個有趣的性質是：`a[0]` 永遠是最小的元素。

上述乍看之下有些奇怪的不變式，是F了實作一個對記憶體來F有效率的方法，其表示方式如同錦標賽一般。下列的數字F *k*，而不是 `a[k]`：

```
                                0

             1                                  2

      3              4                5               6

  7       8       9       10      11      12      13      14

15 16   17 18   19 20   21 22   23 24   25 26   27 28   29 30
```

在上面的樹當中，每個單元 *k* 都會位在 `2*k+1` 與 `2*k+2` 上方。如同體育賽事常見的錦標賽般，每個單元可視F其下方兩個單元當中的贏家，我們可以透過追溯整棵樹來找到該贏家曾經對戰過的所有對手。然而，在許多電腦應用中，我們不需要追溯贏家的完整對戰歷史。F了能更有效率地使用記憶體，當一個贏家F級勝出時，我們用下方較低層級的另一個項目來取代它，至此規則變F一個單元以及它下方兩個單元，包含三個不同項目，但是最上方的單元「勝過」下方兩個單元。

如果能確保滿足這個 heap 的不變式，那F索引 0 顯然是最終的贏家。移除F找到「下一個」贏家最簡單的演算法F：將一個輸家（例如上圖中的單元 30）移動到位置 0，然後從新的位置 0 不斷與下方的位置交F值來向下傳遞，直到滿足不變式F止。這個過程的F雜度顯然是樹的節點數目的對數級F。透過對所有項目F代，可以得到一個F雜度F $O(n \log n)$ 的排序。

這種排序有個好處，只要插入的項目F有「贏過」你最後提取、索引F 0 的元素，你就可以在排序進行的同時有效率地插入新項目。這在模擬情境當中特F有用，其中樹能F保存所有輸入事件，而「贏」意味著最小排程時間。當一個事件排程其它事件的執行時，因這些事件仍在等待進行，所以很容易將它們插入 heap 當中。因此，heap 是一個實現排程器的優秀資料結構（這就是我用以實作 MIDI 編曲器的方法:-）。

多種用於實作排程器的結構現今已被廣泛研究，heap 對此非常有用，因F它們速度相當快，且速度幾乎不受其他因素影響，最壞情F與平均狀F差F無幾。也有其它整體F來更有效率的方法，然而它們的最壞情F可能會非常糟糕。

Heap 在F儲存於硬碟上的大量資料進行排序也非常有用。你可能已經知道，大量資料排序涉及"runs" 的F生（也就是預先排序的序列，其大小通常與 CPU 記憶體的大小有關），之後再對這些 run 合F，而這些合F的過程通常相當巧妙[1]。很重要的一點是，初始排序F生的 run 越長越好。錦標賽是達成這一點的好方法，若你用所有可用記憶體來舉行一場錦標賽，F透過替F與向下交F來處理所有適配當前 run 的值，那F對於隨機F生的輸入，將可以F生長度兩倍於記憶體大小的 run。對於已模糊排序過的輸入，效果更好。

[1] 現今的磁碟平衡演算法因F硬碟查找能力而更加F雜難解。在F有查找功能的裝置如大型磁帶機，狀F又不一樣了，人們必須機智地確保（遠遠提前）每次於磁帶上移動都盡可能是最有效率的（也就是盡可能更好地「推進」合F的過程）。有些磁帶甚至能F向後讀取，這也被用來避免倒轉的時間。相信我，真正優秀的磁帶排序看起來相當壯觀！排序一直以來都是一門偉大的藝術！:-)

此外，若你將索引F 0 的項目輸出至磁碟，F取得一個無法適配當前錦標賽的輸入（因F該值「勝過」最後的輸出值），則該輸入值就無法插入至 heap 當中，因此 heap 的大小會F小。釋放出來的記憶體可以巧妙地立即再被運用，逐步建構出第二個 heap，其大小增加的速度會與第一個 heap F少的速度一致。當第一個 heap 完全消失時，你可以切F至第二個 heap 開F一個新 run 。這真是個聰明且相當有效率的做法!

總結來F，heap 是值得了解的有用記憶體結構。我在一些應用中使用它們，我認F能有一個'heap' 模組是很棒的。:-)

F解

8.7 `bisect` --- 陣列二分演算法 (Array bisection algorithm)

原始碼： Lib/bisect.py

這個模組維護一個已經排序過的 list ，當我們每次做完插入後不需要再次排序整個 list 。一個很長的 list 的比較操作很花費時間，可以透過F性搜索或頻繁地詢問來改善。

這個模組被稱F*bisect* 是因F它使用基本二分演算法來完成其工作。不像其它搜尋特定值的二分法工具，本模組中的函式旨在定位插入點。因此，這些函式永遠不會呼叫 `__eq__()` 方法來確認是否找到一個值。相反地，這些函式只呼叫 `__lt__()` 方法，F在陣列中的值回傳一個插入點。

此模組提供下面的函式：

`bisect.`**`bisect_left`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

在 *a* 當中找到一個位置，讓 *x* 插入後 *a* 仍然是排序好的。參數 *lo* 和 *hi* 用來指定 list 中應該被考慮的子區間，預設是考慮整個 list 。如果 *a* F面已經有 *x* 出現，插入的位置會在所有 *x* 的前面（左邊）。回傳值可以被當作 `list.insert()` 的第一個參數，但列表 *a* 必須先排序過。

回傳的插入點 *ip* 將陣列 *a* 劃分F左右兩個切片，使得對於左切片而言 `all(elem < x for elem in a[lo : ip])` F真，對於右切片而言 `all(elem >= x for elem in a[ip : hi])` F真。

key 可指定一個單一參數的*key function*。函式將套用此 function 在陣列所有元素以得到比較值來計算順位。注意此 function 只會套用在陣列中的元素，不會套用在 *x*。

若 *key* F `None`，元素將直接進行比較，不會呼叫任何鍵函式。

在 3.10 版的變更: 新增 *key* 參數。

`bisect.`**`bisect_right`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

`bisect.`**`bisect`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

類似*`bisect_left()`*，但回傳的插入位置會在所有 *a* 當中的 *x* 的後面（右邊）。

回傳的插入點 *ip* 將陣列 *a* 劃分F左右兩個切片，使得對於左切片而言 `all(elem <= x for elem in a[lo : ip])` F真，對於右切片而言 `all(elem > x for elem in a[ip : hi])` F真。

在 3.10 版的變更: 新增 *key* 參數。

`bisect.`**`insort_left`**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

將元素 *x* 插入 list *a*，F維持順序。

此函式先使用*`bisect_left()`* 搜索插入位置，接著用 `insert()` 於 *a* 以將 *x* 插入，F維持添加元素後的順序。

此函式只有在搜索時會使用 *key* 函式，插入時不會。

注意雖然搜索是 *O*(log *n*)，但插入是 *O*(*n*)，因此此函式整體時間F雜度是 *O*(*n*)。

在 3.10 版的變更: 新增 *key* 參數。

bisect.**insort_right**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

bisect.**insort**(*a*, *x*, *lo=0*, *hi=len(a)*, *, *key=None*)

類似*insort_left()*，但插入的位置會在所有 *a* 當中的 *x* 的後面（右邊）。

此函式先使用*bisect_right()* 搜索插入位置，接著用 `insert()` 於 *a* 以將 *x* 插入，🄵維持添加元素後的順序。

此函式只有在搜索時會使用 *key* 函式，插入時不會。

注意雖然搜索是 $O(\log n)$，但插入是 $O(n)$，因此此函式整體時間🄵雜度是 $O(n)$。

在 3.10 版的變更: 新增 *key* 參數。

8.7.1 效能考量

若在需要關注寫入時間的程式當中使用 *bisect()* 和 *insort()*，請特🄵注意幾個事項：

- 二分法在一段範圍的數值中做搜索的效率較佳，但若是要存取特定數值，使用字典的表現還是比較好。
- *insort()* 函式的🄵雜度🄵 $O(n)$，因🄵對數搜尋是以🄵性時間的插入步驟所主導 (dominate)。
- 搜索函式🄵無狀態的 (stateless)，且鍵函式會在使用過後被🄵🄵。因此，如果搜索函式被使用於🄵圈當中，鍵函式會不斷被重🄵呼叫於相同的 list 元素。如果鍵函式執行速度不快，請考慮將其以*functools.cache()* 包裝起來以🄵少重🄵的計算。另外，也可以透過搜尋預先計算好的鍵列表 (array of precomputed keys) 來定位插入點（如下方範例所示）。

也參考

- 有序容器 (Sorted Collections) 是一個使用 *bisect* 來管理資料之有序集合的高效能模組。
- SortedCollection recipe 使用二分法來建立一個功能完整的集合類🄵 (collection class) 🄵帶有符合直覺的搜索方法 (search methods) 與支援鍵函式。鍵會預先被計算好，以🄵少搜索過程中多余的鍵函式呼叫。

8.7.2 搜尋一個已排序的 list

上面的*bisect functions* 在找到數值插入點上很有用，但一般的數值搜尋任務上就不是那🄵的方便。以下的五個函式展示了如何將其轉🄴成標准的有序列表查找函式：

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
```

(繼續下一頁)

(繼續上一頁)

```
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError
```

8.7.3 范例

bisect() 函式可用於數值表中的查找 (numeric table lookup)，這個範例使用*bisect()* 以基於一組有序的數值分界點來🄴一個考試成績找到相對應的字母等級：90 以上是'A'、80 到 89 🄵'B'，依此類推：

```
>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']
```

bisect() 與*insort()* 函式也適用於🄴容🄵 tuples（元組）的 lists，*key* 引數可被用以取出在數值表中作🄵排序依據的欄位：

```
>>> from collections import namedtuple
>>> from operator import attrgetter
>>> from bisect import bisect, insort
>>> from pprint import pprint

>>> Movie = namedtuple('Movie', ('name', 'released', 'director'))

>>> movies = [
...     Movie('Jaws', 1975, 'Spielberg'),
...     Movie('Titanic', 1997, 'Cameron'),
...     Movie('The Birds', 1963, 'Hitchcock'),
...     Movie('Aliens', 1986, 'Cameron')
... ]

>>> # Find the first movie released after 1960
>>> by_year = attrgetter('released')
>>> movies.sort(key=by_year)
>>> movies[bisect(movies, 1960, key=by_year)]
Movie(name='The Birds', released=1963, director='Hitchcock')

>>> # Insert a movie while maintaining sort order
```

(繼續下一頁)

(繼續上一頁)

```
>>> romance = Movie('Love Story', 1970, 'Hiller')
>>> insort(movies, romance, key=by_year)
>>> pprint(movies)
[Movie(name='The Birds', released=1963, director='Hitchcock'),
 Movie(name='Love Story', released=1970, director='Hiller'),
 Movie(name='Jaws', released=1975, director='Spielberg'),
 Movie(name='Aliens', released=1986, director='Cameron'),
 Movie(name='Titanic', released=1997, director='Cameron')]
```

如果鍵函式會消耗較多運算資源，那可以在預先計算好的鍵列表中搜索該紀🄴的索引值，以🄴少重🄴的函式呼叫：

```
>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])       # Or use operator.itemgetter(1).
>>> keys = [r[1] for r in data]         # Precompute a list of keys.
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)
```

8.8 `array` --- 高效率的數值型陣列

This module defines an object type which can compactly represent an array of basic values: characters, integers, floating-point numbers. Arrays are sequence types and behave very much like lists, except that the type of objects stored in them is constrained. The type is specified at object creation time by using a *type code*, which is a single character. The following type codes are defined:

Type code	C Type	Python Type	所需的最小位元組 (bytes)	🄵解
`'b'`	signed char	int	1	
`'B'`	unsigned char	int	1	
`'u'`	wchar_t	Unicode character	2	(1)
`'h'`	signed short	int	2	
`'H'`	unsigned short	int	2	
`'i'`	signed int	int	2	
`'I'`	unsigned int	int	2	
`'l'`	signed long	int	4	
`'L'`	unsigned long	int	4	
`'q'`	signed long long	int	8	
`'Q'`	unsigned long long	int	8	
`'f'`	float	float	4	
`'d'`	double	float	8	

🄵解：

(1) 根據平台的不同，它有可能是 16 位元或者 32 位元。

在 3.9 版的變更: 目前 `array('u')` 使用 `wchar_t` 取代已[F]用的 `Py_UNICODE` 作[F] C type。這個[F]動[F][F]有影響到它的作用，因爲自從 Python 3.3 開始 `Py_UNICODE` 即[F] `wchar_t` 的[F]名。

Deprecated since version 3.3, will be removed in version 4.0.

實際上數值的表示方法是被機器的架構所[F]定（更精准地[F]，被 C 的實作方法[F]定）。實際的大小可以透過*`array.itemsize`* 屬性存取。

這個模組定義了以下項目：

`array.`**`typecodes`**
一個包含所有可用的 type codes 的字串。

這個模組定義了下方的型[F]：

`class` `array.`**`array`**(*typecode*[, *initializer*])

一個新的陣列中的元素被 *typecode* 限制，[F]由選用的 *initializer* 參數初始化，*initializer* 必須是一個*`bytes`* 或*`bytearray`* 物件、一個 Unicode 字串或包含適當型[F]元素的可[F]代物件 (iterable)。

如果給定的是一個*`bytes`* 或*`bytearray`* 物件，新的陣列初始化時會傳入*`frombytes()`* 方法；如[F] Unicode 字串則會傳入*`fromunicode()`* 方法；其他情[F]時，一個 initializer 的可[F]代物件將被傳入*`extend()`* 方法之中來將初始項目新增至陣列。

陣列支援常見的序列操作，包含索引 (indexing)、切片 (slicing)、串接 (concatenation)、相乘 (multiplication) 等。當使用切片進行賦值時，賦值的陣列必須具備相同的 type code，其他型[F]的數值將導致*`TypeError`*。陣列同時也實作了緩衝區介面，可以在任何支援*bytes-like objects* 的地方使用。

Raises an *auditing event* `array.__new__` with arguments `typecode`, `initializer`.

`typecode`
typecode 字元被用在建立陣列時。

`itemsize`
陣列當中的一個元素在[F]部需要的位元組長度。

`append`(*x*)
新增一個元素 *x* 到陣列的最尾端。

`buffer_info`()
回傳一個 tuple `(address, length)` 表示當前的記憶體位置和陣列儲存元素的緩衝區記憶體長度。緩衝區的長度單位是位元組，[F]可以用 `array.buffer_info()[1] * array.itemsize` 計算得到。這偶爾會在底層操作需要記憶體位置的輸出輸入時很有用，例如 `ioctl()` 指令。只要陣列存在且[F]有使用任何更改長度的操作時，回傳的數值就有效。

> **備[F]**
>
> 當使用來自 C 或 C++ 程式碼（這是唯一使得這個資訊有效的途徑）的陣列物件時，更適當的做法是使用陣列物件支援的緩衝區介面。這個方法維護了向後兼容性，[F]應該在新的程式碼中避免。關於緩衝區介面的文件在 bufferobjects。

`byteswap`()
”Byteswap” 所有陣列中的物件。這只有支援物件長度[F] 1、2、4 或 8 位元組的陣列，其他型[F]的值會導致*`RuntimeError`*。這在從機器讀取位元順序不同的檔案時很有用。

`count`(*x*)
回傳 *x* 在陣列中出現了幾次。

extend(*iterable*)

從 *iterable* 中新增元素到陣列的尾端，如果 *iterable* 是另一個陣列，它必須有完全相同的 type code，如果不同會導致*TypeError*。如果 *iterable* 不是一個陣列，它必須可以被🄵代 (iterable) 且其中的元素必須是可以被加入陣列中的正確型🄵。

frombytes(*buffer*)

從*bytes-like object* 中新增元素。讀取時會將其🄵容當作一個機器數值組成的陣列（就像從檔案中使用*fromfile()* 方法讀出的資料）。

在 3.2 版被加入: 將 `fromstring()` 更名🄵*frombytes()*，使其更加清晰易懂。

fromfile(*f*, *n*)

從*file object* *f* 讀取 *n* 個元素（作🄵機器數值），接著將這些元素加入陣列的最尾端。如果只有少於 *n* 個有效的元素會導致*EOFError*，但有效的元素仍然會被加入陣列中。

fromlist(*list*)

從 list 中新增元素。這等價於 `for x in list: a.append(x)`，除了有型🄵錯誤🄵生時，陣列會保持原狀不會被更改。

fromunicode(*s*)

用給定的 Unicode 字串擴展這個陣列。陣列的 type code 必須是 `u`；其他的型🄵會導致*ValueError* 被引發。使用 `array.frombytes(unicodestring.encode(enc))` 來新增 Unicode 資料到一個其他型🄵的陣列。

index(*x*[, *start*[, *stop*]])

回傳 *i* 的最小數值，使得 *i* 成🄵陣列之中第一次出現 *x* 的索引。選擇性的引數 *start* 及 *stop* 則可以被用來在指定的陣列空間中搜尋 *x*。如果 *x* 不存在將導致*ValueError*。

在 3.10 版的變更: 新增選擇性的參數 *start* 及 *stop*。

insert(*i*, *x*)

在位置 *i* 之前插入一個元素 *x*。負數的索引值會從陣列尾端開始數。

pop([*i*])

移除🄵回傳陣列索引值 *i* 的元素。選擇性的引數 *i* 預設🄵 `-1`，所以預設會🄵除🄵回傳最後一個元素。

remove(*x*)

從陣列中🄵除第一個出現的 *x*。

reverse()

反轉陣列中元素的順序。

tobytes()

將陣列轉🄵另一個機器數值組成的陣列🄵回傳它的位元組表示（跟用*tofile()* 方法寫入檔案時的位元序列相同）。

在 3.2 版被加入: 🄵了明確性，過去的 `tostring()` 已更名🄵*tobytes()*。

tofile(*f*)

將所有元素（作🄵機器數值）寫入*file object* *f*。

tolist()

不更改元素，將陣列轉🄵一般的 list。

tounicode()

將陣列轉🄵一個 Unicode 字串。陣列的型🄵必須🄵 `u`。其他型🄵的陣列會導致*ValueError* 錯誤。請使用 `array.tobytes().decode(enc)` 來🄵其他型🄵的陣列轉🄵 Unicode 字串。

The string representation of array objects has the form `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a Unicode string if the *typecode* is `'u'`, otherwise it is a list of numbers. The string representation is guaranteed to be able to be converted back to an array with the same type and value using *eval()*, so long as the *array* class has been imported using `from array import array`. Variables `inf` and `nan` must also be defined if it contains corresponding floating-point values. Examples:

```
array('l')
array('u', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14, -inf, nan])
```

也參考

***struct* 模組**
將包含不同資料類型的二進位資料包裝與解開包裝。

***xdrlib* 模組**
將 External Data Representation (XDR) 的資料包裝與解開包裝，這用在一些遠端操作的系統 (remote procedure call systems)。

NumPy
NumPy 套件定義了另一個陣列型🄵

8.9 `weakref` --- 弱參照

原始碼： Lib/weakref.py

---

weakref 模組允許 Python 程式設計師建立對物件的 *弱參照*。

在以下文章中，術語 *參照目標 (referent)* 表示被弱參照所參考的物件。

對物件的弱參照不足以使物件保持存在：當對參照目標的唯一剩下的參照是弱參照時，*garbage collection* 可以自由地銷🄵參照目標🄵將其記憶體重新用於其他用途。然而，在物件被確實銷🄵之前，即使🄵有對該物件的🄵參照 (strong reference)，弱參照也可能會回傳該物件。

弱參照的主要用途是實作保存大型物件的快取或對映，其不希望大型物件僅僅因🄵它出現在快取或對映中而保持存在。

例如，如果你有許多大型的二進位影像物件，你可能會想要🄵每個物件關聯 (associate) 一個名稱。如果你使用 Python 字典將名稱對映到影像，或將影像對映到名稱，則影像物件將保持存活，僅因🄵它們在字典中作🄵值 (value) 或鍵 (key) 出現。*weakref* 模組提供的*WeakKeyDictionary* 和*WeakValueDictionary* 類🄵是另一種選擇，它們使用弱參照來建構對映，這些對映不會僅因🄵物件出現在對映物件中而使物件保持存活。例如，如果一個影像物件是*WeakValueDictionary* 中的一個值，那🄵當對該影像物件最後的參照是弱對映 (weak mapping) 所持有的弱參照時，垃圾回收 (garbage collection) 可以回收該物件，且其對應的條目在弱對映中會被完全地🄵除。

WeakKeyDictionary 和*WeakValueDictionary* 在其實作中使用弱參照，在弱參照上設定回呼函式，此弱參照在垃圾回收取回鍵或值時通知弱字典。*WeakSet* 實作了*set* 介面，但保留對其元素的弱參照，就像*WeakKeyDictionary* 一樣。

finalize 提供了一種直接的方法來🄵🄵在物件被垃圾回收時呼叫的清理函式。這比在原始弱參照上設定回呼函式更容易使用，因🄴模組在物件被回收前會自動確保最終化器 (finalizer) 保持存活。

大多數程式應該發現使用這些弱容器種類之一或*finalize* 就足🄵了—通常不需要直接建立自己的弱參照。低層級的機制由*weakref* 模組公開，以利於進階用途。

[F]非所有物件都可以被弱參照。支援弱參照的物件包括類[F]實例、用 Python （但不是 C）編寫的函式、實例方法、集合、凍結集合 (frozenset)、一些檔案物件、[F]生器、類型物件、socket、陣列、雙向[F]列、正規表示式模式物件和程式碼物件。

在 3.2 版的變更: 新增了對 thread.lock、threading.Lock 和程式碼物件的支援。

一些[F]建型[F]，例如*list* 和*dict* 不直接支援弱參照，但可以透過子類[F]化來支援：

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)   # this object is weak referenceable
```

CPython 實作細節： 其他[F]建型[F]，例如*tuple* 和*int* 即使在子類[F]化時也不支援弱參照。

擴充型[F] (extension type) 可以輕易地支援弱參照；請參[F] weakref-support。

當[F]給定的型[F]定義 `__slots__` 時，弱參照支援將被停用，除非 `'__weakref__'` 字串也存在於 `__slots__` 宣告的字串序列中。詳情請參[F] __slots__ 文件。

class weakref.**ref**(*object*[, *callback*])

回傳對 *object* 的弱參照。如果參照目標仍存活，則可以透過呼叫參照物件來取回原始物件；如果參照目標已不存活，呼叫參照物件將導致*None* 被回傳。如果 *callback* 被提供而非*None*，且回傳的弱參照物件仍存活，那[F]當物件即將被最終化 (finalize) 時，回呼將被呼叫；弱參照物件將作[F]唯一的參數傳遞給回呼；參照物件將不再可用。

[F]同一個物件建構多個弱參照是可行的。[F]每個弱參照[F][F]的回呼將按照最新到最舊[F][F]的回呼順序來被呼叫。

回呼引發的例外將在標准錯誤輸出中被[F]明，但無法被傳播；它們的處理方式與物件的 `__del__()` 方法引發的例外完全相同。

如果 *object* 是可雜[F]的，那[F]弱參照就是可雜[F]的。即使在 *object* 被[F]除後，它們仍將保留其雜[F]值。如果僅在 *object* [F]除後才第一次呼叫*hash()*，則該呼叫將引發*TypeError*。

弱參照支援相等性的測試，但不支援排序。如果參照目標仍存活，則兩個參照與其參照目標具有相同的相等關[F]（無論 *callback* 如何）。如果任一參照目標已被[F]除，則僅當參照物件是同一物件時，參照才相等。

這是一個可子類[F]化的型[F]，而不是一個工廠函式。

__callback__

此唯讀屬性回傳目前與弱參照關聯的回呼。如果[F]有回呼或弱參照的參照目標已不存活，那[F]該屬性的值[F] `None`。

在 3.4 版的變更: 新增*__callback__* 屬性。

`weakref.`**proxy**(*object*[, *callback*])

回傳一個使用弱參照的 *object* 的代理 (proxy)。這支援在大多數情境中使用代理，而不需要對弱參照物件明確地取消參照。回傳的物件將具有 `ProxyType` 或 `CallableProxyType` 型[F]，具體取[F]於 *object* 是否[F]可呼叫物件。無論參照目標如何，代理物件都不是*hashable*；這避免了與其基本可變物件本質相關的許多問題，[F]阻止它們作[F]字典的鍵被使用。*callback* 與*ref()* 函式的同名參數是相同的。

在參照目標被垃圾回收後存取代理物件的屬性會引發*ReferenceError*。

在 3.8 版的變更: 提供對代理物件的運算子支援，以包括矩陣乘法運算子 `@` 和 `@=`。

`weakref.`**getweakrefcount**(*object*)

回傳參照 *object* 的弱參照和代理的數量。

weakref.**getweakrefs**(*object*)

回傳參照 *object* 的所有弱參照和代理物件的一個串列。

class weakref.**WeakKeyDictionary**([*dict*])

弱參照鍵的對映類🄴。當不再有對鍵的🄴參照時，字典中的條目將被🄴🄴。這可用於將附加資料與應用程式其他部分擁有的物件相關聯，而無需向這些物件新增屬性。這對於覆蓋屬性存取的物件特🄴有用。

請注意，當將與現有鍵具有相同值的鍵（但識🄴性不相等）插入字典時，它會替🄴該值，但不會替🄵現有鍵。因此，當🄴除對原始鍵的參照時，它也會🄴除字典中的條目：

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1   # d = {k1: 1}
>>> d[k2] = 2   # d = {k1: 2}
>>> del k1      # d = {}
```

一個變通的解法是在重新賦值 (reassignment) 之前🄴除鍵：

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1   # d = {k1: 1}
>>> del d[k1]
>>> d[k2] = 2   # d = {k2: 2}
>>> del k1      # d = {k2: 2}
```

在 3.9 版的變更: 新增 **PEP 584** 所述對於 | 與 |= 運算子的支援。

WeakKeyDictionary 物件有一個直接公開🄴部參照的附加方法。參照在被使用時不保證是" 存活的"，因此在使用之前需要檢查呼叫參照的結果。這可以用來防止建立會導致垃圾回收器保留鍵的時間超過其所需時間的參照。

WeakKeyDictionary.**keyrefs**()

回傳對鍵的弱參照的可🄴代物件。

class weakref.**WeakValueDictionary**([*dict*])

弱參照值的對映類🄴。當不再存在對值的🄴參照時，字典中的條目將被🄴🄴。

在 3.9 版的變更: 新增對 | 和 |= 運算子的支持，如 **PEP 584** 中所🄴明。

WeakValueDictionary 物件有一個附加方法，它與*WeakKeyDictionary.keyrefs()* 方法有相同的問題。

WeakValueDictionary.**valuerefs**()

回傳對值的弱參照的可🄴代物件。

class weakref.**WeakSet**([*elements*])

保留對其元素的弱參照的集合類🄴。當不再存在對某個元素的🄴參照時，該元素將被🄴🄴。

class weakref.**WeakMethod**(*method*[, *callback*])

一個特🄴的*ref* 子類🄴，其模擬對🄴結方法 (bound method)（即在類🄴上定義🄴在實例上查找的方法）的弱參照。由於🄴結方法是短暫存在的，因此標准弱參照無法保留它。*WeakMethod* 有特殊的程式碼來重新建立🄴結方法，直到物件或原始函式死亡：

```
>>> class C:
...     def method(self):
...         print("method called!")
...
>>> c = C()
>>> r = weakref.ref(c.method)
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
<bound method C.method of <__main__.C object at 0x7fc859830220>>
>>> r()()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>
```

callback 與*ref()* 函式的同名參數是相同的。

在 3.4 版被加入.

class weakref.**finalize**(*obj*, *func*, */*, **args*, ***kwargs*)

回傳可呼叫的最終化器物件，此物件在 *obj* 被垃圾回收時會被呼叫。與一般的弱參照不同，最終化器將始終存在，直到參照物件被回收🄵止，從而大大簡化了生命🄵期管理。

最終化器在被呼叫（明確呼叫或在垃圾回收時）之前被視🄵*存活*，之後它就會*死亡*。呼叫存活的最終化器會回傳 `func(*arg, **kwargs)` 的計算結果，而呼叫死亡的最終化器會回傳*None*。

垃圾回收期間最終化器回呼引發的例外會在標准錯誤輸出中顯示，但無法傳播。它們的處理方式與從物件的 `__del__()` 方法或弱參照的回呼引發的例外相同。

當程式結束時，除非該最終化器的*atexit* 屬性已被設定🄵 false，否則每個存活的最終化器會被呼叫。它們以與建立相反的順序被呼叫。

當模組的 globals 可能被*None* 取代時，最終化器永遠不會在*interpreter shutdown* 的後期調用（invoke）其回呼。

__call__()

如果 *self* 仍存活，則將其標記🄵死亡🄵回傳呼叫 `func(*args, **kwargs)` 的結果。如果 *self* 已死亡，則回傳*None*。

detach()

如果 *self* 仍存活，則將其標記🄵死亡🄵回傳元組 `(obj, func, args, kwargs)`。如果 *self* 已死亡，則回傳*None*。

peek()

如果 *self* 仍存活，則回傳元組 `(obj, func, args, kwargs)`。如果 *self* 已死亡，則回傳*None*。

alive

如果最終化器仍存活，則屬性🄵 true，否則🄵 false。

atexit

一個可寫的布林屬性，預設🄵 true。當程式結束時，它會呼叫*atexit* 🄵 true 的所有剩余且仍存活的最終化器。它們以與建立相反的順序被呼叫。

備🄵

確保 *func*、*args* 和 *kwargs* 不直接或間接擁有對 *obj* 的任何參照非常重要，否則 *obj* 將永遠不會被垃圾回收。尤其 *func* 不應該是 *obj* 的🄵結方法。

在 3.4 版被加入.

`weakref.`**`ReferenceType`**
弱參照物件的型🄵物件。

`weakref.`**`ProxyType`**
非可呼叫物件的代理的型🄵物件。

`weakref.`**`CallableProxyType`**
可呼叫物件的代理的型🄵物件。

`weakref.`**`ProxyTypes`**
包含代理的所有型🄵物件的序列。這可以讓測試物件是否🄵代理變得更簡單，而無需依賴命名兩種代理型🄵。

也參考

PEP 205 - 弱參照
此功能的提案和理由，包括早期實作的連結以及其他語言中類似功能的資訊。

8.9.1 弱參照物件

弱參照物件除了*ref.__callback__* 之外🄵有任何方法和屬性。弱參照物件允許透過呼叫來獲取參照目標（如果它仍然存在）：

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

如果參照目標不再存活，則呼叫參照物件將回傳*None*：

```
>>> del o, o2
>>> print(r())
None
```

應該使用運算式 `ref() is not None` 來測試弱參照物件是否仍然存活。需要使用參照物件的應用程式程式碼通常應遵循以下模式：

```
# r is a weak reference object
o = r()
if o is None:
```

(繼續下一頁)

(繼續上一頁)

```
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate.")
else:
    print("Object is still live!")
    o.do_something_useful()
```

使用對「活性 (liveness)」的單獨測試會在執行緒應用程式中建立競🄵條件 (race condition)；另一個執行緒可能在弱參照被呼叫之前讓該弱參照失效；上方顯示的慣用作法在執行緒應用程式和單執行緒應用程式中都是安全的。

可以透過子類🄵化來建立*ref* 物件的特殊版本。這在*WeakValueDictionary* 的實作中被使用，以🄵少對映中每個條目的記憶體開銷。這對於將附加資訊與參照相關聯最有用，但也可用於在呼叫上插入附加處理以檢索參照目標。

這個範例展示如何使用*ref* 的子類🄵來儲存有關物件的附加資訊🄵影響存取參照目標時回傳的值：

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, /, **annotations):
        super().__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.items():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super().__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

8.9.2 范例

這個簡單的範例展示了應用程式如何使用物件 ID 來檢索它以前見過 的物件。物件的 ID 之後可以在其他資料結構中使用，而不必🄴制物件保持存活，但如果這樣做，仍然可以透過 ID 檢索物件。

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]
```

8.9.3 最終化器物件

使用*finalize*的最大優點是可以輕松🄵🄵回呼，而無需保留回傳的最終化器物件。例如

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!")
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

最終化器也可以直接被呼叫。然而，最終化器最多會調用回呼一次。

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
CALLBACK
>>> assert not f.alive
>>> f()                     # callback not called because finalizer dead
>>> del obj                 # callback not called because finalizer dead
```

你可以使用最終化器的*detach()*方法來取消🄵🄵最終化器。這會殺死最終化器🄵回傳建立建構函式時傳遞給建構函式的引數。

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach()
(<...Object object ...>, <function callback ...>, (1, 2), {'z': 3})
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

除非你將*atexit*屬性設🄵*False*，否則當程式結束時，最終化器將會被呼叫如果其仍然存在。例如

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting")
<finalize object at ...; for 'Object' at ...>
>>> exit()
obj dead or exiting
```

8.9.4 最終化器與 __del__() 方法的比較

假設我們要建立一個類🄴，其實例代表臨時目🄵。當以下任一事件發生時，應🄵除目🄵及其🄵容：

- 該物件被垃圾回收，
- 該物件的 remove() 方法被呼叫，或者
- 程式結束。

我們可以用以下的方式來嘗試使用 __del__() 方法實作該類🄴：

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
        return self.name is None

    def __del__(self):
        self.remove()
```

從 Python 3.4 開始，__del__() 方法不再阻止參照循環 (reference cycle) 被垃圾回收，🄵且在*interpreter shutdown* 期間不再🄵制將模組的 globals 設🄵*None*。所以這段程式碼在 CPython 上應該可以正常運作。

然而，🄵所周知，對 __del__() 方法的處理是特地實作的，因🄴它依賴於直譯器的垃圾回收器實作的🄵部細節。

更耐用的替代方案可以是定義一個最終化器，其僅參照需要的特定函式和物件，而不是存取物件的完整狀態：

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()
        self._finalizer = weakref.finalize(self, shutil.rmtree, self.name)

    def remove(self):
        self._finalizer()

    @property
    def removed(self):
        return not self._finalizer.alive
```

定義如下，我們的最終化器僅接收對適當清理目🄵所需的詳細資訊的參照。如果物件從未被垃圾回收，則最終化器仍將在結束時被呼叫。

基於 weakref 的最終化器的另一個優點是它們可用於🄴定義由第三方控制的類🄵🄴🄵最終化器，例如在卸載模組時執行程式碼：

```
import weakref, sys
def unloading_module():
    # implicit reference to the module globals from the function body
weakref.finalize(sys.modules[__name__], unloading_module)
```

備🄵

如果在程式結束時在常駐的 (daemonic) 執行緒中建立最終化器物件，則最終化器有可能在結束時不會被呼叫。然而，在常駐的執行緒中*atexit.register()*、`try: ... finally: ...` 和 `with: ...` 也不保證清理會發生。

8.10 types --- 動態型🄵建立與🄵建型🄵名稱

原始碼： Lib/types.py

This module defines utility functions to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like *int* or *str* are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

8.10.1 Dynamic Type Creation

`types.`**`new_class`**(*name*, *bases=()*, *kwds=None*, *exec_body=None*)

Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The *exec_body* argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: None`.

在 3.3 版被加入.

`types.`**`prepare_class`**(*name*, *bases=()*, *kwds=None*)

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass, namespace, kwds`

metaclass is the appropriate metaclass, *namespace* is the prepared class namespace and *kwds* is an updated copy of the passed in *kwds* argument with any `'metaclass'` entry removed. If no *kwds* argument is passed in, this will be an empty dict.

在 3.3 版被加入.

在 3.6 版的變更: The default value for the `namespace` element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method.

也參考

metaclasses
Full details of the class creation process supported by these functions

PEP 3115 - Metaclasses in Python 3000
Introduced the `__prepare__` namespace hook

`types.`**`resolve_bases`**(*bases*)

Resolve MRO entries dynamically as specified by **PEP 560**.

This function looks for items in *bases* that are not instances of *type*, and returns a tuple where each such object that has an `__mro_entries__()` method is replaced with an unpacked result of calling this method. If a *bases* item is an instance of *type*, or it doesn't have an `__mro_entries__()` method, then it is included in the return tuple unchanged.

在 3.7 版被加入.

`types.`**`get_original_bases`**(*cls*, /)

Return the tuple of objects originally given as the bases of *cls* before the `__mro_entries__()` method has been called on any bases (following the mechanisms laid out in **PEP 560**). This is useful for introspecting *Generics*.

For classes that have an `__orig_bases__` attribute, this function returns the value of `cls.__orig_bases__`. For classes without the `__orig_bases__` attribute, `cls.__bases__` is returned.

Examples:

```
from typing import TypeVar, Generic, NamedTuple, TypedDict

T = TypeVar("T")
class Foo(Generic[T]): ...
class Bar(Foo[int], float): ...
class Baz(list[str]): ...
Eggs = NamedTuple("Eggs", [("a", int), ("b", str)])
Spam = TypedDict("Spam", {"a": int, "b": str})

assert Bar.__bases__ == (Foo, float)
assert get_original_bases(Bar) == (Foo[int], float)

assert Baz.__bases__ == (list,)
assert get_original_bases(Baz) == (list[str],)

assert Eggs.__bases__ == (tuple,)
assert get_original_bases(Eggs) == (NamedTuple,)

assert Spam.__bases__ == (dict,)
assert get_original_bases(Spam) == (TypedDict,)

assert int.__bases__ == (object,)
assert get_original_bases(int) == (object,)
```

在 3.12 版被加入.

也參考

PEP 560 - Core support for typing module and generic types

8.10.2 Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for *`isinstance()`* or *`issubclass()`* checks.

If you instantiate any of these types, note that signatures may vary between Python versions.

Standard names are defined for the following types:

`types.`**`NoneType`**

The type of *`None`*.

在 3.10 版被加入.

`types.`**`FunctionType`**

`types.`**`LambdaType`**

The type of user-defined functions and functions created by `lambda` expressions.

Raises an *auditing event* `function.__new__` with argument `code`.

The audit event only occurs for direct instantiation of function objects, and is not raised for normal compilation.

`types.`**`GeneratorType`**

The type of *generator*-iterator objects, created by generator functions.

`types.`**`CoroutineType`**

The type of *coroutine* objects, created by `async def` functions.

在 3.5 版被加入.

`types.`**`AsyncGeneratorType`**

The type of *asynchronous generator*-iterator objects, created by asynchronous generator functions.

在 3.6 版被加入.

`class` `types.`**`CodeType`**(***kwargs*)

The type of code objects such as returned by *`compile()`*.

Raises an *auditing event* `code.__new__` with arguments `code`, `filename`, `name`, `argcount`, `posonlyargcount`, `kwonlyargcount`, `nlocals`, `stacksize`, `flags`.

Note that the audited arguments may not match the names or positions required by the initializer. The audit event only occurs for direct instantiation of code objects, and is not raised for normal compilation.

`types.`**`CellType`**

The type for cell objects: such objects are used as containers for a function's free variables.

在 3.8 版被加入.

`types.`**`MethodType`**

The type of methods of user-defined class instances.

`types.`**`BuiltinFunctionType`**

`types.`**`BuiltinMethodType`**

The type of built-in functions like *`len()`* or *`sys.exit()`*, and methods of built-in classes. (Here, the term "built-in" means "written in C".)

types.**WrapperDescriptorType**

The type of methods of some built-in data types and base classes such as `object.__init__()` or `object.__lt__()`.

在 3.7 版被加入.

types.**MethodWrapperType**

The type of *bound* methods of some built-in data types and base classes. For example it is the type of `object().__str__`.

在 3.7 版被加入.

types.**NotImplementedType**

The type of *NotImplemented*.

在 3.10 版被加入.

types.**MethodDescriptorType**

The type of methods of some built-in data types such as *str.join()*.

在 3.7 版被加入.

types.**ClassMethodDescriptorType**

The type of *unbound* class methods of some built-in data types such as `dict.__dict__['fromkeys']`.

在 3.7 版被加入.

class types.**ModuleType**(*name*, *doc=None*)

The type of *modules*. The constructor takes the name of the module to be created and optionally its *docstring*.

> **備🄵**
>
> Use *importlib.util.module_from_spec()* to create a new module if you wish to set the various import-controlled attributes.

__doc__

The *docstring* of the module. Defaults to `None`.

__loader__

The *loader* which loaded the module. Defaults to `None`.

This attribute is to match *importlib.machinery.ModuleSpec.loader* as stored in the `__spec__` object.

> **備🄵**
>
> A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__loader__", None)` if you explicitly need to use this attribute.

在 3.4 版的變更: Defaults to `None`. Previously the attribute was optional.

__name__

The name of the module. Expected to match *importlib.machinery.ModuleSpec.name*.

__package__

Which *package* a module belongs to. If the module is top-level (i.e. not a part of any specific package) then the attribute should be set to `''`, else it should be set to the name of the package (which can be `__name__` if the module is a package itself). Defaults to `None`.

This attribute is to match *importlib.machinery.ModuleSpec.parent* as stored in the `__spec__` object.

> **備🄵**
>
> A future version of Python may stop setting this attribute by default. To guard against this potential change, preferably read from the `__spec__` attribute instead or use `getattr(module, "__package__", None)` if you explicitly need to use this attribute.

在 3.4 版的變更: Defaults to `None`. Previously the attribute was optional.

__spec__

A record of the module's import-system-related state. Expected to be an instance of *importlib.machinery.ModuleSpec*.

在 3.4 版被加入.

`types.`**EllipsisType**

The type of *Ellipsis*.

在 3.10 版被加入.

class `types.`**GenericAlias**(*t_origin*, *t_args*)

The type of *parameterized generics* such as `list[int]`.

`t_origin` should be a non-parameterized generic class, such as `list`, `tuple` or `dict`. `t_args` should be a *tuple* (possibly of length 1) of types which parameterize `t_origin`:

```
>>> from types import GenericAlias

>>> list[int] == GenericAlias(list, (int,))
True
>>> dict[str, int] == GenericAlias(dict, (str, int))
True
```

在 3.9 版被加入.

在 3.9.2 版的變更: This type can now be subclassed.

> **也參考**
>
> ***Generic Alias Types***
> In-depth documentation on instances of `types.GenericAlias`
>
> **PEP 585 - Type Hinting Generics In Standard Collections**
> Introducing the `types.GenericAlias` class

class `types.`**UnionType**

The type of *union type expressions*.

在 3.10 版被加入.

class types.**TracebackType**(*tb_next*, *tb_frame*, *tb_lasti*, *tb_lineno*)

The type of traceback objects such as found in `sys.exception().__traceback__`.

See the language reference for details of the available attributes and operations, and guidance on creating tracebacks dynamically.

types.**FrameType**

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

types.**GetSetDescriptorType**

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the *property* type, but for classes defined in extension modules.

types.**MemberDescriptorType**

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the *property* type, but for classes defined in extension modules.

In addition, when a class is defined with a `__slots__` attribute, then for each slot, an instance of `MemberDescriptorType` will be added as an attribute on the class. This allows the slot to appear in the class's *__dict__*.

CPython 實作細節: In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

class types.**MappingProxyType**(*mapping*)

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

在 3.3 版被加入.

在 3.9 版的變更: Updated to support the new union (`|`) operator from **PEP 584**, which simply delegates to the underlying mapping.

key in proxy

Return `True` if the underlying mapping has a key *key*, else `False`.

proxy[key]

Return the item of the underlying mapping with key *key*. Raises a *KeyError* if *key* is not in the underlying mapping.

iter(proxy)

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

len(proxy)

Return the number of items in the underlying mapping.

copy()

Return a shallow copy of the underlying mapping.

get(*key*[, *default*])

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a *KeyError*.

items()

Return a new view of the underlying mapping's items (`(key, value)` pairs).

keys()

Return a new view of the underlying mapping's keys.

values()

Return a new view of the underlying mapping's values.

reversed(proxy)

Return a reverse iterator over the keys of the underlying mapping.

在 3.9 版被加入.

hash(proxy)

Return a hash of the underlying mapping.

在 3.12 版被加入.

8.10.3 Additional Utility Classes and Functions

class types.**SimpleNamespace**

A simple *object* subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike *object*, with SimpleNamespace you can add and remove attributes. If a SimpleNamespace object is initialized with keyword arguments, those are directly added to the underlying namespace.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, /, **kwargs):
        self.__dict__.update(kwargs)

    def __repr__(self):
        items = (f"{k}={v!r}" for k, v in self.__dict__.items())
        return "{}({})".format(type(self).__name__, ", ".join(items))

    def __eq__(self, other):
        if isinstance(self, SimpleNamespace) and isinstance(other,␣
↪SimpleNamespace):
            return self.__dict__ == other.__dict__
        return NotImplemented
```

SimpleNamespace may be useful as a replacement for `class NS: pass`. However, for a structured record type use *namedtuple()* instead.

在 3.3 版被加入.

在 3.9 版的變更: Attribute order in the repr changed from alphabetical to insertion (like dict).

types.**DynamicClassAttribute**(*fget=None*, *fset=None*, *fdel=None*, *doc=None*)

Route attribute access on a class to __getattr__.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's __getattr__ method; this is done by raising AttributeError.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see *enum.Enum* for an example).

在 3.4 版被加入.

8.10.4 Coroutine Utility Functions

`types.`**`coroutine`**(*gen_func*)

This function transforms a *generator* function into a *coroutine function* which returns a generator-based coroutine. The generator-based coroutine is still a *generator iterator*, but is also considered to be a *coroutine* object and is *awaitable*. However, it may not necessarily implement the `__await__()` method.

If *gen_func* is a generator function, it will be modified in-place.

If *gen_func* is not a generator function, it will be wrapped. If it returns an instance of *`collections.abc.Generator`*, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

在 3.5 版被加入.

8.11 `copy` --- 淺層 (shallow) 和深層 (deep) 🄵🄵操作

原始碼： Lib/copy.py

Python 的賦值陳述式不🄵🄵物件，而是建立目標和物件的🄴結 (binding) 關🄴。對於可變 (mutable) 或包含可變項目 (mutable item) 的集合，有時會需要一份副本來改變特定副本，而不必改變其他副本。本模組提供了通用的淺層🄵🄵和深層🄵🄵操作（如下所述）。

介面摘要：

`copy.`**`copy`**(*x*)

回傳 *x* 的淺層🄵🄵。

`copy.`**`deepcopy`**(*x*[, *memo*])

回傳 *x* 的深層🄵🄵。

`exception` `copy.`**`Error`**

引發針對特定模組的錯誤。

淺層與深層🄵🄵的區🄵僅與🄴合物件（即包含 list 或類🄴的實例等其他物件的物件）相關：

- 淺層🄵🄵建構一個新的🄴合物件，然後（在🄴可能的範圍🄴）將原始物件中找到的物件的參照插入其中。
- 深層🄵🄵建構一個新的🄴合物件，然後遞🄴地將在原始物件🄴找到的物件的副本插入其中。

深層🄵🄵操作通常存在兩個問題，而淺層🄵🄵操作🄵不存在這些問題：

- 遞🄴物件（直接或間接包含對自身參照的🄴合物件）可能會導致遞🄵🄵圈。
- 由於深層🄵🄵會🄵🄵所有🄵容，因此可能會有過多🄵🄵（例如應該在副本之間共享的資料）。

`deepcopy()` 函式用以下方式避免了這些問題：

- 保留在當前🄵🄵過程中已🄵🄵的物件的 `memo` 字典；以及
- 允許使用者定義的類🄵🄵寫 (override) 🄵🄵操作或🄵🄵的元件集合。

該模組不🄵🄵模組、方法、堆🄵追🄵（stack trace）、堆🄵框（stack frame）、檔案、socket、視窗、陣列以及任何類似的型🄴。它透過不變更原始物件🄴將其回傳來（淺層或深層地）"🄵🄵" 函式和類🄴；這與*`pickle`* 模組處理這類問題的方式是相似的。

字典的淺層🄵🄵可以使用*`dict.copy()`*，而 list 的淺層🄵🄵可以透過賦值整個 list 的切片 (slice) 完成，例如，`copied_list = original_list[:]`。

類🄵可以使用與操作 pickle 相同的介面來控制🄵🄵操作，關於這些方法的描述資訊請參考*pickle* 模組。實際上，*copy* 模組使用的正是從*copyreg* 模組中🄵🄵的 pickle 函式。

想要🄵一個類🄵定義它自己的🄵🄵操作實作，可以透過定義特殊方法 `__copy__()` 和 `__deepcopy__()`。呼叫前者以實現淺層🄵🄵操作；不必傳入額外引數。呼叫後者以實現深層🄵🄵操作；它應傳入一個引數，即 `memo` 字典。如果 `__deepcopy__()` 實現需要建立一個元件的深層🄵🄵，它應當呼叫*deepcopy()* 函式🄵以該元件作🄵第一個引數、以該 memo 字典作🄵第二個引數。memo 字典應當被當作不透明物件 (opaque object) 來處理。

也參考

***pickle* 模組**
支援物件之狀態檢索 (state retrieval) 和恢復 (restoration) 相關特殊方法的討論。

8.12 `pprint` --- 資料美化列印器

原始碼： Lib/pprint.py

The *pprint* module provides a capability to ”pretty-print” arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don’t fit within the allowed width, adjustable by the *width* parameter defaulting to 80 characters.

Dictionaries are sorted by key before the display is computed.

在 3.9 版的變更: Added support for pretty-printing *types.SimpleNamespace*.

在 3.10 版的變更: Added support for pretty-printing *dataclasses.dataclass*.

8.12.1 Functions

`pprint.`**`pp`**(*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, *, *compact=False*, *sort_dicts=False*, *underscore_numbers=False*)

Prints the formatted representation of *object*, followed by a newline. This function may be used in the interactive interpreter instead of the *print()* function for inspecting values. Tip: you can reassign `print = pprint.pp` for use within a scope.

參數

- **`object`** -- The object to be printed.
- **`stream`** (*file-like object* | None) -- A file-like object to which the output will be written by calling its `write()` method. If `None` (the default), *sys.stdout* is used.
- **`indent`** (`int`) -- The amount of indentation added for each nesting level.
- **`width`** (`int`) -- The desired maximum number of characters per line in the output. If a structure cannot be formatted within the width constraint, a best effort will be made.

- **depth** (int | None) -- The number of nesting levels which may be printed. If the data structure being printed is too deep, the next contained level is replaced by `...`. If `None` (the default), there is no constraint on the depth of the objects being formatted.
- **compact** (bool) -- Control the way long *sequences* are formatted. If `False` (the default), each item of a sequence will be formatted on a separate line, otherwise as many items as will fit within the *width* will be formatted on each output line.
- **sort_dicts** (bool) -- If `True`, dictionaries will be formatted with their keys sorted, otherwise they will be displayed in insertion order (the default).
- **underscore_numbers** (bool) -- If `True`, integers will be formatted with the _ character for a thousands separator, otherwise underscores are not displayed (the default).

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pp(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
 'knights',
 'ni']
```

在 3.8 版被加入.

pprint.**pprint**(*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Alias for *pp()* with *sort_dicts* set to `True` by default, which would automatically sort the dictionaries' keys, you might want to use *pp()* instead where it is `False` by default.

pprint.**pformat**(*object*, *indent=1*, *width=80*, *depth=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Return the formatted representation of *object* as a string. *indent*, *width*, *depth*, *compact*, *sort_dicts* and *underscore_numbers* are passed to the *PrettyPrinter* constructor as formatting parameters and their meanings are as described in the documentation above.

pprint.**isreadable**(*object*)

Determine if the formatted representation of *object* is "readable", or can be used to reconstruct the value using *eval()*. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

pprint.**isrecursive**(*object*)

Determine if *object* requires a recursive representation. This function is subject to the same limitations as noted in *saferepr()* below and may raise an *RecursionError* if it fails to detect a recursive object.

pprint.**saferepr**(*object*)

Return a string representation of *object*, protected against recursion in some common data structures, namely instances of *dict*, *list* and *tuple* or subclasses whose `__repr__` has not been overridden. If the representation of object exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"[<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni']"
```

8.12.2 PrettyPrinter 物件

class pprint.**PrettyPrinter**(*indent=1*, *width=80*, *depth=None*, *stream=None*, ***, *compact=False*, *sort_dicts=True*, *underscore_numbers=False*)

Construct a *PrettyPrinter* instance.

Arguments have the same meaning as for *pp()*. Note that they are in a different order, and that *sort_dicts* defaults to `True`.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[   ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
    'spam',
    'eggs',
    'lumberjack',
    'knights',
    'ni']
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 'spam', 'eggs', 'lumberjack', 'knights',
 'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',)))))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...)))))))
```

在 3.4 版的變更: 新增 *compact* 參數。

在 3.8 版的變更: 新增 *sort_dicts* 參數。

在 3.10 版的變更: 新增 *underscore_numbers* 參數。

在 3.11 版的變更: No longer attempts to write to `sys.stdout` if it is `None`.

PrettyPrinter instances have the following methods:

PrettyPrinter.**pformat**(*object*)

Return the formatted representation of *object*. This takes into account the options passed to the *PrettyPrinter* constructor.

PrettyPrinter.**pprint**(*object*)

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new *PrettyPrinter* objects don't need to be created.

PrettyPrinter.**isreadable**(*object*)

Determine if the formatted representation of the object is "readable," or can be used to reconstruct the value using *eval()*. Note that this returns `False` for recursive objects. If the *depth* parameter of the *PrettyPrinter* is set and the object is deeper than allowed, this returns `False`.

PrettyPrinter.**isrecursive**(*object*)

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the *saferepr()* implementation.

PrettyPrinter.**format**(*object*, *context*, *maxlevels*, *level*)

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the *id()* of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be True. Recursive calls to the *format()* method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be 0 if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

8.12.3 范例

To demonstrate several uses of the *pp()* function and its parameters, let's fetch information about a project from PyPI:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, *pp()* shows the whole object:

```
>>> pprint.pp(project_info)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': ['Development Status :: 3 - Alpha',
                 'Intended Audience :: Developers',
                 'License :: OSI Approved :: MIT License',
                 'Programming Language :: Python :: 2',
                 'Programming Language :: Python :: 2.6',
                 'Programming Language :: Python :: 2.7',
                 'Programming Language :: Python :: 3',
                 'Programming Language :: Python :: 3.2',

 'requires_dist': None,
 'requires_python': None,
 'summary': 'A sample Python project',
 'version': '1.2.0'}
```

The result can be limited to a certain *depth* (ellipsis is used for deeper contents):

```
>>> pprint.pp(project_info, depth=1)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': [...],
 'description': 'A sample Python project\n'
                '=======================\n'
                '\n'
                'This is the description file for the project.\n'
                '\n'
                'The file should use UTF-8 encoding and be written using '
                'ReStructured Text. It\n'
                'will be used to generate the project webpage on PyPI, and '
                'should be written for\n'
                'that purpose.\n'
                '\n'
                'Typical contents for this file would include an overview of '
                'the project, basic\n'
                'usage examples, etc. Generally, including the project '
                'changelog in here is not\n'
                'a good idea, although a simple "What\'s New" section for the '
                'most recent version\n'
                'may be appropriate.',
 'description_content_type': None,
 'docs_url': None,
 'download_url': 'UNKNOWN',
 'downloads': {...},
 'home_page': 'https://github.com/pypa/sampleproject',

8.13 reprlib --- repr() 的替代實作

原始碼： Lib/reprlib.py

The reprlib module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

class reprlib.**Repr**(*, *maxlevel=6*, *maxtuple=6*, *maxlist=6*, *maxarray=5*, *maxdict=4*, *maxset=6*, *maxfrozenset=6*, *maxdeque=6*, *maxstring=30*, *maxlong=40*, *maxother=30*, *fillvalue='...'*, *indent=None*)

Class which provides formatting services useful in implementing functions similar to the built-in *repr()*; size limits for different object types are added to avoid the generation of representations which are excessively long.

The keyword arguments of the constructor can be used as a shortcut to set the attributes of the *Repr* instance. Which means that the following initialization:

```
aRepr = reprlib.Repr(maxlevel=3)
```

Is equivalent to:

```
aRepr = reprlib.Repr()
aRepr.maxlevel = 3
```

See section *Repr Objects* for more information about *Repr* attributes.

在 3.12 版的變更: Allow attributes to be set via keyword arguments.

reprlib.**aRepr**

This is an instance of *Repr* which is used to provide the *repr()* function described below. Changing the attributes of this object will affect the size limits used by *repr()* and the Python debugger.

reprlib.**repr**(*obj*)

This is the *repr()* method of aRepr. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to __repr__() and substituting a placeholder string instead.

@reprlib.**recursive_repr**(*fillvalue='...'*)

Decorator for __repr__() methods to detect recursive calls within the same thread. If a recursive call is made, the *fillvalue* is returned, otherwise, the usual __repr__() call is made. For example:

```
>>> from reprlib import recursive_repr
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
```

(繼續下一頁)

(繼續上一頁)

```
...         return '<' + '|'.join(map(repr, self)) + '>'
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

在 3.2 版被加入.

8.13.1 Repr 物件

Repr instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

Repr.**fillvalue**

This string is displayed for recursive references. It defaults to `...`.

在 3.11 版被加入.

Repr.**maxlevel**

Depth limit on the creation of recursive representations. The default is `6`.

Repr.**maxdict**

Repr.**maxlist**

Repr.**maxtuple**

Repr.**maxset**

Repr.**maxfrozenset**

Repr.**maxdeque**

Repr.**maxarray**

Limits on the number of entries represented for the named object type. The default is `4` for *maxdict*, `5` for *maxarray*, and `6` for the others.

Repr.**maxlong**

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is `40`.

Repr.**maxstring**

Limit on the number of characters in the representation of the string. Note that the "normal" representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is `30`.

Repr.**maxother**

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is `20`.

Repr.**indent**

If this attribute is set to `None` (the default), the output is formatted with no line breaks or indentation, like the standard *repr()*. For example:

```
>>> example = [
...     1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
>>> import reprlib
```

(繼續下一頁)

(繼續上一頁)

```
>>> aRepr = reprlib.Repr()
>>> print(aRepr.repr(example))
[1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
```

If *indent* is set to a string, each recursion level is placed on its own line, indented by that string:

```
>>> aRepr.indent = '-->'
>>> print(aRepr.repr(example))
[
-->1,
-->'spam',
-->{
-->-->'a': 2,
-->-->'b': 'spam eggs',
-->-->'c': {
-->-->-->3: 4.5,
-->-->-->6: [],
-->-->},
-->},
-->'ham',
]
```

Setting *indent* to a positive integer value behaves as if it was set to a string with that number of spaces:

```
>>> aRepr.indent = 4
>>> print(aRepr.repr(example))
[
    1,
    'spam',
    {
        'a': 2,
        'b': 'spam eggs',
        'c': {
            3: 4.5,
            6: [],
        },
    },
    'ham',
]
```

在 3.12 版被加入.

Repr.**repr**(*obj*)

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

Repr.**repr1**(*obj*, *level*)

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with `level - 1` for the value of *level* in the recursive call.

Repr.**repr_TYPE**(*obj*, *level*)

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

8.13.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys

class MyRepr(reprlib.Repr):

    def repr_TextIOWrapper(self, obj, level):
        if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
            return obj.name
        return repr(obj)

aRepr = MyRepr()
print(aRepr.repr(sys.stdin))          # prints '<stdin>'
```

```
<stdin>
```

8.14 enum --- 對列舉的支援

在 3.4 版被加入.

原始碼： Lib/enum.py

Important

本頁包含 API 的參考資訊。關於教學資訊及更多進階主題的討論請參考

- 基本教學
- 進階教學
- 列舉指南

列舉：

- 是一組綁定唯一值的代表名稱（成員）
- 可以用🄴代的方式以定義的順序回傳其正式 (canonical)（即非🄵名）成員
- 使用 *call* 語法來透過值回傳成員
- 使用 *index* 語法來透過名稱回傳成員

列舉透過 `class` 語法或函式呼叫的語法來建立：

```
>>> from enum import Enum

>>> # class syntax
>>> class Color(Enum):
```

(繼續下一頁)

(繼續上一頁)

```
...     RED = 1
...     GREEN = 2
...     BLUE = 3

>>> # functional syntax
>>> Color = Enum('Color', ['RED', 'GREEN', 'BLUE'])
```

雖然我們可以用 `class` 語法來建立列舉，列舉🄵不是標準的 Python 類🄵。參考列舉有何差🄵以取得更多細節。

備🄵

命名方式

- `Color` 類🄵是一個列舉（或 *enum*）
- `Color.RED`、`Color.GREEN` 等屬性是列舉成員（或成員），🄵且使用上可以看作常數。
- 列舉成員有名稱和值（`Color.RED` 的名稱是 `RED`，`Color.BLUE` 的值是 `3` 諸如此類）

8.14.1 模組🄵容

EnumType

Enum 及其子類🄵的 `type`。

Enum

用來建立列舉常數的基礎類🄵。

IntEnum

用來建立列舉常數的基礎類🄵，同時也是*int* 的子類🄵。(備🄵)

StrEnum

用來建立列舉常數的基礎類🄵，同時也是*str* 的子類🄵。(備🄵)

Flag

用來建立列舉常數的基礎類🄵，可以使用位元操作來結合成員且其結果不失去*Flag* 的成員資格。

IntFlag

用來建立列舉常數的基礎類🄵，可以使用位元操作來結合成員且其結果不失去*IntFlag* 的成員資格。*IntFlag* 的成員也是*int* 的子類🄵。(備🄵)

ReprEnum

由*IntEnum*、*StrEnum* 及*IntFlag* 所使用來保留這些混合類型的*str()*。

EnumCheck

一個有 `CONTINUOUS`、`NAMED_FLAGS` 及 `UNIQUE` 這些值的列舉，和*verify()* 一起使用來確保給定的列舉符合多種限制。

FlagBoundary

一個有 STRICT、CONFORM、EJECT 及 KEEP 這些值的列舉，允許列舉對如何處理非法值做更細微的控制。

auto

列舉成員的實例會被取代成合適的值。*StrEnum* 預設是小寫版本的成員名稱，其它列舉則預設是 1 且往後遞增。

property()

允許*Enum* 成員擁有屬性且不會與成員名稱有衝突。value 及 name 屬性是用這個方式來實作。

unique()

Enum 類🄵的裝飾器，用來確保任何值只有綁定到一個名稱上。

verify()

Enum 類🄵的裝飾器，用來檢查列舉上使用者所選的限制。

member()

讓 obj 變成成員。可以當作裝飾器使用。

nonmember()

不讓 obj 變成成員。可以當作裝飾器使用。

global_enum()

修改列舉上的*str()* 及*repr()* ，讓成員顯示🄵屬於模組而不是類🄵，🄵將該列舉成員匯出到全域命名空間。

show_flag_values()

回傳旗標 (flag) 🄵包含的所有 2 的次方的整數串列。

在 3.6 版被加入: Flag, IntFlag, auto

在 3.11 版被加入: StrEnum, EnumCheck, ReprEnum, FlagBoundary, property, member, nonmember, global_enum, show_flag_values

---

8.14.2 資料型🄵

class enum.**EnumType**

EnumType 是列舉的*metaclass*。*EnumType* 可以有子類🄵 -- 細節請參考 建立 EnumType 的子類🄵。

EnumType 負責在最後的列舉上面設定正確的 __repr__()、__str__()、__format__() 及 __reduce__() 方法，以及建立列舉成員，🄵正確處理重🄵，提供列舉類🄵的🄵代等等。

__call__(*cls*, *value*, *names=None*, ***, *module=None*, *qualname=None*, *type=None*, *start=1*, *boundary=None*)

這個方法可以用兩種不同的方式呼叫:

- 查詢已存在的成員:

  cls
  所呼叫的列舉類🄵。

  value
  要查詢的值。

- 使用 cls 列舉來建立新列舉（只有在現有列舉🄵有任何成員時）

cls
所呼叫的列舉類🄵。

value
要建立的新列舉的名稱。

names
新列舉的成員的名稱/值。

module
新列舉要建立在哪個模組名稱下。

qualname
這個列舉在模組🄵實際上的位置。

type
新列舉的混合類型。

start
列舉的第一個整數值（由*auto* 所使用）

boundary
在位元操作時怎🄵處理範圍外的值（只有*Flag* 會用到）

__contains__(*cls*, *member*)

如果 member 屬於 `cls` 則回傳 `True`：

```
>>> some_var = Color.RED
>>> some_var in Color
True
>>> Color.RED.value in Color
True
```

在 3.12 版的變更: 在 Python 3.12 之前，如果用非列舉成員做屬於檢查 (containment check) 會引發 `TypeError`。

__dir__(*cls*)

回傳 `['__class__', '__doc__', '__members__', '__module__']` 及 *cls* 的成員名稱：

```
>>> dir(Color)
['BLUE', 'GREEN', 'RED', '__class__', '__contains__', '__doc__', '__getitem__
↪', '__init_subclass__', '__iter__', '__len__', '__members__', '__module__',
↪'__name__', '__qualname__']
```

__getitem__(*cls*, *name*)

回傳 *cls* 中符合 *name* 的列舉成員，或引發*KeyError*：

```
>>> Color['BLUE']
<Color.BLUE: 3>
```

__iter__(*cls*)

以定義的順序回傳在 *cls* 中的每個成員：

```
>>> list(Color)
[<Color.RED: 1>, <Color.GREEN: 2>, <Color.BLUE: 3>]
```

__len__(*cls*)

回傳 *cls* 的成員數量：

```
>>> len(Color)
3
```

__members__

回傳每個列舉名稱到其成員的對映，包括🄵名

__reversed__(*cls*)

以跟定義相反的順序回傳 *cls* 的每個成員：

```
>>> list(reversed(Color))
[<Color.BLUE: 3>, <Color.GREEN: 2>, <Color.RED: 1>]
```

在 3.11 版被加入: 在 3.11 之前，enum 使用 EnumMeta 類型，目前保留此類型當作🄵名。

class enum.**Enum**

Enum 是所有 *enum* 列舉的基礎類🄵。

name

用來定義 Enum 成員的名稱：

```
>>> Color.BLUE.name
'BLUE'
```

value

Enum 成員給定的值：

```
>>> Color.RED.value
1
```

成員的值，可以在*__new__()* 設定。

備🄵

列舉成員的值

成員的值可以是任何值：*int*、*str* 等等。如果實際使用什🄵值🄵不重要，你可以使用*auto* 實例，它會🄵你選擇合適的值。更多細節請參考*auto*。

While mutable/unhashable values, such as *dict*, *list* or a mutable *dataclass*, can be used, they will have a quadratic performance impact during creation relative to the total number of mutable/unhashable values in the enum.

name

成員名稱。

value

成員的值，可以在*__new__()* 設定。

order

已不再使用，只🄵了向後相容而保留（類🄵屬性，在類🄵建立時移除）

ignore

ignore 只有在建立的時候用到，在列舉建立完成後會被移除。

ignore 是一個不會變成成員的名稱串列，在列舉建立完成後其名稱會被移除。範例請參考 TimePeriod。

__dir__(*self*)

回傳 `['__class__', '__doc__', '__module__', 'name', 'value']` 及任何 *self.__class__* 上定義的公開方法：

```
>>> from datetime import date
>>> class Weekday(Enum):
...     MONDAY = 1
...     TUESDAY = 2
...     WEDNESDAY = 3
...     THURSDAY = 4
...     FRIDAY = 5
...     SATURDAY = 6
...     SUNDAY = 7
...     @classmethod
...     def today(cls):
...         print('today is %s' % cls(date.today().isoweekday()).name)
...
>>> dir(Weekday.SATURDAY)
['__class__', '__doc__', '__eq__', '__hash__', '__module__', 'name', 'today',
↪'value']
```

_generate_next_value_(*name*, *start*, *count*, *last_values*)

name
定義的成員名稱（例如'RED'）。

start
列舉的開始值，預設🄵 1。

count
已定義的成員數量，不包含目前這一個。

last_values
一個之前值的串列。

一個 *staticmethod*，用來🄴定 *auto* 下一個要回傳的值的：

```
>>> from enum import auto
>>> class PowersOfThree(Enum):
...     @staticmethod
...     def _generate_next_value_(name, start, count, last_values):
...         return 3 ** (count + 1)
...     FIRST = auto()
...     SECOND = auto()
...
>>> PowersOfThree.SECOND.value
9
```

__init__(*self*, **args*, ***kwds*)

預設情🄵下，不執行任何操作。如果在成員賦值中給出多個值，這些值將成🄵與 `__init__` 分🄵的引數；例如

```
>>> from enum import Enum
>>> class Weekday(Enum):
...     MONDAY = 1, 'Mon'
```

`Weekday.__init__()` 將被稱🄵 `Weekday.__init__(self, 1, 'Mon')`

__init_subclass__(*cls*, ***kwds*)

一個 *classmethod*，用來進一步設定後續的子類🄴，預設不做任何事。

missing(*cls*, *value*)

一個 *classmethod*，用來查詢在 *cls* 🄴找不到的值。預設不做任何事，但可以被覆寫以實作客🄴化的搜尋行🄵：

```
>>> from enum import StrEnum
>>> class Build(StrEnum):
...     DEBUG = auto()
...     OPTIMIZED = auto()
...     @classmethod
...     def _missing_(cls, value):
...         value = value.lower()
...         for member in cls:
...             if member.value == value:
...                 return member
...         return None
...
>>> Build.DEBUG.value
'debug'
>>> Build('deBUG')
<Build.DEBUG: 'debug'>
```

__new__(*cls*, **args*, ***kwds*)

預設情🄵下不存在。如果有指定，無論是在列舉類🄵定義中還是在 mixin 類🄵中（例如 `int`），都將傳遞成員賦值中給出的所有值；例如

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     TWENTYSIX = '1a', 16
```

results in the call `int('1a', 16)` and a value of `26` for the member.

備🄵

當寫自訂的 `__new__` 時，不要使用 `super().__new__`，而是要呼叫適當的 `__new__`。

__repr__(*self*)

回傳呼叫 *repr()* 時使用的字串。預設回傳 *Enum* 名稱、成員名稱及值，但可以被覆寫：

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __repr__(self):
...         cls_name = self.__class__.__name__
...         return f'{cls_name}.{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.ALTERNATE}"
(OtherStyle.ALTERNATE, 'OtherStyle.ALTERNATE', 'OtherStyle.ALTERNATE')
```

__str__(*self*)

回傳呼叫 *str()* 時使用的字串。預設回傳 *Enum* 名稱及成員名稱，但可以被覆寫：

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __str__(self):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.ALTERNATE}"
(<OtherStyle.ALTERNATE: 1>, 'ALTERNATE', 'ALTERNATE')
```

__format__(*self*)

回傳呼叫 *format()* 及 *f-string* 時使用的字串。預設回傳*__str__()* 的回傳值，但可以被覆寫:

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __format__(self, spec):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"{OtherStyle.ALTERNATE}"
(<OtherStyle.ALTERNATE: 1>, 'OtherStyle.ALTERNATE', 'ALTERNATE')
```

備F

Enum 使用*auto* 會F生從 1 開始遞增的整數。

在 3.12 版的變更: 新增 enum-dataclass-support

class enum.**IntEnum**

IntEnum 和 *Enum* 一樣，但其成員同時也是整數而可以被用在任何使用整數的地方。如果 *IntEnum* 成員經過任何整數運算，其結果會失去列舉狀態。

```
>>> from enum import IntEnum
>>> class Number(IntEnum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...
>>> Number.THREE
<Number.THREE: 3>
>>> Number.ONE + Number.TWO
3
>>> Number.THREE + 5
8
>>> Number.THREE == 3
True
```

備F

IntEnum 使用*auto* 會F生從 1 開始遞增的整數。

在 3.11 版的變更: F了更好地支援現存常數取代 *(replacement of existing constants)* 的使用情

境，`__str__()` 現在會是 `int.__str__()`。🄵了同樣的理由，`__format__()` 已經是 `int.__format__()`。

class enum.**StrEnum**

StrEnum 和 *Enum* 一樣，但其成員同時也是字串而可以被用在幾乎所有使用字串的地方。*StrEnum* 成員經過任何字串操作的結果會不再是列舉的一部份。

> **備🄵**
>
> stdlib 🄵有些地方會檢查只能是 *str* 而不是 *str* 的子類🄵（也就是 `type(unknown) == str` 而不是 `isinstance(unknown, str)`），在這些地方你需要使用 `str(StrEnum.member)`。

> **備🄵**
>
> *StrEnum* 使用 *auto* 會🄵生小寫的成員名稱當作值。

> **備🄵**
>
> 🄵了更好地支援現存常數取代 *(replacement of existing constants)* 的使用情境，`__str__()` 現在會是 `str.__str__()`。🄵了同樣的理由，`__format__()` 也會是 `str.__format__()`。

在 3.11 版被加入.

class enum.**Flag**

`Flag` 與 *Enum* 相同，但其成員支援位元運算子 `&` (*AND*)、`|` (*OR*)、`^` (*XOR*) 和 `~` (*INVERT*)；這些操作的結果是列舉的成員（的🄵名）。

__contains__(*self*, *value*)

如果 value 在 self 🄵則回傳 *True*：

```
>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> purple = Color.RED | Color.BLUE
>>> white = Color.RED | Color.GREEN | Color.BLUE
>>> Color.GREEN in purple
False
>>> Color.GREEN in white
True
>>> purple in white
True
>>> white in purple
False
```

__iter__(self)：

回傳所有包含的非🄵名成員：

```
>>> list(Color.RED)
[<Color.RED: 1>]
>>> list(purple)
[<Color.RED: 1>, <Color.BLUE: 4>]
```

在 3.11 版被加入.

__len__(self):

回傳旗標🄴的成員數量:

```
>>> len(Color.GREEN)
1
>>> len(white)
3
```

__bool__(self):

如果成員在旗標🄴則回傳 *True*，否則回傳 *False*:

```
>>> bool(Color.GREEN)
True
>>> bool(white)
True
>>> black = Color(0)
>>> bool(black)
False
```

__or__(*self*, *other*)

回傳和 other 做 OR 過後的二進位旗標:

```
>>> Color.RED | Color.GREEN
<Color.RED|GREEN: 3>
```

__and__(*self*, *other*)

回傳和 other 做 AND 過後的二進位旗標:

```
>>> purple & white
<Color.RED|BLUE: 5>
>>> purple & Color.GREEN
<Color: 0>
```

__xor__(*self*, *other*)

回傳和 other 做 XOR 過後的二進位旗標:

```
>>> purple ^ white
<Color.GREEN: 2>
>>> purple ^ Color.GREEN
<Color.RED|GREEN|BLUE: 7>
```

__invert__(self):

回傳所有在 *type(self)* 但不在 self 🄴的旗標:

```
>>> ~white
<Color: 0>
>>> ~purple
<Color.GREEN: 2>
```

(繼續下一頁)

(繼續上一頁)

```
>>> ~Color.RED
<Color.GREEN|BLUE: 6>
```

_numeric_repr_()

用來格式化任何剩下未命名數值的函式。預設是值的 repr，常見選擇是`hex()` 和`oct()`。

備🄵

`Flag` 使用`auto` 會🄵生從 1 開始 2 的次方的整數。

在 3.11 版的變更: 值🄵 0 的旗標的 *repr()* 已改變。現在是:

```
>>> Color(0)
<Color: 0>
```

class enum.**IntFlag**

IntFlag 和 *Flag* 一樣，但其成員同時也是整數而可以被用在任何使用整數的地方。

```
>>> from enum import IntFlag, auto
>>> class Color(IntFlag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> Color.RED & 2
<Color: 0>
>>> Color.RED | 2
<Color.RED|GREEN: 3>
```

如果 *IntFlag* 成員經過任何整數運算，其結果不是 *IntFlag*:

```
>>> Color.RED + 2
3
```

如果 *IntFlag* 成員經過 *Flag* 操作且:

- 結果是合法的 *IntFlag*: 回傳 *IntFlag*
- 結果不是合法的 *IntFlag*: 結果會根據 *FlagBoundary* 的設定

未命名且值🄵 0 的旗標的 *repr()* 已改變。現在是:

```
>>> Color(0)
<Color: 0>
```

備🄵

`IntFlag` 使用`auto` 會🄵生從 1 開始 2 的次方的整數。

在 3.11 版的變更: 🄵了更好地支援現存常數取代 *(replacement of existing constants)* 的使用情境，`__str__()` 現在會是 `int.__str__()`。🄵了同樣的理由，`__format__()` 已經是 `int.__format__()`。

IntFlag 的反轉 (inversion) 現在會回傳正值，該值是不在給定旗標的所有旗標聯集，而不是一個負值。這符合現有*Flag* 的行🄵。

class enum.**ReprEnum**

ReprEnum 使用*Enum* 的*repr()*，但使用混合資料類型的*str()*：

- 對*IntEnum* 和*IntFlag* 是 int.__str__()
- 對*StrEnum* 是 str.__str__()

繼承 ReprEnum 來保留混合資料類型的*str()* / *format()*，而不是使用*Enum* 預設的*str()*。

在 3.11 版被加入.

class enum.**EnumCheck**

EnumCheck 包含*verify()* 裝飾器使用的選項，以確保多樣的限制，不符合限制會🄵生*ValueError*。

UNIQUE

確保每個值只有一個名稱：

```
>>> from enum import Enum, verify, UNIQUE
>>> @verify(UNIQUE)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
...     CRIMSON = 1
Traceback (most recent call last):
...
ValueError: aliases found in <enum 'Color'>: CRIMSON -> RED
```

CONTINUOUS

確保在最小值成員跟最大值成員間🄵有缺少值：

```
>>> from enum import Enum, verify, CONTINUOUS
>>> @verify(CONTINUOUS)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 5
Traceback (most recent call last):
...
ValueError: invalid enum 'Color': missing values 3, 4
```

NAMED_FLAGS

確保任何旗標群組 / 遮罩只包含命名旗標 -- 當值是用指定而不是透過*auto()* 🄵生時是很實用的：

```
>>> from enum import Flag, verify, NAMED_FLAGS
>>> @verify(NAMED_FLAGS)
... class Color(Flag):
...     RED = 1
...     GREEN = 2
...     BLUE = 4
...     WHITE = 15
...     NEON = 31
Traceback (most recent call last):
...
ValueError: invalid Flag 'Color': aliases WHITE and NEON are missing combined␣
↪values of 0x18 [use enum.show_flag_values(value) for details]
```

> **備🄵**
>
> CONTINUOUS 和 NAMED_FLAGS 是設計用來運作在整數值的成員上。

在 3.11 版被加入.

class enum.**FlagBoundary**

FlagBoundary 控制在 *Flag* 及其子類🄵中如何處理範圍外的值。

STRICT

範圍外的值會引發*ValueError*。這是*Flag* 的預設行🄵:

```
>>> from enum import Flag, STRICT, auto
>>> class StrictFlag(Flag, boundary=STRICT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> StrictFlag(2**2 + 2**4)
Traceback (most recent call last):
...
ValueError: <flag 'StrictFlag'> invalid value 20
    given 0b0 10100
  allowed 0b0 00111
```

CONFORM

範圍外的值會移除非法值，留下合法的 *Flag* 值:

```
>>> from enum import Flag, CONFORM, auto
>>> class ConformFlag(Flag, boundary=CONFORM):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> ConformFlag(2**2 + 2**4)
<ConformFlag.BLUE: 4>
```

EJECT

範圍外的值會失去它們的 *Flag* 成員資格且恢復成*int*。

```
>>> from enum import Flag, EJECT, auto
>>> class EjectFlag(Flag, boundary=EJECT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> EjectFlag(2**2 + 2**4)
20
```

KEEP

範圍外的值會被保留，*Flag* 成員資格也會被保留。這是*IntFlag* 的預設行🄵:

```
>>> from enum import Flag, KEEP, auto
>>> class KeepFlag(Flag, boundary=KEEP):
...     RED = auto()
```

(繼續下一頁)

(繼續上一頁)

```
...     GREEN = auto()
...     BLUE = auto()
...
>>> KeepFlag(2**2 + 2**4)
<KeepFlag.BLUE|16: 20>
```

在 3.11 版被加入.

支援 __dunder__ 名稱

__members__ 是一個唯讀有序的成員名稱：成員項目的對映。只有在類🄵上可用。

如果指定了*__new__()*，它必須建立🄵回傳列舉成員；適當地設定成員的 _value_ 也是一個很好的主意。一旦所有成員都建立之後就不會再被用到。

支援 _sunder_ 名稱

- *_name_* -- 成員名稱
- *_value_* -- 成員的值；可以在 __new__ 設定
- *_missing_()* -- 當值🄵有被找到時會使用的查詢函式；可以被覆寫
- *_ignore_* -- 一個名稱的串列，可以是*list* 或*str*，它不會被轉🄵成成員，且在最後的類🄵上會被移除
- *_order_* -- 不再被使用，僅🄵了向後相容而保留（類🄵屬性，在類🄵建立時移除）
- *_generate_next_value_()* -- 用來🄵列舉成員取得合適的值；可以被覆寫

> **備🄵**
>
> 對標準的*Enum* 類🄵來🄵，下一個被選擇的值是最後一個看見的值加一。
>
> 對*Flag* 類🄵來🄵，下一個被選擇的值是下一個最大的 2 的次方，不管最後一個看見的值是什🄵。

在 3.6 版被加入: _missing_、_order_、_generate_next_value_

在 3.7 版被加入: _ignore_

8.14.3 通用項目與裝飾器

class enum.**auto**

auto 可以用來取代給值。如果使用的話，*Enum* 系統會呼叫 *Enum* 的*_generate_next_value_()* 來取得合適的值。對 *Enum* 和 *IntEnum* 來🄵，合適的值是最後一個值加一；對 *Flag* 和 *IntFlag* 來🄵，是第一個比最大值還大的 2 的次方的數字；對 *StrEnum* 來🄵，是成員名稱的小寫版本。如果混用 *auto()* 和手動指定值的話要特🄵注意。

auto 實例只有在最上層的賦值時才會被解析：

- FIRST = auto() 可以運作（auto() 會被取代成 1）

- `SECOND = auto(), -2` 可以運作（auto 會被取代成 2, 因此 `2, -2` 會被用來建立列舉成員 `SECOND`;
- `THREE = [auto(), -3]` 無法運作（`<auto 實例>, -3` 會被用來建立列舉成員 `THREE`）

在 3.11.1 版的變更: 在之前的版本中，`auto()` 必須是賦值行🄴的唯一🄴容才能運作正確。

可以覆寫 `_generate_next_value_` 來客🄵 *auto* 使用的值。

備🄴

在 3.13 預設 `_generate_next_value_` 總是回傳最大的成員值加一，如果任何成員是不相容的類型就會失敗。

`@enum.`**`property`**

和🄵建的 *property* 相似的裝飾器，但只專門針對列舉。它允許成員屬性和成員本身有相同名稱。

備🄴

屬性和成員必須定義在分開的類🄵🄵；例如 *value* 和 *name* 屬性定義在 *Enum* 類🄴而 *Enum* 子類🄴可以定義成員名稱🄵 `value` 和 `name`。

在 3.11 版被加入.

`@enum.`**`unique`**

專門針對列舉的 `class` 裝飾器。它搜尋列舉的 *__members__*，🄴集任何它找到的🄴名；如果有找到任何🄴名則引發 *ValueError* 🄴附上細節：

```
>>> from enum import Enum, unique
>>> @unique
... class Mistake(Enum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...     FOUR = 3
...
Traceback (most recent call last):
...
ValueError: duplicate values found in <enum 'Mistake'>: FOUR -> THREE
```

`@enum.`**`verify`**

專門針對列舉的 `class` 裝飾器。使用 *EnumCheck* 🄴的成員來指定在裝飾的列舉上應該檢查什🄴限制。

在 3.11 版被加入.

`@enum.`**`member`**

列舉所使用的裝飾器：其目標會變成成員。

在 3.11 版被加入.

`@enum.`**`nonmember`**

列舉所使用的裝飾器：其目標不會變成成員。

在 3.11 版被加入.

@enum.**global_enum**

修改列舉的*str()* 及*repr()* 的裝飾器，讓成員顯示🄴屬於模組而不是其類🄴。應該只有當列舉成員被匯出到模組的全域命名空間才使用（範例請參考*re.RegexFlag*）。

在 3.11 版被加入.

enum.**show_flag_values**(*value*)

回傳在旗標值中包含的所有 2 的次方的整數串列。

在 3.11 版被加入.

8.14.4 備🄵

IntEnum、*StrEnum* 及*IntFlag*

這三種列舉類型是設計來直接取代現有以整數及字串🄵基底的值；因此它們有額外的限制：

- __str__ 使用值而不是列舉成員的名稱
- __format__ 因🄵使用 __str__，也會使用值而不是列舉成員的名稱

如果你不需要或不想要這些限制，你可以透過混合 int 或 str 類型來建立自己的基礎類🄵：

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     pass
```

或者你也可以在你的列舉重新給定合適的*str()*：

```
>>> from enum import Enum, IntEnum
>>> class MyIntEnum(IntEnum):
...     __str__ = Enum.__str__
```

8.15 graphlib —-- 使用類圖 (graph-like) 結構進行操作的功能

原始碼： Lib/graphlib.py

---

class graphlib.**TopologicalSorter**(*graph=None*)

提供對包含可雜🄵 *(hashable)* 節點之圖 (graph) 進行拓撲排序 (topologically sort) 的功能。

拓撲排序是圖中頂點 (vertex) 的🄴性排序，使得對於從頂點 u 到頂點 v 的每條有向邊 (directed edge) u -> v，頂點 u 在排序中會位於頂點 v 之前。例如，圖的頂點可能代表要執行的任務，而邊可能代表一個任務必須在另一個任務之前執行的限制；在此範例中，拓撲排序只是任務的一種有效序列。若且唯若 (if and only if) 圖🄵有有向環 (directed cycle) 時，即如果它是個有向無環圖 (directed acyclic graph)，則完整的拓撲排序才是可行的。

如果提供了可選的 *graph* 引數，它必須是表示有向無環圖的字典，其中鍵是節點，值是圖中該節點的包含所有前驅節點 (predecessor) 之可🄴代物件（這些前驅節點具有指向以鍵表示之節點的邊）。可以使用*add()* 方法將其他節點新增到圖中。

在一般情🄵下，對給定的圖執行排序所需的步驟如下：

- 以選用的初始圖建立*TopologicalSorter* 的實例。

- 在圖中新增其他節點。
- 呼叫圖的*prepare()*。
- 當*is_active()* [F] True 時，[F]代*get_ready()* 回傳的節點[F]處理它們。在每個節點完成處理時呼叫*done()*。

如果只需要立即對圖中的節點進行排序且不涉及平行性 (parallelism)，則可以直接使用便捷方法*TopologicalSorter.static_order()*：

```
>>> graph = {"D": {"B", "C"}, "C": {"A"}, "B": {"A"}}
>>> ts = TopologicalSorter(graph)
>>> tuple(ts.static_order())
('A', 'C', 'B', 'D')
```

該類[F]設計[F]在節點准備就緒時，簡單支援節點的平行處理。例如：

```
topological_sorter = TopologicalSorter()

# Add nodes to 'topological_sorter'...

topological_sorter.prepare()
while topological_sorter.is_active():
    for node in topological_sorter.get_ready():
        # Worker threads or processes take nodes to work on off the
        # 'task_queue' queue.
        task_queue.put(node)

    # When the work for a node is done, workers put the node in
    # 'finalized_tasks_queue' so we can get more nodes to work on.
    # The definition of 'is_active()' guarantees that, at this point, at
    # least one node has been placed on 'task_queue' that hasn't yet
    # been passed to 'done()', so this blocking 'get()' must (eventually)
    # succeed.  After calling 'done()', we loop back to call 'get_ready()'
    # again, so put newly freed nodes on 'task_queue' as soon as
    # logically possible.
    node = finalized_tasks_queue.get()
    topological_sorter.done(node)
```

add(*node*, **predecessors*)

向圖中新增新節點及其前驅節點。*node* 和 *predecessors* 中的所有元素都必須是可雜[F]的。

如果以相同節點引數多次呼叫，則依賴項的集合將會是傳入的所有依賴項的聯集。

可以新增一個[F]有依賴關[F]的節點（*predecessors* 未提供）或提供兩次依賴關[F]。如果有之前未曾提供的節點被包含在 *predecessors* 中，它將自動新增到[F]有前驅節點的圖中。

如果在*prepare()* 之後呼叫，則引發*ValueError*。

prepare()

將圖標記[F]已完成[F]檢查圖中的循環。如果檢測到任何循環，將引發*CycleError*，但*get_ready()* 仍可用於盡可能獲得更多的節點，直到循環阻塞了進度。呼叫此函式後就無法修改圖，因此無法使用*add()* 來新增更多節點。

is_active()

如果可以有更多進度則回傳 True，否則回傳 False。如果循環不阻塞解析 (resolution) [F]且仍有節點准備就緒但尚未由*TopologicalSorter.get_ready()* 回傳或標記[F]*TopologicalSorter.done()* 的節點數量較*TopologicalSorter.get_ready()* 所回傳的少，則可以繼續取得進度。

此類🄵的 `__bool__()` 方法遵循此函式，因此以下做法：

```
if ts.is_active():
    ...
```

可以簡單地用以下方式替🄵：

```
if ts:
    ...
```

如果呼叫之前🄵有先呼叫*prepare()* 則引發*ValueError*。

done(**nodes*)

將*TopologicalSorter.get_ready()* 回傳的一組節點標記🄵已處理，停止阻塞 *nodes* 中每個節點的任何後繼節點 (successor)，以便將來通過呼叫*TopologicalSorter.get_ready()* 回傳。

若🄵有和該呼叫一起呼叫*prepare()* 或節點還🄵有被*get_ready()* 回傳，且如果 *nodes* 中有任何節點已被先前對此方法的呼叫標記🄵已處理、或者未使用*TopologicalSorter.add()* 將節點新增到圖中，則引發*ValueError*。

get_ready()

回傳一個包含所有准備就緒節點的 `tuple`。最初它回傳🄵有前驅節點的所有節點，一旦通過呼叫*TopologicalSorter.done()* 來將這些節點標記🄵已處理後，進一步的呼叫將回傳所有其全部前驅節點都已被處理的新節點。若無法取得更多進度，將回傳空 tuple。

如果呼叫之前🄵有先呼叫*prepare()* 則引發*ValueError*。

static_order()

回傳一個可🄵代物件，它將按拓撲排序🄵代節點。使用此方法時，不應呼叫*prepare()* 和*done()*。此方法等效於：

```
def static_order(self):
    self.prepare()
    while self.is_active():
        node_group = self.get_ready()
        yield from node_group
        self.done(*node_group)
```

回傳的特定順序可能取🄵於將項目插入圖中的特定順序。例如：

```
>>> ts = TopologicalSorter()
>>> ts.add(3, 2, 1)
>>> ts.add(1, 0)
>>> print([*ts.static_order()])
[2, 0, 1, 3]

>>> ts2 = TopologicalSorter()
>>> ts2.add(1, 0)
>>> ts2.add(3, 2, 1)
>>> print([*ts2.static_order()])
[0, 2, 1, 3]
```

這是因🄵"0" 和"2" 在圖中處於同一級🄵（它們將在對*get_ready()* 的同一呼叫中回傳）🄵且它們之間的順序取🄵於插入順序。

如果檢測到任何循環，則引發*CycleError*。

在 3.9 版被加入.

8.15.1 例外

graphlib 模組定義了以下例外類🄴:

exception graphlib.**CycleError**

ValueError 的子類🄴，如果作用的圖中存在循環則由*TopologicalSorter.prepare()* 引發。如果存在多個循環，則只會報告未定義的其中一個🄴包含在例外中。

檢測到的循環可以通過例外實例的*args* 屬性中第二個元素來存取，其🄴一個節點列表，每個節點在圖中都是列表中下一個節點的直接前驅節點（immediate predecessor，即父節點）。在報告列表中，第一個和最後一個節點將會是相同的，用以明確表示它是循環的。

CHAPTER 9

數值與數學模組

The modules described in this chapter provide numeric and math-related functions and data types. The *numbers* module defines an abstract hierarchy of numeric types. The *math* and *cmath* modules contain various mathematical functions for floating-point and complex numbers. The *decimal* module supports exact representations of decimal numbers, using arbitrary precision arithmetic.

The following modules are documented in this chapter:

9.1 numbers --- 數值的抽象基底類🄵

原始碼： Lib/numbers.py

numbers 模組 (**PEP 3141**) 定義了數值抽象基底類🄵 的階層結構，其中逐一定義了更多操作。此模組中定義的型🄵都不可被實例化。

class numbers.**Number**

數值階層結構的基礎。如果你只想確認引數 *x* 是不是數值、🄵不關心其型🄵，請使用 `isinstance(x, Number)`。

9.1.1 數值的階層

class numbers.**Complex**

這個型🄵的子類🄵描述了🄵數🄵包含適用於🄵建*complex* 型🄵的操作。這些操作有：*complex* 和*bool* 的轉🄵、*real*、*imag*、+、-、*、/、**、*abs()*、*conjugate()*、== 以及 !=。除 - 和 != 之外所有操作都是抽象的。

real

🄵抽象的。取得該數值的實數部分。

imag

🄴抽象的。取得該數值的🄵數部分。

abstractmethod conjugate()

🄴抽象的。回傳共🄵🄵數，例如 (1+3j).conjugate() == (1-3j)。

class numbers.**Real**

相對於*Complex*，Real 加入了只有實數才能進行的操作。

簡單的🄵，有*float* 的轉🄵、*math.trunc()*、*round()*、*math.floor()*、*math.ceil()*、*divmod()*、//、%、<、<=、>、和 >=。

實數同樣提供*complex()*、*real*、*imag* 和*conjugate()* 的預設值。

class numbers.**Rational**

Real 的子型🄵，🄵增加了*numerator* 和*denominator* 這兩種特性。它也會提供*float()* 的預設值。

numerator 和*denominator* 的值必須是*Integral* 的實例且*denominator* 要是正數。

numerator

🄴抽象的。

denominator

🄴抽象的。

class numbers.**Integral**

Rational 的子型🄵，🄵增加了*int* 的轉🄵操作。🄵*float()*、*numerator* 和*denominator* 提供了預設值。🄵*pow()* 方法增加了求余 (modulus) 和位元字串運算 (bit-string operations) 的抽象方法：<<、>>、&、^、|、~。

9.1.2 給型🄵實作者的🄵記

實作者需注意，相等的數值除了大小相等外，還必須擁有同樣的雜🄴值。當使用兩個不同的實數擴充時，這可能是很微妙的。例如，*fractions.Fraction* 底下的*hash()* 實作如下：

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

加入更多數值 ABC

當然，還有更多用於數值的 ABC，如果不加入它們就不會有健全的階層。你可以在*Complex* 和*Real* 中加入 MyFoo，像是：

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

實作算術操作

我們想要實作算術操作，來使得混合模式操作要🄵呼叫一個作者知道兩個引數之型🄵的實作，要🄵將其轉🄵成最接近的🄵建型🄵🄵執行這個操作。對於*Integral* 的子型🄵，這意味著 __add__() 和 __radd__() 必須用如下方式定義：

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(self, other)
        else:
            return NotImplemented

    def __radd__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(other, self)
        elif isinstance(other, OtherTypeIKnowAbout):
            return do_my_other_adding_stuff(other, self)
        elif isinstance(other, Integral):
            return int(other) + int(self)
        elif isinstance(other, Real):
            return float(other) + float(self)
        elif isinstance(other, Complex):
            return complex(other) + complex(self)
        else:
            return NotImplemented
```

Complex 的子類🄵有 5 種不同的混合型🄵操作。我將上面提到所有不涉及 MyIntegral 和 OtherTypeIKnowAbout 的程式碼稱作「模板 (boilerplate)」。a 是*Complex* 之子型🄵 A 的實例 (a : A <: Complex)，同時 b : B <: Complex。我將要計算 a + b：

1. 如果 A 有定義成一個接受 b 的 __add__()，不會發生問題。
2. 如果 A 回退成模板程式碼，它將回傳一個來自 __add__() 的值，🄵喪失讓 B 定義一個更完善的 __radd__() 的機會，因此模板需要回傳一個來自 __add__() 的*NotImplemented*。(或者 A 可能完全不實作 __add__()。)
3. 接著看 B 的 __radd__()。如果它接受 a，不會發生問題。
4. 如果🄵有成功回退到模板，就🄵有更多的方法可以去嘗試，因此這🄵將使用預設的實作。
5. 如果 B <: A，Python 會在 A.__add__ 之前嘗試 B.__radd__。這是可行的，因🄵它是透過對 A 的理解而實作的，所以這可以在交給*Complex* 之前處理好這些實例。

如果 A <: Complex 和 B <: Real 且🄵有共享任何其他型🄵上的理解，那🄵適當的共享操作會涉及🄵建的*complex*，🄵且分🄵用到 __radd__()，因此 a+b == b+a。

由於大部分對任意給定類型的操作都十分相似的，定義一個🄵任意給定運算子生成向前 (forward) 與向後 (reverse) 實例的輔助函式可能會非常有用。例如，*fractions.Fraction* 使用了：

```
def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'
    forward.__doc__ = monomorphic_operator.__doc__

    def reverse(b, a):
        if isinstance(a, Rational):
            # Includes ints.
            return monomorphic_operator(a, b)
        elif isinstance(a, Real):
            return fallback_operator(float(a), float(b))
        elif isinstance(a, Complex):
            return fallback_operator(complex(a), complex(b))
        else:
            return NotImplemented
    reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
    reverse.__doc__ = monomorphic_operator.__doc__

    return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...
```

9.2 math --- 數學函式

此模組提供對 C 標准中定義的數學相關函式的存取。

這些函式不支援🄵數；若您需要計算🄵數，請使用*cmath* 模組的同名函式。這是因🄵大多數的使用者🄵不想學習那🄵多理解🄵數所需的數學概念，所以根據支援🄵數與否分🄵兩種函式。收到一個例外而非🄵數回傳值，有助於程式設計師提早察覺參數中包含非預期的🄵數，進而從源頭查出導致此情🄵的原因。

此模組提供下列函式。除非特意🄵明，否則回傳值皆🄵浮點數。

9.2.1 數論與表現函式

math.**ceil**(*x*)

回傳 *x* 經上取整的值，即大於或等於 *x* 的最小整數。若 *x* F非浮點數，此函式將委派給 `x.__ceil__`，F回傳 *Integral* 型F的值。

math.**comb**(*n*, *k*)

回傳從 *n* 個物品中不重F且不考慮排序地取出 *k* 個物品的方法數。

當 `k <= n` 時其值F `n! / (k! * (n - k)!)`，否則其值F `0`。

因F此值等同於 $(1 + x)^n$ 進行多項式展開後第 k 項的F數，所以又稱F二項式F數。

當任一參數非整數型F時會引發 *TypeError*。當任一參數F負數時會引發 *ValueError*。

在 3.8 版被加入.

math.**copysign**(*x*, *y*)

回傳與 *x* 相同長度（F對值）且與 *y* 同號的浮點數。在支援帶符號零的平臺上，`copysign(1.0, -0.0)` 回傳 *-1.0*。

math.**fabs**(*x*)

回傳 *x* 的F對值。

math.**factorial**(*n*)

以整數回傳 *n* 的階乘。若 *n* 非整數型F或其值F負會引發 *ValueError*。

在 3.9 版之後被F用: 允許傳入其值F整數的浮點數（如: `5.0`）已被F用。

math.**floor**(*x*)

回傳 *x* 經下取整的值，即小於或等於 *x* 的最大整數。若 *x* F非浮點數，此函式將委派給 `x.__floor__`，F回傳 *Integral* 型F的值。

math.**fmod**(*x*, *y*)

回傳 C 函式庫所定義的 `fmod(x, y)` 函式值。請注意此函式與 Python 運算式 `x % y` 可能會回傳不同結果。C 標准要求 `fmod(x, y)` 的回傳值完全等同（數學定義上，即無限精度）於 `x - n*y`，*n* F可使回傳值與 *x* 同號且長度小於 `abs(y)` 的整數。Python 運算式 `x % y` 的回傳值則與 *y* 同號，且可能無法精確地計算浮點數引數。例如: `fmod(-1e-100, 1e100)` 的值F `-1e-100`，但 Python 運算式 `-1e-100 % 1e100` 的結果F `1e100-1e-100`，此值無法准確地表示成浮點數，F會四舍五入F出乎意料的 `1e100`。因此，處理浮點數時通常會選擇函式 *fmod()*，而處理整數時會選擇 Python 運算式 `x % y`。

math.**frexp**(*x*)

以 `(m, e)` 對的格式回傳 *x* 的尾數 *m* 及指數 *e*。*m* 是浮點數而 *e* 是整數，且兩者精確地使 `x == m * 2**e`。若 *x* F零，回傳 `(0.0, 0)`，否則令 `0.5 <= abs(m) < 1`。此函式用於以可F的方式「分割」浮點數F部表示法。

math.**fsum**(*iterable*)

Return an accurate floating-point sum of values in the iterable. Avoids loss of precision by tracking multiple intermediate partial sums.

此演算法准確性奠基於保證 IEEE-754 浮點標准及典型奇進偶舍（half-even）模式。於有些非 Windows 平台建置時，底層 C 函式庫使用延伸精度加法運算，而可能導致對過程中同一部分和重F舍入，F使其最低有效位不如預期。

For further discussion and two alternative approaches, see the ASPN cookbook recipes for accurate floating-point summation.

math.**gcd**(**integers*)

回傳指定整數引數的最大公因數。若存在任一非零引數，回傳值🄴所有引數共有因數中最大的正整數。若所有引數皆🄵零，則回傳值🄴 `0`。`gcd()` 若未傳入任何引數也將回傳 `0`。

在 3.5 版被加入.

在 3.9 版的變更: 新增支援任意數量的引數。先前僅支援兩個引數。

math.**isclose**(*a*, *b*, ***, *rel_tol=1e-09*, *abs_tol=0.0*)

若 *a* 及 *b* 兩值足🄴接近便回傳 `True`，否則回傳 `False`。

兩數是否足🄴接近取🄴於給定的🄴對及相對容許偏差（tolerance）。

rel_tol 🄴相對容許偏差 —— *a* 與 *b* 兩數差的最大容許值，與 *a* 及 *b* 兩數的🄴對值中較大者相關。例如欲設置 5% 的容許偏差，則傳入 `rel_tol=0.05`。其預設值🄴 `1e-09`，該值可確保兩數於大約 9 個十進數位🄴相同。*rel_tol* 須大於 `0`。

abs_tol 🄴最小🄴對容許偏差 —— 於接近零的比較時很有用。*abs_tol* 須大於等於 `0`。

若未發生任何錯誤，函式結果🄴 `abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`。

定義於 IEEE 754 浮點標准中的特殊值 `NaN`、`inf` 和 `-inf` 會根據該標准處理。更明確地🄴，`NaN` 不會與包含自身在🄴的任何數字足🄴接近，而 `inf` 及 `-inf` 皆只與自身接近。

在 3.5 版被加入.

也參考

PEP 485 —— 用於測試近似相等的函式

math.**isfinite**(*x*)

若 *x* 不是無限值或 `NaN` 便回傳 `True`，否則回傳 `False`。（注意 `0.0` 被視🄴有限數。）

在 3.2 版被加入.

math.**isinf**(*x*)

若 *x* 是正無限值或負無限值便回傳 `True`，否則回傳 `False`。

math.**isnan**(*x*)

若 *x* 是 `NaN` —— 即非數字（NaN, not a number）—— 便回傳 `True`，否則回傳 `False`。

math.**isqrt**(*n*)

回傳非負整數 *n* 的整數平方根。此值🄴 *n* 精確平方根經下取整的值，亦等同於滿足 $a^2 \leq n$ 的最大整數值 *a*。

於有些應用程式中，取得滿足 $n \leq a^2$ 的最小整數值 *a* —— 或者🄴 *n* 精確平方根經上取整的值 —— 會更加方便。對正數 *n*，此值可使用 `a = 1 + isqrt(n - 1)` 計算。

在 3.8 版被加入.

math.**lcm**(**integers*)

回傳指定整數引數的最小公倍數。若所有引數值皆非零，回傳值🄴所有引數共有倍數中最小的正整數。若存在任一引數值🄴零，則回傳值🄴 `0`。`lcm()` 若未傳入任何引數將回傳 `1`。

在 3.9 版被加入.

math.**ldexp**(*x*, *i*)

回傳 `x * (2**i)`。此函式本質上🄴*`frexp()`* 的反函式。

math.**modf**(*x*)

Return the fractional and integer parts of *x*. Both results carry the sign of *x* and are floats.

math.**nextafter**(*x*, *y*, *steps=1*)

Return the floating-point value *steps* steps after *x* towards *y*.

If *x* is equal to *y*, return *y*, unless *steps* is zero.

範例：

- `math.nextafter(x, math.inf)` goes up: towards positive infinity.
- `math.nextafter(x, -math.inf)` goes down: towards minus infinity.
- `math.nextafter(x, 0.0)` goes towards zero.
- `math.nextafter(x, math.copysign(math.inf, x))` goes away from zero.

另請參🄵*math.ulp()*。

在 3.9 版被加入.

在 3.12 版的變更: 新增 *steps* 引數。

math.**perm**(*n*, *k=None*)

Return the number of ways to choose *k* items from *n* items without repetition and with order.

Evaluates to `n! / (n - k)!` when `k <= n` and evaluates to zero when `k > n`.

If *k* is not specified or is `None`, then *k* defaults to *n* and the function returns `n!`.

當任一參數非整數型🄵時會引發*TypeError*。當任一參數🄵負數時會引發*ValueError*。

在 3.8 版被加入.

math.**prod**(*iterable*, *, *start=1*)

Calculate the product of all the elements in the input *iterable*. The default *start* value for the product is `1`.

When the iterable is empty, return the start value. This function is intended specifically for use with numeric values and may reject non-numeric types.

在 3.8 版被加入.

math.**remainder**(*x*, *y*)

Return the IEEE 754-style remainder of *x* with respect to *y*. For finite *x* and finite nonzero *y*, this is the difference `x - n*y`, where `n` is the closest integer to the exact value of the quotient `x / y`. If `x / y` is exactly halfway between two consecutive integers, the nearest *even* integer is used for `n`. The remainder `r = remainder(x, y)` thus always satisfies `abs(r) <= 0.5 * abs(y)`.

Special cases follow IEEE 754: in particular, `remainder(x, math.inf)` is *x* for any finite *x*, and `remainder(x, 0)` and `remainder(math.inf, x)` raise *ValueError* for any non-NaN *x*. If the result of the remainder operation is zero, that zero will have the same sign as *x*.

On platforms using IEEE 754 binary floating point, the result of this operation is always exactly representable: no rounding error is introduced.

在 3.7 版被加入.

math.**sumprod**(*p*, *q*)

Return the sum of products of values from two iterables *p* and *q*.

Raises *ValueError* if the inputs do not have the same length.

Roughly equivalent to:

```
sum(itertools.starmap(operator.mul, zip(p, q, strict=True)))
```

For float and mixed int/float inputs, the intermediate products and sums are computed with extended precision.

在 3.12 版被加入.

math.**trunc**(*x*)

Return *x* with the fractional part removed, leaving the integer part. This rounds toward 0: `trunc()` is equivalent to *floor()* for positive *x*, and equivalent to *ceil()* for negative *x*. If *x* is not a float, delegates to `x.__trunc__`, which should return an *Integral* value.

math.**ulp**(*x*)

Return the value of the least significant bit of the float *x*:

- If *x* is a NaN (not a number), return *x*.
- If *x* is negative, return `ulp(-x)`.
- If *x* is a positive infinity, return *x*.
- If *x* is equal to zero, return the smallest positive *denormalized* representable float (smaller than the minimum positive *normalized* float, *sys.float_info.min*).
- If *x* is equal to the largest positive representable float, return the value of the least significant bit of *x*, such that the first float smaller than *x* is `x - ulp(x)`.
- Otherwise (*x* is a positive finite number), return the value of the least significant bit of *x*, such that the first float bigger than *x* is `x + ulp(x)`.

ULP stands for "Unit in the Last Place".

See also *math.nextafter()* and *sys.float_info.epsilon*.

在 3.9 版被加入.

Note that *frexp()* and *modf()* have a different call/return pattern than their C equivalents: they take a single argument and return a pair of values, rather than returning their second return value through an 'output parameter' (there is no such thing in Python).

For the *ceil()*, *floor()*, and *modf()* functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float *x* with `abs(x) >= 2**52` necessarily has no fractional bits.

9.2.2 Power and logarithmic functions

math.**cbrt**(*x*)

Return the cube root of *x*.

在 3.11 版被加入.

math.**exp**(*x*)

Return *e* raised to the power *x*, where *e* = 2.718281... is the base of natural logarithms. This is usually more accurate than `math.e ** x` or `pow(math.e, x)`.

math.**exp2**(*x*)

Return *2* raised to the power *x*.

在 3.11 版被加入.

math.**expm1**(*x*)

Return *e* raised to the power *x*, minus 1. Here *e* is the base of natural logarithms. For small floats *x*, the subtraction in `exp(x) - 1` can result in a significant loss of precision; the *expm1()* function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1  # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5)    # result accurate to full precision
1.0000050000166668e-05
```

在 3.2 版被加入.

math.**log**(*x*[, *base*])

With one argument, return the natural logarithm of *x* (to base *e*).

With two arguments, return the logarithm of *x* to the given *base*, calculated as `log(x)/log(base)`.

math.**log1p**(*x*)

Return the natural logarithm of *1+x* (base *e*). The result is calculated in a way which is accurate for *x* near zero.

math.**log2**(*x*)

Return the base-2 logarithm of *x*. This is usually more accurate than `log(x, 2)`.

在 3.3 版被加入.

也參考

int.bit_length() returns the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros.

math.**log10**(*x*)

Return the base-10 logarithm of *x*. This is usually more accurate than `log(x, 10)`.

math.**pow**(*x*, *y*)

Return `x` raised to the power `y`. Exceptional cases follow the IEEE 754 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when `x` is a zero or a NaN. If both `x` and `y` are finite, `x` is negative, and `y` is not an integer then `pow(x, y)` is undefined, and raises *ValueError*.

Unlike the built-in `**` operator, *math.pow()* converts both its arguments to type *float*. Use `**` or the built-in *pow()* function for computing exact integer powers.

在 3.11 版的變更: The special cases `pow(0.0, -inf)` and `pow(-0.0, -inf)` were changed to return `inf` instead of raising *ValueError*, for consistency with IEEE 754.

math.**sqrt**(*x*)

Return the square root of *x*.

9.2.3 Trigonometric functions

`math.`**`acos`**(*x*)

Return the arc cosine of *x*, in radians. The result is between `0` and `pi`.

`math.`**`asin`**(*x*)

Return the arc sine of *x*, in radians. The result is between `-pi/2` and `pi/2`.

`math.`**`atan`**(*x*)

Return the arc tangent of *x*, in radians. The result is between `-pi/2` and `pi/2`.

`math.`**`atan2`**(*y*, *x*)

Return `atan(y / x)`, in radians. The result is between `-pi` and `pi`. The vector in the plane from the origin to point `(x, y)` makes this angle with the positive X axis. The point of *atan2()* is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both `pi/4`, but `atan2(-1, -1)` is `-3*pi/4`.

`math.`**`cos`**(*x*)

Return the cosine of *x* radians.

`math.`**`dist`**(*p*, *q*)

Return the Euclidean distance between two points *p* and *q*, each given as a sequence (or iterable) of coordinates. The two points must have the same dimension.

Roughly equivalent to:

```
sqrt(sum((px - qx) ** 2.0 for px, qx in zip(p, q)))
```

在 3.8 版被加入.

`math.`**`hypot`**(**coordinates*)

Return the Euclidean norm, `sqrt(sum(x**2 for x in coordinates))`. This is the length of the vector from the origin to the point given by the coordinates.

For a two dimensional point `(x, y)`, this is equivalent to computing the hypotenuse of a right triangle using the Pythagorean theorem, `sqrt(x*x + y*y)`.

在 3.8 版的變更: Added support for n-dimensional points. Formerly, only the two dimensional case was supported.

在 3.10 版的變更: Improved the algorithm's accuracy so that the maximum error is under 1 ulp (unit in the last place). More typically, the result is almost always correctly rounded to within 1/2 ulp.

`math.`**`sin`**(*x*)

Return the sine of *x* radians.

`math.`**`tan`**(*x*)

Return the tangent of *x* radians.

9.2.4 Angular conversion

`math.`**`degrees`**(*x*)

Convert angle *x* from radians to degrees.

`math.`**`radians`**(*x*)

Convert angle *x* from degrees to radians.

9.2.5 Hyperbolic functions

Hyperbolic functions are analogs of trigonometric functions that are based on hyperbolas instead of circles.

`math.`**`acosh`**(*x*)

Return the inverse hyperbolic cosine of *x*.

`math.`**`asinh`**(*x*)

Return the inverse hyperbolic sine of *x*.

`math.`**`atanh`**(*x*)

Return the inverse hyperbolic tangent of *x*.

`math.`**`cosh`**(*x*)

Return the hyperbolic cosine of *x*.

`math.`**`sinh`**(*x*)

Return the hyperbolic sine of *x*.

`math.`**`tanh`**(*x*)

Return the hyperbolic tangent of *x*.

9.2.6 Special functions

`math.`**`erf`**(*x*)

Return the error function at *x*.

The *`erf()`* function can be used to compute traditional statistical functions such as the cumulative standard normal distribution:

```
def phi(x):
    'Cumulative distribution function for the standard normal distribution'
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

在 3.2 版被加入.

`math.`**`erfc`**(*x*)

Return the complementary error function at *x*. The complementary error function is defined as `1.0 - erf(x)`. It is used for large values of *x* where a subtraction from one would cause a loss of significance.

在 3.2 版被加入.

`math.`**`gamma`**(*x*)

Return the Gamma function at *x*.

在 3.2 版被加入.

math.**lgamma**(*x*)

Return the natural logarithm of the absolute value of the Gamma function at *x*.

在 3.2 版被加入.

9.2.7 常數

math.**pi**

The mathematical constant $\pi = 3.141592...$, to available precision.

math.**e**

The mathematical constant $e = 2.718281...$, to available precision.

math.**tau**

The mathematical constant $\tau = 6.283185...$, to available precision. Tau is a circle constant equal to 2π, the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video Pi is (still) Wrong, and start celebrating Tau day by eating twice as much pie!

在 3.6 版被加入.

math.**inf**

A floating-point positive infinity. (For negative infinity, use `-math.inf`.) Equivalent to the output of `float('inf')`.

在 3.5 版被加入.

math.**nan**

A floating-point "not a number" (NaN) value. Equivalent to the output of `float('nan')`. Due to the requirements of the IEEE-754 standard, `math.nan` and `float('nan')` are not considered to equal to any other numeric value, including themselves. To check whether a number is a NaN, use the *`isnan()`* function to test for NaNs instead of `is` or ==. Example:

```
>>> import math
>>> math.nan == math.nan
False
>>> float('nan') == float('nan')
False
>>> math.isnan(math.nan)
True
>>> math.isnan(float('nan'))
True
```

在 3.5 版被加入.

在 3.11 版的變更: It is now always available.

CPython 實作細節： The *`math`* module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise *`ValueError`* for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and *`OverflowError`* for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

9.3 cmath --- F數的數學函式

本模組提供一些適用於F數的數學函式。本模組中的函式接受整數、浮點數或F數作F引數。它們也接受任何具有 `__complex__()` 或 `__float__()` 方法的 Python 物件：這些方法分F用於將物件轉F F F數或浮點數，然後再將函式應用於轉F後的結果。

備F

對於涉及分枝切割 (branch cut) 的函式，我們面臨的問題是F定如何定義在切割本身上的這些函式。遵循 Kahan 的論文"Branch cuts for complex elementary functions"，以及 C99 的附F G 和後來的 C 標准，我們使用零符號來區分分枝切割的兩側：對於沿著（一部分）實數軸的分枝切割，我們查看F部的符號，而對於沿F軸的分枝切割，我們則查看實部的符號。

例如*cmath.sqrt()* 函式具有一條沿負實軸的分枝切割。引數 `complex(-2.0, -0.0)` 被視F位於分枝切割 下方處理，因此給出的結果在負F軸上：

```
>>> cmath.sqrt(complex(-2.0, -0.0))
-1.4142135623730951j
```

但是引數 `complex(-2.0, 0.0)` 會被當成位於分枝切割上方處理：

```
>>> cmath.sqrt(complex(-2.0, 0.0))
1.4142135623730951j
```

9.3.1 轉F到極座標和從極座標做轉F

Python F數 `z` 是用 *直角坐標* 或 *笛卡爾坐標* 儲存在F部的。它完全是由其 *實部* `z.real` 和 F部 `z.imag` 所F定。

極座標 提供了另一種表示F數的方法。在極座標中，F數 *z* 由F對值 (modulus) *r* 和相位角 (phase) *phi* 定義。F對值 *r* 是從 *z* 到原點的距離，而相位角 *phi* 是從正 x 軸到連接原點到 *z* 的F段的逆時針角度（以弧度F單位）。

以下的函式可用於原始直角座標與極座標之間的相互轉F。

`cmath.`**`phase`**(*x*)
以浮點數的形式回傳 *x* 的相位角（也稱F *x* 的 *引數*）。`phase(x)` 等價於 `math.atan2(x.imag, x.real)`。結果將位於 [-*π*, *π*] 的範圍F，且此操作的分枝切割將位於負實軸上。結果的符號會與 `x.imag` 的符號相同，即使 `x.imag` F零：

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

備🄵

🄵數 *x* 的🄵對值可以使用🄵建的*abs()* 函式計算。🄵有單獨的*cmath* 模組函式適用於此操作。

cmath.**polar**(*x*)

回傳 *x* 在極座標中的表達方式。回傳一組數對 `(r, phi)`，*r* 是 *x* 的🄵對值，*phi* 是 *x* 的相位角。`polar(x)` 相當於 `(abs(x), phase(x))`。

cmath.**rect**(*r*, *phi*)

透過極座標 *r* 和 *phi* 回傳🄵數 *x*。相當於 `complex(r * math.cos(phi), r * math.sin(phi))`。

9.3.2 🄵函數和對數函數

cmath.**exp**(*x*)

回傳 *e* 的 *x* 次方，其中 *e* 是自然對數的底數。

cmath.**log**(*x*[, *base*])

回傳 *x* 給定 *base* 的對數。如果未指定 *base*，則傳回 *x* 的自然對數。存在一條分枝切割，從 0 沿負實數軸到 -∞。

cmath.**log10**(*x*)

回傳 *x* 以 10 🄵底的對數。它與*log()* 具有相同的分枝切割。

cmath.**sqrt**(*x*)

回傳 *x* 的平方根。它與*log()* 具有相同的分枝切割。

9.3.3 三角函數

cmath.**acos**(*x*)

回傳 *x* 的反余弦值。存在兩條分枝切割：一條是從 1 沿著實數軸向右延伸到 ∞。另一條從 -1 沿實數軸向左延伸到 -∞。

cmath.**asin**(*x*)

回傳 *x* 的反正弦值。它與*acos()* 具有相同的分枝切割。

cmath.**atan**(*x*)

回傳 *x* 的反正切值。有兩條分枝切割：一條是從 `1j` 沿著🄵軸延伸到 `∞j`。另一條從 `-1j` 沿著🄵軸延伸到 `-∞j`。

cmath.**cos**(*x*)

回傳 *x* 的余弦值。

cmath.**sin**(*x*)

回傳 *x* 的正弦值。

cmath.**tan**(*x*)

回傳 *x* 的正切值。

9.3.4 雙曲函數

cmath.**acosh**(*x*)

回傳 *x* 的反雙曲余弦值。存在一條分枝切割，從 1 沿實數軸向左延伸到 -∞。

cmath.**asinh**(*x*)

回傳 *x* 的反雙曲正弦值。存在兩條分枝切割：一條是從 `1j` 沿著🄵軸延伸到 `∞j`。另一條從 `-1j` 沿著🄵軸延伸到 `-∞j`。

cmath.**atanh**(*x*)

回傳 *x* 的反雙曲正切值。存在兩條分枝切割：一條是從 `1` 沿著實數軸延伸到 ∞。另一條從 `-1` 沿著實數軸延伸到 `-∞`。

cmath.**cosh**(*x*)

回傳 *x* 的反雙曲余弦值。

cmath.**sinh**(*x*)

回傳 *x* 的反雙曲正弦值。

cmath.**tanh**(*x*)

回傳 *x* 的反雙曲正切值。

9.3.5 分類函式

cmath.**isfinite**(*x*)

如果 *x* 的實部和🄵部都是有限的，則回傳 `True`，否則回傳 `False`。

在 3.2 版被加入.

cmath.**isinf**(*x*)

如果 *x* 的實部或🄵部是無窮大，則回傳 `True`，否則回傳 `False`。

cmath.**isnan**(*x*)

如果 *x* 的實部或🄵部🄵 NaN，則回傳 `True`，否則回傳 `False`。

cmath.**isclose**(*a*, *b*, ***, *rel_tol=1e-09*, *abs_tol=0.0*)

如果 *a* 和 *b* 的值相互接近，則回傳 `True`，否則回傳 `False`。

兩個值是否被認🄵相互接近是由給定的🄵對和相對容許偏差 (tolerance) 所🄵定的。

rel_tol 是相對容許偏差 -- 它是 *a* 和 *b* 之間的最大容許偏差值，相對於 *a* 或 *b* 的較大🄵對值。例如，要設定 5% 的容許偏差，請傳遞 `rel_tol=0.05`。預設容許偏差是 `1e-09`，它確保兩個值在大約 9 位十進制數字🄵相同。*rel_tol* 必須大於零。

abs_tol 是最小🄵對容許偏差 -- 對於接近零的比較很有用。*abs_tol* 必須至少🄵零。

如果未發生錯誤，結果將🄵：`abs(a-b) <= max(rel_tol * max(abs(a), abs(b)), abs_tol)`。

IEEE 754 特殊值 `NaN`、`inf` 和 `-inf` 將會根據 IEEE 規則進行處理。具體來🄵，`NaN` 不被認🄵接近任何其他值，包括 `NaN`。`inf` 和 `-inf` 只被認🄵是接近它們自己的。

在 3.5 版被加入.

也參考

PEP 485 -- 一個用來測試近似相等的函式

9.3.6 常數

cmath.**pi**
數學常數 π，作🄵一個浮點數。

cmath.**e**
數學常數 e，作🄵一個浮點數。

cmath.**tau**
數學常數 τ，作🄵一個浮點數。

在 3.6 版被加入.

cmath.**inf**
正無窮大的浮點數。相當於 `float('inf')`。

在 3.6 版被加入.

cmath.**infj**
實部🄵零和🄵部🄵正無窮的🄵數。相當於 `complex(0.0, float('inf'))`。

在 3.6 版被加入.

cmath.**nan**
浮點「非數字」(NaN) 值。相當於 `float('nan')`。

在 3.6 版被加入.

cmath.**nanj**
實部🄵零和🄵部🄵 NaN 的🄵數。相當於 `complex(0.0, float('nan'))`。

在 3.6 版被加入.

請注意，函式的選擇與模組*math* 的類似，但🄵不完全相同。擁有兩個模組的原因是有些用🄵對🄵數不感興趣，甚至根本就不知道它們是什🄵。他們寧願讓 `math.sqrt(-1)` 引發🄵常，也不願它回傳🄵數。另請注意，*cmath* 中所定義的函式始終都會回傳🄵數，即使答案可以表示🄵實數（在這種情🄵下，🄵數的🄵部🄵零）。

關於分枝切割的🄵釋：它們是沿著給定的不連續函式的曲🄵。它們是許多🄵變函數的必要特徵。假設您需要使用🄵變函數進行計算，您將會了解分枝切割的概念。請參🄵幾乎所有關於🄵變函數的（不是太初級的）書籍以獲得🄵發。對於如何正確地基於數值目的選擇分枝切割的相關訊息，以下🄵容應該是一個很好的參考：

也參考

Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), The state of the art in numerical analysis. Clarendon Press (1987) pp165--211.

9.4 `decimal` --- Decimal fixed-point and floating-point arithmetic

原始碼： Lib/decimal.py

The *decimal* module provides support for fast correctly rounded decimal floating-point arithmetic. It offers several advantages over the *float* datatype:

- Decimal "is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle -- computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school." -- excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like `1.1` and `2.2` do not have exact representations in binary floating point. End users typically would not expect `1.1 + 2.2` to display as `3.3000000000000003` as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point, `0.1 + 0.1 + 0.1 - 0.3` is exactly equal to zero. In binary floating point, the result is `5.5511151231257827e-017`. While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that `1.30 + 1.20` is `2.50`. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication, the "schoolbook" approach uses all the figures in the multiplicands. For instance, `1.3 * 1.2` gives `1.56` while `1.30 * 1.20` gives `1.5600`.
- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support "without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic." -- excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as `Infinity`, `-Infinity`, and `NaN`. The standard also differentiates `-0` from `+0`.

The context for arithmetic is an environment specifying precision, rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include *ROUND_CEILING*, *ROUND_DOWN*, *ROUND_FLOOR*, *ROUND_HALF_DOWN*, *ROUND_HALF_EVEN*, *ROUND_HALF_UP*, *ROUND_UP*, and *ROUND_05UP*.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: *Clamped*, *InvalidOperation*, *DivisionByZero*, *Inexact*, *Rounded*, *Subnormal*, *Overflow*, *Underflow* and *FloatOperation*.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

也參考

- IBM's General Decimal Arithmetic Specification, The General Decimal Arithmetic Specification.

9.4.1 Quick-start Tutorial

The usual start to using decimals is importing the module, viewing the current context with *getcontext()* and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[Overflow, DivisionByZero,
        InvalidOperation])

>>> getcontext().prec = 7       # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as `NaN` which stands for "Not a number", positive and negative `Infinity`, and `-0`:

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.140000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.4142135623730950488016887242')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

If the *FloatOperation* signal is trapped, accidental mixing of decimals and floats in constructors or ordering comparisons raises an exception:

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') == 3.5
True
```

在 3.3 版被加入.

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

If the internal limits of the C version are exceeded, constructing a decimal raises *InvalidOperation*:

```
>>> Decimal("1e9999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [<class 'decimal.InvalidOperation'>]
```

在 3.3 版的變更.

Decimals interact well with much of the rest of Python. Here is a small decimal floating-point flying circus:

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

And some mathematical functions are also available to Decimal:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.4142135623730950488016887242')
>>> Decimal(1).exp()
Decimal('2.7182818284590452353602874713')
```

(繼續下一頁)

(繼續上一頁)

```
>>> Decimal('10').ln()
Decimal('2.3025850929940456840179914546')
>>> Decimal('10').log10()
Decimal('1')
```

The *quantize()* method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

As shown above, the *getcontext()* function accesses the current context and allows the settings to be changed. This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the Context() constructor. To make an alternate active, use the *setcontext()* function.

In accordance with the standard, the *decimal* module provides two ready to use standard contexts, *BasicContext* and *ExtendedContext*. The former is especially useful for debugging because many of the traps are enabled:

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the *clear_flags()* method.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[Inexact, Rounded], traps=[])
```

The *flags* entry shows that the rational approximation to pi was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the `traps` attribute of a context:

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pyshell#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to *Decimal* with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

9.4.2 Decimal objects

class decimal.**Decimal**(*value='0'*, *context=None*)

Construct a new *Decimal* object based from *value*.

value can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns `Decimal('0')`. If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters, as well as underscores throughout, are removed:

```
sign           ::=  '+' | '-'
digit          ::=  '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator      ::=  'e' | 'E'
digits         ::=  digit [digit]...
decimal-part   ::=  digits '.' [digits] | ['.'] digits
exponent-part  ::=  indicator [sign] digits
infinity       ::=  'Infinity' | 'Inf'
nan            ::=  'NaN' [digits] | 'sNaN' [digits]
numeric-value  ::=  decimal-part [exponent-part] | infinity
numeric-string ::=  [sign] numeric-value | [sign] nan
```

Other Unicode decimal digits are also permitted where `digit` appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `'\uff10'` through `'\uff19'`.

If *value* is a *tuple*, it should have three components, a sign (`0` for positive or `1` for negative), a *tuple* of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a *float*, the binary floating-point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.100000000000000088817841970012523233890533447265625')`.

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps *InvalidOperation*, an exception is raised; otherwise, the constructor returns a new Decimal with the value of `NaN`.

Once constructed, *Decimal* objects are immutable.

在 3.2 版的變更: The argument to the constructor is now permitted to be a *float* instance.

在 3.3 版的變更: *float* arguments raise an exception if the *FloatOperation* trap is set. By default the trap is off.

在 3.6 版的變更: Underscores are allowed for grouping, as with integral and floating-point literals in code.

Decimal floating-point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *int*).

There are some small differences between arithmetic on Decimal objects and arithmetic on integers and floats. When the remainder operator `%` is applied to Decimal objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity `x == (x // y) * y + x % y`:

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the `remainder` and `divide-integer` operations (respectively) as described in the specification.

Decimal objects cannot generally be combined with floats or instances of *fractions.Fraction* in arithmetic operations: an attempt to add a *Decimal* to a *float*, for example, will raise a *TypeError*. However, it is possible to use Python's comparison operators to compare a *Decimal* instance `x` with another number `y`. This avoids confusing results when doing equality comparisons between numbers of different types.

在 3.2 版的變更: Mixed-type comparisons between *Decimal* instances and other numeric types are now fully supported.

In addition to the standard numeric properties, decimal floating-point objects also have a number of specialized methods:

adjusted()

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

as_integer_ratio()

Return a pair `(n, d)` of integers that represent the given *Decimal* instance as a fraction, in lowest terms and with a positive denominator:

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

The conversion is exact. Raise OverflowError on infinities and ValueError on NaNs.

在 3.6 版被加入.

as_tuple()

Return a *named tuple* representation of the number: `DecimalTuple(sign, digits, exponent)`.

canonical()

Return the canonical encoding of the argument. Currently, the encoding of a *Decimal* instance is always canonical, so this operation returns its argument unchanged.

compare(*other*, *context=None*)

Compare the values of two Decimal instances. *compare()* returns a Decimal instance, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN  ==> Decimal('NaN')
a < b            ==> Decimal('-1')
a == b           ==> Decimal('0')
a > b            ==> Decimal('1')
```

compare_signal(*other*, *context=None*)

This operation is identical to the *compare()* method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

compare_total(*other*, *context=None*)

Compare two operands using their abstract representation rather than their numerical value. Similar to the *compare()* method, but the result gives a total ordering on *Decimal* instances. Two *Decimal* instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')` if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

compare_total_mag(*other*, *context=None*)

Compare two operands using their abstract representation rather than their value as in *compare_total()*, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

conjugate()

Just returns self, this method is only to comply with the Decimal Specification.

copy_abs()

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_negate()

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

copy_sign(*other*, *context=None*)

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

exp(*context=None*)

Return the value of the (natural) exponential function `e**x` at the given number. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

classmethod from_float(*f*)

Alternative constructor that only accepts instances of *float* or *int*.

Note `Decimal.from_float(0.1)` is not the same as `Decimal('0.1')`. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is `0x1.999999999999ap-4`. That equivalent value in decimal is `0.1000000000000000055511151231257827021181583404541015625`.

備🄵

From Python 3.2 onwards, a *Decimal* instance can also be constructed directly from a *float*.

```
>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')
```

在 3.1 版被加入.

fma(*other*, *third*, *context=None*)

Fused multiply-add. Return self*other+third with no rounding of the intermediate product self*other.

```
>>> Decimal(2).fma(3, 5)
Decimal('11')
```

is_canonical()

Return *True* if the argument is canonical and *False* otherwise. Currently, a *Decimal* instance is always canonical, so this operation always returns *True*.

is_finite()

Return *True* if the argument is a finite number, and *False* if the argument is an infinity or a NaN.

is_infinite()

Return *True* if the argument is either positive or negative infinity and *False* otherwise.

is_nan()

Return *True* if the argument is a (quiet or signaling) NaN and *False* otherwise.

is_normal(*context=None*)

Return *True* if the argument is a *normal* finite number. Return *False* if the argument is zero, subnormal, infinite or a NaN.

is_qnan()

Return *True* if the argument is a quiet NaN, and *False* otherwise.

is_signed()

Return *True* if the argument has a negative sign and *False* otherwise. Note that zeros and NaNs can both carry signs.

is_snan()

Return *True* if the argument is a signaling NaN and *False* otherwise.

is_subnormal(*context=None*)

Return *True* if the argument is subnormal, and *False* otherwise.

is_zero()

Return *True* if the argument is a (positive or negative) zero and *False* otherwise.

ln(*context=None*)

Return the natural (base e) logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

log10(*context=None*)

Return the base ten logarithm of the operand. The result is correctly rounded using the *ROUND_HALF_EVEN* rounding mode.

logb(*context=None*)

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the operand is a zero then `Decimal('-Infinity')` is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then `Decimal('Infinity')` is returned.

logical_and(*other*, *context=None*)

logical_and() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `and` of the two operands.

logical_invert(*context=None*)

logical_invert() is a logical operation. The result is the digit-wise inversion of the operand.

logical_or(*other*, *context=None*)

logical_or() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `or` of the two operands.

logical_xor(*other*, *context=None*)

logical_xor() is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

max(*other*, *context=None*)

Like `max(self, other)` except that the context rounding rule is applied before returning and that `NaN` values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

max_mag(*other*, *context=None*)

Similar to the *max()* method, but the comparison is done using the absolute values of the operands.

min(*other*, *context=None*)

Like `min(self, other)` except that the context rounding rule is applied before returning and that `NaN` values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

min_mag(*other*, *context=None*)

Similar to the *min()* method, but the comparison is done using the absolute values of the operands.

next_minus(*context=None*)

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

next_plus(*context=None*)

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

next_toward(*other*, *context=None*)

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

normalize(*context=None*)

Used for producing canonical values of an equivalence class within either the current context or the specified context.

This has the same semantics as the unary plus operation, except that if the final result is finite it is reduced to its simplest form, with all trailing zeros removed and its sign preserved. That is, while the coefficient is non-zero and a multiple of ten the coefficient is divided by ten and the exponent is incremented by 1. Otherwise (the coefficient is zero) the exponent is set to 0. In all cases the sign is unchanged.

For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

Note that rounding is applied *before* reducing to simplest form.

In the latest versions of the specification, this operation is also known as `reduce`.

number_class(*context=None*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.
- `"-Subnormal"`, indicating that the operand is negative and subnormal.
- `"-Zero"`, indicating that the operand is a negative zero.
- `"+Zero"`, indicating that the operand is a positive zero.
- `"+Subnormal"`, indicating that the operand is positive and subnormal.
- `"+Normal"`, indicating that the operand is a positive normal number.
- `"+Infinity"`, indicating that the operand is positive infinity.
- `"NaN"`, indicating that the operand is a quiet NaN (Not a Number).
- `"sNaN"`, indicating that the operand is a signaling NaN.

quantize(*exp*, *rounding=None*, *context=None*)

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the `rounding` argument if given, else by the given `context` argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than `Emax` or less than *Etiny()*.

radix()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

remainder_near(*other*, *context=None*)

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where `n` is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

rotate(*other*, *context=None*)

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

same_quantum(*other*, *context=None*)

Test whether self and other have the same exponent or whether both are `NaN`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise InvalidOperation if the second operand cannot be converted exactly.

scaleb(*other*, *context=None*)

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by `10**other`. The second operand must be an integer.

shift(*other*, *context=None*)

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range -precision through precision. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

sqrt(*context=None*)

Return the square root of the argument to full precision.

to_eng_string(*context=None*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

to_integral(*rounding=None*, *context=None*)

Identical to the *to_integral_value()* method. The `to_integral` name has been kept for compatibility with older versions.

to_integral_exact(*rounding=None*, *context=None*)

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

to_integral_value(*rounding=None*, *context=None*)

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Decimal numbers can be rounded using the *round()* function:

round(number)

round(number, ndigits)

If *ndigits* is not given or `None`, returns the nearest *int* to *number*, rounding ties to even, and ignoring the rounding mode of the *Decimal* context. Raises *OverflowError* if *number* is an infinity or *ValueError* if it is a (quiet or signaling) NaN.

If *ndigits* is an *int*, the context's rounding mode is respected and a *Decimal* representing *number* rounded to the nearest multiple of `Decimal('1E-ndigits')` is returned; in this case, `round(number, ndigits)` is equivalent to `self.quantize(Decimal('1E-ndigits'))`. Returns `Decimal('NaN')` if *number* is a quiet NaN. Raises *InvalidOperation* if *number* is an infinity, a signaling NaN, or if the length of the coefficient after the quantize operation would be greater than the current context's precision. In other words, for the non-corner cases:

- if *ndigits* is positive, return *number* rounded to *ndigits* decimal places;
- if *ndigits* is zero, return *number* rounded to the nearest integer;
- if *ndigits* is negative, return *number* rounded to the nearest multiple of `10**abs(ndigits)`.

For example:

```
>>> from decimal import Decimal, getcontext, ROUND_DOWN
>>> getcontext().rounding = ROUND_DOWN
>>> round(Decimal('3.75'))      # context rounding ignored
4
>>> round(Decimal('3.5'))       # round-ties-to-even
4
>>> round(Decimal('3.75'), 0)   # uses the context rounding
Decimal('3')
>>> round(Decimal('3.75'), 1)
Decimal('3.7')
>>> round(Decimal('3.75'), -1)
Decimal('0E+1')
```

Logical operands

The *logical_and()*, *logical_invert()*, *logical_or()*, and *logical_xor()* methods expect their arguments to be *logical operands*. A *logical operand* is a *Decimal* instance whose exponent and sign are both zero, and whose digits are all either `0` or `1`.

9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the *getcontext()* and *setcontext()* functions:

`decimal.`**`getcontext`**`()`

Return the current context for the active thread.

`decimal.`**`setcontext`**`(`*c*`)`

Set the current context for the active thread to *c*.

You can also use the `with` statement and the *localcontext()* function to temporarily change the active context.

`decimal.`**`localcontext`**`(`*ctx=None*, ***kwargs*`)`

Return a context manager that will set the current context for the active thread to a copy of *ctx* on entry to the with-statement and restore the previous context when exiting the with-statement. If no context is specified, a copy of the current context is used. The *kwargs* argument is used to set the attributes of the new context.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```
from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42   # Perform a high precision calculation
    s = calculate_something()
s = +s  # Round the final result back to the default precision
```

Using keyword arguments, the code would be the following:

```
from decimal import localcontext

with localcontext(prec=42) as ctx:
    s = calculate_something()
s = +s
```

Raises *TypeError* if *kwargs* supplies an attribute that *Context* doesn't support. Raises either *TypeError* or *ValueError* if *kwargs* supplies an invalid value for an attribute.

在 3.11 版的變更: *localcontext()* now supports setting context attributes through the use of keyword arguments.

New contexts can also be created using the *Context* constructor described below. In addition, the module provides three pre-made contexts:

`class` `decimal.`**`BasicContext`**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to *ROUND_HALF_UP*. All flags are cleared. All traps are enabled (treated as exceptions) except *Inexact*, *Rounded*, and *Subnormal*.

Because many of the traps are enabled, this context is useful for debugging.

class decimal.**ExtendedContext**

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to *ROUND_HALF_EVEN*. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of `NaN` or `Infinity` instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

class decimal.**DefaultContext**

This context is used by the *Context* constructor as a prototype for new contexts. Changing a field (such a precision) has the effect of changing the default for new contexts created by the *Context* constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are `Context.prec=28`, `Context.rounding=`*ROUND_HALF_EVEN*, and enabled traps for *Overflow*, *InvalidOperation*, and *DivisionByZero*.

In addition to the three supplied contexts, new contexts can be created with the *Context* constructor.

class decimal.**Context**(*prec=None*, *rounding=None*, *Emin=None*, *Emax=None*, *capitals=None*, *clamp=None*, *flags=None*, *traps=None*)

Creates a new context. If a field is not specified or is *None*, the default values are copied from the *DefaultContext*. If the *flags* field is not specified or is *None*, all flags are cleared.

prec is an integer in the range [`1`, *MAX_PREC*] that sets the precision for arithmetic operations in the context.

The *rounding* option is one of the constants listed in the section *Rounding Modes*.

The *traps* and *flags* fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The *Emin* and *Emax* fields are integers specifying the outer limits allowable for exponents. *Emin* must be in the range [*MIN_EMIN*, `0`], *Emax* in the range [`0`, *MAX_EMAX*].

The *capitals* field is either `0` or `1` (the default). If set to `1`, exponents are printed with a capital `E`; otherwise, a lowercase `e` is used: `Decimal('6.02e+23')`.

The *clamp* field is either `0` (the default) or `1`. If set to `1`, the exponent `e` of a *Decimal* instance representable in this context is strictly limited to the range `Emin - prec + 1 <= e <= Emax - prec + 1`. If *clamp* is `0` then a weaker condition holds: the adjusted exponent of the *Decimal* instance is at most `Emax`. When *clamp* is `1`, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal('1.23e999')
Decimal('1.23000E+999')
```

A *clamp* value of `1` allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The *Context* class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the *Decimal* methods described above (with the exception of the *adjusted()* and *as_tuple()* methods) there is a corresponding *Context* method. For example,

for a *Context* instance `C` and *Decimal* instance `x`, `C.exp(x)` is equivalent to `x.exp(context=C)`. Each *Context* method accepts a Python integer (an instance of *int*) anywhere that a Decimal instance is accepted.

clear_flags()

Resets all of the flags to `0`.

clear_traps()

Resets all of the traps to `0`.

在 3.3 版被加入.

copy()

Return a duplicate of the context.

copy_decimal(*num*)

Return a copy of the Decimal instance num.

create_decimal(*num*)

Creates a new Decimal instance from *num* but using *self* as context. Unlike the *Decimal* constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

create_decimal_from_float(*f*)

Creates a new Decimal instance from a float *f* but rounding using *self* as the context. Unlike the *Decimal.from_float()* class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
    ...
decimal.Inexact: None
```

在 3.1 版被加入.

Etiny()

Returns a value equal to `Emin - prec + 1` which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to *Etiny*.

Etop()

Returns a value equal to `Emax - prec + 1`.

The usual approach to working with decimals is to create *Decimal* instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the *Decimal* class and are only briefly recounted here.

abs(*x*)

Returns the absolute value of *x*.

add(*x*, *y*)

Return the sum of *x* and *y*.

canonical(*x*)

Returns the same Decimal object *x*.

compare(*x*, *y*)

Compares *x* and *y* numerically.

compare_signal(*x*, *y*)

Compares the values of the two operands numerically.

compare_total(*x*, *y*)

Compares two operands using their abstract representation.

compare_total_mag(*x*, *y*)

Compares two operands using their abstract representation, ignoring sign.

copy_abs(*x*)

Returns a copy of *x* with the sign set to 0.

copy_negate(*x*)

Returns a copy of *x* with the sign inverted.

copy_sign(*x*, *y*)

Copies the sign from *y* to *x*.

divide(*x*, *y*)

Return *x* divided by *y*.

divide_int(*x*, *y*)

Return *x* divided by *y*, truncated to an integer.

divmod(*x*, *y*)

Divides two numbers and returns the integer part of the result.

exp(*x*)

Returns `e ** x`.

fma(*x*, *y*, *z*)

Returns *x* multiplied by *y*, plus *z*.

is_canonical(*x*)

Returns `True` if *x* is canonical; otherwise returns `False`.

is_finite(*x*)

Returns `True` if *x* is finite; otherwise returns `False`.

is_infinite(*x*)

Returns `True` if *x* is infinite; otherwise returns `False`.

is_nan (*x*)
Returns `True` if *x* is a qNaN or sNaN; otherwise returns `False`.

is_normal (*x*)
Returns `True` if *x* is a normal number; otherwise returns `False`.

is_qnan (*x*)
Returns `True` if *x* is a quiet NaN; otherwise returns `False`.

is_signed (*x*)
Returns `True` if *x* is negative; otherwise returns `False`.

is_snan (*x*)
Returns `True` if *x* is a signaling NaN; otherwise returns `False`.

is_subnormal (*x*)
Returns `True` if *x* is subnormal; otherwise returns `False`.

is_zero (*x*)
Returns `True` if *x* is a zero; otherwise returns `False`.

ln (*x*)
Returns the natural (base e) logarithm of *x*.

log10 (*x*)
Returns the base 10 logarithm of *x*.

logb (*x*)
Returns the exponent of the magnitude of the operand's MSD.

logical_and (*x*, *y*)
Applies the logical operation *and* between each operand's digits.

logical_invert (*x*)
Invert all the digits in *x*.

logical_or (*x*, *y*)
Applies the logical operation *or* between each operand's digits.

logical_xor (*x*, *y*)
Applies the logical operation *xor* between each operand's digits.

max (*x*, *y*)
Compares two values numerically and returns the maximum.

max_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

min (*x*, *y*)
Compares two values numerically and returns the minimum.

min_mag (*x*, *y*)
Compares the values numerically with their sign ignored.

minus (*x*)
Minus corresponds to the unary prefix minus operator in Python.

multiply(*x*, *y*)

Return the product of *x* and *y*.

next_minus(*x*)

Returns the largest representable number smaller than *x*.

next_plus(*x*)

Returns the smallest representable number larger than *x*.

next_toward(*x*, *y*)

Returns the number closest to *x*, in direction towards *y*.

normalize(*x*)

Reduces *x* to its simplest form.

number_class(*x*)

Returns an indication of the class of *x*.

plus(*x*)

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

power(*x*, *y*, *modulo=None*)

Return `x` to the power of `y`, reduced modulo `modulo` if given.

With two arguments, compute `x**y`. If `x` is negative then `y` must be integral. The result will be inexact unless `y` is integral and the result is finite and can be expressed exactly in 'precision' digits. The rounding mode of the context is used. Results are always correctly rounded in the Python version.

`Decimal(0) ** Decimal(0)` results in `InvalidOperation`, and if `InvalidOperation` is not trapped, then results in `Decimal('NaN')`.

在 3.3 版的變更: The C module computes *power()* in terms of the correctly rounded *exp()* and *ln()* functions. The result is well-defined but only "almost always correctly rounded".

With three arguments, compute `(x**y) % modulo`. For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- `y` must be nonnegative
- at least one of `x` or `y` must be nonzero
- `modulo` must be nonzero and have at most 'precision' digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing `(x**y) % modulo` with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of `x`, `y` and `modulo`. The result is always exact.

quantize(*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

radix()

Just returns 10, as this is Decimal, :)

remainder(*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

remainder_near(*x*, *y*)

Returns `x - y * n`, where *n* is the integer nearest the exact value of `x / y` (if the result is 0 then its sign will be the sign of *x*).

rotate(*x*, *y*)

Returns a rotated copy of *x*, *y* times.

same_quantum(*x*, *y*)

Returns `True` if the two operands have the same exponent.

scaleb(*x*, *y*)

Returns the first operand after adding the second value its exp.

shift(*x*, *y*)

Returns a shifted copy of *x*, *y* times.

sqrt(*x*)

Square root of a non-negative number to context precision.

subtract(*x*, *y*)

Return the difference between *x* and *y*.

to_eng_string(*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

to_integral_exact(*x*)

Rounds to an integer.

to_sci_string(*x*)

Converts a number to a string using scientific notation.

9.4.4 常數

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

	32-bit	64-bit
decimal.**MAX_PREC**	425000000	999999999999999999
decimal.**MAX_EMAX**	425000000	999999999999999999
decimal.**MIN_EMIN**	-425000000	-999999999999999999
decimal.**MIN_ETINY**	-849999999	-1999999999999999997

decimal.**HAVE_THREADS**

The value is `True`. Deprecated, because Python now always has threads.

在 3.9 版之後被🄴用.

decimal.**HAVE_CONTEXTVAR**

The default value is `True`. If Python is `configured using the --without-decimal-contextvar option`, the C version uses a thread-local rather than a coroutine-local context and the value is `False`. This is slightly faster in some nested context scenarios.

在 3.8.3 版被加入.

9.4.5 Rounding modes

decimal.**ROUND_CEILING**

Round towards `Infinity`.

decimal.**ROUND_DOWN**

Round towards zero.

decimal.**ROUND_FLOOR**

Round towards `-Infinity`.

decimal.**ROUND_HALF_DOWN**

Round to nearest with ties going towards zero.

decimal.**ROUND_HALF_EVEN**

Round to nearest with ties going to nearest even integer.

decimal.**ROUND_HALF_UP**

Round to nearest with ties going away from zero.

decimal.**ROUND_UP**

Round away from zero.

decimal.**ROUND_05UP**

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

9.4.6 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the *DivisionByZero* trap is set, then a *DivisionByZero* exception is raised upon encountering the condition.

class decimal.**Clamped**

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's `Emin` and `Emax` limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

class decimal.**DecimalException**

Base class for other signals and a subclass of *ArithmeticError*.

class decimal.**DivisionByZero**

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

class decimal.**Inexact**

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

class decimal.**InvalidOperation**

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity
```

class decimal.**Overflow**

Numerical overflow.

Indicates the exponent is larger than `Context.Emax` after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

class decimal.**Rounded**

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding `5.00` to `5.0`). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

class decimal.**Subnormal**

Exponent was lower than `Emin` prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

class decimal.**Underflow**

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

class decimal.**FloatOperation**

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the *Decimal* constructor, *create_decimal()* and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting *FloatOperation* in the context flags. Explicit conversions with *from_float()* or *create_decimal_from_float()* do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise *FloatOperation*.

The following table summarizes the hierarchy of signals:

```
exceptions.ArithmeticError(exceptions.Exception)
    DecimalException
        Clamped
        DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
        Inexact
            Overflow(Inexact, Rounded)
            Underflow(Inexact, Rounded, Subnormal)
        InvalidOperation
        Rounded
        Subnormal
        FloatOperation(DecimalException, exceptions.TypeError)
```

9.4.7 Floating-Point Notes

Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent `0.1` exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating-point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.5111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The *decimal* module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
```

(繼續下一頁)

(繼續上一頁)

```
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

Special values

The number system for the *decimal* module provides special values including `NaN`, `sNaN`, `-Infinity`, `Infinity`, and two zeros, `+0` and `-0`.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the *DivisionByZero* signal is not trapped. Likewise, when the *Overflow* signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return `NaN`, or if the *InvalidOperation* signal is trapped, raise an exception. For example, `0/0` returns `NaN` which means "not a number". This variety of `NaN` is quiet and, once created, will flow through other computations always resulting in another `NaN`. This behavior can be useful for a series of computations that occasionally have missing inputs --- it allows the calculation to proceed while flagging specific results as invalid.

A variant is `sNaN` which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python's comparison operators can be a little surprising where a `NaN` is involved. A test for equality where one of the operands is a quiet or signaling `NaN` always returns *False* (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns *True*. An attempt to compare two Decimals using any of the `<`, `<=`, `>` or `>=` operators will raise the *InvalidOperation* signal if either operand is a `NaN`, and return *False* if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a `NaN` were taken from the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the *compare()* and *compare_signal()* methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating-point representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

9.4.8 Working with threads

The *getcontext()* function accesses a different *Context* object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the *setcontext()* function automatically assigns its target to the current thread.

If *setcontext()* has not been called before *getcontext()*, then *getcontext()* will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called *DefaultContext*. To control the defaults so that each thread will use the same values throughout the application, directly modify the *DefaultContext* object. This should be done *before* any threads are started so that there won't be a race condition between threads calling *getcontext()*. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
 . . .
```

9.4.9 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the *Decimal* class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:     optional grouping separator (comma, period, space, or blank)
    dp:      decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:     optional sign for positive numbers: '+', space or blank
    neg:     optional sign for negative numbers: '-', '(', space or blank
    trailneg:optional trailing minus indicator:  '-', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
    >>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
    '1.234.568-'
    >>> moneyfmt(d, curr='$', neg='(', trailneg=')')
    '($1,234,567.89)'
    >>> moneyfmt(Decimal(123456789), sep=' ')
    '123 456 789.00'
    >>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
    '<0.02>'

    """
```

(繼續下一頁)

(繼續上一頁)

```
    q = Decimal(10) ** -places      # 2 places --> '0.01'
    sign, digits, exp = value.quantize(q).as_tuple()
    result = []
    digits = list(map(str, digits))
    build, next = result.append, digits.pop
    if sign:
        build(trailneg)
    for i in range(places):
        build(next() if digits else '0')
    if places:
        build(dp)

```

9.4.10 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```
>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')
```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The *quantize()* method rounds to a fixed number of decimal places. If the *Inexact* trap is set, it is also useful for validation:

```
>>> TWOPLACES = Decimal(10) ** -2       # same as Decimal('0.01')
```

```
>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')
```

```
>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')
```

```
>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
   ...
Inexact: None
```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a *quantize()* step:

```
>>> a = Decimal('102.72')           # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                           # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                          # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES)     # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES)     # And quantize division
Decimal('0.03')
```

In developing fixed-point applications, it is convenient to define functions to handle the *quantize()* step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
...
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)
```

```
>>> mul(a, b)                           # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

Q. There are many ways to express the same value. The numbers `200`, `200.000`, `2E2`, and `.02E+4` all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The *normalize()* method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]
```

Q. When does rounding occur in a computation?

A. It occurs *after* the computation. The philosophy of the decimal specification is that numbers are considered exact and are created independent of the current context. They can even have greater precision than current context. Computations process with those exact inputs and then rounding (or other context operations) is applied to the *result* of the computation:

```
>>> getcontext().prec = 5
>>> pi = Decimal('3.1415926535')    # More than 5 digits
>>> pi                              # All digits are retained
Decimal('3.1415926535')
>>> pi + 0                          # Rounded after an addition
Decimal('3.1416')
>>> pi - Decimal('0.00005')         # Subtract unrounded numbers, then round
Decimal('3.1415')
>>> pi + 0 - Decimal('0.00005').    # Intermediate values are rounded
Decimal('3.1416')
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing `5.0E+3` as `5000` keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```
>>> def remove_exponent(d):
...     return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()
```

```
>>> remove_exponent(Decimal('5E+3'))
Decimal('5000')
```

Q. Is there a way to convert a regular float to a *Decimal*?

A. Yes, any binary floating-point number can be exactly expressed as a Decimal though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that "what you type is what you get". A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the *Context.create_decimal()* method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

Q. Is the CPython implementation fast for large numbers?

A. Yes. In the CPython and PyPy3 implementations, the C/CFFI versions of the decimal module integrate the high speed libmpdec library for arbitrary precision correctly rounded decimal floating-point arithmetic[1]. `libmpdec` uses Karatsuba multiplication for medium-sized numbers and the Number Theoretic Transform for very large numbers.

The context must be adapted for exact arbitrary precision arithmetic. `Emin` and `Emax` should always be set to the maximum values, `clamp` should always be 0 (the default). Setting `prec` requires some care.

The easiest approach for trying out bignum arithmetic is to use the maximum value for `prec` as well[2]:

```
>>> setcontext(Context(prec=MAX_PREC, Emax=MAX_EMAX, Emin=MIN_EMIN))
>>> x = Decimal(2) ** 256
>>> x / 128
Decimal('904625697166532776746648320380374280103671755200316906558262375061821325312')
```

For inexact results, *MAX_PREC* is far too large on 64-bit platforms and the available memory will be insufficient:

```
>>> Decimal(1) / 3
Traceback (most recent call last):
```

(繼續下一頁)

[1] 在 3.3 版被加入.

[2] 在 3.9 版的變更: This approach now works for all exact results except for non-integer powers.

(繼續上一頁)

```
  File "<stdin>", line 1, in <module>
MemoryError
```

On systems with overallocation (e.g. Linux), a more sophisticated approach is to adjust `prec` to the amount of available RAM. Suppose that you have 8GB of RAM and expect 10 simultaneous operands using a maximum of 500MB each:

```
>>> import sys
>>>
>>> # Maximum number of digits for a single operand using 500MB in 8-byte words
>>> # with 19 digits per word (4-byte and 9 digits for the 32-bit build):
>>> maxdigits = 19 * ((500 * 1024**2) // 8)
>>>
>>> # Check that this works:
>>> c = Context(prec=maxdigits, Emax=MAX_EMAX, Emin=MIN_EMIN)
>>> c.traps[Inexact] = True
>>> setcontext(c)
>>>
>>> # Fill the available precision with nines:
>>> x = Decimal(0).logical_invert() * 9
>>> sys.getsizeof(x)
524288112
>>> x + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  decimal.Inexact: [<class 'decimal.Inexact'>]
```

In general (and especially on systems without overallocation), it is recommended to estimate even tighter bounds and set the *Inexact* trap if all calculations are expected to be exact.

9.5 fractions --- 有理數

原始碼： Lib/fractions.py

The *fractions* module provides support for rational number arithmetic.

A Fraction instance can be constructed from a pair of integers, from another rational number, or from a string.

class fractions.**Fraction**(*numerator=0*, *denominator=1*)

class fractions.**Fraction**(*other_fraction*)

class fractions.**Fraction**(*float*)

class fractions.**Fraction**(*decimal*)

class fractions.**Fraction**(*string*)

The first version requires that *numerator* and *denominator* are instances of *numbers.Rational* and returns a new *Fraction* instance with value `numerator/denominator`. If *denominator* is `0`, it raises a *ZeroDivisionError*. The second version requires that *other_fraction* is an instance of *numbers.Rational* and returns a *Fraction* instance with the same value. The next two versions accept either a *float* or a *decimal.Decimal* instance, and return a *Fraction* instance with exactly the same value. Note that due to the usual issues with binary floating point (see tut-fp-issues), the argument to `Fraction(1.1)` is not exactly equal to 11/10, and so `Fraction(1.1)` does *not* return `Fraction(11, 10)` as one might expect. (But see the documentation for the *limit_denominator()* method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional `sign` may be either '+' or '-' and `numerator` and `denominator` (if present) are strings of decimal digits (underscores may be used to delimit digits as with integral literals in code). In addition, any string that represents a finite value and is accepted by the *float* constructor is also accepted by the *Fraction* constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```
>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()
Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)
```

The *Fraction* class inherits from the abstract base class *numbers.Rational*, and implements all of the methods and operations from that class. *Fraction* instances are *hashable*, and should be treated as immutable. In addition, *Fraction* has the following properties and methods:

在 3.2 版的變更: The *Fraction* constructor now accepts *float* and *decimal.Decimal* instances.

在 3.9 版的變更: The *math.gcd()* function is now used to normalize the *numerator* and *denominator*. *math.gcd()* always returns an *int* type. Previously, the GCD type depended on *numerator* and *denominator*.

在 3.11 版的變更: Underscores are now permitted when creating a *Fraction* instance from a string, following **PEP 515** rules.

在 3.11 版的變更: *Fraction* implements `__int__` now to satisfy `typing.SupportsInt` instance checks.

在 3.12 版的變更: Space is allowed around the slash for string inputs: `Fraction('2 / 3')`.

在 3.12 版的變更: *Fraction* instances now support float-style formatting, with presentation types `"e"`, `"E"`, `"f"`, `"F"`, `"g"`, `"G"` and `"%"`.

numerator

Numerator of the Fraction in lowest term.

denominator

Denominator of the Fraction in lowest term.

as_integer_ratio()

Return a tuple of two integers, whose ratio is equal to the original Fraction. The ratio is in lowest terms and has a positive denominator.

在 3.8 版被加入.

is_integer()

Return `True` if the Fraction is an integer.

在 3.12 版被加入.

classmethod from_float(*flt*)

Alternative constructor which only accepts instances of *float* or *numbers.Integral*. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

> **備🄵**
>
> From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *float*.

classmethod from_decimal(*dec*)

Alternative constructor which only accepts instances of *decimal.Decimal* or *numbers.Integral*.

> **備🄵**
>
> From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

limit_denominator(*max_denominator=1000000*)

Finds and returns the closest *Fraction* to `self` that has denominator at most max_denominator. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

__floor__()

Returns the greatest *int* `<= self`. This method can also be accessed through the *math.floor()* function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

__ceil__()

Returns the least *int* `>= self`. This method can also be accessed through the *math.ceil()* function.

__round__()

__round__(*ndigits*)

The first version returns the nearest *int* to `self`, rounding half to even. The second version rounds `self` to the nearest multiple of `Fraction(1, 10**ndigits)` (logically, if `ndigits` is negative), again rounding half toward even. This method can also be accessed through the *round()* function.

__format__(*format_spec*, /)

Provides support for float-style formatting of *Fraction* instances via the *str.format()* method, the *format()* built-in function, or Formatted string literals. The presentation types `"e"`, `"E"`, `"f"`, `"F"`, `"g"`, `"G"` and `"%"` are supported. For these presentation types, formatting for a *Fraction* object `x` follows the rules outlined for the *float* type in the 格式規格 *(Format Specification)* 迷你語言 section.

Here are some examples:

```
>>> from fractions import Fraction
>>> format(Fraction(1, 7), '.40g')
'0.1428571428571428571428571428571428571429'
>>> format(Fraction('1234567.855'), '_.2f')
'1_234_567.86'
>>> f"{Fraction(355, 113):*>20.6e}"
'********3.141593e+00'
>>> old_price, new_price = 499, 672
>>> "{:.2%} price increase".format(Fraction(new_price, old_price) - 1)
'34.67% price increase'
```

The abstract base classes making up the numeric tower.

9.6 random --- 生成F隨機數

原始碼： Lib/random.py

本章中所提及的 module（模組）用來實現各種分F的F擬隨機數F生器。

對於整數，可以從範圍中進行均F選擇。對於序列，有一個隨機元素的均F選擇，一個用來原地 (in-place) F生隨機排列清單的函式，以及一個用來隨機F樣不替F的函式。

在實數F上，有一些函式用於處理均F分F、常態分F（高斯分F）、對數常態分F、負指數分F、gamma分F和 Beta 分F。對於生成角度分F，可以使用馮 · 米塞斯分F (von Mises distribution)。

幾乎所有 module 函式都相依於基本函式*random()*，此函式在半開放範圍 `0.0 <= X < 1.0` F均F地生成一個隨機 float（浮點數）。Python 使用 Mersenne Twister（梅森旋轉演算法）作F核心的F生器，它F生 53 位元精度 float，其F期F 2**19937-1，透過 C 語言進行底層的實作既快速又支援執行緒安全 (threadsafe)。Mersenne Twister 是現存最廣泛被驗證的隨機數F生器之一，但是基於完全確定性，它F不適合所有目的，F且完全不適合加密目的。

該 module 提供的函式實際上是*random.Random* class（類F）中一個隱藏實例的綁定方法 (bound method)。你可以實例化自己的*Random* 實例，以得到不共享狀態的F生器。

如果你想使用你自己設計的基本F生器，*Random* 也可以進行子類F化 (subclass)。有關詳細資訊，請參考該類F的文件。

random module 也提供了*SystemRandom* class，使用系統函式*os.urandom()* 從作業系統提供的來源🄵生隨機數。

警告

本章所提及的🄵擬隨機數🄵生器不應該使用於安全目的。有關安全性或加密用途，請參考*secrets* module。

也參考

M. Matsumoto and T. Nishimura, "Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator", ACM Transactions on Modeling and Computer Simulation Vol. 8, No. 1, January pp.3--30 1998.

進位互補乘法 (Complementary-Multiply-with-Carry) 用法，可作🄵隨機數🄵生器的一個可相容替代方案，具有較長的🄵期和相對簡單的更新操作。

9.6.1 簿記函式 (bookkeeping functions)

`random.`**`seed`**(*a=None*, *version=2*)

初始化隨機數🄵生器。

如果 *a* 被省略或🄵 `None`，則使用當前系統時間。如果隨機來源由作業系統提供，則使用它們而不是系統時間（有關可用性的詳細資訊，請參考*os.urandom()* 函式）。

如果 *a* 🄵 int（整數），則直接使用它。

如使用版本 2（預設值），*str*、*bytes* 或*bytearray* 物件將轉🄵🄵*int*，🄵使用其所有位元。

若使用版本 1（🄵復現於舊版本 Python 中🄵生隨機序列而提供），*str* 和*bytes* 的演算法會生成範圍更窄的種子 (seed)。

在 3.2 版的變更: 移至版本 2 方案，該方案使用字串種子中的所有位元。

在 3.11 版的變更: *seed* 必須是以下型🄵之一：`None`、*int*、*float*、*str*、*bytes*、*bytearray*。

`random.`**`getstate`**()

回傳一個物件，捕獲🄵生器的當前🄵部狀態。此物件可以傳遞給*setstate()* 以恢復狀態。

`random.`**`setstate`**(*state*)

state 應該要從之前對*getstate()* 的呼叫中獲得，🄵且以*setstate()* 將🄵生器的🄵部狀態恢復到呼叫*getstate()* 時的狀態。

9.6.2 回傳位元組的函式

`random.`**`randbytes`**(*n*)

🄵生 *n* 個隨機位元組。

此方法不應使用於🄵生安全性權杖 (Token)。請改用*secrets.token_bytes()*。

在 3.9 版被加入.

9.6.3 回傳整數的函式

random.**randrange**(*stop*)

random.**randrange**(*start*, *stop*[, *step*])

傳回從 range(start, stop, step) 中隨機選擇的元素。

這大致相當於 choice(range(start, stop, step))，但支援任意大的範圍，F針對常見情F進行了最佳化。

位置引數模式與*range()* 函式相符。

不應使用關鍵字引數，因F它們可能會以意想不到的方式被直譯。例如 randrange(start=100) 會被直譯F randrange(0, 100, 1)。

在 3.2 版的變更: *randrange()* 在F生均F分F的值方面更FF雜。以前，它使用像 int(random()*n) 這樣的樣式，這可能會F生稍微不均F的分F。

在 3.12 版的變更: 已經不再支援非整數類型到等效整數的自動轉F。像是 randrange(10.0) 和 randrange(Fraction(10, 1)) 的呼叫將會引發*TypeError*。

random.**randint**(*a*, *b*)

回傳一個隨機整數 *N*，使得 a <= N <= b。F randrange(a, b+1) 的F名。

random.**getrandbits**(*k*)

回傳一個具有 *k* 個隨機位元的非負 Python 整數。此方法會隨 Mersenne Twister F生器一起提供，一些其他的F生器也可能將其作F API 的可選部分。如果可用，*getrandbits()* 使*randrange()* 能F處理任意大的範圍。

在 3.9 版的變更: 此方法現在接受 *k* F零。

9.6.4 回傳序列的函式

random.**choice**(*seq*)

從非空序列 *seq* 回傳一個隨機元素。如果 *seq* F空，則引發*IndexError*。

random.**choices**(*population*, *weights=None*, *, *cum_weights=None*, *k=1*)

回傳從 *population* 中重置取樣出的一個大小F *k* 的元素 list。如果 *population* F空，則引發*IndexError*。

如果指定了 *weights* 序列，則根據相對權重進行選擇。另外，如果給定 *cum_weights* 序列，則根據累積權重進行選擇（可能使用*itertools.accumulate()* 計算）。例如，相對權重 [10, 5, 30, 5] 等同於累積權重 [10, 15, 45, 50]。在F部，相對權重在進行選擇之前會轉FF累積權重，因此提供累積權重可以節省工作。

如果既未指定 *weights* 也未指定 *cum_weights*，則以相等的機率進行選擇。如果提供了加權序列，則該序列的長度必須與 *population* 序列的長度相同。它是一個*TypeError* 來指定 *weights* 和 *cum_weights*。

weights 或 *cum_weights* 可以使用任何與*random()* 所回傳的*float* 值（包括整數、float 和分數，但不包括小數）交互操作 (interoperates) 的數值類型。權重假定F非負數和有限的。如果所有權重均F零，則引發*ValueError*。

For a given seed, the *choices()* function with equal weighting typically produces a different sequence than repeated calls to *choice()*. The algorithm used by *choices()* uses floating-point arithmetic for internal consistency and speed. The algorithm used by *choice()* defaults to integer arithmetic with repeated selections to avoid small biases from round-off error.

在 3.6 版被加入.

在 3.9 版的變更: 如果所有權重均F零，則引發*ValueError*。

random.**shuffle**(*x*)

將序列 *x* 原地 (in place) 隨機打亂位置。

要打亂一個不可變的序列🄵回傳一個新的被打亂的 list（串列），請使用 `sample(x, k=len(x))`。

請注意，即使對於較小的 `len(x)`，*x* 的置🄵總數也會快速成長到大於大多數隨機數🄵生器的🄵期。這意味著長序列的大多數置🄵永遠無法🄵生。例如，長度🄵 2080 的序列是 Mersenne Twister 隨機數🄵生器🄵期🄵可以容納的最大序列。

在 3.11 版的變更: 移除可選參數 *random*。

random.**sample**(*population*, *k*, *, *counts=None*)

回傳從母體序列中選擇出的一個包含獨特元素、長度🄵 *k* 的 list。用於不重置的隨機取樣。

回傳包含母體元素的新清單，同時保持原始母體不變。🄵生的清單按選擇順序排列，因此所有子切片也會是有效的隨機樣本。這允許抽🄵獲🄵者（樣本）分🄵大🄵和第二名獲🄵者（子切片）。

母體成員不必是*hashable* 或唯一的。如果母體包含重🄵項，則每次出現都是樣本中可能出現的一個選擇。

可以一次指定一個重🄵元素，也可以使用可選的僅關鍵字 *counts* 參數指定重🄵元素。例如 `sample(['red', 'blue'], counts=[4, 2], k=5)` 等同於 `sample(['red', 'red', 'red', 'red', 'blue', 'blue'], k=5)`。

若要從整數範圍中選擇範例，請使用*range()* 物件作🄵引數。這對於從大型母體中取樣特🄵快速且節省空間：`sample(range(10000000), k=60)`。

如果樣本大小大於母體大小，*ValueError* 會被引發。

在 3.9 版的變更: 新增 *counts* 參數。

在 3.11 版的變更: *population* 必須是一個序列。不再支援將 set 自動轉🄵🄵 list。

9.6.5 離散分布

以下函式🄵生離散分🄵。

random.**binomialvariate**(*n=1*, *p=0.5*)

二項分🄵 (Binomial distribution)。回傳 *n* 個獨立試驗的成功次數，每個試驗的成功機率🄵 *p*：

數學上等價於：

```
sum(random() < p for i in range(n))
```

試驗次數 *n* 應🄵非負整數。成功的機率 *p* 應在 `0.0 <= p <= 1.0` 之間。結果是 `0 <= X <= n` 範圍🄵的整數。

在 3.12 版被加入.

9.6.6 實數分布

以下函式🄵生特定的實數分🄵。函式參數以分🄵方程中的對應變數命名，如常見的數學實踐所示；這些方程式中的大多數都可以在任意統計文本中找到。

random.**random**()

Return the next random floating-point number in the range `0.0 <= X < 1.0`

random.**uniform**(*a*, *b*)

Return a random floating-point number *N* such that `a <= N <= b` for `a <= b` and `b <= N <= a` for `b < a`.

終點值 `b` 可能包含在範圍🄵，也可能不包含在範圍🄵，取🄵於運算式 `a + (b-a) * random()` 中的浮點舍入。

random.**triangular**(*low*, *high*, *mode*)

Return a random floating-point number *N* such that `low <= N <= high` and with the specified *mode* between those bounds. The *low* and *high* bounds default to zero and one. The *mode* argument defaults to the midpoint between the bounds, giving a symmetric distribution.

random.**betavariate**(*alpha*, *beta*)

Beta（貝它）分布。參數的條件🄵 `alpha > 0` 和 `beta > 0`。回傳值的範圍介於 0 和 1 之間。

random.**expovariate**(*lambd=1.0*)

指數分🄵。*lambd* 🄵 1.0 除以所需的平均數。它應該不🄵零。（該參數將被稱🄵"lambda"，但這是 Python 中的保留字）如果 *lambd* 🄵正，則回傳值的範圍從 0 到正無窮大；如果 *lambd* 🄵負，則回傳值的範圍從負無窮大到 0。

在 3.12 版的變更: 新增 `lambd` 的預設值。

random.**gammavariate**(*alpha*, *beta*)

Gamma（伽瑪）分🄵。（不是 Gamma 函式！）。形狀 (shape) 和比例 (scale) 參數 *alpha* 和 *beta* 必須具有正值。（根據呼叫習慣不同，部分來源會將'beta' 定義🄵比例的倒數）。

Probability distribution function（機率密度函式）是：

```
            x ** (alpha - 1) * math.exp(-x / beta)
pdf(x) =  --------------------------------------
            math.gamma(alpha) * beta ** alpha
```

random.**gauss**(*mu=0.0*, *sigma=1.0*)

常態分🄵，也稱🄵高斯分🄵。*mu* 是平均數，*sigma* 是標准差。這比下面定義的*normalvariate()* 函式快一點。

多執行緒須注意：當兩個執行緒同時呼叫此函式時，它們可能會收到相同的傳回值。這可以透過三種方式避免。1）讓每個執行緒使用隨機數🄵生器的不同實例。2）在所有呼叫周圍加鎖。3）使用較慢但執行緒安全的*normalvariate()* 函式代替。

在 3.11 版的變更: *mu* 和 *sigma* 現在有預設引數。

random.**lognormvariate**(*mu*, *sigma*)

對數常態分🄵。如果你取此分🄵的自然對數，你將獲得一個具有平均數 *mu* 和標准差 *sigma* 的常態分🄵。*mu* 可以🄵任何值，🄵且 *sigma* 必須大於零。

random.**normalvariate**(*mu=0.0*, *sigma=1.0*)

常態分🄵。*mu* 是平均數，*sigma* 是標准差。

在 3.11 版的變更: *mu* 和 *sigma* 現在有預設引數。

random.**vonmisesvariate**(*mu*, *kappa*)

mu 是平均角度，以 0 到 2**pi* 之間的弧度表示，*kappa* 是濃度參數，必須大於或等於零。如果 *kappa* 等於零，則此分🄵在 0 到 2**pi* 的範圍🄵將🄵小🄵均🄵的隨機角度。

random.**paretovariate**(*alpha*)

Pareto distribution（柏拉圖分🄵）。*alpha* 是形狀參數。

random.**weibullvariate**(*alpha*, *beta*)

Weibull distribution（韋伯分🄵）。*alpha* 是比例參數，*beta* 是形狀參數。

9.6.7 替代🄵生器

class random.**Random**([*seed*])

實現*random* 模組使用的預設🄵隨機數🄵生器的 class。

在 3.11 版的變更: 過去 *seed* 可以是任何可雜🄵物件，但現在必須是以下類型之一：None、*int*、*float*、*str*、*bytes*、*bytearray*。

如果 Random 的子類🄵希望使用不同的基礎🄵生器，則應該覆寫以下方法：

seed(*a=None*, *version=2*)

在子類🄵中覆寫此方法以自訂 Random 實例的*seed()* 行🄵。

getstate()

在子類🄵中覆寫此方法以自訂 Random 實例的*getstate()* 行🄵。

setstate(*state*)

在子類🄵中覆寫此方法以自訂 Random 實例的*setstate()* 行🄵。

random()

在子類🄵中覆寫此方法以自訂 Random 實例的*random()* 行🄵。

或者，自訂🄵生器子類🄵還可以提供以下方法：

getrandbits(*k*)

在子類🄵中覆寫此方法以自訂 Random 實例的*getrandbits()* 行🄵。

class random.**SystemRandom**([*seed*])

使用*os.urandom()* 函式從作業系統提供的來源🄵生隨機數的 Class。🄵非在所有系統上都可用。不依賴於軟體狀態，🄵且序列不可復現。因此*seed()* 方法🄵有效果且被忽略。如果呼叫*getstate()* 和*setstate()* 方法會引發*NotImplementedError*。

9.6.8 關於 Reproducibility（複現性）的注意事項

有時，能🄵重現🄵隨機數🄵生器給出的序列很有用。只要多執行緒未運行，透過重🄵使用種子值，同一序列就應該可以被復現。

大多數隨機 module 的演算法和 seed 設定函式在 Python 版本中可能會發生變化，但可以保證兩個方面不會改變：

- 如果增加了新的 seed 設定函式，則將提供向後相容的播種器 (seeder)。
- 當相容的播種器被賦予相同的種子時，🄵生器的*random()* 方法將持續🄵生相同的序列。

9.6.9 范例

基礎範例：

```
>>> random()                            # Random float:  0.0 <= x < 1.0
0.37444887175646646

>>> uniform(2.5, 10.0)                  # Random float:  2.5 <= x <= 10.0
3.1800146073117523

>>> expovariate(1 / 5)                  # Interval between arrivals averaging 5 seconds
5.148957571865031
```

(繼續下一頁)

(繼續上一頁)

```
>>> randrange(10)                       # Integer from 0 to 9 inclusive
7

>>> randrange(0, 101, 2)                # Even integer from 0 to 100 inclusive
26

>>> choice(['win', 'lose', 'draw'])     # Single random element from a sequence
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck)                       # Shuffle a list
>>> deck
['four', 'two', 'ace', 'three']

>>> sample([10, 20, 30, 40, 50], k=4) # Four samples without replacement
[40, 10, 50, 30]
```

模擬：

```
>>> # Six roulette wheel spins (weighted sampling with replacement)
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck
>>> # of 52 playing cards, and determine the proportion of cards
>>> # with a ten-value:  ten, jack, queen, or king.
>>> deal = sample(['tens', 'low cards'], counts=[16, 36], k=20)
>>> deal.count('tens') / 20
0.15

>>> # Estimate the probability of getting 5 or more heads from 7 spins
>>> # of a biased coin that settles on heads 60% of the time.
>>> sum(binomialvariate(n=7, p=0.6) >= 5 for i in range(10_000)) / 10_000
0.4169

>>> # Probability of the median of 5 samples being in middle two quartiles
>>> def trial():
...     return 2_500 <= sorted(choices(range(10_000), k=5))[2] < 7_500
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.7958
```

統計 bootstrapping（自助法）的範例，使用有重置的重新取樣來估計樣本平均數的信賴區間：

```
# https://www.thoughtco.com/example-of-bootstrapping-3126155
from statistics import fmean as mean
from random import choices

data = [41, 50, 29, 37, 81, 30, 73, 63, 20, 35, 68, 22, 60, 31, 95]
means = sorted(mean(choices(data, k=len(data))) for i in range(100))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence '
      f'interval from {means[5]:.1f} to {means[94]:.1f}')
```

重新取樣排列測試的範例，來確定觀察到的藥物與安慰劑之間差🄴的統計學意義或 p 值：

```
# Example from "Statistics is Easy" by Dennis Shasha and Manda Wilson
from statistics import fmean as mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
observed_diff = mean(drug) - mean(placebo)

n = 10_000
count = 0
combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances with a difference')
print(f'at least as extreme as the observed difference of {observed_diff:.1f}.')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the null')
print(f'hypothesis that there is no difference between the drug and the placebo.')
```

模擬多伺服器🄴列 (queue) 的到達時間與服務交付：

```
from heapq import heapify, heapreplace
from random import expovariate, gauss
from statistics import mean, quantiles

average_arrival_interval = 5.6
average_service_time = 15.0
stdev_service_time = 3.5
num_servers = 3

waits = []
arrival_time = 0.0
servers = [0.0] * num_servers  # time when each server becomes available
heapify(servers)
for i in range(1_000_000):
    arrival_time += expovariate(1.0 / average_arrival_interval)
    next_server_available = servers[0]
    wait = max(0.0, next_server_available - arrival_time)
    waits.append(wait)
    service_duration = max(0.0, gauss(average_service_time, stdev_service_time))
    service_completed = arrival_time + wait + service_duration
    heapreplace(servers, service_completed)

print(f'Mean wait: {mean(waits):.1f}   Max wait: {max(waits):.1f}')
print('Quartiles:', [round(q, 1) for q in quantiles(waits)])
```

也參考

Statistics for Hackers 是由 Jake Vanderplas 🄵作的教學影片，僅使用幾個基本概念（包括模擬、取樣、洗牌、交叉驗證）進行統計分析。

Economics Simulation是由 Peter Norvig 對市場進行的模擬，顯示了該模組提供的許多工具和分🄴（高斯、均🄴、樣本、beta 變數、選擇，三角形、隨機數）的有效使用。

機率的具體介紹（使用 Python）🄴 Peter Norvig 的教學課程，涵蓋了機率理論的基礎知識與如何模擬以及

使用 Python 執行數據分析。

9.6.10 使用方案

這些使用方案展示了如何有效地從*itertools* 模組的組合🄵代器 (combinatoric iterators) 中進行隨機選擇：

```
def random_product(*args, repeat=1):
    "Random selection from itertools.product(*args, **kwds)"
    pools = [tuple(pool) for pool in args] * repeat
    return tuple(map(random.choice, pools))

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(range(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Choose r elements with replacement.  Order the result to match the iterable."
    # Result will be in set(itertools.combinations_with_replacement(iterable, r)).
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.choices(range(n), k=r))
    return tuple(pool[i] for i in indices)
```

預設的*random()* 回傳 *0.0* ≤ *x* < *1.0* 範圍🄵 2^{-53} 的倍數。所有數字都是均🄵分🄵的，🄵且可以完全表示🄵 Python float。但是，該間隔中的許多其他可表示的 float 不是可能的選擇。例如 `0.05954861408025609` 不是 2^{-53} 的整數倍。

以下範例🄵用不同的方法。間隔中的所有 float 都是可能的選擇。尾數來自 $2^{52} \le$ *尾數* $< 2^{53}$ 範圍🄵的整數均🄵分🄵。指數來自幾何分🄵，其中小於 *-53* 的指數的出現頻率是下一個較大指數的一半。

```
from random import Random
from math import ldexp

class FullRandom(Random):

    def random(self):
        mantissa = 0x10_0000_0000_0000 | self.getrandbits(52)
        exponent = -53
        x = 0
        while not x:
            x = self.getrandbits(32)
            exponent += x.bit_length() - 32
        return ldexp(mantissa, exponent)
```

Class 中的所有實數分🄵都將使用新方法：

```
>>> fr = FullRandom()
>>> fr.random()
0.05954861408025609
>>> fr.expovariate(0.25)
8.87925541791544
```

該範例在概念上等效於一種演算法，該演算法從 *0.0* ≤ *x* < *1.0* 範圍🄵 2^{-1074} 的所有倍數中進行選擇。這些數字都是均🄵分🄵的，但大多數必須向下舍入到最接近的可表示的 Python float。(2^{-1074} 是最小🄵正的非正規化 float，等於 `math.ulp(0.0)`)

也參考

🄵生🄵隨機浮點值 Allen B. Downey 的一篇論文描述了🄵生比通常由 *random()* 🄵生的 float 更 fine-grained（細粒的）的方法。

9.7 `statistics` --- 數學統計函式

在 3.4 版被加入.

原始碼： Lib/statistics.py

這個模組提供計算數值 (`Real`-valued) 資料的數學統計函式。

這個模組🄵非旨在與 NumPy、SciPy 等第三方函式庫，或者像 Minitab、SAS 和 Matlab 等專門設計給專業統計學家的高階統計軟體互相競🄵。此模組的目標在於繪圖和科學計算。

除非特🄵🄵明，這些函數支援 *int*、*float*、*Decimal* 以及 *Fraction*。目前不支援其他型🄵（無論是否🄵數值型🄵）。含有混合型🄵的資料的集合亦是尚未定義，且取🄵於該型🄵的實作。若你的輸入資料含有混合型🄵，你可以考慮使用 *map()* 來確保結果是一致的，例如：`map(float, input_data)`。

有些資料集使用 `NaN`（非數）來表示缺漏的資料。由於 NaN 具有特殊的比較語義，在排序資料或是統計出現次數的統計函數中，會引發意料之外或是未定義的行🄵。受影響的函數包含 `median()`、`median_low()`、`median_high()`、`median_grouped()`、`mode()`、`multimode()` 以及 `quantiles()`。在呼叫這些函數之前，應該先移除 NaN 值：

```
>>> from statistics import median
>>> from math import isnan
>>> from itertools import filterfalse

>>> data = [20.7, float('NaN'),19.2, 18.3, float('NaN'), 14.4]
>>> sorted(data)  # This has surprising behavior
[20.7, nan, 14.4, 18.3, 19.2, nan]
>>> median(data)  # This result is unexpected
16.35

>>> sum(map(isnan, data))     # Number of missing values
2
>>> clean = list(filterfalse(isnan, data))  # Strip NaN values
>>> clean
[20.7, 19.2, 18.3, 14.4]
>>> sorted(clean)  # Sorting now works as expected
[14.4, 18.3, 19.2, 20.7]
```

(繼續下一頁)

(繼續上一頁)

```
>>> median(clean)       # This result is now well defined
18.75
```

9.7.1 平均值與中央位置量數

這些函式計算來自一個母體或樣本的平均值或代表值。

mean()	資料的算術平均數（平均值）。
fmean()	Fast, floating-point arithmetic mean, with optional weighting.
geometric_mean()	資料的幾何平均數。
harmonic_mean()	資料的調和平均數。
median()	資料的中位數（中間值）。
median_low()	資料中較小的中位數。
median_high()	資料中較大的中位數。
median_grouped()	分組資料的中位數（第 50 百分位數）。
mode()	離散 (discrete) 或名目 (nomial) 資料中的🄵數（出現次數最多次的值），只回傳一個。
multimode()	離散或名目資料中的🄵數（出現次數最多次的值）組成的 list。
quantiles()	將資料分成數個具有相等機率的區間，即分位數 (quantile)。

9.7.2 離度 (spread) 的測量

這些函式計算母體或樣本偏離平均值的程度。

pstdev()	資料的母體標准差。
pvariance()	資料的母體變🄵數。
stdev()	資料的樣本標准差。
variance()	資料的樣本變🄵數。

9.7.3 兩個輸入之間的關🄵統計

這些函式計算兩個輸入之間的關🄴統計數據。

covariance()	兩變數的樣本共變🄵數。
correlation()	Pearson 與 Spearman 相關🄵數 (correlation coefficient)。
linear_regression()	簡單🄵性🄵歸的斜率和截距。

9.7.4 函式細節

🄵：這些函數🄵不要求輸入的資料必須排序過。🄵了🄵讀方便，大部份的範例仍已排序過。

statistics.**mean**(*data*)

回傳 *data* 的樣本算數平均數，輸入可🄵一個 sequence 或者 iterable。

算數平均數🄵資料總和除以資料點的數目。他通常被稱🄵「平均值」，🄵管它只是🄵多不同的數學平均值之一。它是衡量資料集中位置的一種指標。

若 *data* 🄵空，則會引發*StatisticsError*。

使用範例：

```
>>> mean([1, 2, 3, 4, 4])
2.8
>>> mean([-1.0, 2.5, 3.25, 5.75])
2.625

>>> from fractions import Fraction as F
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

備🄵

平均值🄵烈受到離群值 (outliers) 的影響，且不一定能當作這些資料點的典型範例。若要使用更穩健但效率較低的集中趨勢 (central tendency) 度量，請參考*median()*。

樣本平均數提供了對真實母體平均數的不偏估計 (unbiased estimate)，所以從所有可能的樣本中取平均值時，`mean(sample)` 會收斂至整個母體的真實平均值。若 *data* 🄵整個母體而非單一樣本，則 `mean(data)` 等同於計算真實的母體平均數 μ。

statistics.**fmean**(*data*, *weights=None*)

將 *data* 轉🄵🄵浮點數🄵計算其算數平均數。

這個函式運算比*mean()* 更快，🄵且它總是回傳一個*float*。*data* 可以是一個 sequence 或者 iterable。如果輸入的資料🄵空，則引發*StatisticsError*。

```
>>> fmean([3.5, 4.0, 5.25])
4.25
```

支援選擇性的加權。例如，一位教授以 20% 的比重計算小考分數，20% 的比重計算作業分數，30% 的比重計算期中考試分數，以及 30% 的比重計算期末考試分數：

```
>>> grades = [85, 92, 83, 91]
>>> weights = [0.20, 0.20, 0.30, 0.30]
>>> fmean(grades, weights)
87.6
```

如果有提供 *weights*，它必須與 *data* 長度相同，否則將引發*ValueError*。

在 3.8 版被加入.

在 3.11 版的變更: 新增 *weights* 的支援。

statistics.**geometric_mean**(*data*)

將 *data* 轉🄴成浮點數🄴計算其幾何平均數。

幾何平均數使用數值的乘積（與之對照，算數平均數使用的是數值的和）來表示 *data* 的集中趨勢或典型值。

若輸入的資料集🄴空、包含零、包含負值，則引發*StatisticsError*。*data* 可🄴 sequence 或者 iterable。

目前🄴有特🄴🄴了精確結果而特🄴多下什🄴工夫。（然而，未來或許會有。）

```
>>> round(geometric_mean([54, 24, 36]), 1)
36.0
```

在 3.8 版被加入.

statistics.**harmonic_mean**(*data*, *weights=None*)

回傳 *data* 的調和平均數。*data* 可🄴實數 (real-valued) sequence 或者 iterable。如果省略 *weights* 或者 *weights* 🄴 `None`，則假設各權重相等。

調和平均數是資料的倒數 (reciprocal) 經過*mean()* 運算過後的倒數。例如，三個數 *a*，*b* 與 *c* 的調和平均數等於 `3/(1/a + 1/b + 1/c)`。若其中一個值🄴零，結果將🄴零。

調和平均數是一種平均數，是衡量資料中心位置的一種方法。它通常用於計算比率 (ratio) 或率 (rate) 的平均，例如速率（speed）。

假設一輛汽車以時速 40 公里的速率行駛 10 公里，然後再以時速 60 公里的速率行駛 10 公里，求汽車的平均速率?

```
>>> harmonic_mean([40, 60])
48.0
```

假設一輛汽車以時速 40 公里的速率行駛 5 公里，然後在交通順暢時，加速到時速 60 公里，以此速度行駛剩下的 30 公里。求汽車的平均速率?

```
>>> harmonic_mean([40, 60], weights=[5, 30])
56.0
```

若 *data* 🄴空、含有任何小於零的元素、或者加權總和不🄴正數，則引發*StatisticsError*。

目前的演算法設計🄴，若在輸入當中遇到零，則會提前退出。這意味著後續的輸入🄴未進行有效性檢查。（這種行🄴在未來可能會改變。）

在 3.6 版被加入.

在 3.10 版的變更: 新增 *weights* 的支援。

statistics.**median**(*data*)

使用常見的「中間兩數取平均」方法回傳數值資料的中位數（中間值）。若 *data* 🄴空，則會引發*StatisticsError*。*data* 可🄴一個 sequence 或者 iterable。

中位數是一種穩健的衡量資料中心位置的方法，較不易被離群值影響。當資料點數量🄴奇數時，會回傳中間的資料點:

```
>>> median([1, 3, 5])
3
```

當資料點數量🄴偶數時，中位數透過中間兩個值的平均數來插值計算:

```
>>> median([1, 3, 5, 7])
4.0
```

若你的資料🄵離散資料，🄵且你不介意中位數可能🄵非真實的資料點，那這函式適合你。

若你的資料🄵順序 (ordinal) 資料（支援排序操作）但🄵非數值型（不支援加法），可以考慮改用*median_low()* 或是*median_high()* 代替。

statistics.**median_low**(*data*)

回傳數值型資料的低中位數 (low median)。若 *data* 🄵空，則引發*StatisticsError*。*data* 可🄵 sequence 或者 iterable。

低中位數一定會在原本的資料集當中。當資料點數量🄵奇數時，回傳中間值。當數量🄵偶數時，回傳兩個中間值當中較小的值。

```
>>> median_low([1, 3, 5])
3
>>> median_low([1, 3, 5, 7])
3
```

當你的資料🄵離散資料，且你希望中位數是實際的資料點而不是插值時，可以用低中位數。

statistics.**median_high**(*data*)

回傳數值型資料的高中位數 (high median)。若 *data* 🄵空，則引發*StatisticsError*。*data* 可🄵 sequence 或者 iterable。

高中位數一定會在原本的資料集當中。當資料點數量🄵奇數時，回傳中間值。當數量🄵偶數時，回傳兩個中間值當中較大的值。

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

當你的資料🄵離散資料，且你希望中位數是實際的資料點而不是插值時，可以用高中位數。

statistics.**median_grouped**(*data*, *interval=1.0*)

Estimates the median for numeric data that has been grouped or binned around the midpoints of consecutive, fixed-width intervals.

The *data* can be any iterable of numeric data with each value being exactly the midpoint of a bin. At least one value must be present.

The *interval* is the width of each bin.

For example, demographic information may have been summarized into consecutive ten-year age groups with each group being represented by the 5-year midpoints of the intervals:

```
>>> from collections import Counter
>>> demographics = Counter({
...    25: 172,   # 20 to 30 years old
...    35: 484,   # 30 to 40 years old
...    45: 387,   # 40 to 50 years old
...    55:  22,   # 50 to 60 years old
...    65:   6,   # 60 to 70 years old
... })
...
```

The 50th percentile (median) is the 536th person out of the 1071 member cohort. That person is in the 30 to 40 year old age group.

The regular *median()* function would assume that everyone in the tricenarian age group was exactly 35 years old. A more tenable assumption is that the 484 members of that age group are evenly distributed between 30 and 40. For that, we use *median_grouped()*:

```
>>> data = list(demographics.elements())
>>> median(data)
35
>>> round(median_grouped(data, interval=10), 1)
37.5
```

The caller is responsible for making sure the data points are separated by exact multiples of *interval*. This is essential for getting a correct result. The function does not check this precondition.

Inputs may be any numeric type that can be coerced to a float during the interpolation step.

statistics.**mode**(*data*)

回傳離散或名目 *data* 中出現次數最多次的值，只回傳一個。🄵數（如果存在）是最典型的值，🄵用來衡量資料的中心位置。

若有多個出現次數相同的🄵數，則回傳在 *data* 中最先出現的🄵數。如果希望回傳其中最小或最大的🄵數，可以使用 `min(multimode(data))` 或 `max(multimode(data))`。如果輸入的 *data* 🄵空，則會引發*StatisticsError*。

`mode` 假定🄵離散資料，🄵回傳單一的值。這也是一般學校教授的標準🄵數定義：

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

🄵數特🄵之處在於它是此套件中唯一也適用於名目（非數值型）資料的統計量：

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
'red'
```

Only hashable inputs are supported. To handle type *set*, consider casting to *frozenset*. To handle type *list*, consider casting to *tuple*. For mixed or nested inputs, consider using this slower quadratic algorithm that only depends on equality tests: `max(data, key=data.count)`.

在 3.8 版的變更: 現在，遇到資料中有多個🄵數時，會回傳第一個遇到的🄵數。在以前，當找到大於一個🄵數時，會引發*StatisticsError*。

statistics.**multimode**(*data*)

回傳一個 list，其組成🄵 *data* 中出現次數最多次的值，🄵按照它們在 *data* 中首次出現的順序排列。如果有多個🄵數，將會回傳所有結果。若 *data* 🄵空，則回傳空的 list：

```
>>> multimode('aabbbbccddddeeffffgg')
['b', 'd', 'f']
>>> multimode('')
[]
```

在 3.8 版被加入.

statistics.**pstdev**(*data*, *mu=None*)

回傳母體標准差（即母體變🄵數的平方根）。有關引數以及其他細節，請參見*pvariance()*。

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

statistics.**pvariance**(*data*, *mu=None*)

回傳 *data* 的母體變🄵數。*data* 可🄵非空實數 sequence 或者 iterable。變🄵數，或者以平均數🄵中心的二階動差，用於衡量資料的變🄵性（離度或分散程度）。變🄵數大表示資料分散，變🄵數小表示資料集中在平均數附近。

若有傳入選擇性的第二個引數 *mu*，該引數應該要是 *data* 的母體平均值 (population mean)。它也可以用於計算非以平均值🄵中心的第二動差。如果🄵有傳入此引數或者引數🄵 `None` （預設值），則自動計算資料的算數平均數。

使用此函式來計算整個母體的變🄵數。如果要從樣本估算變🄵數，*variance()* 通常是較好的選擇。

若 *data* 🄵空，則引發*StatisticsError*。

範例：

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75, 3.25]
>>> pvariance(data)
1.25
```

如果已經計算出資料的平均值，你可以將其作🄵選擇性的第二個引數 *mu* 傳遞以避免重新計算：

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

支援小數 (decimal) 與分數 (fraction)：

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('24.815')

>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

備🄵

當在整個母體上呼叫此函式時，會回傳母體變🄵數 σ^2。當在樣本上呼叫此函式時，會回傳有偏差的樣本變🄵數 s^2，也就是具有 N 個自由度的變🄵數。

若你以某種方式知道真正的母體平均數 μ，你可以將一個已知的母體平均數作🄵第二個引數提供給此函式，用以計算樣本的變🄵數。只要資料點是母體的隨機樣本，結果將是母體變🄵數的不偏估計。

`statistics.`**`stdev`**(*data*, *xbar=None*)

回傳樣本標准差（即樣本變🄵數的平方根）。有關引數以及其他細節，請參見*variance()*。

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

`statistics.`**`variance`**(*data*, *xbar=None*)

回傳 *data* 的樣本變🄵數。*data* 🄵兩個值以上的實數 iterable。變🄵數，或者以平均數🄵中心的二階動差，用於衡量資料的變🄵性（離度或分散程度）。變🄵數大表示資料分散，變🄵數小表示資料集中在平均數附近。

若有傳入選擇性的第二個引數 *xbar*，它應該是 *data* 的樣本平均值 (sample mean)。如果🄵有傳入或者🄵 `None` （預設值），則自動計算資料的平均值。

當你的資料是來自母體的樣本時，請使用此函式。若要從整個母體計算變🄵數，請參見*pvariance()*。

若 *data* 🄵少於兩個值，則引發*StatisticsError*。

範例：

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> variance(data)
1.3720238095238095
```

如果已經計算出資料的樣本平均值，你可以將其作🄵選擇性的第二個引數 *mu* 傳遞以避免重新計算：

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

此函式不會驗證你傳入的 *xbar* 是否🄵實際的平均數。傳入任意的 *xbar* 會導致無效或不可能的結果。

支援小數 (decimal) 與分數 (fraction)：

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('31.01875')

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

備🄵

這是經過 Bessel 校正 (Bessel's correction) 後的樣本變🄵數 s^2，又稱🄵自由度🄵 N-1 的變🄵數。只要資料點具有代表性（例如：獨立且具有相同分布），結果應該會是對真實母體變🄵數的不偏估計。

若你剛好知道真正的母體平均數 μ，你應該將其作🄵 *mu* 參數傳入*pvariance()* 函式來計算樣本變🄵數。

statistics.**quantiles**(*data*, *, *n=4*, *method='exclusive'*)

將 *data* 分成 *n* 個具有相等機率的連續區間。回傳一個包含 `n - 1` 個用於切分各區間的分隔點的 list。

將 *n* 設🄵 4 以表示四分位數 (quartile)（預設值）。將 *n* 設置🄵 100 表示百分位數 (percentile)，這將給出 99 個分隔點將 *data* 分成 100 個大小相等的組。如果 *n* 不是至少🄵 1，則引發*StatisticsError*。

data 可以是包含樣本資料的任何 iterable。🄵了取得有意義的結果，*data* 中的資料點數量應大於 *n*。如果資料點少於兩個，則引發*StatisticsError*。

分隔點是從兩個最近的資料點🄵性🄵插值計算出來的。舉例來🄵，如果分隔點落在兩個樣本值 `100` 與 `112` 之間的距離三分之一處，則分隔點的值將🄵 `104`。

計算分位數的 *method* 可以根據 *data* 是否包含或排除來自母體的最小與最大可能的值而改變。

預設的 *method* 是"exclusive"，用於從可能找到比樣本更極端的值的母體中抽樣的樣本資料。對於 *m* 個已排序的資料點，計算出低於 *i-th* 的部分🄵 `i / (m + 1)`。給定九個樣本資料，此方法將對資料排序且計算下列百分位數：10%、20%、30%、40%、50%、60%、70%、80%、90%。

若將 *method* 設🄵"inclusive"，則用於描述母體或者已知包含母體中最極端值的樣本資料。在 *data* 中的最小值被視🄵第 0 百分位數，最大值🄵第 100 百分位數。對於 *m* 個已排序的資料點，計算出低於 *i-th* 的部分🄵 `(i - 1) / (m - 1)`。給定十一個個樣本資料，此方法將對資料排序且計算下列百分位數：0%、10%、20%、30%、40%、50%、60%、70%、80%、90%、100%。

```
# Decile cut points for empirically sampled data
>>> data = [105, 129, 87, 86, 111, 111, 89, 81, 108, 92, 110,
...         100, 75, 105, 103, 109, 76, 119, 99, 91, 103, 129,
...         106, 101, 84, 111, 74, 87, 86, 103, 103, 106, 86,
```

(繼續下一頁)

(繼續上一頁)

```
...          111, 75, 87, 102, 121, 111, 88, 89, 101, 106, 95,
...          103, 107, 101, 81, 109, 104]
>>> [round(q, 1) for q in quantiles(data, n=10)]
[81.0, 86.2, 89.0, 99.4, 102.5, 103.6, 106.0, 109.8, 111.0]
```

在 3.8 版被加入.

statistics.**covariance**(*x*, *y*, */*)

回傳兩輸入 *x* 與 *y* 的樣本共變𝔽數 (sample covariance)。共變𝔽數是衡量兩輸入的聯合變𝔽性 (joint variability) 的指標。

兩輸入必須具有相同長度（至少兩個），否則會引發*StatisticsError*。

範例：

```
>>> x = [1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> y = [1, 2, 3, 1, 2, 3, 1, 2, 3]
>>> covariance(x, y)
0.75
>>> z = [9, 8, 7, 6, 5, 4, 3, 2, 1]
>>> covariance(x, z)
-7.5
>>> covariance(z, x)
-7.5
```

在 3.10 版被加入.

statistics.**correlation**(*x*, *y*, */*, ***, *method='linear'*)

回傳兩輸入的 Pearson 相關𝔽數 (Pearson's correlation coefficient)。Pearson 相關𝔽數 *r* 的值介於 -1 與 +1 之間。它衡量𝔽性關𝔽的𝔽度與方向。

如果 *method* 𝔽"ranked", 則計算兩輸入的 Spearman 等級相關𝔽數 (Spearman's rank correlation coefficient)。資料將被取代𝔽等級。平手的情𝔽則取平均, 令相同的值排名也相同。所得𝔽數衡量單調關𝔽 (monotonic relationship) 的𝔽度。

Spearman 相關𝔽數適用於順序型資料，或者不符合 Pearson 相關𝔽數要求的𝔽性比例關𝔽的連續型 (continuous) 資料。

兩輸入必須具有相同長度（至少兩個），且不須𝔽常數，否則會引發*StatisticsError*。

以 Kepler 行星運動定律𝔽例：

```
>>> # Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and  Neptune
>>> orbital_period = [88, 225, 365, 687, 4331, 10_756, 30_687, 60_190]    # days
>>> dist_from_sun = [58, 108, 150, 228, 778, 1_400, 2_900, 4_500] # million km

>>> # Show that a perfect monotonic relationship exists
>>> correlation(orbital_period, dist_from_sun, method='ranked')
1.0

>>> # Observe that a linear relationship is imperfect
>>> round(correlation(orbital_period, dist_from_sun), 4)
0.9882

>>> # Demonstrate Kepler's third law: There is a linear correlation
>>> # between the square of the orbital period and the cube of the
>>> # distance from the sun.
>>> period_squared = [p * p for p in orbital_period]
```

(繼續下一頁)

(繼續上一頁)

```
>>> dist_cubed = [d * d * d for d in dist_from_sun]
>>> round(correlation(period_squared, dist_cubed), 4)
1.0
```

在 3.10 版被加入.

在 3.12 版的變更: 新增了對 Spearman 等級相關🄵數的支援。

statistics.**linear_regression**(*x*, *y*, */*, ***, *proportional=False*)

回傳使用普通最小平方法 (ordinary least square) 估計出的簡單🄵性🄵歸 (simple linear regression) 參數中的斜率 (slope) 與截距 (intercept)。簡單🄵性🄵歸描述自變數 (independent variable) *x* 與應變數 (dependent variable) *y* 之間的關🄵，用以下的🄵性函式表示：

y = *slope* * *x* + *intercept* + *noise*

其中 `slope` 和 `intercept` 是被估計的🄵歸參數，而 `noise` 表示由🄵性🄵歸未解釋的資料變🄵性（它等於應變數的預測值與實際值之差）。

兩輸入必須具有相同長度（至少兩個），且自變數 *x* 不得🄵常數，否則會引發*StatisticsError*。

舉例來🄵，我們可以使用 Monty Python 系列電影的上映日期來預測至 2019 年🄵止，假設他們保持固定的🄵作速度，應該會🄵生的 Monty Python 電影的累計數量。

```
>>> year = [1971, 1975, 1979, 1982, 1983]
>>> films_total = [1, 2, 3, 4, 5]
>>> slope, intercept = linear_regression(year, films_total)
>>> round(slope * 2019 + intercept)
16
```

若將 *proportional* 設🄵 True，則假設自變數 *x* 與應變數 *y* 是直接成比例的，資料座落在通過原點的一直🄵上。由於 *intercept* 始終🄵 0.0，因此🄵性函式可簡化如下：

y = *slope* * *x* + *noise*

繼續*correlation()* 中的範例，我們看看基於主要行星的模型可以如何很好地預測矮行星的軌道距離：

```
>>> model = linear_regression(period_squared, dist_cubed, proportional=True)
>>> slope = model.slope

>>> # Dwarf planets:   Pluto,  Eris,    Makemake, Haumea, Ceres
>>> orbital_periods = [90_560, 204_199, 111_845, 103_410, 1_680]  # days
>>> predicted_dist = [math.cbrt(slope * (p * p)) for p in orbital_periods]
>>> list(map(round, predicted_dist))
[5912, 10166, 6806, 6459, 414]

>>> [5_906, 10_152, 6_796, 6_450, 414]  # actual distance in million km
[5906, 10152, 6796, 6450, 414]
```

在 3.10 版被加入.

在 3.11 版的變更: 新增 *proportional* 的支援。

9.7.5 例外

定義了一個單一的例外：

exception statistics.**StatisticsError**

ValueError 的子類🄵，用於和統計相關的例外。

9.7.6 NormalDist 物件

NormalDist 是一種用於建立與操作隨機變數 (random variable) 的常態分布的工具。它是一個將量測資料的平均數與標准差視🄵單一實體的類🄵。

常態分布源自於中央極限定理 (Central Limit Theorem)，在統計學中有著廣泛的應用。

class statistics.**NormalDist**(*mu=0.0*, *sigma=1.0*)

此方法會回傳一個新 *NormalDist* 物件，其中 *mu* 代表算數平均數而 *sigma* 代表標准差。

若 *sigma* 🄵負值，則引發 *StatisticsError*。

mean

常態分布中的算數平均數唯讀屬性。

median

常態分布中的中位數唯讀屬性。

mode

常態分布中的🄵數唯讀屬性。

stdev

常態分布中的標准差唯讀屬性。

variance

常態分布中的變🄵數唯讀屬性。

classmethod from_samples(*data*)

利用 *fmean()* 與 *stdev()* 函式，估計 *data* 的 *mu* 與 *sigma* 參數，建立一個常態分布的實例。

data 可以是任何*iterable*，🄵應包含可以轉🄵🄵 *float* 的值。若 *data* 🄵有包含至少兩個以上的元素在🄵，則引發 *StatisticsError*，因🄵至少需要一個點來估計中央值且至少需要兩個點來估計分散情形。

samples(*n*, *, *seed=None*)

給定平均值與標准差，🄵生 *n* 個隨機樣本。回傳一個由 *float* 組成的 *list*。

若有給定 *seed*，則會建立一個以此🄵基礎的亂數🄵生器實例。這對於建立可重現的結果很有幫助，即使在多執行緒情境下也是如此。

pdf(*x*)

利用機率密度函數 (probability density function, pdf) 計算隨機變數 *X* 接近給定值 *x* 的相對概度 (relative likelihood)。數學上，它是比率 `P(x <= X < x+dx) / dx` 在 *dx* 趨近於零時的極限值。

相對概度是樣本出現在狹窄範圍的機率，除以該範圍的寬度（故稱🄵「密度」）計算而得。由於概度是相對於其它點，故其值可大於 `1.0`。

cdf(*x*)

利用累積分布函式 (cumulative distribution function, cdf) 計算隨機變數 *X* 小於或等於 *x* 的機率。數學上，它記🄵 `P(X <= x)`。

inv_cdf(*p*)

計算反累計分布函式 (inverse cumulative distribution function)，也稱🄵分位數函式 (quantile function) 或者百分率點 (percent-point) 函式。數學上記🄵 `x : P(X <= x) = p`。

找出一個值 *x*，使得隨機變數 *X* 小於或等於該值的機率等於給定的機率 *p*。

overlap(*other*)

衡量兩常態分布之間的一致性。回傳一個介於 0.0 與 1.0 之間的值，表示兩機率密度函式的重🄵區域。

quantiles(*n=4*)

將常態分布分割成 *n* 個具有相等機率的連續區間。回傳一個 list，包含 (n-1) 個切割區間的分隔點。

將 *n* 設定🄵 4 表示四分位數（預設值）。將 *n* 設定🄵 10 表示十分位數。將 *n* 設定🄵 100 表示百分位數，這會🄵生 99 個分隔點，將常態分布切割成大小相等的群組。

zscore(*x*)

計算標准分數 (Standard Score)，用以描述在常態分布中，*x* 高出或低於平均數幾個標准差：`(x - mean) / stdev`。

在 3.9 版被加入.

NormalDist 的實例支援對常數的加法、🄵法、乘法與除法。這些操作用於平移與縮放。例如：

```
>>> temperature_february = NormalDist(5, 2.5)             # Celsius
>>> temperature_february * (9/5) + 32                     # Fahrenheit
NormalDist(mu=41.0, sigma=4.5)
```

不支援將常數除以*NormalDist* 的實例，因🄵結果將不符合常態分布。

由於常態分布源自於自變數的加法效應 (additive effects)，因此可以將兩個獨立的常態分布隨機變數相加與相🄵，🄵且表示🄵*NormalDist* 的實例。例如：

```
>>> birth_weights = NormalDist.from_samples([2.5, 3.1, 2.1, 2.4, 2.7, 3.5])
>>> drug_effects = NormalDist(0.4, 0.15)
>>> combined = birth_weights + drug_effects
>>> round(combined.mean, 1)
3.1
>>> round(combined.stdev, 1)
0.5
```

在 3.8 版被加入.

9.7.7 范例與錦囊妙計

經典機率問題

NormalDist 可以輕易地解🄵經典的機率問題。

例如，給定 SAT 測驗的歷史資料，顯示成績🄵平均 1060、標准差 195 的常態分布。我們要求出分數在 1100 與 1200 之間（四舍五入至最接近的整數）的學生的百分比：

```
>>> sat = NormalDist(1060, 195)
>>> fraction = sat.cdf(1200 + 0.5) - sat.cdf(1100 - 0.5)
>>> round(fraction * 100.0, 1)
18.4
```

找出 SAT 分數的四分位數以及十分位數：

```
>>> list(map(round, sat.quantiles()))
[928, 1060, 1192]
>>> list(map(round, sat.quantiles(n=10)))
[810, 896, 958, 1011, 1060, 1109, 1162, 1224, 1310]
```

用於模擬的蒙地卡羅 (Monte Carlo) 輸入

欲估計一個不易透過解析方法求解的模型的分布，*NormalDist* 可以🄴生輸入樣本以進行蒙地卡羅模擬：

```
>>> def model(x, y, z):
...     return (3*x + 7*x*y - 5*y) / (11 * z)
...
>>> n = 100_000
>>> X = NormalDist(10, 2.5).samples(n, seed=3652260728)
>>> Y = NormalDist(15, 1.75).samples(n, seed=4582495471)
>>> Z = NormalDist(50, 1.25).samples(n, seed=6582483453)
>>> quantiles(map(model, X, Y, Z))
[1.4591308524824727, 1.8035946855390597, 2.175091447274739]
```

近似二項分布

當樣本數量🄴大，且試驗成功的機率接近 50%，可以使用常態分布來近似二項分布 (Binomial distributions)。

例如，一場有 750 位參加者的開源研討會中，有兩間可容納 500 人的會議室。一場是關於 Python 的講座，另一場則是關於 Ruby 的。在過去的會議中，有 65% 的參加者傾向參與 Python 講座。假設參與者的偏好🄴有改變，那🄵 Python 會議室未超過自身容量限制的機率是？

```
>>> n = 750             # Sample size
>>> p = 0.65            # Preference for Python
>>> q = 1.0 - p         # Preference for Ruby
>>> k = 500             # Room capacity

>>> # Approximation using the cumulative normal distribution
>>> from math import sqrt
>>> round(NormalDist(mu=n*p, sigma=sqrt(n*p*q)).cdf(k + 0.5), 4)
0.8402

>>> # Exact solution using the cumulative binomial distribution
>>> from math import comb, fsum
>>> round(fsum(comb(n, r) * p**r * q**(n-r) for r in range(k+1)), 4)
0.8402

>>> # Approximation using a simulation
>>> from random import seed, binomialvariate
>>> seed(8675309)
>>> mean(binomialvariate(n, p) <= k for i in range(10_000))
0.8406
```

單純貝氏分類器 (Naive bayesian classifier)

常態分布常在機器學習問題中出現。

維基百科有個 Naive Bayesian Classifier 的優良範例。課題🄴從身高、體重與鞋子尺寸等符合常態分布的特徵量測值中判斷一個人的性🄴。

給定一組包含八個人的量測值的訓練資料集。假設這些量測值服從常態分布，我們可以利用*NormalDist* 來總結資料：

```
>>> height_male = NormalDist.from_samples([6, 5.92, 5.58, 5.92])
>>> height_female = NormalDist.from_samples([5, 5.5, 5.42, 5.75])
>>> weight_male = NormalDist.from_samples([180, 190, 170, 165])
>>> weight_female = NormalDist.from_samples([100, 150, 130, 150])
>>> foot_size_male = NormalDist.from_samples([12, 11, 12, 10])
>>> foot_size_female = NormalDist.from_samples([6, 8, 7, 9])
```

接著，我們遇到一個新的人，他的特徵量測值已知，但性🄴未知：

```
>>> ht = 6.0        # height
>>> wt = 130        # weight
>>> fs = 8          # foot size
```

從可能🄴男性或女性的 50% 先驗機率 (prior probability) 🄵開端，我們將後驗機率 (posterior probability) 計算🄵先驗機率乘以給定性🄴下，各特徵量測值的概度乘積：

```
>>> prior_male = 0.5
>>> prior_female = 0.5
>>> posterior_male = (prior_male * height_male.pdf(ht) *
...                   weight_male.pdf(wt) * foot_size_male.pdf(fs))

>>> posterior_female = (prior_female * height_female.pdf(ht) *
...                     weight_female.pdf(wt) * foot_size_female.pdf(fs))
```

最終的預測結果將取🄴於最大的後驗機率。這被稱🄵最大後驗機率 (maximum a posteriori) 或者 MAP：

```
>>> 'male' if posterior_male > posterior_female else 'female'
'female'
```

核密度估計 (Kernel density estimation)

可以從固定數量的離散樣本估計出連續機率分布。

基本想法是使用一個核函式如常態分布、三角分布或均🄴分布來使資料更加平滑。平滑程度由一個縮放參數 `h` 控制，被稱🄴 *bandwidth*。

```
from random import choice, random

def kde_normal(data, h):
    "Create a continuous probability distribution from discrete samples."

    # Smooth the data with a normal distribution kernel scaled by h.
    K_h = NormalDist(0.0, h)

    def pdf(x):
        'Probability density function.  P(x <= X < x+dx) / dx'
        return sum(K_h.pdf(x - x_i) for x_i in data) / len(data)
```

(繼續下一頁)

(繼續上一頁)

```
    def cdf(x):
        'Cumulative distribution function.  P(X <= x)'
        return sum(K_h.cdf(x - x_i) for x_i in data) / len(data)

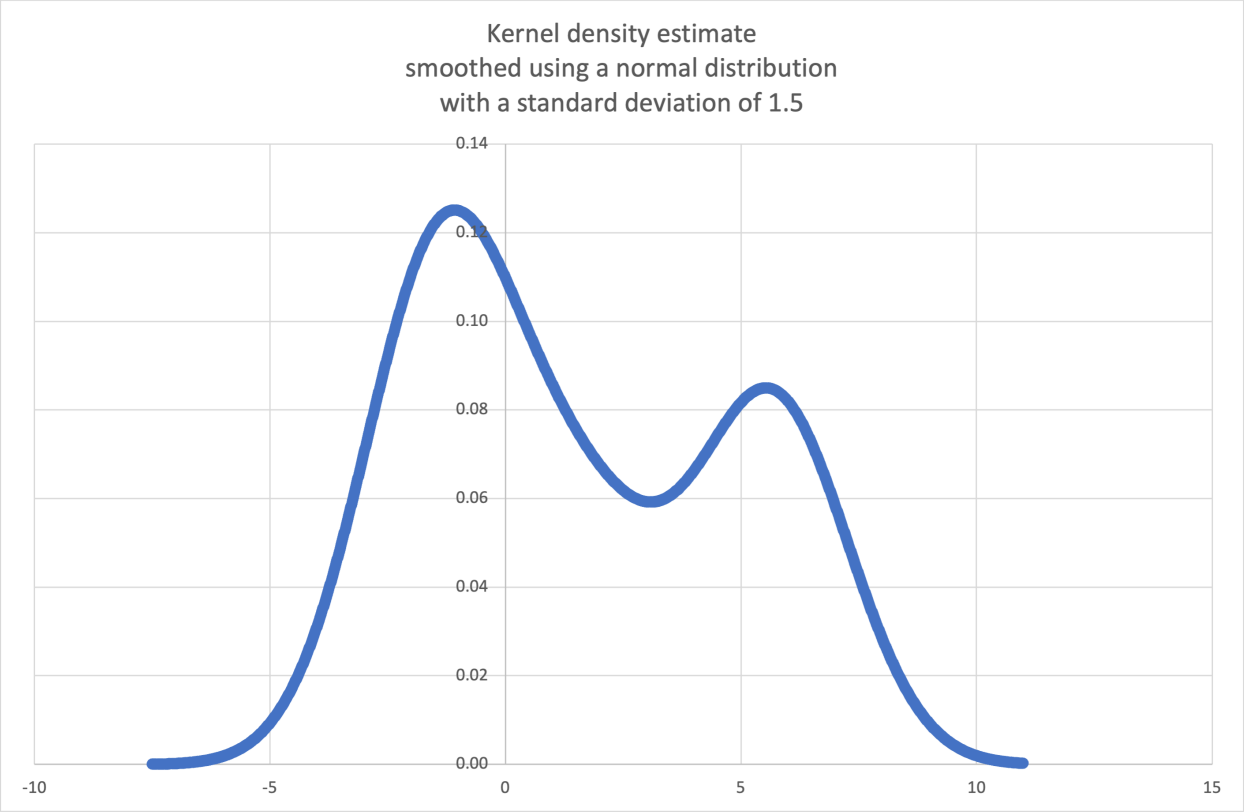
    def rand():
        'Random selection from the probability distribution.'
        return choice(data) + K_h.inv_cdf(random())

    return pdf, cdf, rand
```

維基百科有一個範例，我們可以使用 `kde_normal()` 這個錦囊妙計來生成🄵繪🄵從小樣本估計的機率密度函式：

```
>>> sample = [-2.1, -1.3, -0.4, 1.9, 5.1, 6.2]
>>> pdf, cdf, rand = kde_normal(sample, h=1.5)
>>> xarr = [i/100 for i in range(-750, 1100)]
>>> yarr = [pdf(x) for x in xarr]
```

`xarr` 和 `yarr` 中的點可用於繪🄵 PDF 圖：



Resample the data to produce 100 new selections:

```
>>> new_selections = [rand() for i in range(100)]
```

Determine the probability of a new selection being below `2.0`:

```
>>> round(cdf(2.0), 4)
0.5794
```

Add a new sample data point and find the new CDF at `2.0`:

```
>>> sample.append(4.9)
>>> round(cdf(2.0), 4)
0.5005
```

CHAPTER 10

函式編程模組

The modules described in this chapter provide functions and classes that support a functional programming style, and general operations on callables.

本章包含下列的模組：

10.1 itertools --- 建立🅵生高效率🅵圈之🅵代器的函式

這個模組實作了許多🅵代器 *(iterator)* 構建塊 (building block)，其靈感來自 APL、Haskell 和 SML 的結構。每個構建塊都以適合 Python 的形式來重新設計。

這個模組標准化了快速且高效率利用記憶體的核心工具集，這些工具本身或組合使用都很有用。它們共同構成了一個「🅵代器代數 (iterator algebra)」，使得在純 Python 中簡潔且高效地建構專用工具成🅵可能。

例如，SML 提供了一個造表工具：`tabulate(f)`，它🅵生一個序列 `f(0), f(1), ...`。在 Python 中，可以透過結合*`map()`* 和*`count()`* 組成 `map(f, count())` 以達到同樣的效果。

這些工具及其🅵建的對等部分 (counterpart) 也可以很好地與*`operator`* 模組中的高速函式配合使用。例如，乘法運算子可以對映到兩個向量上以組成高效率的🅵積：`sum(starmap(operator.mul, zip(vec1, vec2, strict=True)))`。

無限🅵代器：

🅵代器	引數	結果	範例
`count()`	[start[, step]]	start, start+step, start+2*step, ...	`count(10) → 10 11 12 13 14 ...`
`cycle()`	p	p0, p1, ... plast, p0, p1, ...	`cycle('ABCD') → A B C D A B C D ...`
`repeat()`	elem [,n]	elem, elem, elem，... 重🅵無限次或 n 次	`repeat(10, 3) → 10 10 10`

在最短輸入序列 (shortest input sequence) 處終止的🄵代器：

🄵代器	引數	結果	範例
accumulate()	p [,func]	p0, p0+p1, p0+p1+p2, ...	`accumulate([1,2,3,4,5]) → 1 3 6 10 15`
batched()	p, n	(p0, p1, ..., p_n-1), ...	`batched('ABCDEFG', n=3) → ABC DEF G`
chain()	p, q, ...	p0, p1, ... plast, q0, q1, ...	`chain('ABC', 'DEF') → A B C D E F`
chain.from_iterable	可🄵代物件	p0, p1, ... plast, q0, q1, ...	`chain.from_iterable(['ABC', 'DEF']) → A B C D E F`
compress()	data, selectors	(d[0] if s[0]), (d[1] if s[1]), ...	`compress('ABCDEF', [1,0,1,0,1,1]) → A C E F`
dropwhile()	predicate, seq	seq[n], seq[n+1], 當 predicate 失敗時開始	`dropwhile(lambda x: x<5, [1,4,6,3,8]) → 6 3 8`
filterfalse()	predicate, seq	當 predicate(elem) 失敗時 seq 的元素	`filterfalse(lambda x: x<5, [1,4,6,3,8]) → 6 8`
groupby()	iterable[, key]	根據 key(v) 的值分組的子🄵代器	
islice()	seq, [start,] stop [, step]	seq[start:stop:step] 的元素	`islice('ABCDEFG', 2, None) → C D E F G`
pairwise()	可🄵代物件	(p[0], p[1]), (p[1], p[2])	`pairwise('ABCDEFG') → AB BC CD DE EF FG`
starmap()	func, seq	func(*seq[0]), func(*seq[1]), ...	`starmap(pow, [(2,5), (3,2), (10,3)]) → 32 9 1000`
takewhile()	predicate, seq	seq[0], seq[1], 直到 predicate 失敗	`takewhile(lambda x: x<5, [1,4,6,3,8]) → 1 4`
tee()	it, n	it1, it2, ... itn，將一個🄵代器分成 n 個	
zip_longest()	p, q, ...	(p[0], q[0]), (p[1], q[1]), ...	`zip_longest('ABCD', 'xy', fillvalue='-') → Ax By C- D-`

組合🄵代器：

🄵代器	引數	結果
product()	p, q, ... [repeat=1]	笛卡爾乘積 (cartesian product)，相當於巢狀的 for 🄵圈
permutations()	p[, r]	長度🄵 r 的元組，所有可能的定序，無重🄵元素
combinations()	p, r	長度🄵 r 的元組，按照排序過後的定序，無重🄵元素
combinations_with_replacement	p, r	長度🄵 r 的元組，按照排序過後的定序，有重🄵元素

範例	結果
`product('ABCD', repeat=2)`	`AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD`
`permutations('ABCD', 2)`	`AB AC AD BA BC BD CA CB CD DA DB DC`
`combinations('ABCD', 2)`	`AB AC AD BC BD CD`
`combinations_with_replacement('ABCD 2)`	`AA AB AC AD BB BC BD CC CD DD`

10.1.1 Itertool 函式

以下的模組函式都會建構🄴回傳🄴代器。一些函式提供無限長度的串流 (stream)，因此應僅由截斷串流的函式或🄵圈來存取它們。

itertools.**accumulate**(*iterable*[, *function*, *, *initial=None*])

建立一個回傳累積和的🄴代器，或其他二進位函式的累積結果。

function 預設🄴加法。*function* 應接受兩個引數，即累積總和和來自 *iterable* 的值。

如果提供了 *initial* 值，則累積將從該值開始，🄴且輸出的元素數將比輸入的可🄴代物件多一個。

大致等價於：

```
def accumulate(iterable, function=operator.add, *, initial=None):
    'Return running totals'
    # accumulate([1,2,3,4,5]) → 1 3 6 10 15
    # accumulate([1,2,3,4,5], initial=100) → 100 101 103 106 110 115
    # accumulate([1,2,3,4,5], operator.mul) → 1 2 6 24 120

    iterator = iter(iterable)
    total = initial
    if initial is None:
        try:
            total = next(iterator)
        except StopIteration:
            return

    yield total
    for element in iterator:
        total = function(total, element)
        yield total
```

function 引數可以被設定🄴*min()* 以得到連續的最小值，設定🄴*max()* 以得到連續的最大值，或者設定🄴*operator.mul()* 以得到連續的乘積。也可以透過累積利息和付款來建立攤銷表 (Amortization tables)：

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
>>> list(accumulate(data, max))                # running maximum
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]
>>> list(accumulate(data, operator.mul))       # running product
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]

# Amortize a 5% loan of 1000 with 10 annual payments of 90
>>> update = lambda balance, payment: round(balance * 1.05) - payment
>>> list(accumulate(repeat(90, 10), update, initial=1_000))
[1000, 960, 918, 874, 828, 779, 728, 674, 618, 559, 497]
```

可參見*functools.reduce()*，其是個類似的函式，但僅回傳最終的累積值。

在 3.2 版被加入.

在 3.3 版的變更: 新增可選的 *function* 參數。

在 3.8 版的變更: 新增可選的 *initial* 參數。

itertools.**batched**(*iterable*, *n*)

將來自 *iterable* 的資料分批🄴長度🄴 *n* 的元組。最後一個批次可能比 *n* 短。

對輸入的可🄴代物件進行🄵圈，🄵將資料累積到大小🄴 *n* 的元組中。輸入是惰性地被消耗 (consumed lazily) 的，會剛好足🄴填充一批的資料。一旦批次填滿或輸入的可🄴代物件耗盡，就會 yield 出結果：

```
>>> flattened_data = ['roses', 'red', 'violets', 'blue', 'sugar', 'sweet']
>>> unflattened = list(batched(flattened_data, 2))
>>> unflattened
[('roses', 'red'), ('violets', 'blue'), ('sugar', 'sweet')]
```

大致等價於:

```
def batched(iterable, n):
    # batched('ABCDEFG', 3) → ABC DEF G
    if n < 1:
        raise ValueError('n must be at least one')
    iterator = iter(iterable)
    while batch := tuple(islice(iterator, n)):
        yield batch
```

在 3.12 版被加入.

itertools.**chain**(**iterables*)

建立一個🄴代器，從第一個可🄵代物件回傳元素直到其耗盡，然後繼續處理下一個可🄵代物件，直到所有可🄵代物件都耗盡。用於將連續的序列做🄵單一序列處理。大致等價於:

```
def chain(*iterables):
    # chain('ABC', 'DEF') → A B C D E F
    for iterable in iterables:
        yield from iterable
```

classmethod chain.**from_iterable**(*iterable*)

chain() 的另一個建構函式。從單個可🄴代的引數中得到鏈接的輸入，該引數是惰性計算的。大致等價於:

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) → A B C D E F
    for iterable in iterables:
        yield from iterable
```

itertools.**combinations**(*iterable*, *r*)

從輸入 *iterable* 中回傳長度🄴 *r* 的元素的子序列。

輸出是*product()* 的子序列，僅保留作🄴 *iterable* 子序列的條目。輸出的長度由*math.comb()* 給定，當 `0 ≤ r ≤ n` 時，計算 `n! / r! / (n - r)!`，當 `r > n` 時🄴零。

根據輸入值 *iterable* 的順序，組合的元組會按照字典順序輸出。如果輸入的 *iterable* 已經排序，則輸出的元組也將按排序的順序🄴生。

元素是根據它們的位置（而非值）來🄴定其唯一性。如果輸入的元素都是獨特的，則每個組合🄴將不會有重🄴的值。

大致等價於:

```
def combinations(iterable, r):
    # combinations('ABCD', 2) → AB AC AD BC BD CD
    # combinations(range(4), 3) → 012 013 023 123

    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
```

(繼續下一頁)

(繼續上一頁)

```
    indices = list(range(r))

    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != i + n - r:
                break
        else:
            return
        indices[i] += 1
        for j in range(i+1, r):
            indices[j] = indices[j-1] + 1
        yield tuple(pool[i] for i in indices)
```

itertools.**combinations_with_replacement**(*iterable*, *r*)

回傳來自輸入 *iterable* 的長度🄵 *r* 的子序列，且允許個🄵元素重🄵多次。

其輸出是一個*product()* 的子序列，僅保留作🄵 *iterable* 子序列（可能有重🄵元素）的條目。當 `n > 0` 時，回傳的子序列數量🄵 `(n + r - 1)! / r! / (n - 1)!`。

根據輸入值 *iterable* 的順序，組合的元組會按照字典順序輸出。如果輸入的 *iterable* 已經排序，則輸出的元組也將按排序的順序🄵生。

元素是根據它們的位置（而非值）來🄵定其唯一性。如果輸入的元素都是獨特的，生成的組合也將是獨特的。

大致等價於：

```
def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) → AA AB AC BB BC CC

    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r

    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)
```

在 3.1 版被加入.

itertools.**compress**(*data*, *selectors*)

建立一個🄵代器，回傳 *data* 中對應 *selectors* 的元素🄵真的元素。當 *data* 或 *selectors* 可🄵代物件耗盡時停止。大致等價於：

```
def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) → A C E F
    return (datum for datum, selector in zip(data, selectors) if selector)
```

在 3.1 版被加入.

itertools.**count**(*start=0*, *step=1*)

建立一個🄴代器，回傳從 *start* 開始的等差的值。可以與*map()* 一起使用來🄴生連續的資料點，或與*zip()* 一起使用來增加序列號。大致等價於：

```
def count(start=0, step=1):
    # count(10) → 10 11 12 13 14 ...
    # count(2.5, 0.5) → 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

When counting with floating-point numbers, better accuracy can sometimes be achieved by substituting multiplicative code such as: `(start + step * i for i in count())`.

在 3.1 版的變更: 新增 *step* 引數🄴允許非整數引數。

itertools.**cycle**(*iterable*)

建立一個🄴代器，回傳 *iterable* 中的元素🄴保存每個元素的副本。當可🄴代物件耗盡時，從保存的副本中回傳元素。會無限次的重🄴。大致等價於：

```
def cycle(iterable):
    # cycle('ABCD') → A B C D A B C D A B C D ...
    saved = []
    for element in iterable:
        yield element
        saved.append(element)
    while saved:
        for element in saved:
            yield element
```

此 itertool 可能需要大量的輔助儲存空間（取🄵於可🄴代物件的長度）。

itertools.**dropwhile**(*predicate*, *iterable*)

建立一個🄴代器，在 *predicate* 🄵真時🄵🄴 *iterable* 中的元素，之後回傳每個元素。大致等價於：

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,3,8]) → 6 3 8

    iterator = iter(iterable)
    for x in iterator:
        if not predicate(x):
            yield x
            break

    for x in iterator:
        yield x
```

注意，在 predicate 首次變🄵 False 之前，這不會🄴生任何輸出，所以此 itertool 可能會有較長的🄵動時間。

itertools.**filterfalse**(*predicate*, *iterable*)

建立一個🄴代器，過濾 *iterable* 中的元素，僅回傳 *predicate* 🄵 False 值的元素。如果 *predicate* 是 `None`，則回傳🄵 False 的項目。大致等價於：

```
def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x<5, [1,4,6,3,8]) → 6 8
```

(繼續下一頁)

(繼續上一頁)

```
    if predicate is None:
        predicate = bool
    for x in iterable:
        if not predicate(x):
            yield x
```

itertools.**groupby**(*iterable*, *key=None*)

建立一個🄵代器，回傳 *iterable* 中連續的鍵和群組。*key* 是一個🄵每個元素計算鍵值的函式。如果其未指定或🄵 None，則 *key* 預設🄵一個識🄵性函式 (identity function)，🄵回傳未被更改的元素。一般來🄵，可🄵代物件需要已經用相同的鍵函式進行排序。

groupby() 的操作類似於 Unix 中的 uniq 過濾器。每當鍵函式的值發生變化時，它會🄵生一個 break 或新的群組（這就是🄵什🄵通常需要使用相同的鍵函式對資料進行排序）。這種行🄵不同於 SQL 的 GROUP BY，其無論輸入順序如何都會聚合相同的元素。

回傳的群組本身是一個與*groupby()* 共享底層可🄵代物件的🄵代器。由於來源是共享的，當*groupby()* 物件前進時，前一個群組將不再可見。因此，如果之後需要該資料，應將其儲存🄵串列：

```
groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)
```

groupby() 大致等價於：

```
def groupby(iterable, key=None):
    # [k for k, g in groupby('AAAABBBCCDAABBB')] --> A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] --> AAAA BBB CC D

    keyfunc = (lambda x: x) if key is None else key
    iterator = iter(iterable)
    exhausted = False

    def _grouper(target_key):
        nonlocal curr_value, curr_key, exhausted
        yield curr_value
        for curr_value in iterator:
            curr_key = keyfunc(curr_value)
            if curr_key != target_key:
                return
            yield curr_value
        exhausted = True

    try:
        curr_value = next(iterator)
    except StopIteration:
        return
    curr_key = keyfunc(curr_value)

    while not exhausted:
        target_key = curr_key
        curr_group = _grouper(target_key)
        yield curr_key, curr_group
```

(繼續下一頁)

(繼續上一頁)

```
        if curr_key == target_key:
            for _ in curr_group:
                pass
```

itertools.**islice**(*iterable*, *stop*)

itertools.**islice**(*iterable*, *start*, *stop*[, *step*])

Make an iterator that returns selected elements from the iterable. Works like sequence slicing but does not support negative values for *start*, *stop*, or *step*.

If *start* is zero or `None`, iteration starts at zero. Otherwise, elements from the iterable are skipped until *start* is reached.

If *stop* is `None`, iteration continues until the iterator is exhausted, if at all. Otherwise, it stops at the specified position.

If *step* is `None`, the step defaults to one. Elements are returned consecutively unless *step* is set higher than one which results in items being skipped.

大致等價於:

```
def islice(iterable, *args):
    # islice('ABCDEFG', 2) → A B
    # islice('ABCDEFG', 2, 4) → C D
    # islice('ABCDEFG', 2, None) → C D E F G
    # islice('ABCDEFG', 0, None, 2) → A C E G

    s = slice(*args)
    start = 0 if s.start is None else s.start
    stop = s.stop
    step = 1 if s.step is None else s.step
    if start < 0 or (stop is not None and stop < 0) or step <= 0:
        raise ValueError

    indices = count() if stop is None else range(max(start, stop))
    next_i = start
    for i, element in zip(indices, iterable):
        if i == next_i:
            yield element
            next_i += step
```

itertools.**pairwise**(*iterable*)

Return successive overlapping pairs taken from the input *iterable*.

The number of 2-tuples in the output iterator will be one fewer than the number of inputs. It will be empty if the input iterable has fewer than two values.

大致等價於:

```
def pairwise(iterable):
    # pairwise('ABCDEFG') → AB BC CD DE EF FG
    iterator = iter(iterable)
    a = next(iterator, None)
    for b in iterator:
        yield a, b
        a = b
```

在 3.10 版被加入.

itertools.**permutations**(*iterable*, *r=None*)

Return successive *r* length permutations of elements from the *iterable*.

If *r* is not specified or is `None`, then *r* defaults to the length of the *iterable* and all possible full-length permutations are generated.

The output is a subsequence of *`product()`* where entries with repeated elements have been filtered out. The length of the output is given by *`math.perm()`* which computes `n! / (n - r)!` when `0 ≤ r ≤ n` or zero when `r > n`.

The permutation tuples are emitted in lexicographic order according to the order of the input *iterable*. If the input *iterable* is sorted, the output tuples will be produced in sorted order.

Elements are treated as unique based on their position, not on their value. If the input elements are unique, there will be no repeated values within a permutation.

大致等價於:

```
def permutations(iterable, r=None):
    # permutations('ABCD', 2) → AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) → 012 021 102 120 201 210

    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return

    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])

    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[i:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return
```

itertools.**product**(**iterables*, *repeat=1*)

Cartesian product of input iterables.

Roughly equivalent to nested for-loops in a generator expression. For example, `product(A, B)` returns the same as `((x,y) for x in A for y in B)`.

The nested loops cycle like an odometer with the rightmost element advancing on every iteration. This pattern creates a lexicographic ordering so that if the input's iterables are sorted, the product tuples are emitted in sorted order.

To compute the product of an iterable with itself, specify the number of repetitions with the optional *repeat* keyword argument. For example, `product(A, repeat=4)` means the same as `product(A, A, A, A)`.

This function is roughly equivalent to the following code, except that the actual implementation does not build up intermediate results in memory:

```
def product(*iterables, repeat=1):
    # product('ABCD', 'xy') → Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) → 000 001 010 011 100 101 110 111

    pools = [tuple(pool) for pool in iterables] * repeat

    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]

    for prod in result:
        yield tuple(prod)
```

Before *product()* runs, it completely consumes the input iterables, keeping pools of values in memory to generate the products. Accordingly, it is only useful with finite inputs.

itertools.**repeat**(*object*[, *times*])

Make an iterator that returns *object* over and over again. Runs indefinitely unless the *times* argument is specified.

大致等價於:

```
def repeat(object, times=None):
    # repeat(10, 3) → 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object
```

A common use for *repeat* is to supply a stream of constant values to *map* or *zip*:

```
>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

itertools.**starmap**(*function*, *iterable*)

Make an iterator that computes the *function* using arguments obtained from the *iterable*. Used instead of *map()* when argument parameters have already been "pre-zipped" into tuples.

The difference between *map()* and *starmap()* parallels the distinction between `function(a,b)` and `function(*c)`. Roughly equivalent to:

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) → 32 9 1000
    for args in iterable:
        yield function(*args)
```

itertools.**takewhile**(*predicate*, *iterable*)

Make an iterator that returns elements from the *iterable* as long as the *predicate* is true. Roughly equivalent to:

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,3,8]) → 1 4
    for x in iterable:
        if not predicate(x):
            break
        yield x
```

Note, the element that first fails the predicate condition is consumed from the input iterator and there is no way to access it. This could be an issue if an application wants to further consume the input iterator after *takewhile* has been run to exhaustion. To work around this problem, consider using more-iterools before_and_after() instead.

itertools.**tee**(*iterable*, *n=2*)

Return *n* independent iterators from a single iterable.

大致等價於:

```
def tee(iterable, n=2):
    iterator = iter(iterable)
    shared_link = [None, None]
    return tuple(_tee(iterator, shared_link) for _ in range(n))

def _tee(iterator, link):
    try:
        while True:
            if link[1] is None:
                link[0] = next(iterator)
                link[1] = [None, None]
            value, link = link
            yield value
    except StopIteration:
        return
```

Once a *tee()* has been created, the original *iterable* should not be used anywhere else; otherwise, the *iterable* could get advanced without the tee objects being informed.

tee iterators are not threadsafe. A *RuntimeError* may be raised when simultaneously using iterators returned by the same *tee()* call, even if the original *iterable* is threadsafe.

This itertool may require significant auxiliary storage (depending on how much temporary data needs to be stored). In general, if one iterator uses most or all of the data before another iterator starts, it is faster to use *list()* instead of *tee()*.

itertools.**zip_longest**(**iterables*, *fillvalue=None*)

Make an iterator that aggregates elements from each of the *iterables*.

If the iterables are of uneven length, missing values are filled-in with *fillvalue*. If not specified, *fillvalue* defaults to None.

Iteration continues until the longest iterable is exhausted.

大致等價於:

```
def zip_longest(*iterables, fillvalue=None):
    # zip_longest('ABCD', 'xy', fillvalue='-') → Ax By C- D-

    iterators = list(map(iter, iterables))
    num_active = len(iterators)
    if not num_active:
        return

    while True:
        values = []
        for i, iterator in enumerate(iterators):
            try:
                value = next(iterator)
            except StopIteration:
                num_active -= 1
```

(繼續下一頁)

(繼續上一頁)

```
                if not num_active:
                    return
                iterators[i] = repeat(fillvalue)
                value = fillvalue
            values.append(value)
        yield tuple(values)
```

If one of the iterables is potentially infinite, then the *zip_longest()* function should be wrapped with something that limits the number of calls (for example *islice()* or *takewhile()*).

10.1.2 Itertools Recipes

This section shows recipes for creating an extended toolset using the existing itertools as building blocks.

The primary purpose of the itertools recipes is educational. The recipes show various ways of thinking about individual tools —for example, that `chain.from_iterable` is related to the concept of flattening. The recipes also give ideas about ways that the tools can be combined —for example, how `starmap()` and `repeat()` can work together. The recipes also show patterns for using itertools with the *operator* and *collections* modules as well as with the built-in itertools such as `map()`, `filter()`, `reversed()`, and `enumerate()`.

A secondary purpose of the recipes is to serve as an incubator. The `accumulate()`, `compress()`, and `pairwise()` itertools started out as recipes. Currently, the `sliding_window()`, `iter_index()`, and `sieve()` recipes are being tested to see whether they prove their worth.

Substantially all of these recipes and many, many others can be installed from the more-itertools project found on the Python Package Index:

```
python -m pip install more-itertools
```

Many of the recipes offer the same high performance as the underlying toolset. Superior memory performance is kept by processing elements one at a time rather than bringing the whole iterable into memory all at once. Code volume is kept small by linking the tools together in a functional style. High speed is retained by preferring "vectorized" building blocks over the use of for-loops and *generators* which incur interpreter overhead.

```
import collections
import contextlib
import functools
import math
import operator
import random

def take(n, iterable):
    "Return first n items of the iterable as a list."
    return list(islice(iterable, n))

def prepend(value, iterable):
    "Prepend a single value in front of an iterable."
    # prepend(1, [2, 3, 4]) → 1 2 3 4
    return chain([value], iterable)

```

10.2 `functools` --- Higher-order functions and operations on callable objects

原始碼： Lib/functools.py

The *`functools`* module is for higher-order functions: functions that act on or return other functions. In general, any callable object can be treated as a function for the purposes of this module.

The *`functools`* module defines the following functions:

`@functools.cache`(*user_function*)

Simple lightweight unbounded function cache. Sometimes called "memoize".

Returns the same as `lru_cache(maxsize=None)`, creating a thin wrapper around a dictionary lookup for the function arguments. Because it never needs to evict old values, this is smaller and faster than *`lru_cache()`* with a size limit.

舉例來🄵:

```
@cache
def factorial(n):
    return n * factorial(n-1) if n else 1

>>> factorial(10)      # no previously cached result, makes 11 recursive calls
3628800
>>> factorial(5)       # just looks up cached value result
120
>>> factorial(12)      # makes two new recursive calls, the other 10 are cached
479001600
```

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

在 3.9 版被加入.

`@functools.`**cached_property**(*func*)

Transform a method of a class into a property whose value is computed once and then cached as a normal attribute for the life of the instance. Similar to *property()*, with the addition of caching. Useful for expensive computed properties of instances that are otherwise effectively immutable.

範例:

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = tuple(sequence_of_numbers)

    @cached_property
    def stdev(self):
        return statistics.stdev(self._data)
```

The mechanics of *cached_property()* are somewhat different from *property()*. A regular property blocks attribute writes unless a setter is defined. In contrast, a *cached_property* allows writes.

The *cached_property* decorator only runs on lookups and only when an attribute of the same name doesn't exist. When it does run, the *cached_property* writes to the attribute with the same name. Subsequent attribute reads and writes take precedence over the *cached_property* method and it works like a normal attribute.

The cached value can be cleared by deleting the attribute. This allows the *cached_property* method to run again.

The *cached_property* does not prevent a possible race condition in multi-threaded usage. The getter function could run more than once on the same instance, with the latest run setting the cached value. If the cached property is idempotent or otherwise not harmful to run more than once on an instance, this is fine. If synchronization is needed, implement the necessary locking inside the decorated getter function or around the cached property access.

Note, this decorator interferes with the operation of **PEP 412** key-sharing dictionaries. This means that instance dictionaries can take more space than usual.

Also, this decorator requires that the `__dict__` attribute on each instance be a mutable mapping. This means it will not work with some types, such as metaclasses (since the `__dict__` attributes on type instances are read-only proxies for the class namespace), and those that specify `__slots__` without including `__dict__` as one of the defined slots (as such classes don't provide a `__dict__` attribute at all).

If a mutable mapping is not available or if space-efficient key sharing is desired, an effect similar to *cached_property()* can also be achieved by stacking *property()* on top of *lru_cache()*. See faq-cache-method-calls for more details on how this differs from *cached_property()*.

在 3.8 版被加入.

在 3.12 版的變更: Prior to Python 3.12, `cached_property` included an undocumented lock to ensure that in multi-threaded usage the getter function was guaranteed to run only once per instance. However, the lock was per-property, not per-instance, which could result in unacceptably high lock contention. In Python 3.12+ this locking is removed.

`functools.`**`cmp_to_key`**(*func*)

Transform an old-style comparison function to a *key function*. Used with tools that accept key functions (such as *`sorted()`*, *`min()`*, *`max()`*, *`heapq.nlargest()`*, *`heapq.nsmallest()`*, *`itertools.groupby()`*). This function is primarily used as a transition tool for programs being converted from Python 2 which supported the use of comparison functions.

A comparison function is any callable that accepts two arguments, compares them, and returns a negative number for less-than, zero for equality, or a positive number for greater-than. A key function is a callable that accepts one argument and returns another value to be used as the sort key.

範例:

```
sorted(iterable, key=cmp_to_key(locale.strcoll))  # locale-aware sort order
```

For sorting examples and a brief sorting tutorial, see sortinghowto.

在 3.2 版被加入.

`@functools.`**`lru_cache`**(*user_function*)

`@functools.`**`lru_cache`**(*maxsize=128*, *typed=False*)

Decorator to wrap a function with a memoizing callable that saves up to the *maxsize* most recent calls. It can save time when an expensive or I/O bound function is periodically called with the same arguments.

The cache is threadsafe so that the wrapped function can be used in multiple threads. This means that the underlying data structure will remain coherent during concurrent updates.

It is possible for the wrapped function to be called more than once if another thread makes an additional call before the initial call has been completed and cached.

Since a dictionary is used to cache results, the positional and keyword arguments to the function must be *hashable*.

Distinct argument patterns may be considered to be distinct calls with separate cache entries. For example, `f(a=1, b=2)` and `f(b=2, a=1)` differ in their keyword argument order and may have two separate cache entries.

If *user_function* is specified, it must be a callable. This allows the *lru_cache* decorator to be applied directly to a user function, leaving the *maxsize* at its default value of 128:

```
@lru_cache
def count_vowels(sentence):
    return sum(sentence.count(vowel) for vowel in 'AEIOUaeiou')
```

If *maxsize* is set to `None`, the LRU feature is disabled and the cache can grow without bound.

If *typed* is set to true, function arguments of different types will be cached separately. If *typed* is false, the implementation will usually regard them as equivalent calls and only cache a single result. (Some types such as *str* and *int* may be cached separately even when *typed* is false.)

Note, type specificity applies only to the function's immediate arguments rather than their contents. The scalar arguments, `Decimal(42)` and `Fraction(42)` are be treated as distinct calls with distinct results. In contrast, the tuple arguments `('answer', Decimal(42))` and `('answer', Fraction(42))` are treated as equivalent.

The wrapped function is instrumented with a `cache_parameters()` function that returns a new *`dict`* showing the values for *maxsize* and *typed*. This is for information purposes only. Mutating the values has no effect.

To help measure the effectiveness of the cache and tune the *maxsize* parameter, the wrapped function is instrumented with a `cache_info()` function that returns a *named tuple* showing *hits*, *misses*, *maxsize* and *currsize*.

The decorator also provides a `cache_clear()` function for clearing or invalidating the cache.

The original underlying function is accessible through the `__wrapped__` attribute. This is useful for introspection, for bypassing the cache, or for rewrapping the function with a different cache.

The cache keeps references to the arguments and return values until they age out of the cache or until the cache is cleared.

If a method is cached, the `self` instance argument is included in the cache. See faq-cache-method-calls

An LRU (least recently used) cache works best when the most recent calls are the best predictors of upcoming calls (for example, the most popular articles on a news server tend to change each day). The cache's size limit assures that the cache does not grow without bound on long-running processes such as web servers.

In general, the LRU cache should only be used when you want to reuse previously computed values. Accordingly, it doesn't make sense to cache functions with side-effects, functions that need to create distinct mutable objects on each call (such as generators and async functions), or impure functions such as time() or random().

Example of an LRU cache for static web content:

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal'
    resource = f'https://peps.python.org/pep-{num:04d}'
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 289, 320, 9991:
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsize=8)
```

Example of efficiently computing Fibonacci numbers using a cache to implement a dynamic programming technique:

```
@lru_cache(maxsize=None)
def fib(n):
    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsize=16)
```

在 3.2 版被加入.

在 3.3 版的變更: 新增 *typed* 選項。

在 3.8 版的變更: 新增 *user_function* 選項。

在 3.9 版的變更: 新增 `cache_parameters()` 函式。

@functools.**total_ordering**

Given a class defining one or more rich comparison ordering methods, this class decorator supplies the rest. This simplifies the effort involved in specifying all of the possible rich comparison operations:

The class must define one of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`. In addition, the class should supply an `__eq__()` method.

舉例來🄵:

```
@total_ordering
class Student:
    def _is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

備🄵

While this decorator makes it easy to create well behaved totally ordered types, it *does* come at the cost of slower execution and more complex stack traces for the derived comparison methods. If performance benchmarking indicates this is a bottleneck for a given application, implementing all six rich comparison methods instead is likely to provide an easy speed boost.

備🄵

This decorator makes no attempt to override methods that have been declared in the class *or its superclasses*. Meaning that if a superclass defines a comparison operator, *total_ordering* will not implement it again, even if the original method is abstract.

在 3.2 版被加入.

在 3.4 版的變更: Returning `NotImplemented` from the underlying comparison function for unrecognised types is now supported.

functools.**partial**(*func*, */*, **args*, ***keywords*)

Return a new *partial object* which when called will behave like *func* called with the positional arguments *args* and keyword arguments *keywords*. If more arguments are supplied to the call, they are appended to *args*. If additional keyword arguments are supplied, they extend and override *keywords*. Roughly equivalent to:

```
def partial(func, /, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = {**keywords, **fkeywords}
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
```

(繼續下一頁)

(繼續上一頁)

```
    newfunc.keywords = keywords
    return newfunc
```

The *partial()* is used for partial function application which "freezes" some portion of a function's arguments and/or keywords resulting in a new object with a simplified signature. For example, *partial()* can be used to create a callable that behaves like the *int()* function where the *base* argument defaults to two:

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

class functools.**partialmethod**(*func*, */*, **args*, ***keywords*)

Return a new *partialmethod* descriptor which behaves like *partial* except that it is designed to be used as a method definition rather than being directly callable.

func must be a *descriptor* or a callable (objects which are both, like normal functions, are handled as descriptors).

When *func* is a descriptor (such as a normal Python function, *classmethod()*, *staticmethod()*, `abstractmethod()` or another instance of *partialmethod*), calls to `__get__` are delegated to the underlying descriptor, and an appropriate *partial object* returned as the result.

When *func* is a non-descriptor callable, an appropriate bound method is created dynamically. This behaves like a normal Python function when used as a method: the *self* argument will be inserted as the first positional argument, even before the *args* and *keywords* supplied to the *partialmethod* constructor.

範例:

```
>>> class Cell:
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
...
>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True
```

在 3.4 版被加入.

functools.**reduce**(*function*, *iterable*[, *initializer*])

Apply *function* of two arguments cumulatively to the items of *iterable*, from left to right, so as to reduce the iterable to a single value. For example, `reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])` calculates `(((((1+2)+3)+4)+5)`. The left argument, *x*, is the accumulated value and the right argument, *y*, is the update value from the *iterable*. If the optional *initializer* is present, it is placed before the items of the iterable in the calculation, and serves as a default when the iterable is empty. If *initializer* is not given and *iterable* contains only one item, the first item is returned.

Roughly equivalent to:

```
def reduce(function, iterable, initializer=None):
    it = iter(iterable)
    if initializer is None:
        value = next(it)
    else:
        value = initializer
    for element in it:
        value = function(value, element)
    return value
```

See *itertools.accumulate()* for an iterator that yields all intermediate values.

`@functools.`**singledispatch**

Transform a function into a *single-dispatch generic function*.

To define a generic function, decorate it with the `@singledispatch` decorator. When defining a function using `@singledispatch`, note that the dispatch happens on the type of the first argument:

```
>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)
```

To add overloaded implementations to the function, use the `register()` attribute of the generic function, which can be used as a decorator. For functions annotated with types, the decorator will infer the type of the first argument automatically:

```
>>> @fun.register
... def _(arg: int, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> @fun.register
... def _(arg: list, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
```

types.UnionType and *typing.Union* can also be used:

```
>>> @fun.register
... def _(arg: int | float, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> from typing import Union
>>> @fun.register
... def _(arg: Union[list, set], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
...
```

For code which doesn't use type annotations, the appropriate type argument can be passed explicitly to the decorator itself:

```
>>> @fun.register(complex)
... def _(arg, verbose=False):
...     if verbose:
...         print("Better than complicated.", end=" ")
...     print(arg.real, arg.imag)
...
```

To enable registering *lambdas* and pre-existing functions, the `register()` attribute can also be used in a functional form:

```
>>> def nothing(arg, verbose=False):
...     print("Nothing.")
...
>>> fun.register(type(None), nothing)
```

The `register()` attribute returns the undecorated function. This enables decorator stacking, *pickling*, and the creation of unit tests for each variant independently:

```
>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False
```

When called, the generic function dispatches on the type of the first argument:

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
1 spam
2 eggs
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

Where there is no registered implementation for a specific type, its method resolution order is used to find a more generic implementation. The original function decorated with `@singledispatch` is registered for the base *object* type, which means it is used if no better implementation is found.

If an implementation is registered to an *abstract base class*, virtual subclasses of the base class will be dispatched to that implementation:

```
>>> from collections.abc import Mapping
>>> @fun.register
... def _(arg: Mapping, verbose=False):
...     if verbose:
...         print("Keys & Values")
...     for key, value in arg.items():
...         print(key, "=>", value)
...
>>> fun({"a": "b"})
a => b
```

To check which implementation the generic function will choose for a given type, use the `dispatch()` attribute:

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict)    # note: default implementation
<function fun at 0x103fe0000>
```

To access all registered implementations, use the read-only `registry` attribute:

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'object'>,
           <class 'decimal.Decimal'>, <class 'list'>,
           <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

在 3.4 版被加入.

在 3.7 版的變更: The `register()` attribute now supports using type annotations.

在 3.11 版的變更: The `register()` attribute now supports *types.UnionType* and *typing.Union* as type annotations.

class functools.**singledispatchmethod**(*func*)

Transform a method into a *single-dispatch generic function*.

To define a generic method, decorate it with the `@singledispatchmethod` decorator. When defining a function using `@singledispatchmethod`, note that the dispatch happens on the type of the first non-*self* or non-*cls* argument:

```
class Negator:
    @singledispatchmethod
    def neg(self, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    def _(self, arg: int):
        return -arg

    @neg.register
    def _(self, arg: bool):
        return not arg
```

`@singledispatchmethod` supports nesting with other decorators such as *@classmethod*. Note that to allow for `dispatcher.register`, `singledispatchmethod` must be the *outer most* decorator. Here is the `Negator` class with the `neg` methods bound to the class, rather than an instance of the class:

```
class Negator:
    @singledispatchmethod
    @classmethod
    def neg(cls, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    @classmethod
    def _(cls, arg: int):
        return -arg

    @neg.register
    @classmethod
    def _(cls, arg: bool):
        return not arg
```

The same pattern can be used for other similar decorators: *@staticmethod*, *@abstractmethod*, and others.

在 3.8 版被加入.

functools.**update_wrapper**(*wrapper*, *wrapped*, *assigned=WRAPPER_ASSIGNMENTS*, *updated=WRAPPER_UPDATES*)

Update a *wrapper* function to look like the *wrapped* function. The optional arguments are tuples to specify which attributes of the original function are assigned directly to the matching attributes on the wrapper function and which attributes of the wrapper function are updated with the corresponding attributes from the original function. The default values for these arguments are the module level constants `WRAPPER_ASSIGNMENTS` (which assigns to the wrapper function's `__module__`, `__name__`, `__qualname__`, `__annotations__`, `__type_params__`, and `__doc__`, the documentation string) and `WRAPPER_UPDATES` (which updates the wrapper function's `__dict__`, i.e. the instance dictionary).

To allow access to the original function for introspection and other purposes (e.g. bypassing a caching decorator such as *lru_cache()*), this function automatically adds a `__wrapped__` attribute to the wrapper that refers to the function being wrapped.

The main intended use for this function is in *decorator* functions which wrap the decorated function and return the wrapper. If the wrapper function is not updated, the metadata of the returned function will reflect the wrapper definition rather than the original function definition, which is typically less than helpful.

update_wrapper() may be used with callables other than functions. Any attributes named in *assigned* or *updated* that are missing from the object being wrapped are ignored (i.e. this function will not attempt to set them on the wrapper function). *AttributeError* is still raised if the wrapper function itself is missing any attributes named in *updated*.

在 3.2 版的變更: The `__wrapped__` attribute is now automatically added. The `__annotations__` attribute is now copied by default. Missing attributes no longer trigger an *AttributeError*.

在 3.4 版的變更: The `__wrapped__` attribute now always refers to the wrapped function, even if that function defined a `__wrapped__` attribute. (see bpo-17482)

在 3.12 版的變更: The `__type_params__` attribute is now copied by default.

@functools.**wraps**(*wrapped*, *assigned=WRAPPER_ASSIGNMENTS*, *updated=WRAPPER_UPDATES*)

This is a convenience function for invoking *update_wrapper()* as a function decorator when defining a wrapper function. It is equivalent to `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`. For example:

```
>>> from functools import wraps
>>> def my_decorator(f):
```

(繼續下一頁)

(繼續上一頁)

```
...     @wraps(f)
...     def wrapper(*args, **kwds):
...         print('Calling decorated function')
...         return f(*args, **kwds)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'
```

Without the use of this decorator factory, the name of the example function would have been `'wrapper'`, and the docstring of the original `example()` would have been lost.

10.2.1 `partial` 物件

partial objects are callable objects created by *partial()*. They have three read-only attributes:

partial.**func**

A callable object or function. Calls to the *partial* object will be forwarded to *func* with new arguments and keywords.

partial.**args**

The leftmost positional arguments that will be prepended to the positional arguments provided to a *partial* object call.

partial.**keywords**

The keyword arguments that will be supplied when the *partial* object is called.

partial objects are like `function` objects in that they are callable, weak referenceable, and can have attributes. There are some important differences. For instance, the *__name__* and `__doc__` attributes are not created automatically. Also, *partial* objects defined in classes behave like static methods and do not transform into bound methods during instance attribute look-up.

10.3 `operator` --- 標準運算子替代函式

原始碼： Lib/operator.py

---

operator module（模組）提供了一套與 Python 原生運算子對應的高效率函式。例如，`operator.add(x, y)` 與表示式 `x+y` 相同。許多函式名與特殊方法名相同，只是🄵有雙底🄵。🄵了向後相容，許多包含雙底🄵的函式被保留了下來，但🄵了易於表達，建議使用🄵有雙底🄵的函式。

函式種類有物件的比較運算、邏輯運算、數學運算以及序列運算。

物件比較函式適用於所有物件，函式根據它們對應的 rich comparison 運算子命名：

operator.**lt**(*a*, *b*)

operator.**le**(*a*, *b*)

operator.**eq**(*a*, *b*)

operator.**ne**(*a*, *b*)

operator.**ge**(*a*, *b*)

operator.**gt**(*a*, *b*)

operator.**__lt__**(*a*, *b*)

operator.**__le__**(*a*, *b*)

operator.**__eq__**(*a*, *b*)

operator.**__ne__**(*a*, *b*)

operator.**__ge__**(*a*, *b*)

operator.**__gt__**(*a*, *b*)

在 *a* 和 *b* 之間進行"rich comparison"。具體來F，`lt(a, b)` 與 `a < b` 相同，`le(a, b)` 與 `a <= b` 相同，`eq(a, b)` 與 `a == b` 相同，`ne(a, b)` 與 `a != b` 相同，`gt(a, b)` 與 `a > b` 相同，`ge(a, b)` 與 `a >= b` 相同。注意這些函式可以回傳任何值，無論它是否可當作 boolean（布林）值。關於 rich comparison 的更多資訊請參考 comparisons。

邏輯運算通常也適用於所有物件，F且支援真值檢測、識F性測試和 boolean 運算：

operator.**not_**(*obj*)

operator.**__not__**(*obj*)

回傳 `not` *obj* 的結果。（請注意物件實例FF有 `__not__()` method（方法）；只有直譯器核心定義此操作。結果會受 `__bool__()` 和 `__len__()` method 影響。）

operator.**truth**(*obj*)

如果 *obj* F真值則回傳*True*，否則回傳*False*。這等價於使用*bool* 建構器。

operator.**is_**(*a*, *b*)

回傳 `a is b`。測試物件識F性。

operator.**is_not**(*a*, *b*)

回傳 `a is not b`。測試物件識F性。

數學和位元運算的種類是最多的：

operator.**abs**(*obj*)

operator.**__abs__**(*obj*)

回傳 *obj* 的F對值。

operator.**add**(*a*, *b*)

operator.**__add__**(*a*, *b*)

對於數字 *a* 和 *b*，回傳 `a + b`。

operator.**and_**(*a*, *b*)

operator.**__and__**(*a*, *b*)

回傳 *x* 和 *y* 位元運算與 (and) 的結果。

operator.**floordiv**(*a*, *b*)

operator.**__floordiv__**(*a*, *b*)

回傳 `a // b`。

operator.**index**(*a*)

operator.**__index__**(*a*)

回傳 *a* 轉FF整數的結果。等價於 `a.__index__()`。

在 3.10 版的變更: 結果總是*int* 型F。在過去的版本中，結果可能F `int` 子類F的實例。

operator.**inv**(*obj*)

operator.**invert**(*obj*)

operator.**__inv__**(*obj*)

operator.**__invert__**(*obj*)

回傳數字 *obj* 按位元取反 (inverse) 的結果。這等價於 `~obj`。

operator.**lshift**(*a*, *b*)

operator.**__lshift__**(*a*, *b*)

回傳 *a* 左移 *b* 位的結果。

operator.**mod**(*a*, *b*)

operator.**__mod__**(*a*, *b*)

回傳 `a % b`。

operator.**mul**(*a*, *b*)

operator.**__mul__**(*a*, *b*)

對於數字 *a* 和 *b*，回傳 `a * b`。

operator.**matmul**(*a*, *b*)

operator.**__matmul__**(*a*, *b*)

回傳 `a @ b`。

在 3.5 版被加入.

operator.**neg**(*obj*)

operator.**__neg__**(*obj*)

回傳 *obj* 取負值的結果 (`-obj`)。

operator.**or_**(*a*, *b*)

operator.**__or__**(*a*, *b*)

回傳 *a* 和 *b* 按位元或 (or) 的結果。

operator.**pos**(*obj*)

operator.**__pos__**(*obj*)

回傳 *obj* 取正的結果 (`+obj`)。

operator.**pow**(*a*, *b*)

operator.**__pow__**(*a*, *b*)

對於數字 *a* 和 *b*，回傳 `a ** b`。

operator.**rshift**(*a*, *b*)

operator.**__rshift__**(*a*, *b*)

回傳 *a* 右移 *b* 位的結果。

operator.**sub**(*a*, *b*)

operator.**__sub__**(*a*, *b*)

回傳 `a - b`。

operator.**truediv**(*a*, *b*)

operator.**__truediv__**(*a*, *b*)
回傳 `a / b`，例如 2/3 將等於.66 而不是 0。這也被稱🄴「真」除法。

operator.**xor**(*a*, *b*)
operator.**__xor__**(*a*, *b*)
回傳 *a* 和 *b* 按位元🄴或 (exclusive or) 的結果。

適用於序列的操作（其中一些也適用於對映 (mapping)），包括：

operator.**concat**(*a*, *b*)
operator.**__concat__**(*a*, *b*)
對於序列 *a* 和 *b*，回傳 `a + b`。

operator.**contains**(*a*, *b*)
operator.**__contains__**(*a*, *b*)
回傳 `b in a` 檢測的結果。請注意運算元是反序的。

operator.**countOf**(*a*, *b*)
回傳 *b* 在 *a* 中的出現次數。

operator.**delitem**(*a*, *b*)
operator.**__delitem__**(*a*, *b*)
移除 *a* 中索引🄴 *b* 的值。

operator.**getitem**(*a*, *b*)
operator.**__getitem__**(*a*, *b*)
回傳 *a* 中索引🄴 *b* 的值。

operator.**indexOf**(*a*, *b*)
回傳 *b* 在 *a* 中首次出現所在的索引。

operator.**setitem**(*a*, *b*, *c*)
operator.**__setitem__**(*a*, *b*, *c*)
將 *a* 中索引🄴 *b* 的值設🄵 *c*。

operator.**length_hint**(*obj*, *default=0*)
回傳物件 *obj* 的估計長度。首先嘗試回傳其實際長度，再使用 `object.__length_hint__()` 得出估計值，最後才是回傳預設值。

在 3.4 版被加入.

The following operation works with callables:

operator.**call**(*obj*, */*, **args*, ***kwargs*)
operator.**__call__**(*obj*, */*, **args*, ***kwargs*)
Return `obj(*args, **kwargs)`.

在 3.11 版被加入.

operator module 還定義了一些用於常規屬性和條目查詢的工具。這些工具適合用來編寫快速欄位提取器以作🄵*map()*、*sorted()*、*itertools.groupby()* 或其他需要函式引數的函式之引數。

operator.**attrgetter**(*attr*)
operator.**attrgetter**(**attrs*)
回傳一個可從運算元中獲取 *attr* 的可呼叫 (callable) 物件。如果請求了一個以上的屬性，則回傳一個包含屬性的 tupple（元組）。屬性名稱還可包含點號。例如：

- 在 `f = attrgetter('name')` 之後，呼叫 `f(b)` 將回傳 `b.name`。

- 在 `f = attrgetter('name', 'date')` 之後，呼叫 `f(b)` 將回傳 `(b.name, b.date)`。
- 在 `f = attrgetter('name.first', 'name.last')` 之後，呼叫 `f(b)` 將回傳 `(b.name.first, b.name.last)`。

等價於：

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g

def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

operator.**itemgetter**(*item*)

operator.**itemgetter**(**items*)

回傳一個使用運算元的 `__getitem__()` 方法從運算元中獲取 *item* 的可呼叫物件。如果指定了多個條目，則回傳一個查詢值的 tupple。例如：

- 在 `f = itemgetter(2)` 之後，呼叫 `f(r)` 將回傳 `r[2]`。
- 在 `g = itemgetter(2, 5, 3)` 之後，呼叫 `g(r)` 將回傳 `(r[2], r[5], r[3])`。

等價於：

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g
```

傳入的條目可以🄵運算元的 `__getitem__()` 所接受的任何型🄵。dictionary（字典）接受任意可雜🄵的值。list、tupple 和字串接受索引或切片：

```
>>> itemgetter(1)('ABCDEFG')
'B'
>>> itemgetter(1, 3, 5)('ABCDEFG')
('B', 'D', 'F')
>>> itemgetter(slice(2, None))('ABCDEFG')
'CDEFG'
>>> soldier = dict(rank='captain', name='dotterbart')
>>> itemgetter('rank')(soldier)
'captain'
```

使用 *itemgetter()* 從 tuple 中提取特定欄位的例子：

```
>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
[('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

operator.**methodcaller**(*name*, */*, **args*, ***kwargs*)

回傳一個在運算元上呼叫 *name* method 的可呼叫物件。如果給定額外的引數和/或關鍵字引數，它們也將被傳給該 method。例如：

- 在 `f = methodcaller('name')` 之後，呼叫 `f(b)` 將回傳 `b.name()`。
- 在 `f = methodcaller('name', 'foo', bar=1)` 之後，呼叫 `f(b)` 將回傳 `b.name('foo', bar=1)`。

等價於：

```
def methodcaller(name, /, *args, **kwargs):
    def caller(obj):
        return getattr(obj, name)(*args, **kwargs)
    return caller
```

10.3.1 運算子與函式間的對映

以下表格表示了抽象運算是如何對應於 Python 語法中的運算子和*operator* module 中的函式。

運算	語法	函式
加法	`a + b`	`add(a, b)`
字串串接	`seq1 + seq2`	`concat(seq1, seq2)`
包含性檢測	`obj in seq`	`contains(seq, obj)`
除法	`a / b`	`truediv(a, b)`
除法	`a // b`	`floordiv(a, b)`
按位元與 (And)	`a & b`	`and_(a, b)`
按位元互斥或 (Exclusive Or)	`a ^ b`	`xor(a, b)`
按位元取反 (Inversion)	`~ a`	`invert(a)`
按位元或 (Or)	`a | b`	`or_(a, b)`
取🄵	`a ** b`	`pow(a, b)`
識🄵性	`a is b`	`is_(a, b)`
識🄵性	`a is not b`	`is_not(a, b)`
索引賦值	`obj[k] = v`	`setitem(obj, k, v)`
索引🄵除	`del obj[k]`	`delitem(obj, k)`
索引取值	`obj[k]`	`getitem(obj, k)`
左移	`a << b`	`lshift(a, b)`
模除 (Modulo)	`a % b`	`mod(a, b)`
乘法	`a * b`	`mul(a, b)`
矩陣乘法	`a @ b`	`matmul(a, b)`
反相（算術）	`- a`	`neg(a)`
反相（邏輯）	`not a`	`not_(a)`
正數	`+ a`	`pos(a)`
右移	`a >> b`	`rshift(a, b)`
切片賦值	`seq[i:j] = values`	`setitem(seq, slice(i, j), values)`

繼續下一頁

表格 1 – 繼續上一頁

運算	語法	函式
切片🄴除	`del seq[i:j]`	`delitem(seq, slice(i, j))`
切片取值	`seq[i:j]`	`getitem(seq, slice(i, j))`
字串格式化	`s % obj`	`mod(s, obj)`
🄴法	`a - b`	`sub(a, b)`
真值檢測	`obj`	`truth(obj)`
比較大小	`a < b`	`lt(a, b)`
比較大小	`a <= b`	`le(a, b)`
相等性	`a == b`	`eq(a, b)`
不等性	`a != b`	`ne(a, b)`
比較大小	`a >= b`	`ge(a, b)`
比較大小	`a > b`	`gt(a, b)`

10.3.2 原地 (in-place) 運算子

許多運算都有「原地」版本。以下列出的是提供對原地運算子（與一般語法相比）更底層存取的函式，例如*statement* `x += y` 相當於 `x = operator.iadd(x, y)`。🄵一種方式來講就是 `z = operator.iadd(x, y)` 等價於🄴合陳述式 `z = x; z += y`。

在這些例子中，請注意當呼叫一個原地方法時，運算和賦值是分成兩個步驟來執行的。下面列出的原地函式只執行第一步，即呼叫原地方法，第二步賦值則不加處理。

對於不可變 (immutable) 的目標例如字串、數字和 tupple，更新的值會被計算，但不會被再被賦值給輸入變數：

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

對於可變 (mutable) 的目標例如 list 和 dictionary，原地方法將執行更新，因此不需要後續賦值操作：

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

operator.**iadd**(*a*, *b*)

operator.**__iadd__**(*a*, *b*)

`a = iadd(a, b)` 等價於 `a += b`。

operator.**iand**(*a*, *b*)

operator.**__iand__**(*a*, *b*)

`a = iand(a, b)` 等價於 `a &= b`。

operator.**iconcat**(*a*, *b*)

operator.**__iconcat__**(*a*, *b*)

`a = iconcat(a, b)` 等價於 `a += b`，其中 *a* 和 *b* 🄵序列。

operator.**ifloordiv**(*a*, *b*)

operator.**__ifloordiv__**(*a*, *b*)
    a = ifloordiv(a, b) 等價於 a //= b。

operator.**ilshift**(*a*, *b*)
operator.**__ilshift__**(*a*, *b*)
    a = ilshift(a, b) 等價於 a <<= b。

operator.**imod**(*a*, *b*)
operator.**__imod__**(*a*, *b*)
    a = imod(a, b) 等價於 a %= b。

operator.**imul**(*a*, *b*)
operator.**__imul__**(*a*, *b*)
    a = imul(a, b) 等價於 a *= b。

operator.**imatmul**(*a*, *b*)
operator.**__imatmul__**(*a*, *b*)
    a = imatmul(a, b) 等價於 a @= b。
    在 3.5 版被加入.

operator.**ior**(*a*, *b*)
operator.**__ior__**(*a*, *b*)
    a = ior(a, b) 等價於 a |= b。

operator.**ipow**(*a*, *b*)
operator.**__ipow__**(*a*, *b*)
    a = ipow(a, b) 等價於 a **= b。

operator.**irshift**(*a*, *b*)
operator.**__irshift__**(*a*, *b*)
    a = irshift(a, b) 等價於 a >>= b。

operator.**isub**(*a*, *b*)
operator.**__isub__**(*a*, *b*)
    a = isub(a, b) 等價於 a -= b。

operator.**itruediv**(*a*, *b*)
operator.**__itruediv__**(*a*, *b*)
    a = itruediv(a, b) 等價於 a /= b。

operator.**ixor**(*a*, *b*)
operator.**__ixor__**(*a*, *b*)
    a = ixor(a, b) 等價於 a ^= b。

CHAPTER 11

檔案與目🄵存取

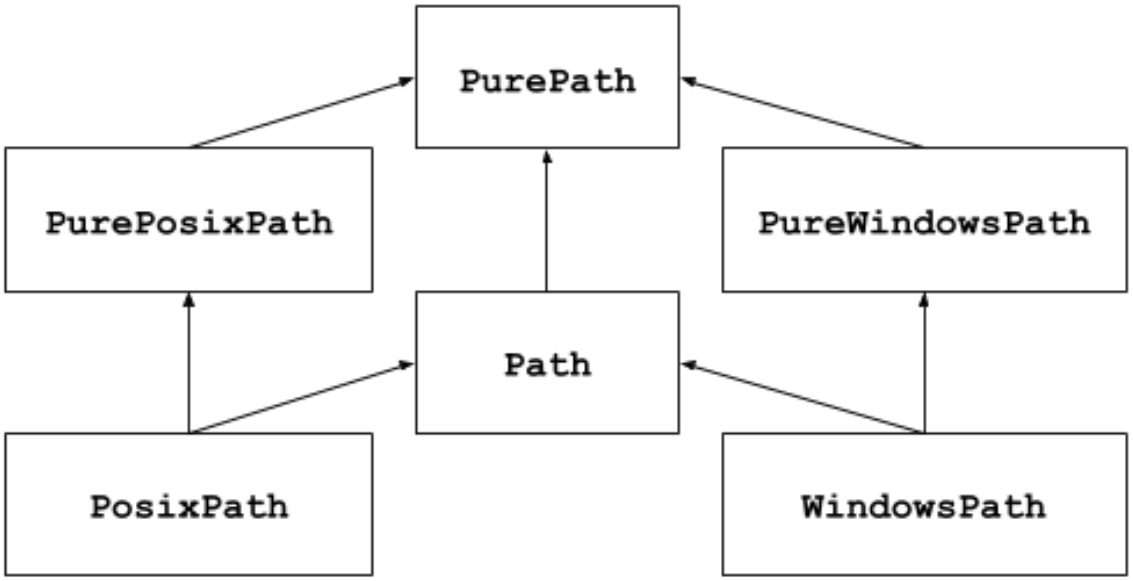
本章中描述的 module（模組）用於處理硬碟檔案和目🄵。例如，有一些 module 用於讀取檔案的屬性、以可🄵 (portable) 方式操作路徑以及建立暫存檔。本章中的完整 module 清單是：

11.1 `pathlib` --- 物件導向檔案系統路徑

在 3.4 版被加入.

原始碼： Lib/pathlib.py

此模組提供代表檔案系統路徑的類🄵，能適用不同作業系統的語意。路徑類🄵分成兩種，一種是*純路徑 (pure paths)*，提供🄵有 I/O 的單純計算操作，另一種是*實體路徑 (concrete paths)*，繼承自純路徑但也提供 IO 操作。



如果你之前從未使用過此模組或不確定哪個類🄵適合你的任務，那你需要的最有可能是*Path*。它針對程式執行所在的平台實例化一個*實體路徑*。

純路徑在某些特殊情境下是有用的，例如：

1. 如果你想在 Unix 機器上處理 Windows 路徑（或反過來），你無法在 Unix 上實例化*WindowsPath*，但你可以實例化*PureWindowsPath*。
2. 你想確保你的程式在操作路徑的時候不會真的存取到 OS。在這個情🄵下，實例化其中一種純路徑類🄵可能是有用的，因🄵它們不會有任何存取 OS 的操作。

也參考

PEP 428：pathlib 模組 -- 物件導向檔案系統路徑。

也參考

針對字串上的底層路徑操作，你也可以使用*os.path* 模組。

11.1.1 基本用法

匯入主要類🄵:

```
>>> from pathlib import Path
```

列出子目🄵:

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

在當前目🄵樹下列出 Python 原始碼檔案:

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

🄵覽目🄵樹🄵部:

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

查詢路徑屬性:

```
>>> q.exists()
True
>>> q.is_dir()
False
```

開🄵檔案:

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

11.1.2 純路徑

純路徑物件提供處理路徑的操作，實際上不會存取檔案系統。有三種方式可以存取這些類🄵，我們也稱之🄵類型 *(flavours)*:

class pathlib.**PurePath**(**pathsegments*)

一個通用的類🄵，表示系統的路徑類型（實例化時會建立一個*PurePosixPath*或*PureWindowsPath*):

```
>>> PurePath('setup.py')      # Running on a Unix machine
PurePosixPath('setup.py')
```

pathsegments 中的每個元素可以是以下的其中一種：一個表示路徑片段的字串，或一個物件，它實作了*os.PathLike* 介面且其中的*__fspath__()* 方法會回傳字串，就像是另一個路徑物件:

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

當🄴有給 *pathsegments* 的時候，會假設是目前的目🄵：

```
>>> PurePath()
PurePosixPath('.')
```

如果一個片段是🄴對路徑，則所有之前的片段會被忽略（類似*os.path.join()*）：

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

在 Windows 系統上，當遇到具有根目🄴的相對路徑片段（例如 `r'\foo'`）時，磁碟機 (drive) 部分不會被重置：

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

不必要的斜🄵和單點會被合🄵，但雙點 (`'..'`) 和前置的雙斜🄵 (`'//'`) 不會被合🄵，因🄵這樣會因🄵各種原因改變路徑的意義（例如符號連結 (symbolic links)、UNC 路徑）：

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('//foo/bar')
PurePosixPath('//foo/bar')
>>> PurePath('foo/./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo/../bar')
PurePosixPath('foo/../bar')
```

（一個使得 `PurePosixPath('foo/../bar')` 等同於 `PurePosixPath('bar')` 的單純方法，但如果 `foo` 是指到另一個目🄴的符號連結，就會是錯誤的。）

純路徑物件實作了*os.PathLike* 介面，使得它們可以在任何接受該介面的地方使用。

在 3.6 版的變更: 新增了對於*os.PathLike* 介面的支援。

class pathlib.**PurePosixPath**(**pathsegments*)

PurePath 的一個子類🄵，該路徑類型表示非 Windows 檔案系統的路徑：

```
>>> PurePosixPath('/etc')
PurePosixPath('/etc')
```

pathsegments 的指定方式與*PurePath* 類似。

class pathlib.**PureWindowsPath**(**pathsegments*)

PurePath 的一個子類🄵，該路徑類型表示 Windows 檔案系統的路徑，包括 UNC paths：

```
>>> PureWindowsPath('c:/Program Files/')
PureWindowsPath('c:/Program Files')
>>> PureWindowsPath('//server/share/file')
PureWindowsPath('//server/share/file')
```

pathsegments 的指定方式與*PurePath* 類似。

不論你使用的是什🄵系統，你都可以實例化這些類🄵，因🄵它們不提供任何涉及系統呼叫的操作。

通用屬性

路徑物件是不可變 (immutable) 且可雜🄵 (*hashable*) 的。相同類型的路徑物件可以被比較和排序。這些屬性遵守該類型的大小寫語意規則：

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

不同類型的路徑物件在比較時視🄵不相等且無法被排序：

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath' and 'PurePosixPath
↪'
```

運算子

斜🄵運算子 (slash operator) 用於建立子路徑，就像是*os.path.join()* 函式一樣。如果引數是🄵對路徑，則忽略前一個路徑。在 Windows 系統上，當引數是具有根目🄵的相對路徑（例如，`r'\foo'`），磁碟機部分不會被重置：

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
>>> p / '/an_absolute_path'
PurePosixPath('/an_absolute_path')
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

路徑物件可以被用在任何可以接受實作*os.PathLike* 的物件的地方：

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

路徑的字串表示是原始的檔案系統路徑本身（以原生的形式，例如在 Windows 下是反斜🄵），你可以將其傳入任何將檔案路徑當作字串傳入的函式：

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

類似地，對路徑呼叫*bytes* 會得到原始檔案系統路徑的 bytes 物件，就像使用*os.fsencode()* 編碼過的一樣：

```
>>> bytes(p)
b'/etc'
```

備🄵

只建議在 Unix 下呼叫*bytes*。在 Windows 🄵，unicode 形式是檔案系統路徑的權威表示方式。

對個🄵組成的存取

可以使用下列屬性來存取路徑的個🄵「組成」(parts, components)：

PurePath.**parts**

一個可存取路徑的各組成的元組：

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

（特🄵注意磁碟機跟本地根目🄵是如何被重新組合成一個單一組成）

方法與屬性

純路徑提供以下方法與屬性：

PurePath.**drive**

若存在則🄵一個表示磁碟機字母 (drive letter) 或磁碟機名稱 (drive name) 的字串：

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
>>> PurePosixPath('/etc').drive
''
```

UNC shares 也被視🄵磁碟機：

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\host\\share'
```

PurePath.**root**

若存在則🄵一個表示（本地或全域）根目🄵的字串：

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
'/'
```

UNC shares 都會有一個根目🄵：

```
>>> PureWindowsPath('//host/share').root
'\\'
```

如果路徑以超過兩個連續的斜🄵開頭，*PurePosixPath* 會合🄵它們：

```
>>> PurePosixPath('//etc').root
'//'
>>> PurePosixPath('///etc').root
'/'
>>> PurePosixPath('////etc').root
'/'
```

備🄵

此行🄵符合 *The Open Group Base Specifications Issue 6*，章節 4.11 路徑名稱解析：

「以兩個連續斜🄵開頭的路徑名懲可以根據實作定義的方式來解讀，🄵管如此，開頭超過兩個斜🄵應該視🄵單一斜🄵。」

PurePath.**anchor**

磁碟機與根目🄵的結合：

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
'/'
>>> PureWindowsPath('//host/share').anchor
'\\\\host\\share\\'
```

PurePath.**parents**

一個不可變的序列，🄵路徑邏輯上的祖先 (logical ancestors) 提供存取：

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

在 3.10 版的變更: 父序列現在支援*slices* 及負的索引值。

PurePath.**parent**

邏輯上的父路徑：

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

你不能越過一個 anchor 或空路徑：

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

備🄵

這是一個純粹字句上的 (lexical) 運算，因此會有以下行🄵：

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

如果你想要沿任意的檔案系統路徑往上走，建議要先呼叫*Path.resolve()* 來解析符號連結 (symlink) 及去除其中的 ”`..`”。

PurePath.**name**

最後的路徑組成 (final path component) 的字串表示，不包含任何磁碟機或根目🄵：

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC 磁碟機名稱🄵🄵有算在🄵：

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

PurePath.**suffix**

若存在則🄵最後的路徑組成的檔案副檔名：

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

PurePath.**suffixes**

路徑檔案副檔名的串列：

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
```

(繼續下一頁)

(繼續上一頁)

```
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

PurePath.**stem**

最後的路徑組成，不包括後綴 (suffix)：

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

PurePath.**as_posix**()

回傳一個使用正斜🄵 (/) 的路徑的字串表示：

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

PurePath.**as_uri**()

以 file URI 來表示一個路徑。如果不是🄴對路徑會引發*ValueError*。

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = PureWindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

PurePath.**is_absolute**()

回傳一個路徑是否是🄴對路徑。一個路徑被視🄵🄴對路徑的條件是它同時有根目🄴及（如果該系統類型允許的話）磁碟機：

```
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False

>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True
```

PurePath.**is_relative_to**(*other*)

回傳此路徑是否🄴 *other* 路徑的相對路徑。

```
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

該方法是基於字串的；它既不存取檔案系統，也不特🄵處理"`..`"片段。以下程式碼是等效的：

```
>>> u = PurePath('/usr')
>>> u == p or u in p.parents
False
```

在 3.9 版被加入.

Deprecated since version 3.12, will be removed in version 3.14: 額外引數的傳入已🄵用；如果有的話，它們會與 *other* 連接在一起。

`PurePath.`**`is_reserved`**`()`

對*`PureWindowsPath`* 來🄵，當路徑在 Windows 下被視🄵保留的話會回傳 `True`，否則回傳 `False`。對*`PurePosixPath`* 來🄵，總是回傳 `False`。

```
>>> PureWindowsPath('nul').is_reserved()
True
>>> PurePosixPath('nul').is_reserved()
False
```

在保留路徑上的檔案系統呼叫會神秘地失敗或有意外的效果。

`PurePath.`**`joinpath`**`(`*`*pathsegments`*`)`

呼叫此方法會依序結合每個所給定的 *pathsegments* 到路徑上：

```
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')
```

`PurePath.`**`match`**`(`*`pattern`*`, *, `*`case_sensitive=None`*`)`

將路徑與 glob 形式的樣式 (glob-style pattern) 做比對。如果比對成功則回傳 `True`，否則回傳 `False`。

如果 *pattern* 是相對的，則路徑可以是相對或🄵對的，而且會從右邊來完成比對：

```
>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False
```

如果 *pattern* 是🄵對的，則路徑必須是🄵對的，且整個路徑都要比對到：

```
>>> PurePath('/a.py').match('/*.py')
True
>>> PurePath('a/b.py').match('/*.py')
False
```

pattern 可以是另一個路徑物件；這會加速對多個檔案比對相同的樣式：

```
>>> pattern = PurePath('*.py')
>>> PurePath('a/b.py').match(pattern)
True
```

備🄵

The recursive wildcard "**" isn't supported by this method (it acts like non-recursive "*".)

在 3.12 版的變更: 接受一個有實作*os.PathLike* 介面的物件。

像其它方法一樣，是否區分大小寫會遵循平台的預設行🄵：

```
>>> PurePosixPath('b.py').match('*.PY')
False
>>> PureWindowsPath('b.py').match('*.PY')
True
```

將 *case_sensitive* 設定成 `True` 或 `False` 會覆蓋這個行🄵。

在 3.12 版的變更: 新增 *case_sensitive* 參數。

`PurePath.`**`relative_to`**(*other*, *walk_up=False*)

計算這個路徑相對於 *other* 所表示路徑的版本。如果做不到會引發*ValueError*：

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not in the subpath of '/usr' OR one path is relative␣
↪and the other is absolute.
```

當 *walk_up* 是 False（預設值），路徑必須以 *other* 🄵開始。當此引數是 True，可能會加入 `..` 以組成相對路徑。在其他情🄵下，例如路徑參考到不同的磁碟機，則會引發*ValueError*：

```
>>> p.relative_to('/usr', walk_up=True)
PurePosixPath('../etc/passwd')
>>> p.relative_to('foo', walk_up=True)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not on the same drive as 'foo' OR one path is␣
↪relative and the other is absolute.
```

警告

這個函式是*PurePath* 的一部分且可以在字串上運作。它不會檢查或存取實際的檔案架構。這

會影響到 *walk_up* 選項，因🄴它假設路徑中🄴有符號連結；如果需要解析符號連結的話可以先呼叫`resolve()`。

在 3.12 版的變更: 加入 *walk_up* 參數（舊的行🄴和 `walk_up=False` 相同）。

Deprecated since version 3.12, will be removed in version 3.14: 額外位置引數的傳入已🄴用；如果有的話，它們會與 *other* 連接在一起。

`PurePath.`**`with_name`**`(`*name*`)`

回傳一個修改`name`後的新路徑。如果原始路徑🄴有名稱則引發 ValueError：

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 751, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

`PurePath.`**`with_stem`**`(`*stem*`)`

回傳一個修改`stem`後的新路徑。如果原始路徑🄴有名稱則引發 ValueError：

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with_stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with_stem('')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 861, in with_stem
    return self.with_name(stem + self.suffix)
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 851, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

在 3.9 版被加入.

`PurePath.`**`with_suffix`**`(`*suffix*`)`

回傳一個修改`suffix`後的新路徑。如果原始路徑🄴有後綴，新的 *suffix* 會附加在後面。如果 *suffix* 是一個空字串，原來的後綴會被移除：

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

PurePath.**with_segments**(**pathsegments*)

透過結合給定的 *pathsegments* 建立一個相同類型的新路徑物件，當一個衍生路徑被建立的時候會呼叫這個方法，例如從*parent* 和*relative_to()* 建立衍生路徑。子類🄵可以覆寫此方法來傳遞資訊給衍生路徑，例如：

```
from pathlib import PurePosixPath

class MyPath(PurePosixPath):
    def __init__(self, *pathsegments, session_id):
        super().__init__(*pathsegments)
        self.session_id = session_id

    def with_segments(self, *pathsegments):
        return type(self)(*pathsegments, session_id=self.session_id)

etc = MyPath('/etc', session_id=42)
hosts = etc / 'hosts'
print(hosts.session_id)  # 42
```

在 3.12 版被加入.

11.1.3 實體路徑

實體路徑是純路徑類🄵的子類🄵。除了後者本來就有提供的操作，它們也提供方法可以對路徑物件做系統呼叫。有三種方式可以實例化實體路徑：

class pathlib.**Path**(**pathsegments*)

PurePath 的子類🄵，此類🄵表示系統的路徑類型的實體路徑（實例化時會建立一個*PosixPath* 或*WindowsPath*）：

```
>>> Path('setup.py')
PosixPath('setup.py')
```

pathsegments 的指定方式與*PurePath* 類似。

class pathlib.**PosixPath**(**pathsegments*)

Path 和*PurePosixPath* 的子類🄵，此類🄵表示實體非 Windows 檔案系統路徑：

```
>>> PosixPath('/etc')
PosixPath('/etc')
```

pathsegments 的指定方式與*PurePath* 類似。

class pathlib.**WindowsPath**(**pathsegments*)

Path 和*PureWindowsPath* 的子類🄵，此類🄵表示實體 Windows 檔案系統路徑：

```
>>> WindowsPath('c:/Program Files/')
WindowsPath('c:/Program Files')
```

pathsegments 的指定方式與*PurePath* 類似。

你只能實例化對應你的系統的類🄵類型（允許在不相容的路徑類型上做系統呼叫可能在你的應用程式導致漏洞或故障）：

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
NotImplementedError: cannot instantiate 'WindowsPath' on your system
```

有些實體路徑方法會在系統呼叫失敗（例如因🄵路徑不存在）時引發*OSError*

Expanding and resolving paths

classmethod Path.**home**()

回傳一個代表使用者家目🄵的新的路徑物件（像以 ~ 構成的*os.path.expanduser()* 的回傳一樣）。如果無法解析家目🄵，會引發*RuntimeError*。

```
>>> Path.home()
PosixPath('/home/antoine')
```

在 3.5 版被加入.

Path.**expanduser**()

回傳一個展開 ~ 和 ~user 構成的新路徑，像*os.path.expanduser()* 回傳的一樣。如果無法解析家目🄵，會引發*RuntimeError*。

```
>>> p = PosixPath('~/films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/films/Monty Python')
```

在 3.5 版被加入.

classmethod Path.**cwd**()

回傳一個代表目前目🄵的新的路徑物件（像*os.getcwd()* 回傳的一樣）：

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

Path.**absolute**()

將路徑轉🄵🄵🄵對路徑，不進行標準化或解析符號連結。回傳一個新的路徑物件：

```
>>> p = Path('tests')
>>> p
PosixPath('tests')
>>> p.absolute()
PosixPath('/home/antoine/pathlib/tests')
```

Path.**resolve**(*strict=False*)

將路徑轉🄵🄵🄵對路徑，解析所有符號連結。回傳一個新的路徑物件：

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

同時也會消除".." 的路徑組成（只有此方法這樣做）：

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

如果路徑不存在且 *strict* 🄵 `True`，則引發*FileNotFoundError*。如果 *strict* 🄵 `False`，則將盡可能解析該路徑，🄴將任何剩余部分追加到路徑中，而不檢查其是否存在。如果在解析過程中遇到無窮🄴圈，則引發*RuntimeError*。

在 3.6 版的變更: 新增 *strict* 參數（在 3.6 版本之前的行🄴是嚴格的）。

`Path.`**`readlink`**`()`

回傳符號連結指向的路徑（如*os.readlink()* 的回傳值）：

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

在 3.9 版被加入.

Querying file type and status

在 3.8 版的變更: *exists()*、*is_dir()*、*is_file()*、*is_mount()*、*is_symlink()*、*is_block_device()*、*is_char_device()*、*is_fifo()*、*is_socket()* 遇到路徑包含 OS 層無法表示的字元時現在會回傳 `False` 而不是引發例外。

`Path.`**`stat`**`(*, follow_symlinks=True)`

Return an *os.stat_result* object containing information about this path, like *os.stat()*. The result is looked up at each call to this method.

此方法通常會跟隨 (follow) 符號連結；想要取得符號連結的資訊，可以加上引數 `follow_symlinks=False` 或使用*lstat()*。

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

在 3.10 版的變更: 新增 *follow_symlinks* 參數。

`Path.`**`lstat`**`()`

類似*Path.stat()*，但如果該路徑指向一個符號連結，則回傳符號連結的資訊而不是其指向的目標。

`Path.`**`exists`**`(*, follow_symlinks=True)`

如果路徑指向存在的檔案或目🄴則回傳 `True`。

此方法通常會跟隨符號連結；如果想檢查符號連結是否存在，可以加上引數 `follow_symlinks=False`。

```
>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

在 3.12 版的變更: 新增 *follow_symlinks* 參數。

`Path.`**`is_file`**`()`

如果該路徑指向一個普通檔案（或者是一個指向普通檔案的符號連結）則回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.`**`is_dir`**`()`

如果該路徑指向一個目𝔽（或者是一個指向目𝔽的符號連結）則回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.`**`is_symlink`**`()`

如果該路徑指向一個符號連結則回傳 `True`，否則回傳 `False`。

如果該路徑不存在也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.`**`is_junction`**`()`

如果該路徑指向一個連接點 (junction) 則回傳 `True`，對其他類型的檔案則回傳 `False`。目前只有 Windows 支援連接點。

在 3.12 版被加入.

`Path.`**`is_mount`**`()`

如果路徑是一個 *mount point*（一個檔案系統𝔽𝔽載不同檔案系統的存取點）則回傳 `True`。在 POSIX 上，此函式檢查 *path* 的父路徑 `path/..` 是否和 *path* 在不同的裝置上，或者 `path/..` 和 *path* 是否指向相同裝置的相同 i-node —— 這對於所有 Unix 和 POSIX 變體來𝔽應該會偵測出𝔽載點。在 Windows 上，一個𝔽載點被視𝔽一個根磁碟機字母（例如 `c:\`）、一個 UNC share（例如 `\\server\share`）或是𝔽載的檔案系統目𝔽。

在 3.7 版被加入.

在 3.12 版的變更: 加入對 Windows 的支援。

`Path.`**`is_socket`**`()`

如果該路徑指向一個 Unix socket（或者是一個指向 Unix socket 的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.`**`is_fifo`**`()`

如果該路徑指向一個 FIFO（或者是一個指向 FIFO 的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

Path.**is_block_device**()

如果該路徑指向一個區塊裝置 (block device)（或者是一個指向區塊裝置的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

Path.**is_char_device**()

如果該路徑指向一個字元裝置 (character device)（或者是一個指向字元裝置的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

Path.**samefile**(*other_path*)

回傳此路徑是否指向與 *other_path* 相同的檔案，*other_path* 可以是路徑 (Path) 物件或字串。其語義類似於*os.path.samefile()* 和*os.path.samestat()*。

若任何一個檔案因🄵某些原因無法存取，則引發*OSError*。

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

在 3.5 版被加入.

Reading and writing files

Path.**open**(*mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*)

開🄵該路徑指向的檔案，像🄵建的*open()* 函式做的一樣：

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

Path.**read_text**(*encoding=None*, *errors=None*)

將路徑指向的檔案的解碼🄵容以字串形式回傳：

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

該檔案被打開🄵且隨後關閉。可選參數的含義與*open()* 中的相同。

在 3.5 版被加入.

Path.**read_bytes**()

將路徑指向的檔案的二進位🄵容以一個位元組物件回傳：

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

在 3.5 版被加入.

Path.**write_text**(*data*, *encoding=None*, *errors=None*, *newline=None*)

以文字模式開🄵指向的檔案，將 *data* 寫到檔案，🄵關閉檔案::：

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

一個名稱相同的已存在檔案會被覆寫。可選參數和*open()* 的參數有相同意義。

在 3.5 版被加入.

在 3.10 版的變更: 新增 *newline* 參數。

Path.**write_bytes**(*data*)

以位元組模式開🄵指向的檔案，將 *data* 寫到檔案，🄵關閉檔案::：

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

一個名稱相同的已存在檔案會被覆寫。

在 3.5 版被加入.

讀取目🄵

Path.**iterdir**()

當該路徑指向一個目🄵，會 yield 目🄵🄵面的路徑物件：

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

子路徑會以任意順序被 yield，且不會包含特殊項目 `'.'` 和 `'..'`。如果一個檔案在建立這個🄵代器之後加到該目🄵或從目🄵🄵除，這個檔案的路徑物件是否會被包含是🄵有明定的。

If the path is not a directory or otherwise inaccessible, *OSError* is raised.

Path.**glob**(*pattern*, *, *case_sensitive=None*)

在該路徑表示的目🄵🄵，以 glob 方式比對所給定的相對 *pattern*，🄵 yield 所有比對到的檔案（任意類型）：

```
>>> sorted(Path('.').glob('*.py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), PosixPath('test_pathlib.py')]
>>> sorted(Path('.').glob('*/*.py'))
[PosixPath('docs/conf.py')]
```

模式 (pattern) 和給*fnmatch* 的一樣，加上"**" 代表「目前目🄵及所有遞🄵的子目🄵」。也就是🄵它能🄵做遞🄵的 glob 比對：

```
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

此方法在頂層目🄵上呼叫*Path.is_dir()* 🄵傳遞引發的任何*OSError* 例外。將會抑制在目🄵對於*OSError* 例外的後續掃描。

預設情🄵下，或者當 *case_sensitive* 僅限關鍵字引數被設定🄵 None 的時候，此方法會使用平台特定的大小寫規則來比對路徑；通常在 POSIX 上會區分大小寫，而在 Windows 上不區分大小寫。將 *case_sensitive* 設成 True 或 False 會覆寫這個行🄵。

備🄵

在很大的目🄵樹🄵使用"**" 可能會耗費過多的時間。

Raises an *auditing event* pathlib.Path.glob with arguments self, pattern.

在 3.11 版的變更: 如果 *pattern* 以路徑名稱組成的分隔符號（*sep* 或*altsep*）作結尾則只會回傳目🄵。

在 3.12 版的變更: 新增 *case_sensitive* 參數。

Path.**rglob**(*pattern*, *, *case_sensitive=None*)

遞🄵地 glob 給定的相對 *pattern*。這相當於在給定的相對 *pattern* 前面加上"**/" 🄵呼叫*Path.glob()*，其中 *patterns* 和給*fnmatch* 的相同：

```
>>> sorted(Path().rglob("*.py"))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

預設情🄵下，或者當 *case_sensitive* 僅限關鍵字引數被設定🄵 None 的時候，此方法會使用平台特定的大小寫規則來比對路徑；通常在 POSIX 上會區分大小寫，而在 Windows 上不區分大小寫。將 *case_sensitive* 設成 True 或 False 會覆寫這個行🄵。

Raises an *auditing event* pathlib.Path.rglob with arguments self, pattern.

在 3.11 版的變更: 如果 *pattern* 以路徑名稱組成的分隔符號（*sep* 或*altsep*）作結尾則只會回傳目🄵。

在 3.12 版的變更: 新增 *case_sensitive* 參數。

Path.**walk**(*top_down=True*, *on_error=None*, *follow_symlinks=False*)

透過由上而下或由下而上地走訪目F樹F生目F樹F的檔案名稱。

對每個以 *self* F根且在目F樹F的目F（包含 *self* 但不包含'.' 和'..'），此方法會 yield 一個 `(dirpath, dirnames, filenames)` 的三元素元組。

dirpath 是一個目前走訪到的目F的*Path*，*dirnames* 是一個 *dirpath* F的子目F名稱的字串串列（不包含 `'.'` 和 `'..'`），而 *filenames* 是一個 *dirpath* F非目F檔案名稱的字串串列。要取得在 *dirpath* F檔案或目F的完整路徑（以 *self* 開頭），可以使用 `dirpath / name`。會根據檔案系統來F定串列是否有排序。

如果可選引數 *top_down* 是 true（預設值），一個目F的三元素元組會在其任何子目F的三元素元組之前F生（目F是由上而下走訪）。如果 *top_down* 是 false，一個目F的三元素元組會在其所有子目F的三元素元組之後F生（目F是由下而上走訪）。不論 *top_down* 的值是什F，子目F的串列會在走訪該目F及其子目F的三元素元組之前取得。

當 *top_down* 是 true，呼叫者可以原地 (in-place) 修改 *dirnames* 串列（例如使用 `del` 或切片賦值 (slice assignment)），且*Path.walk()* 只會遞F進名稱依然留在 *dirnames* F的子目F。這可以用來修剪搜尋，或者F加特定順序的訪問，或者甚至在繼續*Path.walk()* 之前，用來告訴*Path.walk()* 關於呼叫者建立或重新命名的目F。當 *top_down* 是 false 的時候，修改 *dirnames* 對*Path.walk()* 的行FF有影響，因F *dirnames* F的目F已經在 *dirnames* yield 給呼叫者之前被F生。

預設來自*os.scandir()* 的錯誤會被忽略。如果指定了可選引數 *on_error*（它應該要是一個可呼叫物件），它會被以一個*OSError* 實例F引數來呼叫。這個可呼叫物件可以處理錯誤以繼續走訪，或者再次引發錯誤來停止走訪。注意，檔案名稱可以從例外物件的 `filename` 屬性來取得。

預設*Path.walk()* 不會跟隨符號連結，而是會把它們加到 *filenames* 串列。將 *follow_symlinks* 設定F true 會解析符號連結，F將它們根據其指向的目標放在適當的 *dirnames* 和 *filenames*，而因此訪問到符號連結指向的目F（在有支援符號連結的地方）。

備F

需要注意的是如果符號連結指向一個其本身的父目F，則將 *follow_symlinks* 設定F true 會導致無窮的遞F。*Path.walk()* 不會紀F其已經訪問過的目F。

備F

Path.walk() 假設其走訪的目F在執行過程中不會被修改。舉例來F，如果在 *dirnames* F的目F已經被一個符號連結取代，且 *follow_symlinks* 是 false，*Path.walk()* 依然會試著往下進入它。F了防止這樣的行F，可以從 *dirnames* 適當地移除目F。

備F

如果 *follow_symlinks* 是 false，和*os.walk()* 行F不同的是*Path.walk()* 會將指向目F的符號連結放在 *filenames* 串列。

這個範例會顯示在每個目FF所有檔案使用的位元組數量，同時間忽略 `__pycache__` 目F：

```
from pathlib import Path
for root, dirs, files in Path("cpython/Lib/concurrent").walk(on_error=print):
  print(
      root,
```

(繼續下一頁)

(繼續上一頁)

```
      "consumes",
      sum((root / file).stat().st_size for file in files),
      "bytes in",
      len(files),
      "non-directory files"
  )
  if '__pycache__' in dirs:
        dirs.remove('__pycache__')
```

下一個範例是*shutil.rmtree()* 的一個簡單的實作方式。由下而上走訪目🄵樹是必要的，因🄵*rmdir()* 不允許在目🄵🄵空之前🄵除它：

```
# Delete everything reachable from the directory "top".
# CAUTION:  This is dangerous! For example, if top == Path('/'),
# it could delete all of your files.
for root, dirs, files in top.walk(top_down=False):
    for name in files:
        (root / name).unlink()
    for name in dirs:
        (root / name).rmdir()
```

在 3.12 版被加入.

建立檔案與目🄵

Path.**touch**(*mode=0o666*, *exist_ok=True*)

根據給定路徑來建立一個檔案。如果 *mode* 有給定，它會與行程的 umask 值結合，以確定檔案模式和存取旗標。當檔案已經存在時，若 *exist_ok* 🄵 true 則函式不會失敗（其變更時間會被更新🄴當下時間），否則會引發*FileExistsError*。

也參考

The *open()*, *write_text()* and *write_bytes()* methods are often used to create files.

Path.**mkdir**(*mode=0o777*, *parents=False*, *exist_ok=False*)

在給定路徑下建立一個新的目🄵。如果有給 *mode* 則會結合行程 (process) 的 umask 值來🄵定檔案模式與存取旗標 (access flag)。如果路徑已經存在，會引發*FileExistsError*。

如果 *parents* 是 true，則任何缺少的父路徑都會依需要被建立；它們不考慮 *mode* 而會以預設的權限來建立（模仿 POSIX 的 mkdir -p 指令）。

如果 *parents* 是 false（預設值），缺少的父路徑會引發*FileNotFoundError*。

如果 *exist_ok* 是 false（預設值），則當目標目🄵已經存在的話會引發*FileExistsError*。

如果 *exist_ok* 是 true，只有當最後的路徑組成不是一個已存在的非目🄵檔案，*FileExistsError* 例外會被忽略（與 POSIX 的 mkdir -p 指令行🄵相同）。

在 3.5 版的變更: 新增 *exist_ok* 參數。

Path.**symlink_to**(*target*, *target_is_directory=False*)

使這個路徑成🄵一個指向 *target* 的符號連結。

在 Windows 上，符號連結代表一個檔案或目🄴，且不會隨著目標 (target) 動態改變。如果目標存在，則符號連結的類型會被建立來符合其目標。否則如果 *target_is_directory* 是 true，該符號連結會被建立成目🄵，如果不是則建立成檔案（預設值）。在非 Windows 平台上，*target_is_directory* 會被忽略。

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

備🄵

引數的順序 (link, target) 和*os.symlink()* 相反。

Path.**hardlink_to**(*target*)

使這個路徑成🄵與 *target* 相同檔案的一個硬連結 (hard link)。

備🄵

引數的順序 (link, target) 和*os.link()* 相反。

在 3.10 版被加入.

Renaming and deleting

Path.**rename**(*target*)

將此檔案或目🄵重新命名🄵給定的 *target* ，🄵回傳一個新的 Path 實例指向該 *target*。在 Unix 系統上，若 *target* 存在且🄵一個檔案，若使用者有權限，則會在不顯示訊息的情🄵下進行取代。在 Windows 系統上，若 *target* 存在，則會引發*FileExistsError* 錯誤。*target* 可以是字串或另一個路徑物件:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

目標路徑可以是🄵對路徑或相對路徑。相對路徑會相對於當前的工作目🄵進行解釋，而不是相對於 Path 物件所在的目🄵。

此功能是使用*os.rename()* 實現的，🄵提供相同的保證。

在 3.8 版的變更: 新增了回傳值，回傳新的 Path 實例。

Path.**replace**(*target*)

將此檔案或目🄵重新命名🄵給定的 *target*，🄵回傳一個指向 *target* 的新 Path 實例。如果 *target* 指向一個現有的檔案或空目🄵，它將被無條件地取代。

目標路徑可以是🄵對路徑或相對路徑。相對路徑會相對於當前的工作目🄵進行解釋，而不是相對於 Path 物件所在的目🄵。

在 3.8 版的變更: 新增了回傳值，回傳新的 Path 實例。

Path.**unlink**(*missing_ok=False*)

移除這個檔案或符號連結。如果路徑指向目🄵，請改用*Path.rmdir()*。

如果 *missing_ok* 是 false（預設值），*FileNotFoundError* 會在路徑不存在時被引發。

如果 *missing_ok* 是 true，*FileNotFoundError* 例外會被忽略（行🄵與 POSIX `rm -f` 指令相同）。

在 3.8 版的變更: 新增 *missing_ok* 參數。

Path.**rmdir**()

移除此目🄵。該目🄵必須🄵空。

Permissions and ownership

Path.**owner**()

回傳擁有該檔案的用🄵名稱。如果在系統資料庫中找不到該檔案的使用者識🄵字 (UID)，則會引發*KeyError*。

Path.**group**()

回傳擁有該檔案的群組名稱。如果在系統資料庫🄵找不到檔案的群組識🄵字 (GID) 會引發*KeyError*。

Path.**chmod**(*mode*, *, *follow_symlinks=True*)

修改檔案模式 (file mode) 與權限，像*os.chmod()* 一樣。

此方法通常會跟隨符號連結。一些 Unix 類型支援修改符號連結本身的權限；在這些平台上你可以加上引數 `follow_symlinks=False` 或使用*lchmod()*。

```
>>> p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060
```

在 3.10 版的變更: 新增 *follow_symlinks* 參數。

Path.**lchmod**(*mode*)

類似*Path.chmod()*，但如果該路徑指向一個符號連結，則符號連結的模式 (mode) 會被改變而不是其指向的目標。

11.1.4 與 os 模組🄵的工具的對應關🄵

以下是一張表格，對應許多*os* 函式及其相符於*PurePath*/*Path* 的項目。

os 和*os.path*	*pathlib*
os.path.dirname()	*PurePath.parent*
os.path.basename()	*PurePath.name*
os.path.splitext()	*PurePath.stem*, *PurePath.suffix*
os.path.join()	*PurePath.joinpath()*
os.path.isabs()	*PurePath.is_absolute()*
os.path.relpath()	*PurePath.relative_to()*[1]
os.path.expanduser()	*Path.expanduser()*[2]
os.path.realpath()	*Path.resolve()*
os.path.abspath()	*Path.absolute()*[3]

繼續下一頁

表格 1 – 繼續上一頁

os 和os.path	pathlib
os.path.exists()	Path.exists()
os.path.isfile()	Path.is_file()
os.path.isdir()	Path.is_dir()
os.path.islink()	Path.is_symlink()
os.path.isjunction()	Path.is_junction()
os.path.ismount()	Path.is_mount()
os.path.samefile()	Path.samefile()
os.getcwd()	Path.cwd()
os.stat()	Path.stat()
os.lstat()	Path.lstat()
os.listdir()	Path.iterdir()
os.walk()	Path.walk()[4]
os.mkdir(), os.makedirs()	Path.mkdir()
os.link()	Path.hardlink_to()
os.symlink()	Path.symlink_to()
os.readlink()	Path.readlink()
os.rename()	Path.rename()
os.replace()	Path.replace()
os.remove()、os.unlink()	Path.unlink()
os.rmdir()	Path.rmdir()
os.chmod()	Path.chmod()
os.lchmod()	Path.lchmod()

🄵解

11.2 os.path --- 常見的路徑名操作

原始碼： Lib/genericpath.py、Lib/posixpath.py (用於 POSIX 系統) 和 Lib/ntpath.py (用於 Windows).

該模組實現了一些有用的路徑名操作函式。若要讀取或寫入檔案，請參🄵open() 函數，要存取檔案系統，請參🄵os 模組。路徑參數可以以字串、位元組或任何依照os.PathLike 協議實作的物件傳遞。

與 Unix shell 不同，Python 不會自動進行路徑展開 (path expansions)。當應用程式需要進行類似 shell 的路徑展開時，可以明確地呼叫expanduser() 和expandvars() 等函式。(另請參🄵glob 模組。)

也參考

pathlib 模組提供了高階的路徑物件。

[1] os.path.relpath() calls abspath() to make paths absolute and remove ”..” parts, whereas PurePath.relative_to() is a lexical operation that raises ValueError when its inputs' anchors differ (e.g. if one path is absolute and the other relative.)

[2] os.path.expanduser() returns the path unchanged if the home directory can't be resolved, whereas Path.expanduser() raises RuntimeError.

[3] os.path.abspath() removes ”..” components without resolving symlinks, which may change the meaning of the path, whereas Path.absolute() leaves any ”..” components in the path.

[4] os.walk() always follows symlinks when categorizing paths into *dirnames* and *filenames*, whereas Path.walk() categorizes all symlinks into *filenames* when *follow_symlinks* is false (the default.)

備🄵

所有這些函數都只接受位元組或字串物件作🄵參數。如果回傳的是路徑或檔案名稱，結果將是相同型🄵的物件。

備🄵

由於不同的作業系統具有不同的路徑命名慣例，在標準函式庫中的路徑模組有數個版本可供使用，而*os.path* 模組都會是運行 Python 之作業系統所適用本地路徑。然而，如果你想要操作始終以某個不同於本機格式表示的路徑，你也可以引入🄵使用對應的模組。它們都具有相同的介面：

- `posixpath` 用於 UNIX 形式的路徑
- `ntpath` 用於 Windows 的路徑

在 3.8 版的變更: 對於包含有作業系統層級無法表示之字元或位元組的路徑，*exists()*、*lexists()*、*isdir()*、*isfile()*、*islink()* 和*ismount()* 函式現在會回傳 `False`，而不是引發例外。

`os.path.`**`abspath`**(*path*)

回傳經正規化的🄵對路徑名 *path* 。在大多數平台上，這等效於按照以下方式呼叫*normpath()* 函式：`normpath(join(os.getcwd(), path))`。

在 3.6 版的變更: 接受一個*path-like object*。

`os.path.`**`basename`**(*path*)

回傳路徑名 *path* 的基底名稱。這是將 *path* 傳遞給函式*split()* 後回傳結果中的第二個元素。請注意，此函式的結果與 Unix 的 **basename** 程式不同；對於 `'/foo/bar/'`，**basename** 回傳 `'bar'`，而*basename()* 函式回傳空字串（`''`）。

在 3.6 版的變更: 接受一個*path-like object*。

`os.path.`**`commonpath`**(*paths*)

回傳序列 *paths* 中每個路徑名的最長共同子路徑。如果 *paths* 同時包含🄵對路徑和相對路徑、*paths* 位於不同的驅動機或 *paths* 🄵空，則引發*ValueError*。與*commonprefix()* 不同，此函式回傳的是有效路徑。

在 3.5 版被加入.

在 3.6 版的變更: 接受一個類路徑物件的序列。

`os.path.`**`commonprefix`**(*list*)

回傳 *list* 中所有路徑的最長路徑前綴（逐字元比較）。如果 *list* 🄵空，則回傳空字串（`''`）。

備🄵

由於此函式是逐字元比較，因此可能會回傳無效的路徑。若要獲得有效的路徑，請參考*commonpath()* 函式。

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib'])
'/usr/l'

>>> os.path.commonpath(['/usr/lib', '/usr/local/lib'])
'/usr'
```

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**dirname**(*path*)

回傳路徑名 *path* 的目F名稱。這是將 *path* 傳遞給函式*split()* 後回傳之成對結果中的第一個元素。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**exists**(*path*)

如果 *path* 是一個存在的路徑或一個開F的檔案描述器則回傳 True。對於已損壞的符號連結則回傳 False。在某些平台上，即使 *path* 實際存在，如果未被授予執行*os.stat()* 的權限，此函式仍可能回傳 False。

在 3.3 版的變更: 現在 *path* 可以是一個整數：如果它是一個開F的檔案描述器，則回傳 True；否則回傳 False。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**lexists**(*path*)

如果 *path* 是一個存在的路徑則回傳 True，對已損壞的符號連結也是。在缺乏*os.lstat()* 的平台上，與*exists()* 函式等效。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**expanduser**(*path*)

在 Unix 和 Windows 上，將引數中以 ~ 或 ~user 開頭的部分替FF該 *user* 的家目F。

在 Unix 上，如果環境變數 HOME 有被設置，則將初始的 ~ 替FF該變數的值；否則將使用F建模組*pwd* 在密碼目F中查找當前使用者的家目F。對於初始的 ~user，直接在密碼目F中查找該使用者的家目F。

在 Windows 上，如果 USERPROFILE 有被設置，則使用該變數的值；否則將結合 HOMEPATH 和 HOMEDRIVE。對於初始的 ~user，會檢查當前使用者的家目F的最後一個目F元件是否與 USERNAME 相符，如果相符則替F它。

如果展開失敗或路徑不以波浪符號 (tilde) 開頭，則回傳原始路徑，不做任何變更。

在 3.6 版的變更: 接受一個*path-like object*。

在 3.8 版的變更: 在 Windows 上不再使用 HOME 變數。

os.path.**expandvars**(*path*)

回傳已展開環境變數的引數。形如 $name 或 ${name} 的子字串會被替FF環境變數 *name* 的值。無效的變數名稱和對不存在變數的引用保持不變。

在 Windows 上，除了支援 $name 和 ${name} 形式的展開外，還支援 %name% 形式的展開。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**getatime**(*path*)

Return the time of last access of *path*. The return value is a floating-point number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

os.path.**getmtime**(*path*)

Return the time of last modification of *path*. The return value is a floating-point number giving the number of seconds since the epoch (see the *time* module). Raise *OSError* if the file does not exist or is inaccessible.

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**getctime**(*path*)

回傳系統的 ctime。在某些系統（如 Unix）上，這是最後一次元數據 (metadata) 更改的時間，在其他系統（如 Windows）上則是 *path* 的建立時間。回傳值是一個浮點數，表示自紀元（參見*time* 模組）以來的秒數。如果檔案不存在或無法存取），則引發*OSError*。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**getsize**(*path*)

回傳 *path* 的大小（以位元組🄴單位）。如果檔案不存在或無法存取，則引發*OSError*。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**isabs**(*path*)

如果 *path* 是🄴對路徑名，則回傳 True。在 Unix 上，這表示它以斜🄴開頭；在 Windows 上，表示在去除可能的驅動機字母後，以（反）斜🄴開頭。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**isfile**(*path*)

如果 *path* 是一個已存在的常規檔案，則回傳 True。這將跟隨符號連結，因此同一個路徑可以同時回傳*islink()* 和*isfile()* 的結果🄵真。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**isdir**(*path*)

如果 *path* 是一個已存在的目🄴，則回傳 True。這將跟隨符號連結，因此同一個路徑可以同時回傳*islink()* 和*isfile()* 的結果🄵真。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**isjunction**(*path*)

如果 *path* 是指向已存在的目🄴條目且🄵聯接點 (junction)，則回傳 True。如果目前平台不支援聯接點，則始終返回 False。

在 3.12 版被加入.

os.path.**islink**(*path*)

如果 *path* 是指向已存在的目🄴項目且🄵符號連結，則回傳 True。如果 Python 執行時不支援符號連結，則始終回傳 False。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**ismount**(*path*)

如果路徑名 *path* 是一個🄴載點 (*mount point*)，則回傳 True：即在檔案系統中🄴載了不同的檔案系統。在 POSIX 系統上，該函式檢查 *path* 的父目🄴 *path*`/..` 是否位於不同的設備上，或者 *path*`/..` 和 *path* 是否指向同一設備上的相同 i-node --- 這應該能🄴檢測出所有 Unix 和 POSIX 變體的🄴載點。但無法可靠地檢測出相同檔案系統上的綁定🄵載點 (bind mount)。在 Windows 上，以驅動機字母開頭的根目🄴和 UNC 共享路徑始終是🄵載點，對於任何其他路徑，會呼叫 GetVolumePathName 函式來檢查它是否與輸入路徑不同。

在 3.4 版的變更: 新增在 Windows 上檢測非根目🄴🄵載點的支援。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**isdevdrive**(*path*)

如果路徑名 *path* 位於 Windows Dev 驅動機上，則回傳 True。Dev 驅動機針對開發人員場景進行了優化，提供更快的讀寫檔案性能。建議將其用於原始程式碼、臨時建置目🄴、封包快取和其他 I/O 密集型操作。

可能會對無效的路徑引發錯誤，例如，🄴有可識🄴的驅動機的路徑，但在不支援 Dev 磁碟機的平台上返回 False。請參🄵 Windows 文件以了解有關🄵用和建立 Dev 驅動機的資訊。

適用： Windows。

在 3.12 版被加入.

os.path.**join**(*path*, **paths*)

聰明地連接一個或多個路徑段。回傳值是 *path* 和 **paths* 的所有成員的串聯，每個非空部分後面都有一個目□分隔符號，除了最後一個部分。□句話□，如果最後一個部分□空或以分隔符號結尾，結果只會以分隔符號結尾。如果一個段是□對路徑（在 Windows 上需要驅動機和根），則忽略所有之前的段，□從□對路徑段繼續連接。

在 Windows 上，當遇到根路徑段（例如，`r'\foo'`）時，驅動機不會被重置。如果一個段位於不同的驅動機上，或者是□對路徑，則將忽略所有之前的段□重置驅動機。請注意，由於每個驅動機都有當前目□，`os.path.join("c:", "foo")` 表示相對於驅動機 `C:` 的當前目□的路徑（即 `c:foo`），而不是 `c:\foo`。

在 3.6 版的變更: *path* 和 *paths* 接受*path-like object* 作□參數。

os.path.**normcase**(*path*)

將路徑名的大小寫規範化。在 Windows 上，將路徑名中的所有字元轉□□小寫，□將正斜□轉□□反斜□。在其他作業系統上，回傳原始路徑。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**normpath**(*path*)

通過合□多余的分隔符號和上層引用來標准化路徑名，使得 `A//B`、`A/B/`、`A/./B` 和 `A/foo/../B` 都變成 `A/B`。這種字串操作可能會改變包含符號連結的路徑的含義。在 Windows 上，它將正斜□轉□□反斜□。要標准化大小寫，請使用*`normcase()`*。

備□

在 POSIX 系統中，根據 IEEE Std 1003.1 2013 版; 4.13 Pathname Resolution 標准，如果一個路徑名恰好以兩個斜□開頭，則在前導字元後的第一個部分可能會以由實作品自行定義的方式解釋，雖然多於兩個前導字元應該被視□單個字元。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**realpath**(*path*, *, *strict=False*)

回傳指定檔案名稱的規範路徑，消除路徑中遇到的所有符號連結（如果作業系統支援）。

如果路徑不存在或遇到符號連結□圈，且 *strict* □ `True`，則引發*`OSError`*。如果 *strict* □ `False`，則將路徑盡可能解析，□將任何剩余部分附加在後面，而不檢查其是否存在。

備□

此函式模擬作業系統使路徑成□規範的過程，Windows 和 UNIX 之間在鏈接和後續路徑部份交互方式方面略有不同。

作業系統的 API 會根據需要自動使路徑正則，因此通常不需要呼叫此函式。

在 3.6 版的變更: 接受一個*path-like object*。

在 3.8 版的變更: 在 Windows 上，現在會解析符號連結和連接點。

在 3.10 版的變更: 新增 *strict* 參數。

os.path.**relpath**(*path*, *start=os.curdir*)

從當前目□或可選的 *start* 目□回傳到 *path* 的相對檔案路徑。這是一個路徑計算：不會訪問檔案系統來確認 *path* 或 *start* 的存在或屬性。在 Windows 上，當 *path* 和 *start* 在不同的驅動機上時，會引發*`ValueError`*。

start 的預設值□*`os.curdir`*。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**samefile**(*path1*, *path2*)

如果兩個路徑名引數指向同一個檔案或目🄵，則回傳 `True`。這是通過設備編號和 i-node 編號來確定的，如果對任一路徑名的`os.stat()` 呼叫失敗，則會引發🄵常。

在 3.2 版的變更: 新增對 Windows 的支援。

在 3.4 版的變更: 現在在 Windows 上使用與其他所有平台相同的實作方式。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**sameopenfile**(*fp1*, *fp2*)

如果文件描述符 *fp1* 和 *fp2* 指向同一個檔案，則回傳 `True`。

在 3.2 版的變更: 新增對 Windows 的支援。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**samestat**(*stat1*, *stat2*)

如果 stat 值組 *stat1* 和 *stat2* 指向同一個檔案，則回傳 `True`。這些結構可能由`os.fstat()`、`os.lstat()` 或`os.stat()` 回傳。此函式使用`samefile()` 和`sameopenfile()` 實現了底層比較。

在 3.4 版的變更: 新增對 Windows 的支援。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**split**(*path*)

將路徑名 *path* 拆分🄵 `(head, tail)` 一對，其中 *tail* 是最後一個路徑名部份，*head* 是在它之前的所有部分。*tail* 部分不會包含斜🄵；如果 *path* 以斜🄵結尾，則 *tail* 將🄵空。如果 *path* 中🄵有斜🄵，則 *head* 將🄵空。如果 *path* 🄵空，則 *head* 和 *tail* 都🄵空。除非 *head* 是根目🄵（僅有一個或多個斜🄵），否則從 *head* 中🄵除尾部的斜🄵。在所有情🄵下，`join(head, tail)` 回傳指向與 *path* 相同位置的路徑（但字串可能不同）。還可以參考函式`dirname()` 和`basename()`。

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**splitdrive**(*path*)

將路徑名 *path* 拆分🄵 `(drive, tail)` 一對，其中 *drive* 是🄵載點或空字串。在不使用驅動機規範的系統上，*drive* 將始終🄵空字串。在所有情🄵下，`drive + tail` 將與 *path* 相同。

在 Windows 上，將路徑名拆分🄵驅動機或 UNC 共享點以及相對路徑。

如果路徑包含驅動機字母，則 *drive* 將包含從頭到冒號（包括冒號）的所有🄵容：

```
>>> splitdrive("c:/dir")
("c:", "/dir")
```

如果路徑包含 UNC 路徑，則驅動機將包含主機名和共享名：

```
>>> splitdrive("//host/computer/dir")
("//host/computer", "/dir")
```

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**splitroot**(*path*)

將路徑名 *path* 拆分🄵一個 3 項值組 `(drive, root, tail)`，其中 *drive* 是設備名稱或🄵載點，*root* 是驅動機後的分隔符字串，*tail* 是在根後的所有🄵容。這些項目中的任何一個都可能是空字串。在所有情🄵下，`drive + root + tail` 將與 *path* 相同。

在 POSIX 系統上，*drive* 始終🄵空。*root* 可能🄵空（如果 *path* 是相對路徑），一個斜🄵（如果 *path* 是🄵對路徑），或者兩個斜🄵（根據 IEEE Std 1003.1-2017; 4.13 Pathname Resolution 的實作定義）。例如：

```
>>> splitroot('/home/sam')
('', '/', 'home/sam')
>>> splitroot('//home/sam')
('', '//', 'home/sam')
>>> splitroot('///home/sam')
('', '/', '//home/sam')
```

在 Windows 上，*drive* 可能🄵空、驅動機名稱、UNC 共享或設備名稱。*root* 可能🄵空，斜🄵或反斜🄵。例如：

```
>>> splitroot('C:/Users/Sam')
('C:', '/', 'Users/Sam')
>>> splitroot('//Server/Share/Users/Sam')
('//Server/Share', '/', 'Users/Sam')
```

在 3.12 版被加入.

os.path.**splitext**(*path*)

將路徑名 *path* 拆分🄵一對 `(root, ext)`，使得 `root + ext == path`，且副檔名 *ext* 🄵空或以點開頭且最多包含一個點 (period)。

如果路徑不包含副檔名，則 *ext* 將🄵 `''`：

```
>>> splitext('bar')
('bar', '')
```

如果路徑包含副檔名，則 *ext* 將設置🄵該副檔名，包括前導的點。請注意，前面的點將被忽略：

```
>>> splitext('foo.bar.exe')
('foo.bar', '.exe')
>>> splitext('/foo/bar.exe')
('/foo/bar', '.exe')
```

路徑的最後一個部份的前導點被認🄵是根的一部分：

```
>>> splitext('.cshrc')
('.cshrc', '')
>>> splitext('/foo/....jpg')
('/foo/....jpg', '')
```

在 3.6 版的變更: 接受一個*path-like object*。

os.path.**supports_unicode_filenames**

如果可以使用任意的 Unicode 字串作🄵檔案名（在檔案系統所施加的限制範圍🄵），則回傳 `True`。

11.3 `fileinput` --- 逐列🄵代多個輸入串流

原始碼： Lib/fileinput.py

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see *`open()`*.

The typical use is:

```
import fileinput
for line in fileinput.input(encoding="utf-8"):
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is `'-'`, it is also replaced by `sys.stdin` and the optional arguments *mode* and *openhook* are ignored. To specify an alternative list of filenames, pass it as the first argument to *input()*. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the *mode* parameter in the call to *input()* or *FileInput*. If an I/O error occurs during opening or reading a file, *OSError* is raised.

在 3.3 版的變更: *IOError* used to be raised; it is now an alias of *OSError*.

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the *openhook* parameter to *fileinput.input()* or *FileInput()*. The hook must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. If *encoding* and/or *errors* are specified, they will be passed to the hook as additional keyword arguments. This module provides a *hook_compressed()* to support compressed files.

The following function is the primary interface of this module:

`fileinput.`**`input`**(*files=None*, *inplace=False*, *backup=''*, ***, *mode='r'*, *openhook=None*, *encoding=None*, *errors=None*)

Create an instance of the *FileInput* class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the *FileInput* class.

The *FileInput* instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt'), encoding="utf-8") as f:
    for line in f:
        process(line)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameters *mode* and *openhook* are now keyword-only.

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

The following functions use the global state created by *fileinput.input()*; if there is no active state, *RuntimeError* is raised.

`fileinput.`**`filename`**()

Return the name of the file currently being read. Before the first line has been read, returns `None`.

`fileinput.`**`fileno`**()

Return the integer "file descriptor" for the current file. When no file is opened (before the first line and between files), returns `-1`.

`fileinput.`**`lineno`**()

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

fileinput.**filelineno**()

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

fileinput.**isfirstline**()

Return `True` if the line just read is the first line of its file, otherwise return `False`.

fileinput.**isstdin**()

Return `True` if the last line was read from `sys.stdin`, otherwise return `False`.

fileinput.**nextfile**()

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

fileinput.**close**()

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

class fileinput.**FileInput**(*files=None*, *inplace=False*, *backup=''*, ***, *mode='r'*, *openhook=None*, *encoding=None*, *errors=None*)

Class *FileInput* is the implementation; its methods *filename()*, *fileno()*, *lineno()*, *filelineno()*, *isfirstline()*, *isstdin()*, *nextfile()* and *close()* correspond to the functions of the same name in the module. In addition it is *iterable* and has a *readline()* method which returns the next input line. The sequence must be accessed in strictly sequential order; random access and *readline()* cannot be mixed.

With *mode* you can specify which file mode will be passed to *open()*. It must be one of `'r'` and `'rb'`.

The *openhook*, when given, must be a function that takes two arguments, *filename* and *mode*, and returns an accordingly opened file-like object. You cannot use *inplace* and *openhook* together.

You can specify *encoding* and *errors* that is passed to *open()* or *openhook*.

A *FileInput* instance can be used as a context manager in the `with` statement. In this example, *input* is closed after the `with` statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as input:
    process(input)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameter *mode* and *openhook* are now keyword-only.

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

在 3.11 版的變更: The `'rU'` and `'U'` modes and the `__getitem__()` method have been removed.

Optional in-place filtering: if the keyword argument `inplace=True` is passed to *fileinput.input()* or to the *FileInput* constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the *backup* parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

fileinput.**hook_compressed**(*filename*, *mode*, *, *encoding=None*, *errors=None*)

Transparently opens files compressed with gzip and bzip2 (recognized by the extensions `'.gz'` and `'.bz2'`) using the *gzip* and *bz2* modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using *open()* without any decompression).

The *encoding* and *errors* values are passed to *io.TextIOWrapper* for compressed files and open for normal files.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed, encoding="utf-8")`

在 3.10 版的變更: The keyword-only parameter *encoding* and *errors* are added.

fileinput.**hook_encoded**(*encoding*, *errors=None*)

Returns a hook which opens each file with *open()*, using the given *encoding* and *errors* to read the file.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("utf-8", "surrogateescape"))`

在 3.6 版的變更: 新增可選參數 *errors*。

在 3.10 版之後被🄴用: This function is deprecated since *fileinput.input()* and *FileInput* now have *encoding* and *errors* parameters.

11.4 stat --- 直譯 stat() 的結果

原始碼： Lib/stat.py

The *stat* module defines constants and functions for interpreting the results of *os.stat()*, *os.fstat()* and *os.lstat()* (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

在 3.4 版的變更: The stat module is backed by a C implementation.

The *stat* module defines the following functions to test for specific file types:

stat.**S_ISDIR**(*mode*)

Return non-zero if the mode is from a directory.

stat.**S_ISCHR**(*mode*)

Return non-zero if the mode is from a character special device file.

stat.**S_ISBLK**(*mode*)

Return non-zero if the mode is from a block special device file.

stat.**S_ISREG**(*mode*)

Return non-zero if the mode is from a regular file.

stat.**S_ISFIFO**(*mode*)

Return non-zero if the mode is from a FIFO (named pipe).

stat.**S_ISLNK**(*mode*)

Return non-zero if the mode is from a symbolic link.

stat.**S_ISSOCK**(*mode*)

Return non-zero if the mode is from a socket.

stat.**S_ISDOOR**(*mode*)

Return non-zero if the mode is from a door.

在 3.4 版被加入.

stat.**S_ISPORT**(*mode*)

Return non-zero if the mode is from an event port.

在 3.4 版被加入.

stat.**S_ISWHT**(*mode*)

Return non-zero if the mode is from a whiteout.

在 3.4 版被加入.

Two additional functions are defined for more general manipulation of the file's mode:

stat.**S_IMODE**(*mode*)

Return the portion of the file's mode that can be set by *os.chmod()*---that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

stat.**S_IFMT**(*mode*)

Return the portion of the file's mode that describes the file type (used by the S_IS*() functions above).

Normally, you would use the os.path.is*() functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the stat() system call for each test. These are also useful when checking for information about a file that isn't handled by *os.path*, like the tests for block and character devices.

範例:

```
import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
       calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.lstat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)
```

An additional utility function is provided to convert a file's mode in a human readable string:

stat.**filemode**(*mode*)

Convert a file's mode to a string of the form '-rwxrwxrwx'.

在 3.3 版被加入.

在 3.4 版的變更: The function supports *S_IFDOOR*, *S_IFPORT* and *S_IFWHT*.

All the variables below are simply symbolic indexes into the 10-tuple returned by *os.stat()*, *os.fstat()* or *os.lstat()*.

stat.**ST_MODE**

Inode protection mode.

stat.**ST_INO**

Inode number.

stat.**ST_DEV**

Device inode resides on.

stat.**ST_NLINK**

Number of links to the inode.

stat.**ST_UID**

User id of the owner.

stat.**ST_GID**

Group id of the owner.

stat.**ST_SIZE**

Size in bytes of a plain file; amount of data waiting on some special files.

stat.**ST_ATIME**

Time of last access.

stat.**ST_MTIME**

Time of last modification.

stat.**ST_CTIME**

The "ctime" as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of "file size" changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the "size" is the number of bytes waiting to be read at the time of the call to *os.stat()*, *os.fstat()*, or *os.lstat()*; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the *ST_MODE* field.

Use of the functions above is more portable than use of the first set of flags:

stat.**S_IFSOCK**

Socket.

stat.**S_IFLNK**

Symbolic link.

stat.**S_IFREG**

Regular file.

stat.**S_IFBLK**
Block device.

stat.**S_IFDIR**
Directory.

stat.**S_IFCHR**
Character device.

stat.**S_IFIFO**
FIFO.

stat.**S_IFDOOR**
Door.

在 3.4 版被加入.

stat.**S_IFPORT**
Event port.

在 3.4 版被加入.

stat.**S_IFWHT**
Whiteout.

在 3.4 版被加入.

備🄵

S_IFDOOR, *S_IFPORT* or *S_IFWHT* are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the *mode* argument of *os.chmod()*:

stat.**S_ISUID**
Set UID bit.

stat.**S_ISGID**
Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the *S_ISGID* bit set. For a file that does not have the group execution bit (*S_IXGRP*) set, the set-group-ID bit indicates mandatory file/record locking (see also *S_ENFMT*).

stat.**S_ISVTX**
Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

stat.**S_IRWXU**
Mask for file owner permissions.

stat.**S_IRUSR**
Owner has read permission.

stat.**S_IWUSR**
Owner has write permission.

stat.**S_IXUSR**
Owner has execute permission.

stat.**S_IRWXG**
Mask for group permissions.

stat.**S_IRGRP**
Group has read permission.

stat.**S_IWGRP**
Group has write permission.

stat.**S_IXGRP**
Group has execute permission.

stat.**S_IRWXO**
Mask for permissions for others (not in group).

stat.**S_IROTH**
Others have read permission.

stat.**S_IWOTH**
Others have write permission.

stat.**S_IXOTH**
Others have execute permission.

stat.**S_ENFMT**
System V file locking enforcement. This flag is shared with *S_ISGID*: file/record locking is enforced on files that do not have the group execution bit (*S_IXGRP*) set.

stat.**S_IREAD**
Unix V7 synonym for *S_IRUSR*.

stat.**S_IWRITE**
Unix V7 synonym for *S_IWUSR*.

stat.**S_IEXEC**
Unix V7 synonym for *S_IXUSR*.

The following flags can be used in the *flags* argument of *os.chflags()*:

stat.**UF_NODUMP**
Do not dump the file.

stat.**UF_IMMUTABLE**
The file may not be changed.

stat.**UF_APPEND**
The file may only be appended to.

stat.**UF_OPAQUE**
The directory is opaque when viewed through a union stack.

stat.**UF_NOUNLINK**
The file may not be renamed or deleted.

stat.**UF_COMPRESSED**
The file is stored compressed (macOS 10.6+).

stat.**UF_HIDDEN**
The file should not be displayed in a GUI (macOS 10.5+).

stat.**SF_ARCHIVED**
The file may be archived.

stat.**SF_IMMUTABLE**
The file may not be changed.

stat.**SF_APPEND**
The file may only be appended to.

stat.**SF_NOUNLINK**
The file may not be renamed or deleted.

stat.**SF_SNAPSHOT**
The file is a snapshot file.

See the *BSD or macOS systems man page *chflags(2)* for more information.

On Windows, the following file attribute constants are available for use when testing bits in the st_file_attributes member returned by *os.stat()*. See the Windows API documentation for more detail on the meaning of these constants.

stat.**FILE_ATTRIBUTE_ARCHIVE**
stat.**FILE_ATTRIBUTE_COMPRESSED**
stat.**FILE_ATTRIBUTE_DEVICE**
stat.**FILE_ATTRIBUTE_DIRECTORY**
stat.**FILE_ATTRIBUTE_ENCRYPTED**
stat.**FILE_ATTRIBUTE_HIDDEN**
stat.**FILE_ATTRIBUTE_INTEGRITY_STREAM**
stat.**FILE_ATTRIBUTE_NORMAL**
stat.**FILE_ATTRIBUTE_NOT_CONTENT_INDEXED**
stat.**FILE_ATTRIBUTE_NO_SCRUB_DATA**
stat.**FILE_ATTRIBUTE_OFFLINE**
stat.**FILE_ATTRIBUTE_READONLY**
stat.**FILE_ATTRIBUTE_REPARSE_POINT**
stat.**FILE_ATTRIBUTE_SPARSE_FILE**
stat.**FILE_ATTRIBUTE_SYSTEM**
stat.**FILE_ATTRIBUTE_TEMPORARY**
stat.**FILE_ATTRIBUTE_VIRTUAL**
在 3.5 版被加入.

On Windows, the following constants are available for comparing against the st_reparse_tag member returned by *os.lstat()*. These are well-known constants, but are not an exhaustive list.

stat.**IO_REPARSE_TAG_SYMLINK**
stat.**IO_REPARSE_TAG_MOUNT_POINT**
stat.**IO_REPARSE_TAG_APPEXECLINK**
在 3.8 版被加入.

11.5 filecmp --- 檔案與目🄵比較

原始碼： Lib/filecmp.py

The *filecmp* module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the *difflib* module.

The *filecmp* module defines the following functions:

filecmp.**cmp**(*f1*, *f2*, *shallow=True*)

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true and the *os.stat()* signatures (file type, size, and modification time) of both files are identical, the files are taken to be equal.

Otherwise, the files are treated as different if their sizes or contents differ.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the *os.stat()* information for the file changes. The entire cache may be cleared using *clear_cache()*.

filecmp.**cmpfiles**(*dir1*, *dir2*, *common*, *shallow=True*)

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for *filecmp.cmp()*.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare `a/c` with `b/c` and `a/d/e` with `b/d/e`. `'c'` and `'d/e'` will each be in one of the three returned lists.

filecmp.**clear_cache**()

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

在 3.4 版被加入.

11.5.1 The dircmp class

class filecmp.**dircmp**(*a*, *b*, *ignore=None*, *hide=None*)

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to *filecmp.DEFAULT_IGNORES*. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The *dircmp* class compares files by doing *shallow* comparisons as described for *filecmp.cmp()*.

The *dircmp* class provides the following methods:

report()

Print (to *sys.stdout*) a comparison between *a* and *b*.

report_partial_closure()

Print a comparison between *a* and *b* and common immediate subdirectories.

report_full_closure()

Print a comparison between *a* and *b* and common subdirectories (recursively).

The *dircmp* class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

left

The directory *a*.

right

The directory *b*.

left_list

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

right_list

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

common

Files and subdirectories in both *a* and *b*.

left_only

Files and subdirectories only in *a*.

right_only

Files and subdirectories only in *b*.

common_dirs

Subdirectories in both *a* and *b*.

common_files

Files in both *a* and *b*.

common_funny

Names in both *a* and *b*, such that the type differs between the directories, or names for which *os.stat()* reports an error.

same_files

Files which are identical in both *a* and *b*, using the class's file comparison operator.

diff_files

Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

funny_files

Files which are in both *a* and *b*, but could not be compared.

subdirs

A dictionary mapping names in *common_dirs* to *dircmp* instances (or MyDirCmp instances if this instance is of type MyDirCmp, a subclass of *dircmp*).

在 3.10 版的變更: Previously entries were always *dircmp* instances. Now entries are the same type as *self*, if *self* is a subclass of *dircmp*.

filecmp.**DEFAULT_IGNORES**

在 3.4 版被加入.

List of directories ignored by *dircmp* by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name, dcmp.left,
...               dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

11.6 `tempfile` --- 生成臨時檔案和目🄵

原始碼： Lib/tempfile.py

該 module（模組）用於建立臨時檔案和目🄵，它可以在所有有支援的平臺上使用。*TemporaryFile*、*NamedTemporaryFile*、*TemporaryDirectory* 和 *SpooledTemporaryFile* 是有自動清除功能的高階介面，可作🄵情境管理器 *(context manager)* 使用。*mkstemp()* 和 *mkdtemp()* 是低階函式，使用完畢後需手動清理。

所有可被使用者呼叫的函式和建構函式都帶有可以設定臨時檔案和臨時目🄵的路徑和名稱的引數。此 module 所使用的檔名🄵一個隨機字元組成的字串，這讓檔案可以更安全地在共享的臨時目🄵中被建立。🄵了維持向後相容性，引數的順序會稍微奇怪，所以🄵了讓程式更容易被理解，建議使用關鍵字引數。

這個 module 定義了以下可供使用者呼叫的項目：

tempfile.**TemporaryFile**(*mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, ***, *errors=None*)

回傳一個可當作臨時儲存區域的類檔案物件。建立該檔案使用了與 *mkstemp()* 相同的安全規則。它將在關閉（包括當物件被垃圾回收 (garbage collect) 時的隱式關閉）後立即銷🄵。在 Unix 下，該檔案所在的目🄵可能根本不被建立、或者在建立檔案後立即就被🄵除，其他平臺不支援此功能；你的程式不應依賴使用此功能建立的臨時檔案名稱，因🄵它在檔案系統中的名稱有可能是不可見的。

生成的物件可以作🄵情境管理器使用（參見範例）。完成情境或銷🄵臨時檔案物件後，臨時檔案將從檔案系統中🄵除。

mode 參數預設🄵 `'w+b'`，所以建立的檔案不用關閉就可以讀取或寫入。因🄵用的是二進位制模式，所以無論存的是什🄵資料，它在所有平臺上的行🄵都一致。*buffering*、*encoding*、*errors* 和 *newline* 的含義與 *open()* 中的相同。

參數 *dir*、*prefix* 和 *suffix* 的含義和預設值都與它們在 *mkstemp()* 中的相同。

在 POSIX 平臺上，回傳物件是真實的檔案物件。在其他平臺上，它是一個 file-like object，它的 `file` 屬性🄵底層的真實檔案物件。

如果可用且可運作，則使用 *os.O_TMPFILE* 旗標（僅限於 Linux，需要 3.11 版本以上的核心）。

在不是 Posix 或 Cygwin 的平臺上，TemporaryFile 是 NamedTemporaryFile 的🄵名。

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

在 3.5 版的變更: 如果可用，自此開始使用 *os.O_TMPFILE* 旗標。

在 3.8 版的變更: 新增 *errors* 參數。

tempfile.**NamedTemporaryFile**(*mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, *delete=True*, ***, *errors=None*, *delete_on_close=True*)

此函式的操作與*TemporaryFile()* 完全相同，但存在以下差F:

- 此函式回傳一個保證在檔案系統中具有可見名稱的檔案。
- F了管理指定檔案，它使用 *delete* 和 *delete_on_close* 參數擴充*TemporaryFile()* 來指定是否以及如何自動F除指定檔案。

回傳的物件始終是一個類檔案物件，其 `file` 屬性是底層的真實檔案物件。這個類檔案物件可以在 `with` 陳述式中使用，就像普通檔案一樣。臨時檔案的名稱可以從回傳的類檔案物件的:attr:!name‘ 屬性中取得。在 Unix 上則與*TemporaryFile()* 不同，目F條目不會在檔案建立後立即被取消鏈接 (unlink)。

如果 *delete* F true（預設值）F且 *delete_on_close* F true（預設值），則檔案在關閉後會立即被F除。如果 *delete* F true F且 *delete_on_close* F false，則僅在情境管理器退出時F除檔案，或者在類檔案物件完結時F除檔案。在這種情F下，F不總是保證能成功F除（請參F `object.__del__()`）。如果 *delete* F false，則會忽略 *delete_on_close* 的值。

因此，要在關閉檔案後使用臨時檔案的名稱重新打開檔案，請確保在關閉時不F除檔案（將 *delete* 參數設定F false），或者如果臨時檔案是以 `with` 陳述式建立，要將 *delete_on_close* 參數設定F false。建議使用後者，因F它有助於在情境管理器退出時自動清理臨時檔案。

在臨時檔案仍處於打開狀態時再次按其名稱打開它，其作用方式如下:

- 在 POSIX 上，檔案始終可以再次打開。
- 在 Windows 上，確保至少滿足以下條件之一:
  - *delete* F false
  - 額外的 open 會共享F除存取權限（例如，通過使用旗標 `O_TEMPORARY` 來呼叫*os.open()*）
  - *delete* F true 但 *delete_on_close* F false。請注意，在這種情F下不共享F除存取權限的其他 open（例如透過F建的*open()* 建立）必須在退出情境管理器之前關閉，否則情境管理器上的*os.unlink()* 呼叫退出將失敗F出現*PermissionError*。

在 Windows 上，如果 *delete_on_close* F false，F且檔案是在使用者缺乏F除存取權限的目F中建立的，則情境管理器退出時的*os.unlink()* 呼叫將失敗，F引發*PermissionError*。當 *delete_on_close* F true 時，不會發生這種情F，因FF除存取權限是由 open 來要求的，如果未授予存取權限則會立即失敗。

（僅）在 POSIX 上，因使用 SIGKILL 而被終止的行程無法自動F除它建立的任何 NamedTemporaryFiles。

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

在 3.8 版的變更: 新增 *errors* 參數。

在 3.12 版的變更: 新增 *delete_on_close* 參數。

class tempfile.**SpooledTemporaryFile**(*max_size=0*, *mode='w+b'*, *buffering=-1*, *encoding=None*, *newline=None*, *suffix=None*, *prefix=None*, *dir=None*, ***, *errors=None*)

此類F執行的操作與*TemporaryFile()* 完全相同，但會將資料排存 (spool) 於在記憶體中，直到檔案大小超過 *max_size*，或檔案的*fileno()* 方法被呼叫F止，此時資料會被寫入磁碟，F且之後的操作與*TemporaryFile()* 相同。

rollover()

生成的檔案物件有一個額外的方法 `rollover()`，忽略檔案大小F立即將其寫入磁碟。

回傳的物件是 file-like object，它的 `_file` 屬性是*io.BytesIO* 或*io.TextIOWrapper* 物件（取🄵於指定的是二進位制模式還是文字模式）或真實的檔案物件（取🄵於是否已呼叫*rollover()*）。file-like object 可以像普通檔案一樣在 `with` 陳述式中使用。

在 3.3 版的變更: 現在，檔案的截斷方法 (truncate method) 可接受一個 *size* 引數。

在 3.8 版的變更: 新增 *errors* 參數。

在 3.11 版的變更: 完全實作*io.BufferedIOBase* 和*io.TextIOBase* 抽象基底類🄴（取🄵於指定的是二進位還是文本 *mode*）。

class tempfile.**TemporaryDirectory**(*suffix=None*, *prefix=None*, *dir=None*, *ignore_cleanup_errors=False*, ***, *delete=True*)

此類🄴會使用與*mkdtemp()* 相同安全規則來建立一個臨時目🄵。回傳物件可當作情境管理器使用（參見範例）。在完成情境或銷🄴臨時目🄵物件時，新建立的臨時目🄵及其所有🄵容會從檔案系統中被移除。

name

可以從回傳物件的 `name` 屬性中找到的臨時目🄵名稱。當回傳的物件用作情境管理器時，這個 `name` 會作🄵 `with` 陳述句中 `as` 子句的目標（如果有 as 的話）。

cleanup()

此目🄵可透過呼叫 `cleanup()` 方法來顯式地清理。如果 *ignore_cleanup_errors* 🄵 true，則在顯式或隱式清理期間出現的未處理例外（例如在 Windows 上移除開🄵的檔案而引發的*PermissionError*）將被忽略，🄵且剩余的可移除條目會「🄵可能」地被🄵除。在其他情🄵下，錯誤將在任何情境清理發生時被引發（`cleanup()` 呼叫、退出情境管理器、物件被作🄵垃圾回收或直譯器關閉等）。

delete 參數可以停用在退出情境時對目🄵樹的清理，雖然停用情境管理器在退出情境時所🄵取的操作似乎不常見，但它在除錯期間或當你需要基於其他邏輯的清理行🄵時會非常有用。

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

在 3.2 版被加入.

在 3.10 版的變更: 新增 *ignore_cleanup_errors* 參數。

在 3.12 版的變更: 新增 *delete* 參數。

tempfile.**mkstemp**(*suffix=None*, *prefix=None*, *dir=None*, *text=False*)

盡可能以最安全的方式建立一個臨時檔案。假設所在平臺正確實作了*os.open()* 的*os.O_EXCL* 旗標，則建立檔案時不會有 race condition（競🄵條件）的情🄵。該檔案只能由建立者讀寫，如果所在平臺用 permission bit（許可權位元）來表示檔案是否可執行，則🄵有人有執行權。檔案描述器不會被子行程繼承。

與*TemporaryFile()* 不同，*mkstemp()* 使用者用完臨時檔案後需要自行將其🄵除。

如果 *suffix* 不是 `None` 則檔名將以該後綴結尾，若🄵 `None` 則🄵有後綴。*mkstemp()* 不會在檔名和後綴之間加點 (dot)，如果需要加一個點號，請將其放在 *suffix* 的開頭。

如果 *prefix* 不是 `None` 則檔名將以該字首開頭，若🄵 `None` 則使用預設前綴。預設前綴是*gettempprefix()* 或*gettempprefixb()* 函式的回傳值（自動呼叫合適的函式）。

如果 *dir* 不🄵 `None` 則在指定的目🄵建立檔案，若🄵 `None` 則使用預設目🄵。預設目🄵是從一個相依於平臺的列表中選擇出來的，但是使用者可以設定 *TMPDIR*、*TEMP* 或 *TMP* 環境變數來設定目🄵的位置。因此，不能保證生成的臨時檔案路徑是使用者友善的，比如透過 `os.popen()` 將路徑傳遞給外部命令時仍需要加引號 (quoting)。

如果 *suffix*、*prefix* 和 *dir* 中的任何一個不是 `None`，就要保證它們資料型🄵相同。如果它們是位元組串，則回傳名稱的型🄵就是位元組串而非字串。如果不想遵循預設行🄵但又想要回傳值是位元組串型🄵，請傳入 `suffix=b''`。

如果指定了 *text* 且[F]真值，檔案會以文字模式開[F]。否則，檔案（預設）以二進位制模式開[F]。

mkstemp() 回傳一個 tuple，tuple 中，第一個元素是一個作業系統層級 (OS-level) 控制代碼，指向一個開[F]的檔案（如同*os.open()* 的回傳值），第二元素是該檔案的[F]對路徑。

Raises an *auditing event* `tempfile.mkstemp` with argument `fullpath`.

在 3.5 版的變更: 現在，*suffix*、*prefix* 和 *dir* 可以以位元組串型[F]按順序提供，以獲得位元組串型[F]的回傳值。在之前只允許使用字串。*suffix* 和 *prefix* 現在可以接受 `None`，[F]且預設[F] `None` 以使用合適的預設值。

在 3.6 版的變更: *dir* 參數現在可接受一個類路徑物件 (*path-like object*)。

`tempfile.`**`mkdtemp`**(*suffix=None*, *prefix=None*, *dir=None*)

盡可能以最安全的方式建立一個臨時目[F]，建立該目[F]時不會有 race condition 的情[F]，該目[F]只能由建立者讀取、寫入和搜尋。

mkdtemp() 的使用者用完臨時目[F]後需要自行將其[F]除。

引數 *prefix*、*suffix* 和 *dir* 的含義與它們在*mkstemp()* 中相同。

mkdtemp() 回傳新目[F]的[F]對路徑名稱。

Raises an *auditing event* `tempfile.mkdtemp` with argument `fullpath`.

在 3.5 版的變更: 現在，*suffix*、*prefix* 和 *dir* 可以以位元組串型[F]按順序提供，以獲得位元組串型[F]的回傳值。在之前只允許使用字串。*suffix* 和 *prefix* 現在可以接受 `None`，[F]且預設[F] `None` 以使用合適的預設值。

在 3.6 版的變更: *dir* 參數現在可接受一個類路徑物件 (*path-like object*)。

在 3.12 版的變更: *mkdtemp()* 現在都會回傳[F]對路徑，即使 *dir* 是相對路徑。

`tempfile.`**`gettempdir`**()

回傳儲存臨時檔案的目[F]名稱。這設定了此 module 所有函式 *dir* 引數的預設值。

Python 搜尋標准目[F]列表來找到呼叫者可以在其中建立檔案的目[F]。這個列表是:

1. `TMPDIR` 環境變數指向的目[F]。
2. `TEMP` 環境變數指向的目[F]。
3. `TMP` 環境變數指向的目[F]。
4. 與平臺相關的位置:
   - 在 Windows 上，目[F]依次[F] `C:\TEMP`、`C:\TMP`、`\TEMP` 和 `\TMP`。
   - 在所有其他平臺上，目[F]依次[F] `/tmp`、`/var/tmp` 和 `/usr/tmp`。
5. 不得已時，使用當前工作目[F]。

搜尋的結果會被 cache（快取）起來，請見下面*tempdir* 的描述。

在 3.10 版的變更: 回傳一個字串。在之前的版本中它會回傳任意*tempdir* 的值而不考慮它的型[F]，只要它不[F] `None`。

`tempfile.`**`gettempdirb`**()

與*gettempdir()* 相同，但回傳值[F]位元組串型[F]。

在 3.5 版被加入.

`tempfile.`**`gettempprefix`**()

回傳用於建立臨時檔案的檔名前綴，它不包含目[F]部分。

tempfile.**gettempprefixb**()

與*gettempprefix()* 相同，但回傳值🄵位元組串型🄵。

在 3.5 版被加入.

此 module 使用一個全域性變數來儲存由*gettempdir()* 回傳的臨時檔案使用的目🄵路徑。它可被直接設定以覆蓋選擇過程，但不建議這樣做。此 module 中的所有函式都接受一個 *dir* 引數，它可被用於指定目🄵。這是個推薦的做法，它不會透過改變全域性 API 行🄵而對其他不預期此行🄵的程式造成影響。

tempfile.**tempdir**

當被設🄵 None 以外的值時，此變數會🄵此 module 所定義函式的引數 *dir* 定義預設值，包括確定其型🄵🄵位元組串還是字串。它不可以🄵*path-like object*。

如果在呼叫除*gettempprefix()* 外的上述任何函式時 tempdir 🄵 None (預設值) 則它會按照*gettempdir()* 中所描述的演算法來初始化。

備🄵

請注意如果你將 tempdir 設🄵位元組串值，會有一個麻煩的副作用：*mkstemp()* 和*mkdtemp()* 的全域性預設回傳型🄵會在🄵有提供明顯字串型🄵的 prefix、suffix 或 dir 時被改🄵位元組串。請不要編寫預期此行🄵或依賴於此行🄵的程式。這個奇怪的行🄵是🄵了維持與以往實作版本的相容性。

11.6.1 范例

以下是*tempfile* module 的一些常見用法範例：

```
>>> import tempfile

# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()

# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed

# create a temporary file using a context manager
# close the file, use the name to open the file again
>>> with tempfile.NamedTemporaryFile(delete_on_close=False) as fp:
...     fp.write(b'Hello world!')
...     fp.close()
... # the file is closed, but not removed
... # open the file again by using its name
```

(繼續下一頁)

(繼續上一頁)

```
...     with open(fp.name, mode='rb') as f:
...         f.read()
b'Hello world!'
>>>
# file is now removed

# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed
```

11.6.2 已🄵用的函式和變數

在過去，建立臨時檔案首先使用*mktemp()* 函式生成一個檔名，然後使用該檔名建立檔案。不幸的是這🄴不安全的，因🄵在呼叫*mktemp()* 與隨後嘗試建立檔案之間的時間🄴，其他程式可能會使用該名稱建立檔案。解🄴方案是將兩個步驟結合起來，🄵立即建立檔案。這個方案目前被*mkstemp()* 和上述其他函式所🄴用。

tempfile.**mktemp**(*suffix=''*, *prefix='tmp'*, *dir=None*)

在 2.3 版之後被🄴用: 使用*mkstemp()* 代替。

回傳一個在呼叫本方法時不存在檔案的🄵對路徑。引數 *prefix*、*suffix* 和 *dir* 與*mkstemp()* 中所用的類似，除了在於不支援位元組串型🄵的檔名且不支援 `suffix=None` 和 `prefix=None`。

警告

使用此功能可能會在程式中引入安全漏洞。當你開始使用本方法回傳的檔案執行任何操作時，可能有人已經捷足先登了。*mktemp()* 的功能可以很輕松地用帶有 `delete=False` 參數的*NamedTemporaryFile()* 代替:

```
>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmptjujjt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False
```

11.7 `glob` --- Unix 風格的路徑名稱模式擴展

原始碼： Lib/glob.py

---

glob 模組根據 Unix shell 使用的規則查找與指定模式匹配的所有路徑名稱，結果以任意順序回傳。🄵有波浪號 (tilde) 擴展，但是 `*`、`?` 和用 `[]` 表示的字元範圍將被正確匹配。這是透過同時使用*os.scandir()* 和*fnmatch.fnmatch()* 函式來完成的，而🄴有實際調用 subshell。

請注意，以點 (`.`) 開頭的檔案只能與同樣以點開頭的模式匹配，這與*fnmatch.fnmatch()* 或*pathlib.Path.glob()* 不同。（對於波浪號和 shell 變數擴展，請使用*os.path.expanduser()* 和*os.path.expandvars()*。）

對於文本 (literal) 匹配，將元字元 (meta-character) 括在方括號中。例如，`'[?]'` 會匹配 `'?'` 字元。

也參考

pathlib 模組提供高階路徑物件。

`glob.`**`glob`**(*pathname*, *, *root_dir=None*, *dir_fd=None*, *recursive=False*, *include_hidden=False*)

回傳與 *pathname* 匹配、可能🄵空的路徑名稱 list，它必須是包含路徑規範的字串。*pathname* 可以是🄵對的（如 `/usr/src/Python-1.5/Makefile`）或相對的（如 `../../Tools/*/*.gif`），🄵且可以包含 shell 樣式的通用字元 (wildcard)。已損壞的符號連接也會（如同在 shell）被包含在結果中。結果是否排序取🄵於檔案系統 (file system)。如果在呼叫此函式期間🄵除或新增滿足條件的檔案，則結果不一定會包含該檔案的路徑名稱。

如果 *root_dir* 不是 `None`，它應該是一個指定搜索根目🄵的*path-like object*。它在呼叫它之前更改當前目🄵的影響與*glob()* 相同。如果 *pathname* 是相對的，結果將包含相對於 *root_dir* 的路徑。

此函式可以支援以 *dir_fd* 參數使用相對目🄵描述器的路徑。

如果 *recursive* 🄵真，模式”`**`” 將匹配任何檔案、零個或多個目🄵、子目🄵和目🄵的符號連結。如果模式後面有*os.sep* 或*os.altsep* 那🄵檔案將不會被匹配。

如果 *include_hidden* 🄵真，”`**`” 模式將匹配被隱藏的目🄵。

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

Raises an *auditing event* `glob.glob/2` with arguments `pathname`, `recursive`, `root_dir`, `dir_fd`.

備🄵

在大型目🄵樹中使用”`**`” 模式可能會消耗過多的時間。

備🄵

This function may return duplicate path names if *pathname* contains multiple ”`**`” patterns and *recursive* is true.

在 3.5 版的變更: 支援以”`**`” 使用遞🄵 glob。

在 3.10 版的變更: 新增 *root_dir* 與 *dir_fd* 參數。

在 3.11 版的變更: 新增 *include_hidden* 參數。

`glob.`**`iglob`**(*pathname*, *, *root_dir=None*, *dir_fd=None*, *recursive=False*, *include_hidden=False*)

回傳一個會🄵生與*glob()* 相同的值的*iterator*，而不是同時存儲全部的值。

Raises an *auditing event* `glob.glob` with arguments `pathname`, `recursive`.

Raises an *auditing event* `glob.glob/2` with arguments `pathname`, `recursive`, `root_dir`, `dir_fd`.

備□

This function may return duplicate path names if *pathname* contains multiple "**" patterns and *recursive* is true.

在 3.5 版的變更: 支援以"**" 使用遞□ glob。

在 3.10 版的變更: 新增 *root_dir* 與 *dir_fd* 參數。

在 3.11 版的變更: 新增 *include_hidden* 參數。

glob.**escape**(*pathname*)

跳□ (escape) 所有特殊字元（'?'、'*' 和 '['）。如果你想匹配其中可能包含特殊字元的任意文本字串，這將會很有用。驅動器 (drive)/UNC 共享點 (sharepoints) 中的特殊字元不會被跳□，例如在 Windows 上，escape('//?/c:/Quo vadis?.txt') 會回傳 '//?/c:/Quo vadis[?].txt'。

在 3.4 版被加入.

例如，在一個包含以下檔案的目□：1.gif、2.txt、card.gif，和一個僅包含 3.txt 檔案的子目□ sub，*glob()* 將□生以下結果。請注意路徑的任何前導部分是如何保留的。

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
['2.txt', 'sub/3.txt']
>>> glob.glob('./**/', recursive=True)
['./', './sub/']
```

如果目□包含以 . 開頭的檔案，則預設情□下不會去匹配到它們。例如，一個包含 card.gif 和 .card.gif 的目□：

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.c*')
['.card.gif']
```

也參考

***fnmatch* 模組**
Shell 風格檔案名（不是路徑）的擴展

11.8 fnmatch --- Unix 檔案名稱模式比對

原始碼： Lib/fnmatch.py

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the *re* module). The special characters used in shell-style wildcards are:

Pattern	Meaning
`*`	matches everything
`?`	matches any single character
`[seq]`	matches any character in *seq*
`[!seq]`	matches any character not in *seq*

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module *glob* for pathname expansion (*glob* uses *filter()* to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

Also note that *functools.lru_cache()* with the *maxsize* of 32768 is used to cache the compiled regex patterns in the following functions: *fnmatch()*, *fnmatchcase()*, *filter()*.

fnmatch.**fnmatch**(*name*, *pat*)

Test whether the filename string *name* matches the pattern string *pat*, returning `True` or `False`. Both parameters are case-normalized using *os.path.normcase()*. *fnmatchcase()* can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

fnmatch.**fnmatchcase**(*name*, *pat*)

Test whether the filename string *name* matches the pattern string *pat*, returning `True` or `False`; the comparison is case-sensitive and does not apply *os.path.normcase()*.

fnmatch.**filter**(*names*, *pat*)

Construct a list from those elements of the *iterable* *names* that match pattern *pat*. It is the same as `[n for n in names if fnmatch(n, pat)]`, but implemented more efficiently.

fnmatch.**translate**(*pat*)

Return the shell-style pattern *pat* converted to a regular expression for using with *re.match()*.

範例：

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\\.txt)\\Z'
```

(繼續下一頁)

(繼續上一頁)

```
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<re.Match object; span=(0, 10), match='foobar.txt'>
```

也參考

glob 模組
Unix shell-style path expansion.

11.9 linecache --- 隨機存取文字列

原始碼： Lib/linecache.py

The *linecache* module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the *traceback* module to retrieve source lines for inclusion in the formatted traceback.

The *tokenize.open()* function is used to open files. This function uses *tokenize.detect_encoding()* to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The *linecache* module defines the following functions:

linecache.**getline**(*filename*, *lineno*, *module_globals=None*)

Get line *lineno* from file named *filename*. This function will never raise an exception --- it will return `''` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function first checks for a **PEP 302** `__loader__` in *module_globals*. If there is such a loader and it defines a `get_source` method, then that determines the source lines (if `get_source()` returns `None`, then `''` is returned). Finally, if *filename* is a relative filename, it is looked up relative to the entries in the module search path, `sys.path`.

linecache.**clearcache**()

Clear the cache. Use this function if you no longer need lines from files previously read using *getline()*.

linecache.**checkcache**(*filename=None*)

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If *filename* is omitted, it will check all the entries in the cache.

linecache.**lazycache**(*filename*, *module_globals*)

Capture enough detail about a non-file-based module to permit getting its lines later via *getline()* even if *module_globals* is `None` in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

在 3.5 版被加入.

範例：

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

11.10 shutil —高階檔案操作

原始碼： Lib/shutil.py

The *shutil* module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the *os* module.

警告

Even the higher-level file copying functions (*shutil.copy()*, *shutil.copy2()*) cannot copy all file metadata.

On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

11.10.1 Directory and files operations

shutil.**copyfileobj**(*fsrc*, *fdst*[, *length*])

Copy the contents of the *file-like object* *fsrc* to the file-like object *fdst*. The integer *length*, if given, is the buffer size. In particular, a negative *length* value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the *fsrc* object is not 0, only the contents from the current file position to the end of the file will be copied.

shutil.**copyfile**(*src*, *dst*, *, *follow_symlinks=True*)

Copy the contents (no metadata) of the file named *src* to a file named *dst* and return *dst* in the most efficient way possible. *src* and *dst* are *path-like objects* or path names given as strings.

dst must be the complete target file name; look at *copy()* for a copy that accepts a target directory path. If *src* and *dst* specify the same file, *SameFileError* is raised.

The destination location must be writable; otherwise, an *OSError* exception will be raised. If *dst* already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If *follow_symlinks* is false and *src* is a symbolic link, a new symbolic link will be created instead of copying the file *src* points to.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

在 3.3 版的變更: *IOError* used to be raised instead of *OSError*. Added *follow_symlinks* argument. Now returns *dst*.

在 3.4 版的變更: Raise *SameFileError* instead of *Error*. Since the former is a subclass of the latter, this change is backward compatible.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

exception shutil.**SameFileError**

This exception is raised if source and destination in *copyfile()* are the same file.

在 3.4 版被加入.

shutil.**copymode**(*src*, *dst*, *, *follow_symlinks=True*)

Copy the permission bits from *src* to *dst*. The file contents, owner, and group are unaffected. *src* and *dst* are *path-like objects* or path names given as strings. If *follow_symlinks* is false, and both *src* and *dst* are symbolic links, `copymode()` will attempt to modify the mode of *dst* itself (rather than the file it points to). This functionality is not available on every platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

Raises an *auditing event* `shutil.copymode` with arguments `src`, `dst`.

在 3.3 版的變更: 新增 *follow_symlinks* 引數。

shutil.**copystat**(*src*, *dst*, *, *follow_symlinks=True*)

Copy the permission bits, last access time, last modification time, and flags from *src* to *dst*. On Linux, `copystat()` also copies the "extended attributes" where possible. The file contents, owner, and group are unaffected. *src* and *dst* are *path-like objects* or path names given as strings.

If *follow_symlinks* is false, and *src* and *dst* both refer to symbolic links, `copystat()` will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the *src* symbolic link, and writing the information to the *dst* symbolic link.

備🄵

Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.

- If `os.chmod in os.supports_follow_symlinks` is `True`, `copystat()` can modify the permission bits of a symbolic link.
- If `os.utime in os.supports_follow_symlinks` is `True`, `copystat()` can modify the last access and modification times of a symbolic link.
- If `os.chflags in os.supports_follow_symlinks` is `True`, `copystat()` can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)

On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, `copystat()` will copy everything it can. `copystat()` never returns failure.

更多資訊請見`os.supports_follow_symlinks`。

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

在 3.3 版的變更: Added *follow_symlinks* argument and support for Linux extended attributes.

shutil.**copy**(*src*, *dst*, *, *follow_symlinks=True*)

Copies the file *src* to the file or directory *dst*. *src* and *dst* should be *path-like objects* or strings. If *dst* specifies a directory, the file will be copied into *dst* using the base filename from *src*. If *dst* specifies a file that already exists, it will be replaced. Returns the path to the newly created file.

If *follow_symlinks* is false, and *src* is a symbolic link, *dst* will be created as a symbolic link. If *follow_symlinks* is true and *src* is a symbolic link, *dst* will be a copy of the file *src* refers to.

`copy()` copies the file data and the file's permission mode (see `os.chmod()`). Other metadata, like the file's creation and modification times, is not preserved. To preserve all file metadata from the original, use `copy2()` instead.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copymode` with arguments `src`, `dst`.

在 3.3 版的變更: Added *follow_symlinks* argument. Now returns path to the newly created file.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

shutil.**copy2**(*src*, *dst*, *, *follow_symlinks=True*)

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

When *follow_symlinks* is false, and *src* is a symbolic link, `copy2()` attempts to copy all metadata from the *src* symbolic link to the newly created *dst* symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, `copy2()` will preserve all the metadata it can; `copy2()` never raises an exception because it cannot preserve file metadata.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information about platform support for modifying symbolic link metadata.

Raises an *auditing event* `shutil.copyfile` with arguments `src`, `dst`.

Raises an *auditing event* `shutil.copystat` with arguments `src`, `dst`.

在 3.3 版的變更: Added *follow_symlinks* argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

shutil.**ignore_patterns**(**patterns*)

This factory function creates a function that can be used as a callable for `copytree()`'s *ignore* argument, ignoring files and directories that match one of the glob-style *patterns* provided. See the example below.

shutil.**copytree**(*src*, *dst*, *symlinks=False*, *ignore=None*, *copy_function=copy2*, *ignore_dangling_symlinks=False*, *dirs_exist_ok=False*)

Recursively copy an entire directory tree rooted at *src* to a directory named *dst* and return the destination directory. All intermediate directories needed to contain *dst* will also be created by default.

Permissions and times of directories are copied with `copystat()`, individual files are copied using `copy2()`.

If *symlinks* is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When *symlinks* is false, if the file pointed to by the symlink doesn't exist, an exception will be added in the list of errors raised in an `Error` exception at the end of the copy process. You can set the optional *ignore_dangling_symlinks* flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If *ignore* is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the *ignore* callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

If *copy_function* is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `copy2()` is used, but any function that supports the same signature (like `copy()`) can be used.

If *dirs_exist_ok* is false (the default) and *dst* already exists, a `FileExistsError` is raised. If *dirs_exist_ok* is true, the copying operation will continue if it encounters existing directories, and files within the *dst* tree will be overwritten by corresponding files from the *src* tree.

Raises an *auditing event* `shutil.copytree` with arguments `src`, `dst`.

在 3.2 版的變更: Added the *copy_function* argument to be able to provide a custom copy function. Added the *ignore_dangling_symlinks* argument to silence dangling symlinks errors when *symlinks* is false.

在 3.3 版的變更: Copy metadata when *symlinks* is false. Now returns *dst*.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

在 3.8 版的變更: 新增 *dirs_exist_ok* 參數。

shutil.**rmtree**(*path*, *ignore_errors=False*, *onerror=None*, *, *onexc=None*, *dir_fd=None*)

Delete an entire directory tree; *path* must point to a directory (but not a symbolic link to a directory). If *ignore_errors* is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by *onexc* or *onerror* or, if both are omitted, exceptions are propagated to the caller.

This function can support *paths relative to directory descriptors*.

備🄵

On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink attack: given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the `rmtree.avoids_symlink_attacks` function attribute to determine which case applies.

If *onexc* is provided, it must be a callable that accepts three parameters: *function*, *path*, and *excinfo*.

The first parameter, *function*, is the function which raised the exception; it depends on the platform and implementation. The second parameter, *path*, will be the path name passed to *function*. The third parameter, *excinfo*, is the exception that was raised. Exceptions raised by *onexc* will not be caught.

The deprecated *onerror* is similar to *onexc*, except that the third parameter it receives is the tuple returned from `sys.exc_info()`.

Raises an *auditing event* `shutil.rmtree` with arguments `path`, `dir_fd`.

在 3.3 版的變更: Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

在 3.8 版的變更: On Windows, will no longer delete the contents of a directory junction before removing the junction.

在 3.11 版的變更: 新增 *dir_fd* 參數。

在 3.12 版的變更: 新增 *onexc* 參數🄵🄵用 *onerror*。

rmtree.**avoids_symlink_attacks**

Indicates whether the current platform and implementation provides a symlink attack resistant version of `rmtree()`. Currently this is only true for platforms supporting fd-based directory access functions.

在 3.3 版被加入.

shutil.**move**(*src*, *dst*, *copy_function=copy2*)

Recursively move a file or directory (*src*) to another location and return the destination.

If *dst* is an existing directory or a symlink to a directory, then *src* is moved inside that directory. The destination path in that directory must not already exist.

If *dst* already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied to the destination using *copy_function* and then removed. In case of symlinks, a new symlink pointing to the target of *src* will be created as the destination and *src* will be removed.

If *copy_function* is given, it must be a callable that takes two arguments, *src* and the destination, and will be used to copy *src* to the destination if `os.rename()` cannot be used. If the source is a directory, `copytree()` is called, passing it the *copy_function*. The default *copy_function* is `copy2()`. Using `copy()` as the *copy_function* allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

Raises an *auditing event* `shutil.move` with arguments `src`, `dst`.

在 3.3 版的變更: Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's **mv**. Now returns *dst*.

在 3.5 版的變更: 新增 *copy_function* 關鍵字引數。

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

在 3.9 版的變更: Accepts a *path-like object* for both *src* and *dst*.

`shutil.`**`disk_usage`**(*path*)

Return disk usage statistics about the given path as a *named tuple* with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. *path* may be a file or a directory.

> **備🄵**
>
> On Unix filesystems, *path* must point to a path within a **mounted** filesystem partition. On those platforms, CPython doesn't attempt to retrieve disk usage information from non-mounted filesystems.

在 3.3 版被加入.

在 3.8 版的變更: On Windows, *path* can now be a file or directory.

適用： Unix、Windows。

`shutil.`**`chown`**(*path*, *user=None*, *group=None*)

Change owner *user* and/or *group* of the given *path*.

user can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also `os.chown()`, the underlying function.

Raises an *auditing event* `shutil.chown` with arguments `path`, `user`, `group`.

適用： Unix。

在 3.3 版被加入.

`shutil.`**`which`**(*cmd*, *mode=os.F_OK | os.X_OK*, *path=None*)

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return `None`.

mode is a permission mask passed to `os.access()`, by default determining if the file exists and is executable.

When no *path* is specified, the results of `os.environ()` are used, returning either the "PATH" value or a fallback of `os.defpath`.

On Windows, the current directory is prepended to the *path* if *mode* does not include `os.X_OK`. When the *mode* does include `os.X_OK`, the Windows API `NeedCurrentDirectoryForExePathW` will be consulted to

determine if the current directory should be prepended to *path*. To avoid consulting the current working directory for executables: set the environment variable `NoDefaultCurrentDirectoryInExePath`.

Also on Windows, the `PATHEXT` variable is used to resolve commands that may not already include an extension. For example, if you call `shutil.which("python")`, *which()* will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

This is also applied when *cmd* is a path that contains a directory component:

```
>> shutil.which("C:\\Python33\\python")
'C:\\Python33\\python.EXE'
```

在 3.3 版被加入.

在 3.8 版的變更: The *bytes* type is now accepted. If *cmd* type is *bytes*, the result type is also *bytes*.

在 3.12 版的變更: On Windows, the current directory is no longer prepended to the search path if *mode* includes `os.X_OK` and WinAPI `NeedCurrentDirectoryForExePathW(cmd)` is false, else the current directory is prepended even if it is already in the search path; `PATHEXT` is used now even when *cmd* includes a directory component or ends with an extension that is in `PATHEXT`; and filenames that have no extension can now be found.

在 3.12.1 版的變更: On Windows, if *mode* includes `os.X_OK`, executables with an extension in `PATHEXT` will be preferred over executables without a matching extension. This brings behavior closer to that of Python 3.11.

exception `shutil.`**Error**

This exception collects exceptions that are raised during a multi-file operation. For *copytree()*, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

Platform-dependent efficient copy operations

Starting from Python 3.8, all functions involving a file copy (*copyfile()*, *copy()*, *copy2()*, *copytree()*, and *move()*) may use platform-specific "fast-copy" syscalls in order to copy the file more efficiently (see bpo-33671). "fast-copy" means that the copying operation occurs within the kernel, avoiding the use of userspace buffers in Python as in "`outfd.write(infd.read())`".

On macOS fcopyfile is used to copy the file content (not metadata).

On Linux *os.sendfile()* is used.

On Windows *shutil.copyfile()* uses a bigger default buffer size (1 MiB instead of 64 KiB) and a *memoryview()*-based variant of *shutil.copyfileobj()* is used.

If the fast-copy operation fails and no data was written in the destination file then shutil will silently fallback on using less efficient *copyfileobj()* function internally.

在 3.8 版的變更.

copytree example

An example that uses the *ignore_patterns()* helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the *ignore* argument to add a logging call:

```
from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
    return []   # nothing will be ignored

copytree(source, destination, ignore=_logpath)
```

rmtree 范例

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the onexc callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```
import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
    func(path)

shutil.rmtree(directory, onexc=remove_readonly)
```

11.10.2 Archiving operations

在 3.2 版被加入.

在 3.5 版的變更: 新增 *xztar* 格式的支援。

High-level utilities to create and read compressed and archived files are also provided. They rely on the *zipfile* and *tarfile* modules.

`shutil.`**`make_archive`**(*base_name*, *format*[, *root_dir*[, *base_dir*[, *verbose*[, *dry_run*[, *owner*[, *group*[, *logger*]]]]]]])

Create an archive file (such as zip or tar) and return its name.

base_name is the name of the file to create, including the path, minus any format-specific extension.

format is the archive format: one of ”zip” (if the *zlib* module is available), ”tar”, ”gztar” (if the *zlib* module is available), ”bztar” (if the *bz2* module is available), or ”xztar” (if the *lzma* module is available).

root_dir is a directory that will be the root directory of the archive, all paths in the archive will be relative to it; for example, we typically chdir into *root_dir* before creating the archive.

base_dir is the directory where we start archiving from; i.e. *base_dir* will be the common prefix of all files and directories in the archive. *base_dir* must be given relative to *root_dir*. See *Archiving example with base_dir* for how to use *base_dir* and *root_dir* together.

root_dir and *base_dir* both default to the current directory.

If *dry_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

owner and *group* are used when creating a tar archive. By default, uses the current owner and group.

logger must be an object compatible with **PEP 282**, usually an instance of `logging.Logger`.

The *verbose* argument is unused and deprecated.

Raises an *auditing event* `shutil.make_archive` with arguments `base_name`, `format`, `root_dir`, `base_dir`.

> **備🄵**
>
> This function is not thread-safe when custom archivers registered with `register_archive_format()` do not support the *root_dir* argument. In this case it temporarily changes the current working directory of the process to *root_dir* to perform archiving.

在 3.8 版的變更: The modern pax (POSIX.1-2001) format is now used instead of the legacy GNU format for archives created with `format="tar"`.

在 3.10.6 版的變更: This function is now made thread-safe during creation of standard `.zip` and tar archives.

`shutil.`**`get_archive_formats`**`()`

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple `(name, description)`.

By default `shutil` provides these formats:

- *zip*: ZIP file (if the `zlib` module is available).
- *tar*: Uncompressed tar file. Uses POSIX.1-2001 pax format for new archives.
- *gztar*: gzip'ed tar-file (if the `zlib` module is available).
- *bztar*: bzip2'ed tar-file (if the `bz2` module is available).
- *xztar*: xz'ed tar-file (if the `lzma` module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

`shutil.`**`register_archive_format`**`(`*name*, *function*[, *extra_args*[, *description*]]`)`

Register an archiver for the format *name*.

function is the callable that will be used to unpack archives. The callable will receive the *base_name* of the file to create, followed by the *base_dir* (which defaults to `os.curdir`) to start archiving from. Further arguments are passed as keyword arguments: *owner*, *group*, *dry_run* and *logger* (as passed in `make_archive()`).

If *function* has the custom attribute `function.supports_root_dir` set to `True`, the *root_dir* argument is passed as a keyword argument. Otherwise the current working directory of the process is temporarily changed to *root_dir* before calling *function*. In this case `make_archive()` is not thread-safe.

If given, *extra_args* is a sequence of `(name, value)` pairs that will be used as extra keywords arguments when the archiver callable is used.

description is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty string.

在 3.12 版的變更: Added support for functions supporting the *root_dir* argument.

`shutil.`**`unregister_archive_format`**(*name*)

Remove the archive format *name* from the list of supported formats.

`shutil.`**`unpack_archive`**(*filename*[, *extract_dir*[, *format*[, *filter*]]])

Unpack an archive. *filename* is the full path of the archive.

extract_dir is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

format is the archive format: one of "zip", "tar", "gztar", "bztar", or "xztar". Or any other format registered with `register_unpack_format()`. If not provided, `unpack_archive()` will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a `ValueError` is raised.

The keyword-only *filter* argument is passed to the underlying unpacking function. For zip files, *filter* is not accepted. For tar files, it is recommended to set it to `'data'`, unless using features specific to tar and UNIX-like filesystems. (See *Extraction filters* for details.) The `'data'` filter will become the default for tar files in Python 3.14.

Raises an *auditing event* `shutil.unpack_archive` with arguments `filename`, `extract_dir`, `format`.

警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of the path specified in the *extract_dir* argument, e.g. members that have absolute filenames starting with "/" or filenames with two dots "..".

在 3.7 版的變更: Accepts a *path-like object* for *filename* and *extract_dir*.

在 3.12 版的變更: 新增 *filter* 引數。

`shutil.`**`register_unpack_format`**(*name*, *extensions*, *function*[, *extra_args*[, *description*]])

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

function is the callable that will be used to unpack archives. The callable will receive:

- the path of the archive, as a positional argument;
- the directory the archive must be extracted to, as a positional argument;
- possibly a *filter* keyword argument, if it was given to `unpack_archive()`;
- additional keyword arguments, specified by *extra_args* as a sequence of `(name, value)` tuples.

description can be provided to describe the format, and will be returned by the `get_unpack_formats()` function.

`shutil.`**`unregister_unpack_format`**(*name*)

Unregister an unpack format. *name* is the name of the format.

`shutil.`**`get_unpack_formats`**()

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple `(name, extensions, description)`.

By default `shutil` provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).

- *tar*: uncompressed tar file.
- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own unpacker for any existing formats, by using *register_unpack_format()*.

Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx------ tarek/staff       0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff     609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff      65 2008-06-09 13:26:54 ./config
-rwx------ tarek/staff     668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff     609 2008-06-09 13:26:54 ./id_dsa.pub
-rw------- tarek/staff    1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff     397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff   37192 2010-02-06 18:23:10 ./known_hosts
```

Archiving example with *base_dir*

In this example, similar to the *one above*, we show how to use *make_archive()*, but this time with the usage of *base_dir*. We now have the following directory structure:

```
$ tree tmp
tmp
└── root
    └── structure
        ├── content
        │   └── please_add.txt
        └── do_not_add.txt
```

In the final archive, `please_add.txt` should be included, but `do_not_add.txt` should not. Therefore we use the following:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> make_archive(
...     archive_name,
...     'tar',
```

(繼續下一頁)

(繼續上一頁)

```
...     root_dir='tmp/root',
...     base_dir='structure/content',
... )
'/Users/tarek/my_archive.tar'
```

Listing the files in the resulting archive gives us:

```
$ python -m tarfile -l /Users/tarek/myarchive.tar
structure/content/
structure/content/please_add.txt
```

11.10.3 Querying the size of the output terminal

shutil.**get_terminal_size**(*fallback=(columns, lines)*)

Get the size of the terminal window.

For each of the two dimensions, the environment variable, COLUMNS and LINES respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When COLUMNS or LINES is not defined, which is the common case, the terminal connected to *sys.__stdout__* is queried by invoking *os.get_terminal_size()*.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in fallback parameter is used. fallback defaults to (80, 24) which is the default size used by many terminal emulators.

The value returned is a named tuple of type *os.terminal_size*.

See also: The Single UNIX Specification, Version 2, Other Environment Variables.

在 3.3 版被加入.

在 3.11 版的變更: The fallback values are also used if *os.get_terminal_size()* returns zeroes.

CHAPTER 12

資料持久性 (Data Persistence)

The modules described in this chapter support storing Python data in a persistent form on disk. The `pickle` and `marshal` modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings.

本章節所描述的模組列表🄵:

12.1 `pickle` --- Python 物件序列化

原始碼： Lib/pickle.py

The `pickle` module implements binary protocols for serializing and de-serializing a Python object structure. *"Pickling"* is the process whereby a Python object hierarchy is converted into a byte stream, and *"unpickling"* is the inverse operation, whereby a byte stream (from a *binary file* or *bytes-like object*) is converted back into an object hierarchy. Pickling (and unpickling) is alternatively known as "serialization", "marshalling,"[1] or "flattening"; however, to avoid confusion, the terms used here are "pickling" and "unpickling".

警告

The `pickle` module **is not secure**. Only unpickle data you trust.

It is possible to construct malicious pickle data which will **execute arbitrary code during unpickling**. Never unpickle data that could have come from an untrusted source, or that could have been tampered with.

Consider signing data with `hmac` if you need to ensure that it has not been tampered with.

Safer serialization formats such as `json` may be more appropriate if you are processing untrusted data. See *和 json 的比較*.

[1] Don't confuse this with the `marshal` module

12.1.1 和其他 Python 模組的關🄵

和 marshal 的比較

Python has a more primitive serialization module called *marshal*, but in general *pickle* should always be the preferred way to serialize Python objects. *marshal* exists primarily to support Python's `.pyc` files.

The *pickle* module differs from *marshal* in several significant ways:

- The *pickle* module keeps track of the objects it has already serialized, so that later references to the same object won't be serialized again. *marshal* doesn't do this.

  This has implications both for recursive objects and object sharing. Recursive objects are objects that contain references to themselves. These are not handled by marshal, and in fact, attempting to marshal recursive objects will crash your Python interpreter. Object sharing happens when there are multiple references to the same object in different places in the object hierarchy being serialized. *pickle* stores such objects only once, and ensures that all other references point to the master copy. Shared objects remain shared, which can be very important for mutable objects.

- *marshal* cannot be used to serialize user-defined classes and their instances. *pickle* can save and restore class instances transparently, however the class definition must be importable and live in the same module as when the object was stored.

- The *marshal* serialization format is not guaranteed to be portable across Python versions. Because its primary job in life is to support `.pyc` files, the Python implementers reserve the right to change the serialization format in non-backwards compatible ways should the need arise. The *pickle* serialization format is guaranteed to be backwards compatible across Python releases provided a compatible pickle protocol is chosen and pickling and unpickling code deals with Python 2 to Python 3 type differences if your data is crossing that unique breaking change language boundary.

和 json 的比較

There are fundamental differences between the pickle protocols and JSON (JavaScript Object Notation):

- JSON is a text serialization format (it outputs unicode text, although most of the time it is then encoded to `utf-8`), while pickle is a binary serialization format;
- JSON 是人類可讀的，而 pickle 不是；
- JSON is interoperable and widely used outside of the Python ecosystem, while pickle is Python-specific;
- JSON, by default, can only represent a subset of the Python built-in types, and no custom classes; pickle can represent an extremely large number of Python types (many of them automatically, by clever usage of Python's introspection facilities; complex cases can be tackled by implementing *specific object APIs*);
- Unlike pickle, deserializing untrusted JSON does not in itself create an arbitrary code execution vulnerability.

The *json* module: a standard library module allowing JSON serialization and deserialization.

12.1.2 Data stream format

The data format used by *pickle* is Python-specific. This has the advantage that there are no restrictions imposed by external standards such as JSON or XDR (which can't represent pointer sharing); however it means that non-Python programs may not be able to reconstruct pickled Python objects.

By default, the *pickle* data format uses a relatively compact binary representation. If you need optimal size characteristics, you can efficiently *compress* pickled data.

The module *pickletools* contains tools for analyzing data streams generated by *pickle*. *pickletools* source code has extensive comments about opcodes used by pickle protocols.

There are currently 6 different protocols which can be used for pickling. The higher the protocol used, the more recent the version of Python needed to read the pickle produced.

- Protocol version 0 is the original "human-readable" protocol and is backwards compatible with earlier versions of Python.
- Protocol version 1 is an old binary format which is also compatible with earlier versions of Python.
- Protocol version 2 was introduced in Python 2.3. It provides much more efficient pickling of *new-style classes*. Refer to **PEP 307** for information about improvements brought by protocol 2.
- Protocol version 3 was added in Python 3.0. It has explicit support for *bytes* objects and cannot be unpickled by Python 2.x. This was the default protocol in Python 3.0--3.7.
- Protocol version 4 was added in Python 3.4. It adds support for very large objects, pickling more kinds of objects, and some data format optimizations. It is the default protocol starting with Python 3.8. Refer to **PEP 3154** for information about improvements brought by protocol 4.
- Protocol version 5 was added in Python 3.8. It adds support for out-of-band data and speedup for in-band data. Refer to **PEP 574** for information about improvements brought by protocol 5.

備🄵

Serialization is a more primitive notion than persistence; although *pickle* reads and writes file objects, it does not handle the issue of naming persistent objects, nor the (even more complicated) issue of concurrent access to persistent objects. The *pickle* module can transform a complex object into a byte stream and it can transform the byte stream into an object with the same internal structure. Perhaps the most obvious thing to do with these byte streams is to write them onto a file, but it is also conceivable to send them across a network or store them in a database. The *shelve* module provides a simple interface to pickle and unpickle objects on DBM-style database files.

12.1.3 模組介面

To serialize an object hierarchy, you simply call the *dumps()* function. Similarly, to de-serialize a data stream, you call the *loads()* function. However, if you want more control over serialization and de-serialization, you can create a *Pickler* or an *Unpickler* object, respectively.

pickle 模組提供以下常數:

pickle.**HIGHEST_PROTOCOL**

An integer, the highest *protocol version* available. This value can be passed as a *protocol* value to functions *dump()* and *dumps()* as well as the *Pickler* constructor.

pickle.**DEFAULT_PROTOCOL**

An integer, the default *protocol version* used for pickling. May be less than *HIGHEST_PROTOCOL*. Currently the default protocol is 4, first introduced in Python 3.4 and incompatible with previous versions.

在 3.0 版的變更: 預設協定🄵 3。

在 3.8 版的變更: 預設協定🄵 4。

The *pickle* module provides the following functions to make the pickling process more convenient:

pickle.**dump**(*obj*, *file*, *protocol=None*, ***, *fix_imports=True*, *buffer_callback=None*)

Write the pickled representation of the object *obj* to the open *file object* *file*. This is equivalent to `Pickler(file, protocol).dump(obj)`.

Arguments *file*, *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the *Pickler* constructor.

在 3.8 版的變更: 新增 *buffer_callback* 引數。

pickle.**dumps**(*obj*, *protocol=None*, ***, *fix_imports=True*, *buffer_callback=None*)

Return the pickled representation of the object *obj* as a *bytes* object, instead of writing it to a file.

Arguments *protocol*, *fix_imports* and *buffer_callback* have the same meaning as in the *Pickler* constructor.

在 3.8 版的變更: 新增 *buffer_callback* 引數。

pickle.**load**(*file*, ***, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

Read the pickled representation of an object from the open *file object* *file* and return the reconstituted object hierarchy specified therein. This is equivalent to `Unpickler(file).load()`.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *file*, *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the *Unpickler* constructor.

在 3.8 版的變更: 新增 *buffer* 引數。

pickle.**loads**(*data*, */*, ***, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

Return the reconstituted object hierarchy of the pickled representation *data* of an object. *data* must be a *bytes-like object*.

The protocol version of the pickle is detected automatically, so no protocol argument is needed. Bytes past the pickled representation of the object are ignored.

Arguments *fix_imports*, *encoding*, *errors*, *strict* and *buffers* have the same meaning as in the *Unpickler* constructor.

在 3.8 版的變更: 新增 *buffer* 引數。

The *pickle* module defines three exceptions:

exception pickle.**PickleError**

Common base class for the other pickling exceptions. It inherits from *Exception*.

exception pickle.**PicklingError**

Error raised when an unpicklable object is encountered by *Pickler*. It inherits from *PickleError*.

Refer to *What can be pickled and unpickled?* to learn what kinds of objects can be pickled.

exception pickle.**UnpicklingError**

Error raised when there is a problem unpickling an object, such as a data corruption or a security violation. It inherits from *PickleError*.

Note that other exceptions may also be raised during unpickling, including (but not necessarily limited to) AttributeError, EOFError, ImportError, and IndexError.

The *pickle* module exports three classes, *Pickler*, *Unpickler* and *PickleBuffer*:

class pickle.**Pickler**(*file*, *protocol=None*, *, *fix_imports=True*, *buffer_callback=None*)

This takes a binary file for writing a pickle data stream.

The optional *protocol* argument, an integer, tells the pickler to use the given protocol; supported protocols are 0 to *HIGHEST_PROTOCOL*. If not specified, the default is *DEFAULT_PROTOCOL*. If a negative number is specified, *HIGHEST_PROTOCOL* is selected.

The *file* argument must have a write() method that accepts a single bytes argument. It can thus be an on-disk file opened for binary writing, an *io.BytesIO* instance, or any other custom object that meets this interface.

If *fix_imports* is true and *protocol* is less than 3, pickle will try to map the new Python 3 names to the old module names used in Python 2, so that the pickle data stream is readable with Python 2.

If *buffer_callback* is `None` (the default), buffer views are serialized into *file* as part of the pickle stream.

If *buffer_callback* is not `None`, then it can be called any number of times with a buffer view. If the callback returns a false value (such as `None`), the given buffer is *out-of-band*; otherwise the buffer is serialized in-band, i.e. inside the pickle stream.

It is an error if *buffer_callback* is not `None` and *protocol* is `None` or smaller than 5.

在 3.8 版的變更: 新增 *buffer_callback* 引數。

dump(*obj*)

Write the pickled representation of *obj* to the open file object given in the constructor.

persistent_id(*obj*)

Do nothing by default. This exists so a subclass can override it.

If *persistent_id()* returns `None`, *obj* is pickled as usual. Any other value causes *Pickler* to emit the returned value as a persistent ID for *obj*. The meaning of this persistent ID should be defined by *Unpickler.persistent_load()*. Note that the value returned by *persistent_id()* cannot itself have a persistent ID.

關於細節與用法範例請見*Persistence of External Objects*。

dispatch_table

A pickler object's dispatch table is a registry of *reduction functions* of the kind which can be declared using *copyreg.pickle()*. It is a mapping whose keys are classes and whose values are reduction functions. A reduction function takes a single argument of the associated class and should conform to the same interface as a *__reduce__()* method.

By default, a pickler object will not have a *dispatch_table* attribute, and it will instead use the global dispatch table managed by the *copyreg* module. However, to customize the pickling for a specific pickler object one can set the *dispatch_table* attribute to a dict-like object. Alternatively, if a subclass of *Pickler* has a *dispatch_table* attribute then this will be used as the default dispatch table for instances of that class.

關於用法範例請見*Dispatch Tables*。

在 3.3 版被加入.

reducer_override(*obj*)

Special reducer that can be defined in *Pickler* subclasses. This method has priority over any reducer in the *dispatch_table*. It should conform to the same interface as a *__reduce__()* method, and can optionally return *NotImplemented* to fallback on *dispatch_table*-registered reducers to pickle `obj`.

For a detailed example, see *Custom Reduction for Types, Functions, and Other Objects*.

在 3.8 版被加入.

fast

Deprecated. Enable fast mode if set to a true value. The fast mode disables the usage of memo, therefore speeding the pickling process by not generating superfluous PUT opcodes. It should not be used with self-referential objects, doing otherwise will cause `Pickler` to recurse infinitely.

Use `pickletools.optimize()` if you need more compact pickles.

class pickle.**Unpickler**(*file*, *, *fix_imports=True*, *encoding='ASCII'*, *errors='strict'*, *buffers=None*)

This takes a binary file for reading a pickle data stream.

The protocol version of the pickle is detected automatically, so no protocol argument is needed.

The argument *file* must have three methods, a read() method that takes an integer argument, a readinto() method that takes a buffer argument and a readline() method that requires no arguments, as in the `io.BufferedIOBase` interface. Thus *file* can be an on-disk file opened for binary reading, an `io.BytesIO` object, or any other custom object that meets this interface.

The optional arguments *fix_imports*, *encoding* and *errors* are used to control compatibility support for pickle stream generated by Python 2. If *fix_imports* is true, pickle will try to map the old Python 2 names to the new names used in Python 3. The *encoding* and *errors* tell pickle how to decode 8-bit string instances pickled by Python 2; these default to 'ASCII' and 'strict', respectively. The *encoding* can be 'bytes' to read these 8-bit string instances as bytes objects. Using `encoding='latin1'` is required for unpickling NumPy arrays and instances of `datetime`, `date` and `time` pickled by Python 2.

If *buffers* is `None` (the default), then all data necessary for deserialization must be contained in the pickle stream. This means that the *buffer_callback* argument was `None` when a `Pickler` was instantiated (or when `dump()` or `dumps()` was called).

If *buffers* is not `None`, it should be an iterable of buffer-enabled objects that is consumed each time the pickle stream references an *out-of-band* buffer view. Such buffers have been given in order to the *buffer_callback* of a Pickler object.

在 3.8 版的變更: 新增 *buffer* 引數。

load()

Read the pickled representation of an object from the open file object given in the constructor, and return the reconstituted object hierarchy specified therein. Bytes past the pickled representation of the object are ignored.

persistent_load(*pid*)

Raise an `UnpicklingError` by default.

If defined, `persistent_load()` should return the object specified by the persistent ID *pid*. If an invalid persistent ID is encountered, an `UnpicklingError` should be raised.

關於細節與用法範例請見*Persistence of External Objects*。

find_class(*module*, *name*)

Import *module* if necessary and return the object called *name* from it, where the *module* and *name* arguments are `str` objects. Note, unlike its name suggests, `find_class()` is also used for finding functions.

Subclasses may override this to gain control over what type of objects and how they can be loaded, potentially reducing security risks. Refer to *Restricting Globals* for details.

Raises an *auditing event* `pickle.find_class` with arguments `module`, `name`.

class pickle.**PickleBuffer**(*buffer*)

A wrapper for a buffer representing picklable data. *buffer* must be a buffer-providing object, such as a *bytes-like object* or a N-dimensional array.

PickleBuffer is itself a buffer provider, therefore it is possible to pass it to other APIs expecting a buffer-providing object, such as *memoryview*.

PickleBuffer objects can only be serialized using pickle protocol 5 or higher. They are eligible for *out-of-band serialization*.

在 3.8 版被加入.

raw()

Return a *memoryview* of the memory area underlying this buffer. The returned object is a one-dimensional, C-contiguous memoryview with format `B` (unsigned bytes). *BufferError* is raised if the buffer is neither C- nor Fortran-contiguous.

release()

Release the underlying buffer exposed by the PickleBuffer object.

12.1.4 What can be pickled and unpickled?

The following types can be pickled:

- built-in constants (`None`, `True`, `False`, `Ellipsis`, and *NotImplemented*);
- integers, floating-point numbers, complex numbers;
- strings, bytes, bytearrays;
- tuples, lists, sets, and dictionaries containing only picklable objects;
- functions (built-in and user-defined) accessible from the top level of a module (using `def`, not `lambda`);
- classes accessible from the top level of a module;
- instances of such classes whose the result of calling *__getstate__()* is picklable (see section *Pickling Class Instances* for details).

Attempts to pickle unpicklable objects will raise the *PicklingError* exception; when this happens, an unspecified number of bytes may have already been written to the underlying file. Trying to pickle a highly recursive data structure may exceed the maximum recursion depth, a *RecursionError* will be raised in this case. You can carefully raise this limit with *sys.setrecursionlimit()*.

Note that functions (built-in and user-defined) are pickled by fully *qualified name*, not by value.[2] This means that only the function name is pickled, along with the name of the containing module and classes. Neither the function's code, nor any of its function attributes are pickled. Thus the defining module must be importable in the unpickling environment, and the module must contain the named object, otherwise an exception will be raised.[3]

Similarly, classes are pickled by fully qualified name, so the same restrictions in the unpickling environment apply. Note that none of the class's code or data is pickled, so in the following example the class attribute `attr` is not restored in the unpickling environment:

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

These restrictions are why picklable functions and classes must be defined at the top level of a module.

Similarly, when class instances are pickled, their class's code and data are not pickled along with them. Only the instance data are pickled. This is done on purpose, so you can fix bugs in a class or add methods to the class and still load objects

[2] This is why `lambda` functions cannot be pickled: all `lambda` functions share the same name: `<lambda>`.
[3] The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

that were created with an earlier version of the class. If you plan to have long-lived objects that will see many versions of a class, it may be worthwhile to put a version number in the objects so that suitable conversions can be made by the class's *__setstate__()* method.

12.1.5 Pickling Class Instances

In this section, we describe the general mechanisms available to you to define, customize, and control how class instances are pickled and unpickled.

In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def restore(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.`**`__getnewargs_ex__`**`()`

In protocols 2 and newer, classes that implements the *__getnewargs_ex__()* method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where *args* is a tuple of positional arguments and *kwargs* a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement *__getnewargs__()*.

在 3.6 版的變更: *__getnewargs_ex__()* is now used in protocols 2 and 3.

`object.`**`__getnewargs__`**`()`

This method serves a similar purpose as *__getnewargs_ex__()*, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

__getnewargs__() will not be called if *__getnewargs_ex__()* is defined.

在 3.6 版的變更: Before Python 3.6, *__getnewargs__()* was called instead of *__getnewargs_ex__()* in protocols 2 and 3.

`object.`**`__getstate__`**`()`

Classes can further influence how their instances are pickled by overriding the method *__getstate__()*. It is called and the returned object is pickled as the contents for the instance, instead of a default state. There are several cases:

- For a class that has no instance *__dict__* and no `__slots__`, the default state is `None`.
- For a class that has an instance *__dict__* and no `__slots__`, the default state is `self.__dict__`.
- For a class that has an instance *__dict__* and `__slots__`, the default state is a tuple consisting of two dictionaries: `self.__dict__`, and a dictionary mapping slot names to slot values. Only slots that have a value are included in the latter.

- For a class that has __slots__ and no instance *__dict__*, the default state is a tuple whose first item is None and whose second item is a dictionary mapping slot names to slot values described in the previous bullet.

在 3.11 版的變更: Added the default implementation of the __getstate__() method in the *object* class.

object.**__setstate__**(*state*)

Upon unpickling, if the class defines *__setstate__()*, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

> **備F**
>
> If *__reduce__()* returns a state with value None at pickling, the *__setstate__()* method will not be called upon unpickling.

Refer to the section *Handling Stateful Objects* for more information about how to use the methods *__getstate__()* and *__setstate__()*.

> **備F**
>
> At unpickling time, some methods like __getattr__(), __getattribute__(), or __setattr__() may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement __new__() to establish such an invariant, as __init__() is not called when unpickling an instance.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the *__reduce__()* special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects.[4]

Although powerful, implementing *__reduce__()* directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., *__getnewargs_ex__()*, *__getstate__()* and *__setstate__()*) whenever possible. We will show, however, cases where using __reduce__() is the only option or leads to more efficient pickling or both.

object.**__reduce__**()

The interface is currently defined as follows. The *__reduce__()* method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the "reduce value").

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object's local name relative to its module; the pickle module searches the module namespace to determine the object's module. This behaviour is typically useful for singletons.

When a tuple is returned, it must be between two and six items long. Optional items can either be omitted, or None can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object's state, which will be passed to the object's *__setstate__()* method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object's *__dict__* attribute.

[4] The *copy* module uses this protocol for shallow and deep copying operations.

- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have *append and extend methods* with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.
- Optionally, a callable with a `(obj, state)` signature. This callable allows the user to programmatically control the state-updating behavior of a specific object, instead of using `obj`'s static *`__setstate__()`* method. If not `None`, this callable will have priority over `obj`'s *`__setstate__()`*.

  在 3.8 版被加入: The optional sixth tuple item, `(obj, state)`, was added.

`object.`**`__reduce_ex__`**(*protocol*)

Alternatively, a *`__reduce_ex__()`* method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the *`__reduce__()`* method. In addition, *`__reduce__()`* automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

Persistence of External Objects

For the benefit of object persistence, the *`pickle`* module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0)[5] or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the *`pickle`* module; it will delegate this resolution to the user-defined methods on the pickler and unpickler, *`persistent_id()`* and *`persistent_load()`* respectively.

To pickle objects that have an external persistent ID, the pickler must have a custom *`persistent_id()`* method that takes an object as an argument and returns either `None` or the persistent ID for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent ID string is returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom *`persistent_load()`* method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.

import pickle
import sqlite3
from collections import namedtuple

# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance, we emit a
```

(繼續下一頁)

[5] The limitation on alphanumeric characters is due to the fact that persistent IDs in protocol 0 are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickled data will become unreadable.

(繼續上一頁)

```
        # persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, containing a tag and a
            # key, which refers to a specific record in the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None. This means obj
            # needs to be pickled as usual.
            return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is encountered.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # Fetch the referenced record from the database and return it.
            cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # Always raises an error if you cannot return the correct object.
            # Otherwise, the unpickler will think None is the object referenced
            # by the persistent ID.
            raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
    import pprint

    # Initialize and populate our database.
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
        'fight with a zebra',
        )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))

    # Fetch the records to be pickled.
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor]
    # Save the records using our custom DBPickler.
    file = io.BytesIO()
    DBPickler(file).dump(memos)
```

(繼續下一頁)

(繼續上一頁)

```
    print("Pickled records:")
    pprint.pprint(memos)

    # Update a record, just for good measure.
    cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

    # Load the records from the pickle data stream.
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

    print("Unpickled records:")
    pprint.pprint(memos)

if __name__ == '__main__':
    main()
```

Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the *copyreg* module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

舉例來🄵:

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

creates an instance of *pickle.Pickler* with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same but all instances of `MyPickler` will by default share the private dispatch table. On the other hand, the code

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

modifies the global dispatch table shared by all users of the *copyreg* module.

Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class below opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The `__setstate__()` and `__getstate__()` methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
            return None
        if line.endswith('\n'):
            line = line[:-1]
        return "%i: %s" % (self.lineno, line)

    def __getstate__(self):
        # Copy the object's state from self.__dict__ which contains
        # all our instance attributes. Always use the dict.copy()
        # method to avoid modifying the original state.
        state = self.__dict__.copy()
        # Remove the unpicklable entries.
        del state['file']
        return state

    def __setstate__(self, state):
        # Restore instance attributes (i.e., filename and lineno).
        self.__dict__.update(state)
        # Restore the previously opened file's state. To do so, we need to
        # reopen it and read from it until the line count is restored.
        file = open(self.filename)
        for _ in range(self.lineno):
            file.readline()
        # Finally, save the file.
        self.file = file
```

A sample usage might be something like this:

```
>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'
```

12.1.6 Custom Reduction for Types, Functions, and Other Objects

在 3.8 版被加入.

Sometimes, *dispatch_table* may not be flexible enough. In particular we may want to customize pickling based on another criterion than the object's type, or we may want to customize the pickling of functions and classes.

For those cases, it is possible to subclass from the *Pickler* class and implement a *reducer_override()* method. This method can return an arbitrary reduction tuple (see *__reduce__()*). It can alternatively return *NotImplemented* to fallback to the traditional behavior.

If both the *dispatch_table* and *reducer_override()* are defined, then *reducer_override()* method takes priority.

備🄵

For performance reasons, *reducer_override()* may not be called for the following objects: `None`, `True`, `False`, and exact instances of *int*, *float*, *bytes*, *str*, *dict*, *set*, *frozenset*, *list* and *tuple*.

Here is a simple example where we allow pickling and reconstructing a given class:

```
import io
import pickle

class MyClass:
    my_attribute = 1

class MyPickler(pickle.Pickler):
    def reducer_override(self, obj):
        """Custom reducer for MyClass."""
        if getattr(obj, "__name__", None) == "MyClass":
            return type, (obj.__name__, obj.__bases__,
                          {'my_attribute': obj.my_attribute})
        else:
            # For any other object, fallback to usual reduction
            return NotImplemented

f = io.BytesIO()
p = MyPickler(f)
p.dump(MyClass)

del MyClass

unpickled_class = pickle.loads(f.getvalue())

assert isinstance(unpickled_class, type)
assert unpickled_class.__name__ == "MyClass"
assert unpickled_class.my_attribute == 1
```

12.1.7 Out-of-band Buffers

在 3.8 版被加入.

In some contexts, the *pickle* module is used to transfer massive amounts of data. Therefore, it can be important to minimize the number of memory copies, to preserve performance and resource consumption. However, normal operation of the *pickle* module, as it transforms a graph-like structure of objects into a sequential stream of bytes, intrinsically involves copying data to and from the pickle stream.

This constraint can be eschewed if both the *provider* (the implementation of the object types to be transferred) and the *consumer* (the implementation of the communications system) support the out-of-band transfer facilities provided by pickle protocol 5 and higher.

Provider API

The large data objects to be pickled must implement a *__reduce_ex__()* method specialized for protocol 5 and higher, which returns a *PickleBuffer* instance (instead of e.g. a *bytes* object) for any large data.

A *PickleBuffer* object *signals* that the underlying buffer is eligible for out-of-band data transfer. Those objects remain compatible with normal usage of the *pickle* module. However, consumers can also opt-in to tell *pickle* that they will handle those buffers by themselves.

Consumer API

A communications system can enable custom handling of the *PickleBuffer* objects generated when serializing an object graph.

On the sending side, it needs to pass a *buffer_callback* argument to *Pickler* (or to the *dump()* or *dumps()* function), which will be called with each *PickleBuffer* generated while pickling the object graph. Buffers accumulated by the *buffer_callback* will not see their data copied into the pickle stream, only a cheap marker will be inserted.

On the receiving side, it needs to pass a *buffers* argument to *Unpickler* (or to the *load()* or *loads()* function), which is an iterable of the buffers which were passed to *buffer_callback*. That iterable should produce buffers in the same order as they were passed to *buffer_callback*. Those buffers will provide the data expected by the reconstructors of the objects whose pickling produced the original *PickleBuffer* objects.

Between the sending side and the receiving side, the communications system is free to implement its own transfer mechanism for out-of-band buffers. Potential optimizations include the use of shared memory or datatype-dependent compression.

范例

Here is a trivial example where we implement a *bytearray* subclass able to participate in out-of-band buffer pickling:

```
class ZeroCopyByteArray(bytearray):

    def __reduce_ex__(self, protocol):
        if protocol >= 5:
            return type(self)._reconstruct, (PickleBuffer(self),), None
        else:
            # PickleBuffer is forbidden with pickle protocols <= 4.
            return type(self)._reconstruct, (bytearray(self),)

    @classmethod
    def _reconstruct(cls, obj):
```

(繼續下一頁)

(繼續上一頁)

```
        with memoryview(obj) as m:
            # Get a handle over the original buffer object
            obj = m.obj
            if type(obj) is cls:
                # Original buffer object is a ZeroCopyByteArray, return it
                # as-is.
                return obj
            else:
                return cls(obj)
```

The reconstructor (the `_reconstruct` class method) returns the buffer's providing object if it has the right type. This is an easy way to simulate zero-copy behaviour on this toy example.

On the consumer side, we can pickle those objects the usual way, which when unserialized will give us a copy of the original object:

```
b = ZeroCopyByteArray(b"abc")
data = pickle.dumps(b, protocol=5)
new_b = pickle.loads(data)
print(b == new_b)  # True
print(b is new_b)  # False: a copy was made
```

But if we pass a *buffer_callback* and then give back the accumulated buffers when unserializing, we are able to get back the original object:

```
b = ZeroCopyByteArray(b"abc")
buffers = []
data = pickle.dumps(b, protocol=5, buffer_callback=buffers.append)
new_b = pickle.loads(data, buffers=buffers)
print(b == new_b)  # True
print(b is new_b)  # True: no copy was made
```

This example is limited by the fact that *bytearray* allocates its own memory: you cannot create a *bytearray* instance that is backed by another object's memory. However, third-party datatypes such as NumPy arrays do not have this limitation, and allow use of zero-copy pickling (or making as few copies as possible) when transferring between distinct processes or systems.

也參考

PEP 574 -- Pickle protocol 5 with out-of-band data

12.1.8 Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
hello world
0
```

In this example, the unpickler imports the *os.system()* function and then apply the string argument "echo hello world". Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing *Unpickler.find_class()*. Unlike its name suggests, *Unpickler.find_class()* is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the *builtins* module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
                                     (module, name))

def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working as intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                  b'(S\'getattr(__import__("os"), "system")'
...                  b'("echo hello world")\'\ntR.')
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in *xmlrpc.client* or third-party solutions.

12.1.9 Performance

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the *pickle* module has a transparent optimizer written in C.

12.1.10 范例

For the simplest code, use the *dump()* and *load()* functions.

```
import pickle

# An arbitrary collection of objects supported by pickle.
data = {
    'a': [1, 2.0, 3+4j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol available.
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically, so we do not
    # have to specify it.
    data = pickle.load(f)
```

🄵解

12.2 copyreg --- 🄵🄵 pickle 支援函式

原始碼： Lib/copyreg.py

---

copyreg 模組提供了一種用以定義在 pickle 特定物件時使用之函式的方式。*pickle* 和*copy* 模組在 pickle/copy 這些物件時使用這些函式。此模組提供有關非類🄴物件之建構函式的配置資訊。此類建構函式可以是工廠函式 (factory function) 或類🄴實例。

copyreg.**constructor**(*object*)

宣告 *object* 是一個有效的建構函式。如果 *object* 不可呼叫（因此不可作🄴有效的建構函式），則會引發*TypeError*。

copyreg.**pickle**(*type*, *function*, *constructor_ob=None*)

宣告 *function* 應該用作 *type* 型🄴之物件的「歸約 (”reduction”)」函式。*function* 必須回傳字串或包含 2 到 6 個元素的元組。有關 *function* 介面的更多詳細資訊，請參🄴*dispatch_table*。

constructor_ob 參數是一個遺留功能，現在已被忽略，但如果要傳遞它的話則必須是個可呼叫物件。

請注意，pickler 物件或*pickle.Pickler* 子類🄴的*dispatch_table* 屬性也可用於宣告歸約函式。

12.2.1 范例

下面範例展示如何🄵🄵一個 pickle 函式以及如何使用它：

```
>>> import copyreg, copy, pickle
>>> class C:
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

12.3 shelve --- Python object persistence

原始碼： Lib/shelve.py

A ”shelf” is a persistent, dictionary-like object. The difference with ”dbm” databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects --- anything that the *pickle* module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

shelve.**open**(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of *dbm.open()*.

By default, pickles created with *pickle.DEFAULT_PROTOCOL* are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see 範例). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on *sync()* and *close()*; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

在 3.10 版的變更: *pickle.DEFAULT_PROTOCOL* is now used as the default pickle protocol.

在 3.11 版的變更: Accepts *path-like object* for filename.

備🄵

Do not rely on the shelf being closed automatically; always call *close()* explicitly when you don't need it any more, or use *shelve.open()* as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

警告

Because the *shelve* module is backed by *pickle*, it is insecure to load a shelf from an untrusted source. Like with pickle, loading a shelf can execute arbitrary code.

Shelf objects support most of methods and operations supported by dictionaries (except copying, constructors and operators `|` and `|=`). This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

Shelf.**sync**()

Write back all entries in the cache if the shelf was opened with *writeback* set to *True*. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with *close()*.

Shelf.**close**()

Synchronize and close the persistent *dict* object. Operations on a closed shelf will fail with a *ValueError*.

也參考

Persistent dictionary recipe with widely supported storage formats and having the speed of native dictionaries.

12.3.1 Restrictions

- The choice of which database package will be used (such as *dbm.ndbm* or *dbm.gnu*) depends on which interface is available. Therefore it is not safe to open the database directly using *dbm*. The database is also (unfortunately) subject to the limitations of *dbm*, if it is used --- this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The *shelve* module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.
- On macOS *dbm.ndbm* can silently corrupt the database file on updates, which can cause hard crashes when trying to read from the database.

class shelve.**Shelf**(*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of *collections.abc.MutableMapping* which stores pickled values in the *dict* object.

By default, pickles created with *pickle.DEFAULT_PROTOCOL* are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the *pickle* documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A *Shelf* object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

在 3.2 版的變更: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

在 3.4 版的變更: 新增情境管理器的支援。

在 3.10 版的變更: *pickle.DEFAULT_PROTOCOL* is now used as the default pickle protocol.

class shelve.**BsdDbShelf**(*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of *Shelf* which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` methods. These are available in the third-party `bsddb` module from pybsddb but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the *Shelf* class.

class shelve.**DbfilenameShelf**(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which accepts a *filename* instead of a dict-like object. The underlying file will be opened using *dbm.open()*. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the *open()* function. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

12.3.2 范例

To summarize the interface (`key` is a string, `data` is an arbitrary object):

```
import shelve

d = shelve.open(filename)  # open -- file may get suffix added by low-level
                           # library

d[key] = data              # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at key (raise KeyError
                           # if no such key)
del d[key]                 # delete data stored at key (raises KeyError
                           # if no such key)

flag = key in d            # true if the key exists
klist = list(d.keys())     # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]        # this works as expected, but...
d['xx'].append(3)          # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']             # extracts the copy
temp.append(5)             # mutates the copy
d['xx'] = temp             # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()                  # close it
```

***dbm* 模組**
Generic interface to `dbm`-style databases.

***pickle* 模組**
Object serialization used by *shelve*.

12.4 `marshal` --- 內部 Python 物件序列化

此 module（模組）包含一個能以二進位制格式來讀寫 Python 值的函式。這種格式是 Python 專屬但獨立於機器架構的（例如，你可以在一臺 PC 上寫入某個 Python 值，再將檔案傳到一臺 Mac 上F在那F讀取它）。這種格式的細節是有意地不在文件上F明的；它可能在不同 Python 版本中被改變（雖然這種情F極少發生）。[1]

這不是一個通用「持續性 (persistence)」module 。關於通用持續性以及透過 RPC 呼叫傳遞 Python 物件，請參F*pickle* 和*shelve* 等 module 。*marshal* module 主要是F了支援用來讀寫「F編譯 (pseudo-compiled)」

[1] 此 module 的名稱來源於 Modula-3 (及其他語言) 的設計者所使用的術語，他們使用"marshal" 來表示自包含 (self-contained) 形式資料的傳輸。嚴格來F，將資料從F部形式轉FF外部形式 (例如用於 RPC 緩衝區) 稱F"marshal"，而其反向過程則稱F"unmarshal"。

.pyc 檔案的 Python module。因此，Python 維護者保留了在必要時以不向後相容的方式修改 marshal 格式的權利。如果你要序列化和反序列化 Python 物件，請改用*pickle* module -- 其執行效率相當、有保證版本獨立性，且實質上 pickle 還支援比 marshal 更多樣的物件。

警告

marshal module 對於錯誤或惡意構建的資料來🄵是不安全的。永遠不要 unmarshal 來自不受信任的或來源未經驗證的資料。

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating-point numbers, complex numbers, strings, bytes, bytearrays, tuples, lists, sets, frozensets, dictionaries, and code objects, where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported. The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

有些函式可以讀/寫檔案，還有些函式可以操作類位元組串物件 (bytes-like object)。

這個 module 定義了以下函式：

marshal.**dump**(*value*, *file*[, *version*])

將值寫入被開🄴的檔案。值必須🄵受支援的型🄵，檔案必須🄴可寫入的*binary file*。

如果值具有（或其所包含的物件具有）不支援的型🄵，則會引發*ValueError* 例外 --- 但是垃圾資料 (garbage data) 也將寫入檔案，物件也無法正確地透過*load()* 重新讀取。

version 引數指明 dump 應該使用的資料格式（見下文）。

Raises an *auditing event* marshal.dumps with arguments value, version.

marshal.**load**(*file*)

從開🄴的檔案讀取一個值🄵回傳。如果讀不到有效的值（例如，由於資料🄵不同 Python 版本的不相容 marshal 格式），則會引發*EOFError*、*ValueError* 或*TypeError*。檔案必須🄴可讀取的*binary file*。

Raises an *auditing event* marshal.load with no arguments.

備🄵

如果透過*dump()* marshal 了一個包含不支援型🄵的物件，*load()* 會將不可 marshal 的型🄵替🄵🄵 None。

在 3.10 版的變更: 使用此呼叫🄵每個程式碼物件引發一個 code.__new__ 稽核事件。現在它會🄵整個載入操作引發單個 marshal.load 事件。

marshal.**dumps**(*value*[, *version*])

回傳將透過 dump(value, file) 來被寫入一個檔案的位元組串物件，其值必須是有支援的型🄵，如果值（或其包含的任一物件）🄵不支援的型🄵則會引發*ValueError*。

version 引數指明 dumps 應當使用的資料型🄵（見下文）。

Raises an *auditing event* marshal.dumps with arguments value, version.

marshal.**loads**(*bytes*)

將*bytes-like object* 轉🄵🄵一個值。如果找不到有效的值，則會引發*EOFError*、*ValueError* 或*TypeError*。輸入中額外的位元組串會被忽略。

Raises an *auditing event* marshal.loads with argument bytes.

在 3.10 版的變更: 使用此呼叫🄴每個程式碼物件引發一個 `code.__new__` 稽核事件。現在它會🄴整個載入操作引發單個 `marshal.loads` 事件。

此外，還定義了以下常數:

`marshal.`**`version`**

Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating-point numbers. Version 3 adds support for object instancing and recursion. The current version is 4.

🄵解

12.5 dbm --- Unix "databases" 的介面

原始碼: Lib/dbm/__init__.py

---

dbm is a generic interface to variants of the DBM database --- *dbm.gnu* or *dbm.ndbm*. If none of these modules is installed, the slow-but-simple implementation in module *dbm.dumb* will be used. There is a third party interface to the Oracle Berkeley DB.

exception dbm.**error**

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named *dbm.error* as the first item --- the latter is used when *dbm.error* is raised.

dbm.**whichdb**(*filename*)

This function attempts to guess which of the several simple database modules available --- *dbm.gnu*, *dbm.ndbm* or *dbm.dumb* --- should be used to open a given file.

回傳以下其中一個值:

- `None` if the file can't be opened because it's unreadable or doesn't exist
- the empty string (`''`) if the file's format can't be guessed
- a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`

在 3.11 版的變更: *filename* accepts a *path-like object*.

dbm.**open**(*file*, *flag='r'*, *mode=0o666*)

Open a database and return the corresponding database object.

參數

- **file** (*path-like object*) -- 要打開的資料庫檔案

  If the database file already exists, the *whichdb()* function is used to determine its type and the appropriate module is used; if it does not exist, the first submodule listed above that can be imported is used.

- **flag** (`str`) --
  - `'r'` (default): Open existing database for reading only.
  - `'w'`: Open existing database for reading and writing.
  - `'c'`: Open database for reading and writing, creating it if it doesn't exist.
  - `'n'`: Always create a new, empty database, open for reading and writing.

- **mode** (int) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

在 3.11 版的變更: *file* 接受一個類路徑物件。

The object returned by *open()* supports the same basic functionality as a *dict*; keys and their corresponding values can be stored, retrieved, and deleted, and the in operator and the keys() method are available, as well as get() and setdefault() methods.

Key and values are always stored as *bytes*. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a with statement, which will automatically close them when done.

在 3.2 版的變更: get() and setdefault() methods are now available for all *dbm* backends.

在 3.4 版的變更: Added native support for the context management protocol to the objects returned by *open()*.

在 3.8 版的變更: Deleting a key from a read-only database raises a database module specific exception instead of *KeyError*.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception (most
    # likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.
```

也參考

***shelve* 模組**
Persistence module which stores non-string data.

The individual submodules are described in the following sections.

12.5.1 dbm.gnu --- GNU 資料庫管理器

原始碼： Lib/dbm/gnu.py

The *dbm.gnu* module provides an interface to the GDBM (GNU dbm) library, similar to the *dbm.ndbm* module, but with additional functionality like crash tolerance.

備🄵

The file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible and can not be used interchangeably.

exception dbm.gnu.**error**

Raised on *dbm.gnu*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.gnu.**open**(*filename*, *flag='r'*, *mode=0o666*, */*)

Open a GDBM database and return a gdbm object.

參數

- **filename** (*path-like object*) -- 要打開的資料庫檔案
- **flag** (str) --
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.

  The following additional characters may be appended to control how the database is opened:
  - 'f': Open the database in fast mode. Writes to the database will not be synchronized.
  - 's': Synchronized mode. Changes to the database will be written immediately to the file.
  - 'u': 不要鎖住資料庫。

  Not all flags are valid for all versions of GDBM. See the *open_flags* member for a list of supported flag characters.
- **mode** (int) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

引發

error -- 如果一個無效的 *flag* 引數被傳入。

在 3.11 版的變更: *filename* accepts a *path-like object*.

dbm.gnu.**open_flags**

A string of characters the *flag* parameter of *open()* supports.

gdbm objects behave similar to *mappings*, but items() and values() methods are not supported. The following methods are also provided:

gdbm.**firstkey**()

It's possible to loop over every key in the database using this method and the *nextkey()* method. The traversal is ordered by GDBM's internal hash values, and won't be sorted by the key values. This method returns the starting key.

gdbm.**nextkey**(*key*)

Returns the key that follows *key* in the traversal. The following code prints every key in the database db, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k is not None:
    print(k)
    k = db.nextkey(k)
```

gdbm.**reorganize**()

If you have carried out a lot of deletions and would like to shrink the space used by the GDBM file, this routine will reorganize the database. gdbm objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

gdbm.**sync**()

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

gdbm.**close**()

關閉 GDBM 資料庫。

12.5.2 dbm.ndbm --- 新資料庫管理器

原始碼： Lib/dbm/ndbm.py

The *dbm.ndbm* module provides an interface to the NDBM (New Database Manager) library. This module can be used with the "classic" NDBM interface or the GDBM compatibility interface.

備🄵

The file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible and can not be used interchangeably.

警告

The NDBM library shipped as part of macOS has an undocumented limitation on the size of values, which can result in corrupted database files when storing values larger than this limit. Reading such corrupted files can result in a hard crash (segmentation fault).

exception dbm.ndbm.**error**

Raised on *dbm.ndbm*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.ndbm.**library**

Name of the NDBM implementation library used.

dbm.ndbm.**open**(*filename*, *flag='r'*, *mode=0o666*, */*)

Open an NDBM database and return an ndbm object.

參數

- **filename** (*path-like object*) -- The basename of the database file (without the .dir or .pag extensions).
- **flag** (str) --
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (int) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

ndbm objects behave similar to *mappings*, but items() and values() methods are not supported. The following methods are also provided:

在 3.11 版的變更: Accepts *path-like object* for filename.

ndbm.**close**()

關閉 NDBM 資料庫。

12.5.3 dbm.dumb --- 可🄵式 DBM 實作

原始碼： Lib/dbm/dumb.py

備🄵

The *dbm.dumb* module is intended as a last resort fallback for the *dbm* module when a more robust module is not available. The *dbm.dumb* module is not written for speed and is not nearly as heavily used as the other database modules.

The *dbm.dumb* module provides a persistent *dict*-like interface which is written entirely in Python. Unlike other *dbm* backends, such as *dbm.gnu*, no external library is required.

dbm.dumb 模組定義了以下項目：

exception dbm.dumb.**error**

Raised on *dbm.dumb*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.dumb.**open**(*filename*, *flag='c'*, *mode=0o666*)

Open a dbm.dumb database. The returned database object behaves similar to a *mapping*, in addition to providing *sync()* and *close()* methods.

參數

- **filename** -- The basename of the database file (without extensions). A new database creates the following files:
  - *filename*.dat

  - *filename*.dir

- **flag** (str) --
  - 'r': Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c' (default): Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (int) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

警告

It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to stack depth limitations in Python's AST compiler.

在 3.5 版的變更: *open()* always creates a new database when *flag* is 'n'.

在 3.8 版的變更: A database opened read-only if *flag* is 'r'. A database is not created if it does not exist if *flag* is 'r' or 'w'.

在 3.11 版的變更: *filename* accepts a *path-like object*.

In addition to the methods provided by the *collections.abc.MutableMapping* class, the following methods are provided:

dumbdbm.**sync**()

Synchronize the on-disk directory and data files. This method is called by the Shelve.sync() method.

dumbdbm.**close**()

關閉資料庫。

12.6 sqlite3 --- SQLite 資料庫的 DB-API 2.0 介面

原始碼: Lib/sqlite3/ SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The sqlite3 module was written by Gerhard Häring. It provides an SQL interface compliant with the DB-API 2.0 specification described by **PEP 249**, and requires SQLite 3.7.15 or newer.

此文件包含四個主要章節:

- *Tutorial* 教導如何使用 sqlite3 模組。
- *Reference* 描述此模組定義的類🄴與函式。
- *How-to guides* 詳細🄴明如何處理特定工作。
- *解釋* 深入提供交易 (transaction) 控制的背景。

Tutorial, reference and examples for learning SQL syntax.

PEP 249 - 資料庫 API 規格 2.0
PEP 由 Marc-André Lemburg 撰寫。

12.6.1 Tutorial

In this tutorial, you will create a database of Monty Python movies using basic `sqlite3` functionality. It assumes a fundamental understanding of database concepts, including cursors and transactions.

First, we need to create a new database and open a database connection to allow `sqlite3` to work with it. Call *`sqlite3.connect()`* to create a connection to the database `tutorial.db` in the current working directory, implicitly creating it if it does not exist:

```
import sqlite3
con = sqlite3.connect("tutorial.db")
```

The returned *`Connection`* object `con` represents the connection to the on-disk database.

In order to execute SQL statements and fetch results from SQL queries, we will need to use a database cursor. Call *`con.cursor()`* to create the *`Cursor`*:

```
cur = con.cursor()
```

Now that we've got a database connection and a cursor, we can create a database table `movie` with columns for title, release year, and review score. For simplicity, we can just use column names in the table declaration -- thanks to the flexible typing feature of SQLite, specifying the data types is optional. Execute the `CREATE TABLE` statement by calling *`cur.execute(...)`*:

```
cur.execute("CREATE TABLE movie(title, year, score)")
```

We can verify that the new table has been created by querying the `sqlite_master` table built-in to SQLite, which should now contain an entry for the `movie` table definition (see The Schema Table for details). Execute that query by calling *`cur.execute(...)`*, assign the result to `res`, and call *`res.fetchone()`* to fetch the resulting row:

```
>>> res = cur.execute("SELECT name FROM sqlite_master")
>>> res.fetchone()
('movie',)
```

We can see that the table has been created, as the query returns a *`tuple`* containing the table's name. If we query `sqlite_master` for a non-existent table `spam`, `res.fetchone()` will return `None`:

```
>>> res = cur.execute("SELECT name FROM sqlite_master WHERE name='spam'")
>>> res.fetchone() is None
True
```

Now, add two rows of data supplied as SQL literals by executing an `INSERT` statement, once again by calling *`cur.execute(...)`*:

```
cur.execute("""
    INSERT INTO movie VALUES
        ('Monty Python and the Holy Grail', 1975, 8.2),
        ('And Now for Something Completely Different', 1971, 7.5)
""")
```

The `INSERT` statement implicitly opens a transaction, which needs to be committed before changes are saved in the database (see *Transaction control* for details). Call *con.commit()* on the connection object to commit the transaction:

```
con.commit()
```

We can verify that the data was inserted correctly by executing a `SELECT` query. Use the now-familiar *cur.execute(...)* to assign the result to `res`, and call *res.fetchall()* to return all resulting rows:

```
>>> res = cur.execute("SELECT score FROM movie")
>>> res.fetchall()
[(8.2,), (7.5,)]
```

The result is a *list* of two `tuples`, one per row, each containing that row's `score` value.

Now, insert three more rows by calling *cur.executemany(...)*:

```
data = [
    ("Monty Python Live at the Hollywood Bowl", 1982, 7.9),
    ("Monty Python's The Meaning of Life", 1983, 7.5),
    ("Monty Python's Life of Brian", 1979, 8.0),
]
cur.executemany("INSERT INTO movie VALUES(?, ?, ?)", data)
con.commit()  # Remember to commit the transaction after executing INSERT.
```

Notice that `?` placeholders are used to bind `data` to the query. Always use placeholders instead of string formatting to bind Python values to SQL statements, to avoid SQL injection attacks (see *How to use placeholders to bind values in SQL queries* for more details).

We can verify that the new rows were inserted by executing a `SELECT` query, this time iterating over the results of the query:

```
>>> for row in cur.execute("SELECT year, title FROM movie ORDER BY year"):
...     print(row)
(1971, 'And Now for Something Completely Different')
(1975, 'Monty Python and the Holy Grail')
(1979, "Monty Python's Life of Brian")
(1982, 'Monty Python Live at the Hollywood Bowl')
(1983, "Monty Python's The Meaning of Life")
```

Each row is a two-item *tuple* of `(year, title)`, matching the columns selected in the query.

Finally, verify that the database has been written to disk by calling *con.close()* to close the existing connection, opening a new one, creating a new cursor, then querying the database:

```
>>> con.close()
>>> new_con = sqlite3.connect("tutorial.db")
>>> new_cur = new_con.cursor()
>>> res = new_cur.execute("SELECT title, year FROM movie ORDER BY score DESC")
>>> title, year = res.fetchone()
>>> print(f'The highest scoring Monty Python movie is {title!r}, released in {year}')
The highest scoring Monty Python movie is 'Monty Python and the Holy Grail', released␣
```

(繼續下一頁)

(繼續上一頁)

```
↪in 1975
>>> new_con.close()
```

You've now created an SQLite database using the `sqlite3` module, inserted data and retrieved values from it in multiple ways.

12.6.2 Reference

Module functions

sqlite3.**connect**(*database*, *timeout=5.0*, *detect_types=0*, *isolation_level='DEFERRED'*, *check_same_thread=True*, *factory=sqlite3.Connection*, *cached_statements=128*, *uri=False*, ***, *autocommit=sqlite3.LEGACY_TRANSACTION_CONTROL*)

Open a connection to an SQLite database.

參數

- **database** (*path-like object*) -- The path to the database file to be opened. You can pass `":memory:"` to create an SQLite database existing only in memory, and open a connection to it.
- **timeout** (`float`) -- How many seconds the connection should wait before raising an *`OperationalError`* when a table is locked. If another connection opens a transaction to modify a table, that table will be locked until the transaction is committed. Default five seconds.
- **detect_types** (`int`) -- Control whether and how data types not *natively supported by SQLite* are looked up to be converted to Python types, using the converters registered with *`register_converter()`*. Set it to any combination (using `|`, bitwise or) of *`PARSE_DECLTYPES`* and *`PARSE_COLNAMES`* to enable this. Column names takes precedence over declared types if both flags are set. Types cannot be detected for generated fields (for example `max(data)`), even when the *detect_types* parameter is set; *`str`* will be returned instead. By default (`0`), type detection is disabled.
- **isolation_level** (`str | None`) -- Control legacy transaction handling behaviour. See *`Connection.isolation_level`* and *Transaction control via the isolation_level attribute* for more information. Can be `"DEFERRED"` (default), `"EXCLUSIVE"` or `"IMMEDIATE"`; or `None` to disable opening transactions implicitly. Has no effect unless *`Connection.autocommit`* is set to *`LEGACY_TRANSACTION_CONTROL`* (the default).

- **check_same_thread** (bool) -- If True (default), *ProgrammingError* will be raised if the database connection is used by a thread other than the one that created it. If False, the connection may be accessed in multiple threads; write operations may need to be serialized by the user to avoid data corruption. See *threadsafety* for more information.
- **factory** (Connection) -- A custom subclass of *Connection* to create the connection with, if not the default *Connection* class.
- **cached_statements** (int) -- The number of statements that sqlite3 should internally cache for this connection, to avoid parsing overhead. By default, 128 statements.
- **uri** (bool) -- If set to True, *database* is interpreted as a URI (Uniform Resource Identifier) with a file path and an optional query string. The scheme part *must* be "file:", and the path can be relative or absolute. The query string allows passing parameters to SQLite, enabling various *How to work with SQLite URIs*.
- **autocommit** (bool) -- Control **PEP 249** transaction handling behaviour. See *Connection.autocommit* and *Transaction control via the autocommit attribute* for more information. *autocommit* currently defaults to *LEGACY_TRANSACTION_CONTROL*. The default will change to False in a future Python release.

回傳型🄵
Connection

Raises an *auditing event* sqlite3.connect with argument database.

Raises an *auditing event* sqlite3.connect/handle with argument connection_handle.

在 3.4 版的變更: 新增 *uri* 參數。

在 3.7 版的變更: *database* can now also be a *path-like object*, not only a string.

在 3.10 版的變更: 新增 sqlite3.connect/handle 稽核事件。

在 3.12 版的變更: 新增 *autocommit* 參數。

sqlite3.**complete_statement**(*statement*)

Return True if the string *statement* appears to contain one or more complete SQL statements. No syntactic verification or parsing of any kind is performed, other than checking that there are no unclosed string literals and the statement is terminated by a semicolon.

範例:

```
>>> sqlite3.complete_statement("SELECT foo FROM bar;")
True
>>> sqlite3.complete_statement("SELECT foo")
False
```

This function may be useful during command-line input to determine if the entered text seems to form a complete SQL statement, or if additional input is needed before calling *execute()*.

See runsource() in Lib/sqlite3/__main__.py for real-world use.

sqlite3.**enable_callback_tracebacks**(*flag*, */*)

Enable or disable callback tracebacks. By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to True. Afterwards, you will get tracebacks from callbacks on *sys.stderr*. Use False to disable the feature again.

> **備🄵**
>
> Errors in user-defined function callbacks are logged as unraisable exceptions. Use an *unraisable hook handler* for introspection of the failed callback.

sqlite3.**register_adapter**(*type*, *adapter*, /)

Register an *adapter* *callable* to adapt the Python type *type* into an SQLite type. The adapter is called with a Python object of type *type* as its sole argument, and must return a value of a *type that SQLite natively understands*.

sqlite3.**register_converter**(*typename*, *converter*, /)

Register the *converter* *callable* to convert SQLite objects of type *typename* into a Python object of a specific type. The converter is invoked for all SQLite values of type *typename*; it is passed a *bytes* object and should return an object of the desired Python type. Consult the parameter *detect_types* of *connect()* for information regarding how type detection works.

Note: *typename* and the name of the type in your query are matched case-insensitively.

Module constants

sqlite3.**LEGACY_TRANSACTION_CONTROL**

Set *autocommit* to this constant to select old style (pre-Python 3.12) transaction control behaviour. See *Transaction control via the isolation_level attribute* for more information.

sqlite3.**PARSE_COLNAMES**

Pass this flag value to the *detect_types* parameter of *connect()* to look up a converter function by using the type name, parsed from the query column name, as the converter dictionary key. The type name must be wrapped in square brackets (`[]`).

```
SELECT p as "p [point]" FROM test;  ! will look up converter "point"
```

This flag may be combined with *PARSE_DECLTYPES* using the `|` (bitwise or) operator.

sqlite3.**PARSE_DECLTYPES**

Pass this flag value to the *detect_types* parameter of *connect()* to look up a converter function using the declared types for each column. The types are declared when the database table is created. `sqlite3` will look up a converter function using the first word of the declared type as the converter dictionary key. For example:

```
CREATE TABLE test(
   i integer primary key,  ! will look up a converter named "integer"
   p point,                ! will look up a converter named "point"
   n number(10)            ! will look up a converter named "number"
)
```

This flag may be combined with *PARSE_COLNAMES* using the `|` (bitwise or) operator.

sqlite3.**SQLITE_OK**

sqlite3.**SQLITE_DENY**

sqlite3.**SQLITE_IGNORE**

Flags that should be returned by the *authorizer_callback* *callable* passed to *Connection.set_authorizer()*, to indicate whether:

- Access is allowed (`SQLITE_OK`),
- The SQL statement should be aborted with an error (`SQLITE_DENY`)

- The column should be treated as a `NULL` value (`SQLITE_IGNORE`)

`sqlite3.`**`apilevel`**

String constant stating the supported DB-API level. Required by the DB-API. Hard-coded to `"2.0"`.

`sqlite3.`**`paramstyle`**

String constant stating the type of parameter marker formatting expected by the `sqlite3` module. Required by the DB-API. Hard-coded to `"qmark"`.

> **備🄵**
>
> The `named` DB-API parameter style is also supported.

`sqlite3.`**`sqlite_version`**

Version number of the runtime SQLite library as a *`string`*.

`sqlite3.`**`sqlite_version_info`**

Version number of the runtime SQLite library as a *`tuple`* of *`integers`*.

`sqlite3.`**`threadsafety`**

Integer constant required by the DB-API 2.0, stating the level of thread safety the `sqlite3` module supports. This attribute is set based on the default threading mode the underlying SQLite library is compiled with. The SQLite threading modes are:

1. **Single-thread**: In this mode, all mutexes are disabled and SQLite is unsafe to use in more than a single thread at once.
2. **Multi-thread**: In this mode, SQLite can be safely used by multiple threads provided that no single database connection is used simultaneously in two or more threads.
3. **Serialized**: In serialized mode, SQLite can be safely used by multiple threads with no restriction.

The mappings from SQLite threading modes to DB-API 2.0 threadsafety levels are as follows:

SQLite threading mode	thread-safety	SQLITE_THREADSA	DB-API 2.0 meaning
single-thread	0	0	Threads may not share the module
multi-thread	1	2	Threads may share the module, but not connections
serialized	3	1	Threads may share the module, connections and cursors

在 3.11 版的變更: Set *threadsafety* dynamically instead of hard-coding it to `1`.

`sqlite3.`**`version`**

Version number of this module as a *`string`*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the `pysqlite` package, a third-party library which used to upstream changes to `sqlite3`. Today, it carries no meaning or practical value.

`sqlite3.`**`version_info`**

Version number of this module as a *`tuple`* of *`integers`*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the `pysqlite` package, a third-party library which used to upstream changes to `sqlite3`. Today, it carries no meaning or practical value.

sqlite3.**SQLITE_DBCONFIG_DEFENSIVE**
sqlite3.**SQLITE_DBCONFIG_DQS_DDL**
sqlite3.**SQLITE_DBCONFIG_DQS_DML**
sqlite3.**SQLITE_DBCONFIG_ENABLE_FKEY**
sqlite3.**SQLITE_DBCONFIG_ENABLE_FTS3_TOKENIZER**
sqlite3.**SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION**
sqlite3.**SQLITE_DBCONFIG_ENABLE_QPSG**
sqlite3.**SQLITE_DBCONFIG_ENABLE_TRIGGER**

SQLite docs: Database Connection Configuration Options

Connection 物件

class sqlite3.**Connection**

Each open SQLite database is represented by a `Connection` object, which is created using *sqlite3.connect()*. Their main purpose is creating *Cursor* objects, and *Transaction control*.

也參考

- *How to use connection shortcut methods*
- *How to use the connection context manager*

An SQLite database connection has the following attributes and methods:

cursor(*factory=Cursor*)

Create and return a *Cursor* object. The cursor method accepts a single optional parameter *factory*. If supplied, this must be a *callable* returning an instance of *Cursor* or its subclasses.

blobopen(*table*, *column*, *row*, */*, ***, *readonly=False*, *name='main'*)

Open a *Blob* handle to an existing BLOB (Binary Large OBject).

參數

- **table** (str) -- The name of the table where the blob is located.
- **column** (str) -- The name of the column where the blob is located.
- **row** (str) -- The name of the row where the blob is located.
- **readonly** (bool) -- Set to `True` if the blob should be opened without write permissions. Defaults to `False`.
- **name** (str) -- The name of the database where the blob is located. Defaults to `"main"`.

引發

OperationalError -- When trying to open a blob in a `WITHOUT ROWID` table.

回傳型🄵

Blob

備🄵

The blob size cannot be changed using the *Blob* class. Use the SQL function `zeroblob` to create a blob with a fixed size.

在 3.11 版被加入.

commit()

Commit any pending transaction to the database. If *autocommit* is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was committed by this method.

rollback()

Roll back to the start of any pending transaction. If *autocommit* is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was rolled back by this method.

close()

Close the database connection. If *autocommit* is `False`, any pending transaction is implicitly rolled back. If `autocommit` is `True` or *LEGACY_TRANSACTION_CONTROL*, no implicit transaction control is executed. Make sure to *commit()* before closing to avoid losing pending changes.

execute(*sql*, *parameters=()*, */*)

Create a new *Cursor* object and call *execute()* on it with the given *sql* and *parameters*. Return the new cursor object.

executemany(*sql*, *parameters*, */*)

Create a new *Cursor* object and call *executemany()* on it with the given *sql* and *parameters*. Return the new cursor object.

executescript(*sql_script*, */*)

Create a new *Cursor* object and call *executescript()* on it with the given *sql_script*. Return the new cursor object.

create_function(*name*, *narg*, *func*, ***, *deterministic=False*)

Create or remove a user-defined SQL function.

參數

- **name** (str) -- The name of the SQL function.
- **narg** (int) -- The number of arguments the SQL function can accept. If `-1`, it may take any number of arguments.
- **func** (*callback* | None) -- A *callable* that is called when the SQL function is invoked. The callable must return *a type natively supported by SQLite*. Set to `None` to remove an existing SQL function.
- **deterministic** (bool) -- If `True`, the created SQL function is marked as deterministic, which allows SQLite to perform additional optimizations.

引發

NotSupportedError -- If *deterministic* is used with SQLite versions older than 3.8.3.

在 3.8 版的變更: 新增 *deterministic* 參數。

範例:

```
>>> import hashlib
>>> def md5sum(t):
...     return hashlib.md5(t).hexdigest()
>>> con = sqlite3.connect(":memory:")
>>> con.create_function("md5", 1, md5sum)
>>> for row in con.execute("SELECT md5(?)", (b"foo",)):
...     print(row)
('acbd18db4cc2f85cedef654fccc4a4d8',)
>>> con.close()
```

create_aggregate(*name*, *n_arg*, *aggregate_class*)

Create or remove a user-defined SQL aggregate function.

參數

- **name** (str) -- The name of the SQL aggregate function.
- **n_arg** (int) -- The number of arguments the SQL aggregate function can accept. If `-1`, it may take any number of arguments.
- **aggregate_class** (*class* | None) -- A class must implement the following methods:
  - `step()`: Add a row to the aggregate.
  - `finalize()`: Return the final result of the aggregate as *a type natively supported by SQLite*.

  The number of arguments that the `step()` method must accept is controlled by *n_arg*.

  Set to `None` to remove an existing SQL aggregate function.

範例:

```
class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count
```

(繼續下一頁)

(繼續上一頁)

```
con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.execute("CREATE TABLE test(i)")
cur.execute("INSERT INTO test(i) VALUES(1)")
cur.execute("INSERT INTO test(i) VALUES(2)")
cur.execute("SELECT mysum(i) FROM test")
print(cur.fetchone()[0])

con.close()
```

create_window_function(*name*, *num_params*, *aggregate_class*, */*)

Create or remove a user-defined aggregate window function.

參數

- **name** (`str`) -- The name of the SQL aggregate window function to create or remove.
- **num_params** (`int`) -- The number of arguments the SQL aggregate window function can accept. If `-1`, it may take any number of arguments.
- **aggregate_class** (*class* | None) -- A class that must implement the following methods:
  - `step()`: Add a row to the current window.
  - `value()`: Return the current value of the aggregate.
  - `inverse()`: Remove a row from the current window.
  - `finalize()`: Return the final result of the aggregate as *a type natively supported by SQLite*.

  The number of arguments that the `step()` and `value()` methods must accept is controlled by *num_params*.

  Set to `None` to remove an existing SQL aggregate window function.

引發

NotSupportedError -- If used with a version of SQLite older than 3.25.0, which does not support aggregate window functions.

在 3.11 版被加入.

範例:

```
# Example taken from https://www.sqlite.org/windowfunctions.html#udfwinfunc
class WindowSumInt:
    def __init__(self):
        self.count = 0

    def step(self, value):
        """Add a row to the current window."""
        self.count += value

    def value(self):
        """Return the current value of the aggregate."""
        return self.count

    def inverse(self, value):
        """Remove a row from the current window."""
```

(繼續下一頁)

(繼續上一頁)

```
        self.count -= value

    def finalize(self):
        """Return the final value of the aggregate.

        Any clean-up actions should be placed here.
        """
        return self.count

con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE test(x, y)")
values = [
    ("a", 4),
    ("b", 5),
    ("c", 3),
    ("d", 8),
    ("e", 1),
]
cur.executemany("INSERT INTO test VALUES(?, ?)", values)
con.create_window_function("sumint", 1, WindowSumInt)
cur.execute("""
    SELECT x, sumint(y) OVER (
        ORDER BY x ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING
    ) AS sum_y
    FROM test ORDER BY x
""")
print(cur.fetchall())
con.close()
```

create_collation(*name*, *callable*, */*)

Create a collation named *name* using the collating function *callable*. *callable* is passed two *string* arguments, and it should return an *integer*:

- `1` if the first is ordered higher than the second
- `-1` if the first is ordered lower than the second
- `0` if they are ordered equal

The following example shows a reverse sorting collation:

```
def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.execute("CREATE TABLE test(x)")
cur.executemany("INSERT INTO test(x) VALUES(?)", [("a",), ("b",)])
cur.execute("SELECT x FROM test ORDER BY x COLLATE reverse")
for row in cur:
```

(繼續下一頁)

(繼續上一頁)

```
    print(row)
con.close()
```

Remove a collation function by setting *callable* to `None`.

在 3.11 版的變更: The collation name can contain any Unicode character. Earlier, only ASCII characters were allowed.

interrupt()

Call this method from a different thread to abort any queries that might be executing on the connection. Aborted queries will raise an *OperationalError*.

set_authorizer(*authorizer_callback*)

Register *callable* *authorizer_callback* to be invoked for each attempt to access a column of a table in the database. The callback should return one of *SQLITE_OK*, *SQLITE_DENY*, or *SQLITE_IGNORE* to signal how access to the column should be handled by the underlying SQLite library.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database ("main", "temp", etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

Passing `None` as *authorizer_callback* will disable the authorizer.

在 3.11 版的變更: Added support for disabling the authorizer using `None`.

set_progress_handler(*progress_handler*, *n*)

Register *callable* *progress_handler* to be invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *progress_handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise a *DatabaseError* exception.

set_trace_callback(*trace_callback*)

Register *callable* *trace_callback* to be invoked for each SQL statement that is actually executed by the SQLite backend.

The only argument passed to the callback is the statement (as *str*) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the *Cursor.execute()* methods. Other sources include the *transaction management* of the `sqlite3` module and the execution of triggers defined in the current database.

Passing `None` as *trace_callback* will disable the trace callback.

備F

Exceptions raised in the trace callback are not propagated. As a development and debugging aid, use *enable_callback_tracebacks()* to enable printing tracebacks from exceptions raised in the trace callback.

在 3.3 版被加入.

enable_load_extension(*enabled*, */*)

Enable the SQLite engine to load SQLite extensions from shared libraries if *enabled* is `True`; else, disallow loading SQLite extensions. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

> **備🄵**
>
> The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably macOS) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass the `--enable-loadable-sqlite-extensions` option to **configure**.

Raises an *auditing event* `sqlite3.enable_load_extension` with arguments `connection`, `enabled`.

在 3.2 版被加入.

在 3.10 版的變更: 加入 `sqlite3.enable_load_extension` 稽核事件。

```
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("CREATE VIRTUAL TABLE recipe USING fts3(name, ingredients)")
con.executescript("""
    INSERT INTO recipe (name, ingredients) VALUES('broccoli stew', 'broccoli␣
↪peppers cheese tomatoes');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin stew', 'pumpkin␣
↪onions garlic celery');
    INSERT INTO recipe (name, ingredients) VALUES('broccoli pie', 'broccoli␣
↪cheese onions flour');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin pie', 'pumpkin␣
↪sugar flour butter');
    """)
for row in con.execute("SELECT rowid, name, ingredients FROM recipe WHERE␣
↪name MATCH 'pie'"):
    print(row)
```

load_extension(*path*, */*, *, *entrypoint=None*)

Load an SQLite extension from a shared library. Enable extension loading with *enable_load_extension()* before calling this method.

參數

- **path** (`str`) -- The path to the SQLite extension.
- **entrypoint** (`str | None`) -- Entry point name. If `None` (the default), SQLite will come up with an entry point name of its own; see the SQLite docs Loading an Extension for details.

Raises an *auditing event* `sqlite3.load_extension` with arguments `connection`, `path`.

在 3.2 版被加入.

在 3.10 版的變更: 加入 `sqlite3.load_extension` 稽核事件。

在 3.12 版的變更: 新增 *entrypoint* 參數。

iterdump()

Return an *iterator* to dump the database as SQL source code. Useful when saving an in-memory database for later restoration. Similar to the `.dump` command in the **sqlite3** shell.

範例:

```
# Convert file example.db to SQL dump file dump.sql
con = sqlite3.connect('example.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
con.close()
```

也參考

How to handle non-UTF-8 text encodings

backup(*target*, ***, *pages=-1*, *progress=None*, *name='main'*, *sleep=0.250*)

Create a backup of an SQLite database.

Works even if the database is being accessed by other clients or concurrently by the same connection.

參數

- **target** (`Connection`) -- The database connection to save the backup to.
- **pages** (`int`) -- The number of pages to copy at a time. If equal to or less than `0`, the entire database is copied in a single step. Defaults to `-1`.
- **progress** (*callback* | None) -- If set to a *callable*, it is invoked with three integer arguments for every backup iteration: the *status* of the last iteration, the *remaining* number of pages still to be copied, and the *total* number of pages. Defaults to `None`.
- **name** (`str`) -- The name of the database to back up. Either `"main"` (the default) for the main database, `"temp"` for the temporary database, or the name of a custom database as attached using the `ATTACH DATABASE` SQL statement.
- **sleep** (`float`) -- The number of seconds to sleep between successive attempts to back up remaining pages.

Example 1, copy an existing database into another:

```
def progress(status, remaining, total):
    print(f'Copied {total-remaining} of {total} pages...')

src = sqlite3.connect('example.db')
dst = sqlite3.connect('backup.db')
with dst:
    src.backup(dst, pages=1, progress=progress)
dst.close()
src.close()
```

Example 2, copy an existing database into a transient copy:

```
src = sqlite3.connect('example.db')
dst = sqlite3.connect(':memory:')
src.backup(dst)
dst.close()
src.close()
```

在 3.7 版被加入.

也參考

How to handle non-UTF-8 text encodings

getlimit(*category*, */*)

Get a connection runtime limit.

參數

category (int) -- The SQLite limit category to be queried.

回傳型🄵

int

引發

ProgrammingError -- If *category* is not recognised by the underlying SQLite library.

Example, query the maximum length of an SQL statement for *Connection* con (the default is 1000000000):

```
>>> con.getlimit(sqlite3.SQLITE_LIMIT_SQL_LENGTH)
1000000000
```

在 3.11 版被加入.

setlimit(*category*, *limit*, */*)

Set a connection runtime limit. Attempts to increase a limit above its hard upper bound are silently truncated to the hard upper bound. Regardless of whether or not the limit was changed, the prior value of the limit is returned.

參數

- **category** (int) -- The SQLite limit category to be set.
- **limit** (int) -- The value of the new limit. If negative, the current limit is unchanged.

回傳型🄵

int

引發

ProgrammingError -- If *category* is not recognised by the underlying SQLite library.

Example, limit the number of attached databases to 1 for *Connection* con (the default limit is 10):

```
>>> con.setlimit(sqlite3.SQLITE_LIMIT_ATTACHED, 1)
10
>>> con.getlimit(sqlite3.SQLITE_LIMIT_ATTACHED)
1
```

在 3.11 版被加入.

getconfig(*op*, */*)

Query a boolean connection configuration option.

參數

op (`int`) -- A *SQLITE_DBCONFIG code*.

回傳型🄵

bool

在 3.12 版被加入.

setconfig(*op*, *enable=True*, */*)

Set a boolean connection configuration option.

參數

- **op** (`int`) -- A *SQLITE_DBCONFIG code*.
- **enable** (`bool`) -- `True` if the configuration option should be enabled (default); `False` if it should be disabled.

在 3.12 版被加入.

serialize(*, *name='main'*)

Serialize a database into a *`bytes`* object. For an ordinary on-disk database file, the serialization is just a copy of the disk file. For an in-memory database or a "temp" database, the serialization is the same sequence of bytes which would be written to disk if that database were backed up to disk.

參數

name (`str`) -- The database name to be serialized. Defaults to `"main"`.

回傳型🄵

bytes

備🄵

This method is only available if the underlying SQLite library has the serialize API.

在 3.11 版被加入.

deserialize(*data*, */*, *, *name='main'*)

Deserialize a *`serialized`* database into a *`Connection`*. This method causes the database connection to disconnect from database *name*, and reopen *name* as an in-memory database based on the serialization contained in *data*.

參數

- **data** (`bytes`) -- A serialized database.
- **name** (`str`) -- The database name to deserialize into. Defaults to `"main"`.

引發

- ***`OperationalError`*** -- If the database connection is currently involved in a read transaction or a backup operation.
- ***`DatabaseError`*** -- If *data* does not contain a valid SQLite database.
- ***`OverflowError`*** -- If *`len(data)`* is larger than `2**63 - 1`.

> **備🄵**
>
> This method is only available if the underlying SQLite library has the deserialize API.

在 3.11 版被加入.

autocommit

This attribute controls **PEP 249**-compliant transaction behaviour. `autocommit` has three allowed values:

- `False`: Select **PEP 249**-compliant transaction behaviour, implying that `sqlite3` ensures a transaction is always open. Use *`commit()`* and *`rollback()`* to close transactions.

  This is the recommended value of `autocommit`.

- `True`: Use SQLite's autocommit mode. *`commit()`* and *`rollback()`* have no effect in this mode.

- *`LEGACY_TRANSACTION_CONTROL`*: Pre-Python 3.12 (non-**PEP 249**-compliant) transaction control. See *`isolation_level`* for more details.

  This is currently the default value of `autocommit`.

Changing `autocommit` to `False` will open a new transaction, and changing it to `True` will commit any pending transaction.

更多詳情請見*Transaction control via the autocommit attribute*。

> **備🄵**
>
> The *`isolation_level`* attribute has no effect unless *`autocommit`* is *`LEGACY_TRANSACTION_CONTROL`*.

在 3.12 版被加入.

in_transaction

This read-only attribute corresponds to the low-level SQLite autocommit mode.

`True` if a transaction is active (there are uncommitted changes), `False` otherwise.

在 3.2 版被加入.

isolation_level

Controls the *legacy transaction handling mode* of `sqlite3`. If set to `None`, transactions are never implicitly opened. If set to one of `"DEFERRED"`, `"IMMEDIATE"`, or `"EXCLUSIVE"`, corresponding to the underlying SQLite transaction behaviour, *implicit transaction management* is performed.

If not overridden by the *isolation_level* parameter of *`connect()`*, the default is `""`, which is an alias for `"DEFERRED"`.

> **備🄵**
>
> Using *`autocommit`* to control transaction handling is recommended over using `isolation_level`. `isolation_level` has no effect unless *`autocommit`* is set to *`LEGACY_TRANSACTION_CONTROL`* (the default).

row_factory

The initial *row_factory* for *Cursor* objects created from this connection. Assigning to this attribute does not affect the row_factory of existing cursors belonging to this connection, only new ones. Is None by default, meaning each row is returned as a *tuple*.

更多詳情請見*How to create and use row factories*。

text_factory

A *callable* that accepts a *bytes* parameter and returns a text representation of it. The callable is invoked for SQLite values with the TEXT data type. By default, this attribute is set to *str*.

更多詳情請見*How to handle non-UTF-8 text encodings*。

total_changes

Return the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

Cursor 物件

A Cursor object represents a database cursor which is used to execute SQL statements, and manage the context of a fetch operation. Cursors are created using *Connection.cursor()*, or by using any of the *connection shortcut methods*.

Cursor objects are *iterators*, meaning that if you *execute()* a SELECT query, you can simply iterate over the cursor to fetch the resulting rows:

```
for row in cur.execute("SELECT t FROM data"):
    print(row)
```

class sqlite3.**Cursor**

A *Cursor* instance has the following attributes and methods.

execute(*sql*, *parameters=()*, */*)

Execute a single SQL statement, optionally binding Python values using *placeholders*.

參數

- **sql** (str) -- 單一個 SQL 陳述式。
- **parameters** (*dict* | *sequence*) -- Python values to bind to placeholders in *sql*. A dict if named placeholders are used. A sequence if unnamed placeholders are used. See *How to use placeholders to bind values in SQL queries*.

引發

ProgrammingError -- If *sql* contains more than one SQL statement.

If *autocommit* is *LEGACY_TRANSACTION_CONTROL*, *isolation_level* is not None, *sql* is an INSERT, UPDATE, DELETE, or REPLACE statement, and there is no open transaction, a transaction is implicitly opened before executing *sql*.

Deprecated since version 3.12, will be removed in version 3.14: *DeprecationWarning* is emitted if *named placeholders* are used and *parameters* is a sequence instead of a *dict*. Starting with Python 3.14, *ProgrammingError* will be raised instead.

Use *executescript()* to execute multiple SQL statements.

executemany(*sql*, *parameters*, */*)

For every item in *parameters*, repeatedly execute the *parameterized* DML (Data Manipulation Language) SQL statement *sql*.

Uses the same implicit transaction handling as `execute()`.

參數

- **sql** (`str`) -- A single SQL DML statement.
- **parameters** (*iterable*) -- An iterable of parameters to bind with the placeholders in *sql*. See *How to use placeholders to bind values in SQL queries*.

引發

ProgrammingError -- If *sql* contains more than one SQL statement, or is not a DML statement.

範例:

```
rows = [
    ("row1",),
    ("row2",),
]
# cur is an sqlite3.Cursor object
cur.executemany("INSERT INTO data VALUES(?)", rows)
```

備🄵

Any resulting rows are discarded, including DML statements with RETURNING clauses.

Deprecated since version 3.12, will be removed in version 3.14: `DeprecationWarning` is emitted if *named placeholders* are used and the items in *parameters* are sequences instead of `dict`s. Starting with Python 3.14, `ProgrammingError` will be raised instead.

executescript(*sql_script*, */*)

Execute the SQL statements in *sql_script*. If the `autocommit` is `LEGACY_TRANSACTION_CONTROL` and there is a pending transaction, an implicit `COMMIT` statement is executed first. No other implicit transaction control is performed; any transaction control must be added to *sql_script*.

sql_script must be a `string`.

範例:

```
# cur is an sqlite3.Cursor object
cur.executescript("""
    BEGIN;
    CREATE TABLE person(firstname, lastname, age);
    CREATE TABLE book(title, author, published);
    CREATE TABLE publisher(name, address);
    COMMIT;
""")
```

fetchone()

If `row_factory` is `None`, return the next row query result set as a `tuple`. Else, pass it to the row factory and return its result. Return `None` if no more data is available.

fetchmany(*size=cursor.arraysize*)

Return the next set of rows of a query result as a `list`. Return an empty list if no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If *size* is not given, *arraysize* determines the number of rows to be fetched. If fewer than *size* rows are available, as many rows as are available are returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the arraysize attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()

Return all (remaining) rows of a query result as a *list*. Return an empty list if no rows are available. Note that the *arraysize* attribute can affect the performance of this operation.

close()

Close the cursor now (rather than whenever __del__ is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

setinputsizes(*sizes*, /)

Required by the DB-API. Does nothing in sqlite3.

setoutputsize(*size*, *column=None*, /)

Required by the DB-API. Does nothing in sqlite3.

arraysize

Read/write attribute that controls the number of rows returned by *fetchmany()*. The default value is 1 which means a single row would be fetched per call.

connection

Read-only attribute that provides the SQLite database *Connection* belonging to the cursor. A *Cursor* object created by calling *con.cursor()* will have a *connection* attribute that refers to *con*:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
>>> con.close()
```

description

Read-only attribute that provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are None.

It is set for SELECT statements without any matching rows as well.

lastrowid

Read-only attribute that provides the row id of the last inserted row. It is only updated after successful INSERT or REPLACE statements using the *execute()* method. For other statements, after *executemany()* or *executescript()*, or if the insertion failed, the value of lastrowid is left unchanged. The initial value of lastrowid is None.

備🄵

Inserts into WITHOUT ROWID tables are not recorded.

在 3.6 版的變更: 新增 REPLACE 陳述式的支援。

rowcount

Read-only attribute that provides the number of modified rows for `INSERT`, `UPDATE`, `DELETE`, and `REPLACE` statements; is `-1` for other statements, including CTE (Common Table Expression) queries. It is only updated by the *`execute()`* and *`executemany()`* methods, after the statement has run to completion. This means that any resulting rows must be fetched in order for `rowcount` to be updated.

row_factory

Control how a row fetched from this `Cursor` is represented. If `None`, a row is represented as a *`tuple`*. Can be set to the included *`sqlite3.Row`*; or a *callable* that accepts two arguments, a *`Cursor`* object and the `tuple` of row values, and returns a custom object representing an SQLite row.

Defaults to what *`Connection.row_factory`* was set to when the `Cursor` was created. Assigning to this attribute does not affect *`Connection.row_factory`* of the parent connection.

更多詳情請見*How to create and use row factories*。

Row 物件

class sqlite3.**Row**

A `Row` instance serves as a highly optimized *`row_factory`* for *`Connection`* objects. It supports iteration, equality testing, *`len()`*, and *mapping* access by column name and index.

Two `Row` objects compare equal if they have identical column names and values.

更多詳情請見*How to create and use row factories*。

keys()

Return a *`list`* of column names as *`strings`*. Immediately after a query, it is the first member of each tuple in *`Cursor.description`*.

在 3.5 版的變更: 新增對切片的支援。

Blob 物件

class sqlite3.**Blob**

在 3.11 版被加入.

A *`Blob`* instance is a *file-like object* that can read and write data in an SQLite BLOB. Call *`len(blob)`* to get the size (number of bytes) of the blob. Use indices and *slices* for direct access to the blob data.

Use the *`Blob`* as a *context manager* to ensure that the blob handle is closed after use.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE test(blob_col blob)")
con.execute("INSERT INTO test(blob_col) VALUES(zeroblob(13))")

# Write to our blob, using two write operations:
with con.blobopen("test", "blob_col", 1) as blob:
    blob.write(b"hello, ")
    blob.write(b"world.")
    # Modify the first and last bytes of our blob
    blob[0] = ord("H")
    blob[-1] = ord("!")

# Read the contents of our blob
with con.blobopen("test", "blob_col", 1) as blob:
```

(繼續下一頁)

(繼續上一頁)

```
    greeting = blob.read()

print(greeting)  # outputs "b'Hello, world!'"
con.close()
```

close()

Close the blob.

The blob will be unusable from this point onward. An *Error* (or subclass) exception will be raised if any further operation is attempted with the blob.

read(*length=-1*, */*)

Read *length* bytes of data from the blob at the current offset position. If the end of the blob is reached, the data up to EOF (End of File) will be returned. When *length* is not specified, or is negative, *read()* will read until the end of the blob.

write(*data*, */*)

Write *data* to the blob at the current offset. This function cannot change the blob length. Writing beyond the end of the blob will raise *ValueError*.

tell()

Return the current access position of the blob.

seek(*offset*, *origin=os.SEEK_SET*, */*)

Set the current access position of the blob to *offset*. The *origin* argument defaults to *os.SEEK_SET* (absolute blob positioning). Other values for *origin* are *os.SEEK_CUR* (seek relative to the current position) and *os.SEEK_END* (seek relative to the blob's end).

PrepareProtocol 物件

class sqlite3.**PrepareProtocol**

The PrepareProtocol type's single purpose is to act as a **PEP 246** style adaption protocol for objects that can *adapt themselves* to *native SQLite types*.

例外

The exception hierarchy is defined by the DB-API 2.0 (**PEP 249**).

exception sqlite3.**Warning**

This exception is not currently raised by the `sqlite3` module, but may be raised by applications using `sqlite3`, for example if a user-defined function truncates data while inserting. `Warning` is a subclass of *Exception*.

exception sqlite3.**Error**

The base class of the other exceptions in this module. Use this to catch all errors with one single `except` statement. `Error` is a subclass of *Exception*.

If the exception originated from within the SQLite library, the following two attributes are added to the exception:

sqlite_errorcode

The numeric error code from the SQLite API

在 3.11 版被加入.

sqlite_errorname

The symbolic name of the numeric error code from the SQLite API

在 3.11 版被加入.

exception sqlite3.**InterfaceError**

Exception raised for misuse of the low-level SQLite C API. In other words, if this exception is raised, it probably indicates a bug in the `sqlite3` module. `InterfaceError` is a subclass of *`Error`*.

exception sqlite3.**DatabaseError**

Exception raised for errors that are related to the database. This serves as the base exception for several types of database errors. It is only raised implicitly through the specialised subclasses. `DatabaseError` is a subclass of *`Error`*.

exception sqlite3.**DataError**

Exception raised for errors caused by problems with the processed data, like numeric values out of range, and strings which are too long. `DataError` is a subclass of *`DatabaseError`*.

exception sqlite3.**OperationalError**

Exception raised for errors that are related to the database's operation, and not necessarily under the control of the programmer. For example, the database path is not found, or a transaction could not be processed. `OperationalError` is a subclass of *`DatabaseError`*.

exception sqlite3.**IntegrityError**

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of *`DatabaseError`*.

exception sqlite3.**InternalError**

Exception raised when SQLite encounters an internal error. If this is raised, it may indicate that there is a problem with the runtime SQLite library. `InternalError` is a subclass of *`DatabaseError`*.

exception sqlite3.**ProgrammingError**

Exception raised for `sqlite3` API programming errors, for example supplying the wrong number of bindings to a query, or trying to operate on a closed *`Connection`*. `ProgrammingError` is a subclass of *`DatabaseError`*.

exception sqlite3.**NotSupportedError**

Exception raised in case a method or database API is not supported by the underlying SQLite library. For example, setting *deterministic* to `True` in *`create_function()`*, if the underlying SQLite library does not support deterministic functions. `NotSupportedError` is a subclass of *`DatabaseError`*.

SQLite and Python types

SQLite natively supports the following types: `NULL`, `INTEGER`, `REAL`, `TEXT`, `BLOB`.

The following Python types can thus be sent to SQLite without any problem:

Python type	SQLite type
`None`	`NULL`
`int`	`INTEGER`
`float`	`REAL`
`str`	`TEXT`
`bytes`	`BLOB`

This is how SQLite types are converted to Python types by default:

SQLite type	Python type
NULL	None
INTEGER	*int*
REAL	*float*
TEXT	depends on *text_factory*, *str* by default
BLOB	*bytes*

The type system of the sqlite3 module is extensible in two ways: you can store additional Python types in an SQLite database via *object adapters*, and you can let the sqlite3 module convert SQLite types to Python types via *converters*.

Default adapters and converters (deprecated)

備🄵

The default adapters and converters are deprecated as of Python 3.12. Instead, use the *Adapter and converter recipes* and tailor them to your needs.

The deprecated default adapters and converters consist of:

- An adapter for *datetime.date* objects to *strings* in ISO 8601 format.
- An adapter for *datetime.datetime* objects to strings in ISO 8601 format.
- A converter for *declared* "date" types to *datetime.date* objects.
- A converter for declared "timestamp" types to *datetime.datetime* objects. Fractional parts will be truncated to 6 digits (microsecond precision).

備🄵

The default "timestamp" converter ignores UTC offsets in the database and always returns a naive *datetime.datetime* object. To preserve UTC offsets in timestamps, either leave converters disabled, or register an offset-aware converter with *register_converter()*.

在 3.12 版之後被🄵用.

命令列介面

The sqlite3 module can be invoked as a script, using the interpreter's -m switch, in order to provide a simple SQLite shell. The argument signature is as follows:

```
python -m sqlite3 [-h] [-v] [filename] [sql]
```

Type .quit or CTRL-D to exit the shell.

-h, --help
Print CLI help.

-v, --version
Print underlying SQLite library version.

在 3.12 版被加入.

12.6.3 How-to guides

How to use placeholders to bind values in SQL queries

SQL operations usually need to use values from Python variables. However, beware of using Python's string operations to assemble queries, as they are vulnerable to SQL injection attacks. For example, an attacker can simply close the single quote and inject `OR TRUE` to select all rows:

```
>>> # Never do this -- insecure!
>>> symbol = input()
' OR TRUE; --
>>> sql = "SELECT * FROM stocks WHERE symbol = '%s'" % symbol
>>> print(sql)
SELECT * FROM stocks WHERE symbol = '' OR TRUE; --'
>>> cur.execute(sql)
```

Instead, use the DB-API's parameter substitution. To insert a variable into a query string, use a placeholder in the string, and substitute the actual values into the query by providing them as a *tuple* of values to the second argument of the cursor's *execute()* method.

An SQL statement may use one of two kinds of placeholders: question marks (qmark style) or named placeholders (named style). For the qmark style, *parameters* must be a *sequence* whose length must match the number of placeholders, or a *ProgrammingError* is raised. For the named style, *parameters* must be an instance of a *dict* (or a subclass), which must contain keys for all named parameters; any extra items are ignored. Here's an example of both styles:

```
con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE lang(name, first_appeared)")

# This is the named style used with executemany():
data = (
    {"name": "C", "year": 1972},
    {"name": "Fortran", "year": 1957},
    {"name": "Python", "year": 1991},
    {"name": "Go", "year": 2009},
)
cur.executemany("INSERT INTO lang VALUES(:name, :year)", data)

# This is the qmark style used in a SELECT query:
params = (1972,)
cur.execute("SELECT * FROM lang WHERE first_appeared = ?", params)
print(cur.fetchall())
con.close()
```

備🄵

PEP 249 numeric placeholders are *not* supported. If used, they will be interpreted as named placeholders.

How to adapt custom Python types to SQLite values

SQLite supports only a limited set of data types natively. To store custom Python types in SQLite databases, *adapt* them to one of the *Python types SQLite natively understands*.

There are two ways to adapt Python objects to SQLite types: letting your object adapt itself, or using an *adapter callable*. The latter will take precedence above the former. For a library that exports a custom type, it may make sense to enable that type to adapt itself. As an application developer, it may make more sense to take direct control by registering custom adapter functions.

How to write adaptable objects

Suppose we have a `Point` class that represents a pair of coordinates, `x` and `y`, in a Cartesian coordinate system. The coordinate pair will be stored as a text string in the database, using a semicolon to separate the coordinates. This can be implemented by adding a `__conform__(self, protocol)` method which returns the adapted value. The object passed to *protocol* will be of type *`PrepareProtocol`*.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return f"{self.x};{self.y}"

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(4.0, -3.2),))
print(cur.fetchone()[0])
con.close()
```

How to register adapter callables

The other possibility is to create a function that converts the Python object to an SQLite-compatible type. This function can then be registered using *`register_adapter()`*.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return f"{point.x};{point.y}"

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(1.0, 2.5),))
print(cur.fetchone()[0])
con.close()
```

How to convert SQLite values to custom Python types

Writing an adapter lets you convert *from* custom Python types *to* SQLite values. To be able to convert *from* SQLite values *to* custom Python types, we use *converters*.

Let's go back to the `Point` class. We stored the x and y coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

備🄵

Converter functions are **always** passed a *bytes* object, no matter the underlying SQLite data type.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

We now need to tell `sqlite3` when it should convert a given SQLite value. This is done when connecting to a database, using the *detect_types* parameter of *connect()*. There are three options:

- Implicit: set *detect_types* to *PARSE_DECLTYPES*
- Explicit: set *detect_types* to *PARSE_COLNAMES*
- Both: set *detect_types* to `sqlite3.PARSE_DECLTYPES | sqlite3.PARSE_COLNAMES`. Column names take precedence over declared types.

The following example illustrates the implicit and explicit approaches:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return f"Point({self.x}, {self.y})"

def adapt_point(point):
    return f"{point.x};{point.y}"

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter and converter
sqlite3.register_adapter(Point, adapt_point)
sqlite3.register_converter("point", convert_point)

# 1) Parse using declared types
p = Point(4.0, -3.2)
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.execute("CREATE TABLE test(p point)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute("SELECT p FROM test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()
```

(繼續下一頁)

(繼續上一頁)

```
# 2) Parse using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.execute("CREATE TABLE test(p)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute('SELECT p AS "p [point]" FROM test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()
```

Adapter and converter recipes

This section shows recipes for common adapters and converters.

```
import datetime
import sqlite3

def adapt_date_iso(val):
    """Adapt datetime.date to ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_iso(val):
    """Adapt datetime.datetime to timezone-naive ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_epoch(val):
    """Adapt datetime.datetime to Unix timestamp."""
    return int(val.timestamp())

sqlite3.register_adapter(datetime.date, adapt_date_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_epoch)

def convert_date(val):
    """Convert ISO 8601 date to datetime.date object."""
    return datetime.date.fromisoformat(val.decode())

def convert_datetime(val):
    """Convert ISO 8601 datetime to datetime.datetime object."""
    return datetime.datetime.fromisoformat(val.decode())

def convert_timestamp(val):
    """Convert Unix epoch timestamp to datetime.datetime object."""
    return datetime.datetime.fromtimestamp(int(val))

sqlite3.register_converter("date", convert_date)
sqlite3.register_converter("datetime", convert_datetime)
sqlite3.register_converter("timestamp", convert_timestamp)
```

How to use connection shortcut methods

Using the *execute()*, *executemany()*, and *executescript()* methods of the *Connection* class, your code can be written more concisely because you don't have to create the (often superfluous) *Cursor* objects explicitly. Instead, the *Cursor* objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the *Connection* object.

```
# Create and fill the table.
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(name, first_appeared)")
data = [
    ("C++", 1985),
    ("Objective-C", 1984),
]
con.executemany("INSERT INTO lang(name, first_appeared) VALUES(?, ?)", data)

# Print the table contents
for row in con.execute("SELECT name, first_appeared FROM lang"):
    print(row)

print("I just deleted", con.execute("DELETE FROM lang").rowcount, "rows")

# close() is not a shortcut method and it's not called automatically;
# the connection object should be closed manually
con.close()
```

How to use the connection context manager

A *Connection* object can be used as a context manager that automatically commits or rolls back open transactions when leaving the body of the context manager. If the body of the `with` statement finishes without exceptions, the transaction is committed. If this commit fails, or if the body of the `with` statement raises an uncaught exception, the transaction is rolled back. If *autocommit* is `False`, a new transaction is implicitly opened after committing or rolling back.

If there is no open transaction upon leaving the body of the `with` statement, or if *autocommit* is `True`, the context manager does nothing.

備🄵

The context manager neither implicitly opens a new transaction nor closes the connection. If you need a closing context manager, consider using *contextlib.closing()*.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(id INTEGER PRIMARY KEY, name VARCHAR UNIQUE)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))

# con.rollback() is called after the with block finishes with an exception,
# the exception is still raised and must be caught
try:
    with con:
        con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))
except sqlite3.IntegrityError:
```

(繼續下一頁)

(繼續上一頁)

```
    print("couldn't add Python twice")

# Connection object used as context manager only commits or rollbacks transactions,
# so the connection object should be closed manually
con.close()
```

How to work with SQLite URIs

Some useful URI tricks include:

- Open a database in read-only mode:

```
>>> con = sqlite3.connect("file:tutorial.db?mode=ro", uri=True)
>>> con.execute("CREATE TABLE readonly(data)")
Traceback (most recent call last):
OperationalError: attempt to write a readonly database
```

- Do not implicitly create a new database file if it does not already exist; will raise *OperationalError* if unable to create a new file:

```
>>> con = sqlite3.connect("file:nosuchdb.db?mode=rw", uri=True)
Traceback (most recent call last):
OperationalError: unable to open database file
```

- Create a shared named in-memory database:

```
db = "file:mem1?mode=memory&cache=shared"
con1 = sqlite3.connect(db, uri=True)
con2 = sqlite3.connect(db, uri=True)
with con1:
    con1.execute("CREATE TABLE shared(data)")
    con1.execute("INSERT INTO shared VALUES(28)")
res = con2.execute("SELECT data FROM shared")
assert res.fetchone() == (28,)

con1.close()
con2.close()
```

More information about this feature, including a list of parameters, can be found in the SQLite URI documentation.

How to create and use row factories

By default, `sqlite3` represents each row as a *tuple*. If a `tuple` does not suit your needs, you can use the *sqlite3.Row* class or a custom *row_factory*.

While `row_factory` exists as an attribute both on the *Cursor* and the *Connection*, it is recommended to set *Connection.row_factory*, so all cursors created from the connection will use the same row factory.

`Row` provides indexed and case-insensitive named access to columns, with minimal memory overhead and performance impact over a `tuple`. To use `Row` as a row factory, assign it to the `row_factory` attribute:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = sqlite3.Row
```

Queries now return `Row` objects:

```
>>> res = con.execute("SELECT 'Earth' AS name, 6378 AS radius")
>>> row = res.fetchone()
>>> row.keys()
['name', 'radius']
>>> row[0]          # Access by index.
'Earth'
>>> row["name"]     # Access by name.
'Earth'
>>> row["RADIUS"]  # Column names are case-insensitive.
6378
>>> con.close()
```

備🄵

The `FROM` clause can be omitted in the `SELECT` statement, as in the above example. In such cases, SQLite returns a single row with columns defined by expressions, e.g. literals, with the given aliases `expr AS alias`.

You can create a custom *`row_factory`* that returns each row as a *`dict`*, with column names mapped to values:

```
def dict_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    return {key: value for key, value in zip(fields, row)}
```

Using it, queries now return a `dict` instead of a `tuple`:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = dict_factory
>>> for row in con.execute("SELECT 1 AS a, 2 AS b"):
...     print(row)
{'a': 1, 'b': 2}
>>> con.close()
```

The following row factory returns a *named tuple*:

```
from collections import namedtuple

def namedtuple_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    cls = namedtuple("Row", fields)
    return cls._make(row)
```

`namedtuple_factory()` can be used as follows:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = namedtuple_factory
>>> cur = con.execute("SELECT 1 AS a, 2 AS b")
>>> row = cur.fetchone()
>>> row
Row(a=1, b=2)
>>> row[0]  # Indexed access.
1
>>> row.b   # Attribute access.
2
>>> con.close()
```

With some adjustments, the above recipe can be adapted to use a *dataclass*, or any other custom class, instead of a *namedtuple*.

How to handle non-UTF-8 text encodings

By default, sqlite3 uses *str* to adapt SQLite values with the TEXT data type. This works well for UTF-8 encoded text, but it might fail for other encodings and invalid UTF-8. You can use a custom *text_factory* to handle such cases.

Because of SQLite's flexible typing, it is not uncommon to encounter table columns with the TEXT data type containing non-UTF-8 encodings, or even arbitrary data. To demonstrate, let's assume we have a database with ISO-8859-2 (Latin-2) encoded text, for example a table of Czech-English dictionary entries. Assuming we now have a *Connection* instance con connected to this database, we can decode the Latin-2 encoded text using this *text_factory*:

```
con.text_factory = lambda data: str(data, encoding="latin2")
```

For invalid UTF-8 or arbitrary data in stored in TEXT table columns, you can use the following technique, borrowed from the unicode-howto:

```
con.text_factory = lambda data: str(data, errors="surrogateescape")
```

備🄵

The sqlite3 module API does not support strings containing surrogates.

unicode-howto

12.6.4 解釋

Transaction control

sqlite3 offers multiple methods of controlling whether, when and how database transactions are opened and closed. *Transaction control via the autocommit attribute* is recommended, while *Transaction control via the isolation_level attribute* retains the pre-Python 3.12 behaviour.

Transaction control via the autocommit attribute

The recommended way of controlling transaction behaviour is through the *Connection.autocommit* attribute, which should preferably be set using the *autocommit* parameter of *connect()*.

It is suggested to set *autocommit* to False, which implies **PEP 249**-compliant transaction control. This means:

- sqlite3 ensures that a transaction is always open, so *connect()*, *Connection.commit()*, and *Connection.rollback()* will implicitly open a new transaction (immediately after closing the pending one, for the latter two). sqlite3 uses BEGIN DEFERRED statements when opening transactions.
- Transactions should be committed explicitly using commit().
- Transactions should be rolled back explicitly using rollback().

- An implicit rollback is performed if the database is *close()*-ed with pending changes.

Set *autocommit* to `True` to enable SQLite's autocommit mode. In this mode, *Connection.commit()* and *Connection.rollback()* have no effect. Note that SQLite's autocommit mode is distinct from the **PEP 249**-compliant *Connection.autocommit* attribute; use *Connection.in_transaction* to query the low-level SQLite autocommit mode.

Set *autocommit* to *LEGACY_TRANSACTION_CONTROL* to leave transaction control behaviour to the *Connection.isolation_level* attribute. See *Transaction control via the isolation_level attribute* for more information.

Transaction control via the `isolation_level` attribute

備🄵

The recommended way of controlling transactions is via the *autocommit* attribute. See *Transaction control via the autocommit attribute*.

If *Connection.autocommit* is set to *LEGACY_TRANSACTION_CONTROL* (the default), transaction behaviour is controlled using the *Connection.isolation_level* attribute. Otherwise, `isolation_level` has no effect.

If the connection attribute *isolation_level* is not `None`, new transactions are implicitly opened before *execute()* and *executemany()* executes `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statements; for other statements, no implicit transaction handling is performed. Use the *commit()* and *rollback()* methods to respectively commit and roll back pending transactions. You can choose the underlying SQLite transaction behaviour —that is, whether and what type of `BEGIN` statements `sqlite3` implicitly executes –via the *isolation_level* attribute.

If *isolation_level* is set to `None`, no transactions are implicitly opened at all. This leaves the underlying SQLite library in autocommit mode, but also allows the user to perform their own transaction handling using explicit SQL statements. The underlying SQLite library autocommit mode can be queried using the *in_transaction* attribute.

The *executescript()* method implicitly commits any pending transaction before execution of the given SQL script, regardless of the value of *isolation_level*.

在 3.6 版的變更: `sqlite3` used to implicitly commit an open transaction before DDL statements. This is no longer the case.

在 3.12 版的變更: The recommended way of controlling transactions is now via the *autocommit* attribute.

CHAPTER 13

資料壓縮與保存

本章中描述的模組支援使用 zlib、gzip、bzip2 和 lzma 演算法進行資料壓縮，以及建立 ZIP 和 tar 格式的存檔。另請參閱 *shutil* 模組提供的*Archiving operations*。

13.1 zlib --- 相容於 gzip 的壓縮

對於需要資料壓縮的應用程式，此模組提供了能使用 zlib 函式庫進行壓縮和解壓縮的函式。zlib 函式庫有自己的主頁 https://www.zlib.net。已知 Python 模組與早於 1.1.3 的 zlib 函式庫版本之間不相容；1.1.3 存在安全漏洞，因此我們建議使用 1.1.4 或更新的版本。

zlib 的函式有很多選項，且通常需要按特定順序使用。本文件不打算解所有選項排列組合的效果；相關官方資訊，請參 http://www.zlib.net/manual.html 上的 zlib 手。

若要讀寫 `.gz` 文件，請參 *gzip* 模組。

該模組中可用的例外和函式是：

exception zlib.**error**

當壓縮和解壓縮發生錯誤時引發的例外。

zlib.**adler32**(*data*[, *value*])

計算 *data* 的 Adler-32 核對和 (checksum)。（Adler-32 核對和幾乎與 CRC32 一樣可靠，但計算速度更快。）結果是一個 unsigned（無符號的）32-bit 整數。如果有提供 *value*，則將其用作核對和的起始值，否則使用預設值 1。傳入 *value* 允許了於多個輸入的串聯 (concatenation) 上計算核對和。該演算法的加密度不高，不該用於身份驗證 (authentication) 或數位簽章 (digital signature)。由於該演算法是核對和演算法而設計的，它不適合作通用的雜演算法。

在 3.0 版的變更: 結果總是 unsigned。

zlib.**compress**(*data*, */*, *level=-1*, *wbits=MAX_WBITS*)

壓縮 *data* 中的位元組，回傳一個包含壓縮資料的位元組物件。*level* 是從 0 到 9 或 -1 的整數，控制了壓縮的級F；1 (Z_BEST_SPEED) 最快但壓縮程度較小，9 (Z_BEST_COMPRESSION) 最慢但壓縮最多。0 (Z_NO_COMPRESSION) 代表不壓縮。預設值F -1 (Z_DEFAULT_COMPRESSION)。Z_DEFAULT_COMPRESSION 表示預設的速度和壓縮間折衷方案（目前相當於級F 6）。

wbits 引數控制了壓縮資料時所使用的歷史紀F緩衝區 (history buffer) 大小（或「視窗大小」），以及輸出中是否包含標題和尾末 (trailer)。它可以F用多個值的範圍，預設F 15 (MAX_WBITS)：

- +9 到 +15：視窗大小的以二F底的對數，因此範圍在 512 到 32768 之間。較大的值會F生更佳的壓縮，但會F用更多的記憶體。生成輸出將包含特定於 zlib 的標頭和尾末。
- −9 到 −15：使用 *wbits* 的F對值作F視窗大小的對數，同時生成F有標頭或尾末核對和的原始輸出串流。
- +25 到 +31 = 16 +（9 到 15）：使用數值的最低 4 位元作F視窗大小的對數，同時在輸出中包含基本的 gzip 標頭和尾末核對和。

如果發生任何錯誤，則引發*error* 例外。

在 3.6 版的變更: *level* 現在可以用作關鍵字參數。

在 3.11 版的變更: *wbits* 參數現在可用於設定視窗位元和壓縮型F。

zlib.**compressobj**(*level=-1*, *method=DEFLATED*, *wbits=MAX_WBITS*, *memLevel=DEF_MEM_LEVEL*, *strategy=Z_DEFAULT_STRATEGY*[, *zdict*])

回傳一個壓縮物件，用於壓縮不能一次全部放入記憶體中的資料串流。

level 是壓縮級F -- 從 0 到 9 或 -1 的整數。1 (Z_BEST_SPEED) 最快但壓縮程度較小，而 9 (Z_BEST_COMPRESSION) 最慢但壓縮最多。0 (Z_NO_COMPRESSION) 代表不壓縮。預設值F -1 (Z_DEFAULT_COMPRESSION)。Z_DEFAULT_COMPRESSION 表示預設的速度和壓縮間折衷方案（目前相當於級F 6）。

method 代表壓縮演算法。目前唯一支援的值是 DEFLATED。

wbits 參數控制歷史紀F緩衝區的大小（或「視窗大小」），以及將使用的標頭和尾末格式。它與前面F述的 *compress()* 具有相同的含義。

memLevel 引數控制用於F部壓縮狀態的記憶體大小。有效值範圍F 1 到 9。較高的值會使用更多的記憶體，但速度更快FF生更小的輸出。

strategy 被用於調整壓縮演算法。可用的值F Z_DEFAULT_STRATEGY、Z_FILTERED、Z_HUFFMAN_ONLY、Z_RLE (zlib 1.2.0.1) 和 Z_FIXED (zlib 1.2.2.2)。

zdict 是事先定義好的的壓縮字典。這是一個位元組序列（例如一個*bytes* 物件），其中包含預期在要壓縮的資料中頻繁出現的子序列。那些預期會最常見的子序列應該出現在字典的尾末。

在 3.3 版的變更: 新增 *zdict* 參數與支援關鍵字引數。

zlib.**crc32**(*data*[, *value*])

計算 *data* 的 CRC（Cyclic Redundancy Check，循環冗余核對）核對和，結果會是一個 unsigned 32-bit 整數。如果 *value* 存在，則將其用作核對和的起始值，否則使用預設值 0。傳入 *value* 允許在多個輸入的串聯上計算核對和。該演算法的加密F度不F高，不該用於身份驗證或數位簽章。由於該演算法是F核對和演算法而設計的，它F不適合作F通用的雜F演算法。

在 3.0 版的變更: 結果總是F unsigned。

zlib.**decompress**(*data*, */*, *wbits=MAX_WBITS*, *bufsize=DEF_BUF_SIZE*)

解壓縮 *data* 中的位元組，回傳包含未壓縮資料的位元組物件。*wbits* 參數依賴於 *data* 的格式，下面將進一步討論。如果有給定 *bufsize*，它會被用作輸出緩衝區的初始大小。如果發生任何錯誤，則引發*error* 例外。

wbits 參數控制歷史紀🄴緩衝區的大小（或「視窗大小」），以及期望的標頭和尾末格式。它類似於*compressobj()* 的參數，但接受更多範圍的值：

- +8 到 +15：視窗大小的以二🄴底的對數。輸入必須包括一個 zlib 標頭和尾末。
- 0：根據 zlib 標頭檔自動🄴定視窗大小。僅有在 zlib 1.2.3.5 或更新的版本支援。
- −8 to −15：使用 *wbits* 的🄴對值作🄴視窗大小的對數，輸入必須是🄴有標頭或尾末的原始串流。
- +24 到 +31 = 16 + （8 到 15）：取值的最低 4 位元作🄴視窗大小的對數，輸入必須包含 gzip 標頭和尾末。
- +40 到 +47 = 32 + （8 到 15）：使用值的最低 4 位元作🄴視窗大小的對數，🄴自動接受 zlib 或 gzip 格式。

當解壓縮一個串流時，視窗大小不得小於最初用於壓縮串流的大小；使用太小的值可能會導致*error* 例外。預設的 *wbits* 值對應於最大的視窗大小，🄴且需要包含 zlib 標頭和尾末。

bufsize 是用於保存解壓縮資料的緩衝區的初始大小。如果需要更多空間，緩衝區大小將根據需求來增加，因此你不需要讓該值完全剛好；調整它只會節省幾次對 `malloc()` 的呼叫。

在 3.6 版的變更: *wbits* 和 *bufsize* 可以用作關鍵字引數。

`zlib.`**`decompressobj`**(*wbits=MAX_WBITS*[, *zdict*])

回傳一個解壓縮物件，用於解壓縮不能一次全部放入記憶體的資料串流。

wbits 引數控制歷史紀🄴緩衝區的大小（或「視窗大小」），以及期望的標頭和尾末格式。它與前面🄵述的 *decompress()* 具有相同的含義。

zdict 參數指定是先定義好的壓縮字典。如果有提供，這必須與生成要解壓縮資料的壓縮器所使用的字典相同。

備🄵

如果 *zdict* 是一個可變物件 (mutable object)（例如一個*bytearray*），你不能在呼叫*decompressobj()* 和第一次呼叫解壓縮器的 `decompress()` 方法之間修改它的🄴容。

在 3.3 版的變更: 新增 *zdict* 參數。

壓縮物件支援以下方法：

`Compress.`**`compress`**(*data*)

壓縮 *data*，回傳一個位元組物件，其中至少包含 *data* 中部分資料的壓縮資料。此資料應串聯到任何先前呼叫*compress()* 方法所🄵生的輸出。一些輸入可能會保存在🄵部緩衝區中以供後續處理。

`Compress.`**`flush`**([*mode*])

處理所有待處理的輸入，🄵回傳包含剩余壓縮輸出的位元組物件。*mode* 可以從以下常數中選擇：`Z_NO_FLUSH`、`Z_PARTIAL_FLUSH`、`Z_SYNC_FLUSH`、`Z_FULL_FLUSH`、`Z_BLOCK` (zlib 1.2.3.4) 或 `Z_FINISH`，預設🄵 `Z_FINISH`。除了 `Z_FINISH` 之外，所有常數都允許壓縮更多的資料位元組字串，而 `Z_FINISH` 會完成壓縮串流🄵同時防止壓縮更多資料。在 *mode* 設定🄵 `Z_FINISH` 的情🄵下呼叫*flush()* 後，無法再次呼叫*compress()* 方法；唯一可行的作法是🄵除物件。

`Compress.`**`copy`**()

回傳壓縮物件的副本，這可用於有效壓縮一組共用初始前綴的資料。

在 3.8 版的變更: 於壓縮物件新增對*copy.copy()* 和*copy.deepcopy()* 的支援。

解壓縮物件支援以下方法和屬性：

Decompress.**unused_data**

一個位元組物件，它包含壓縮資料結束之後的任何位元組。也就是🄵，在包含壓縮資料的最後一個位元組可用之前，它會一直保持🄵 `b""`。如果整個位元組字串 (bytestring) 有包含壓縮資料，這會是 `b""`，也就是一個空位元組物件。

Decompress.**unconsumed_tail**

一個位元組物件，包含前一次*decompress()* 的呼叫因超出了未壓縮資料緩衝區的限制而🄵消耗掉的任何資料。zlib 機制尚未看到此資料，因此您必須將其（和可能有和它串聯的其他資料）反饋給後續的*decompress()* 方法呼叫以獲得正確的輸出。

Decompress.**eof**

一個布林值，代表是否已到達壓縮資料串流的尾末。

這使其能🄵區分有正確建構的壓縮串流和不完整或被截斷的串流。

在 3.3 版被加入.

Decompress.**decompress**(*data*, *max_length=0*)

解壓縮 *data* 🄵回傳一個位元組物件，其包含與 *string* 中至少與部分資料相對應的未壓縮資料。此資料應串聯到任何先前呼叫*decompress()* 方法所🄵生的輸出。一些輸入資料可能會保存在🄵部緩衝區中以供後續處理。

如果可選參數 *max_length* 不是零，則回傳值長度將不超過 *max_length*。這代表著🄵不是所有的已壓縮輸入都可以被處理；未使用的資料將被存儲在屬性*unconsumed_tail* 中。如果要繼續解壓縮，則必須將此位元組字串傳遞給後續對*decompress()* 的呼叫。如果 *max_length* 🄵零，則整個輸入會被解壓縮，🄵且*unconsumed_tail* 🄵空。

在 3.6 版的變更: *max_length* 可以用作關鍵字引數。

Decompress.**flush**([*length*])

處理所有待處理的輸入，🄵回傳包含剩余未壓縮輸出的位元組物件。呼叫*flush()* 後，無法再次呼叫*decompress()* 方法；唯一可行的方法是🄵除該物件。

可選參數 *length* 設定了輸出緩衝區的初始大小。

Decompress.**copy**()

回傳解壓物件的副本，這可用於在資料串流中途保存解壓縮器的狀態，以便在未來某個時間點加速對串流的隨機搜索 (random seek)。

在 3.8 版的變更: 於解壓縮物件新增對*copy.copy()* 和*copy.deepcopy()* 支援。

有關正在使用的 zlib 函式庫版本資訊可通過以下常數獲得：

zlib.**ZLIB_VERSION**

用於建置模組的 zlib 函式庫版本字串。這可能與實際在執行環境 (runtime) 使用的 zlib 函式庫不同，後者以*ZLIB_RUNTIME_VERSION* 提供。

zlib.**ZLIB_RUNTIME_VERSION**

直譯器實際載入的 zlib 函式庫版本字串。

在 3.3 版被加入.

13.2 gzip --- gzip 檔案的支援

原始碼： Lib/gzip.py

This module provides a simple interface to compress and decompress files just like the GNU programs **gzip** and **gunzip** would.

The data compression is provided by the *zlib* module.

The *gzip* module provides the *GzipFile* class, as well as the *open()*, *compress()* and *decompress()* convenience functions. The *GzipFile* class reads and writes **gzip**-format files, automatically compressing or decompressing the data so that it looks like an ordinary *file object*.

Note that additional file formats which can be decompressed by the **gzip** and **gunzip** programs, such as those produced by **compress** and **pack**, are not supported by this module.

此模組定義了以下項目：

gzip.**open**(*filename*, *mode='rb'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)

Open a gzip-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'` or `'xb'` for binary mode, or `'rt'`, `'at'`, `'wt'`, or `'xt'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 0 to 9, as for the *GzipFile* constructor.

For binary mode, this function is equivalent to the *GzipFile* constructor: `GzipFile(filename, mode, compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *GzipFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

在 3.3 版的變更: Added support for *filename* being a file object, support for text mode, and the *encoding*, *errors* and *newline* arguments.

在 3.4 版的變更: 新增 `'x'`、`'xb'` 和 `'xt'` 模式的支援。

在 3.6 版的變更: 接受類路徑物件。

exception gzip.**BadGzipFile**

An exception raised for invalid gzip files. It inherits from *OSError*. *EOFError* and *zlib.error* can also be raised for invalid gzip files.

在 3.8 版被加入.

class gzip.**GzipFile**(*filename=None*, *mode=None*, *compresslevel=9*, *fileobj=None*, *mtime=None*)

Constructor for the *GzipFile* class, which simulates most of the methods of a *file object*, with the exception of the *truncate()* method. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, an *io.BytesIO* object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the **gzip** file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'`, or `'xb'`, depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is `'rb'`. In future Python releases the mode of *fileobj* will not be used. It is better to always specify *mode* for writing.

Note that the file is always opened in binary mode. To open a compressed file in text mode, use *open()* (or wrap your *GzipFile* with an *io.TextIOWrapper*).

The *compresslevel* argument is an integer from `0` to `9` controlling the level of compression; `1` is fastest and produces the least compression, and `9` is slowest and produces the most compression. `0` is no compression. The default is `9`.

The *mtime* argument is an optional numeric timestamp to be written to the last modification time field in the stream when compressing. It should only be provided in compression mode. If omitted or `None`, the current time is used. See the *mtime* attribute for more details.

Calling a *GzipFile* object's `close()` method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an *io.BytesIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *io.BytesIO* object's *getvalue()* method.

GzipFile supports the *io.BufferedIOBase* interface, including iteration and the `with` statement. Only the *truncate()* method isn't implemented.

GzipFile 也提供了以下的方法和屬性:

peek(*n*)

Read *n* uncompressed bytes without advancing the file position. At most one single read on the compressed stream is done to satisfy the call. The number of bytes returned may be more or less than requested.

> **備🄵**
>
> While calling *peek()* does not change the file position of the *GzipFile*, it may change the position of the underlying file object (e.g. if the *GzipFile* was constructed with the *fileobj* parameter).

在 3.2 版被加入.

mtime

When decompressing, the value of the last modification time field in the most recently read header may be read from this attribute, as an integer. The initial value before reading any headers is `None`.

All **gzip** compressed streams are required to contain this timestamp field. Some programs, such as **gunzip**, make use of the timestamp. The format is the same as the return value of *time.time()* and the *st_mtime* attribute of the object returned by *os.stat()*.

name

The path to the gzip file on disk, as a *str* or *bytes*. Equivalent to the output of *os.fspath()* on the original input path, with no other normalization, resolution or expansion.

在 3.1 版的變更: Support for the `with` statement was added, along with the *mtime* constructor argument and *mtime* attribute.

在 3.2 版的變更: Support for zero-padded and unseekable files was added.

在 3.3 版的變更: *io.BufferedIOBase.read1()* 方法現在已有實作。

在 3.4 版的變更: 新增 `'x'` 和 `'xb'` 模式的支援。

在 3.5 版的變更: Added support for writing arbitrary *bytes-like objects*. The `read()` method now accepts an argument of `None`.

在 3.6 版的變更: 接受類路徑物件。

在 3.12 版的變更: Remove the `filename` attribute, use the `name` attribute instead.

在 3.9 版之後被🄵用: Opening `GzipFile` for writing without specifying the *mode* argument is deprecated.

`gzip.`**`compress`**(*data*, *compresslevel=9*, ***, *mtime=None*)

Compress the *data*, returning a `bytes` object containing the compressed data. *compresslevel* and *mtime* have the same meaning as in the `GzipFile` constructor above. When *mtime* is set to `0`, this function is equivalent to `zlib.compress()` with *wbits* set to `31`. The zlib function is faster.

在 3.2 版被加入.

在 3.8 版的變更: Added the *mtime* parameter for reproducible output.

在 3.11 版的變更: Speed is improved by compressing all data at once instead of in a streamed fashion. Calls with *mtime* set to `0` are delegated to `zlib.compress()` for better speed. In this situation the output may contain a gzip header "OS" byte value other than 255 "unknown" as supplied by the underlying zlib implementation.

`gzip.`**`decompress`**(*data*)

Decompress the *data*, returning a `bytes` object containing the uncompressed data. This function is capable of decompressing multi-member gzip data (multiple gzip blocks concatenated together). When the data is certain to contain only one member the `zlib.decompress()` function with *wbits* set to 31 is faster.

在 3.2 版被加入.

在 3.11 版的變更: Speed is improved by decompressing members at once in memory instead of in a streamed fashion.

13.2.1 用法范例

如何讀取壓縮檔案的範例:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

如何建立一個壓縮的 GZIP 檔案的範例:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

如何壓縮一個已存在的檔案的範例:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

如何壓縮一個二進位字串的範例:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

也參考

***zlib* 模組**
The basic data compression module needed to support the **gzip** file format.

13.2.2 命令列介面

The *gzip* module provides a simple command line interface to compress or decompress files.

Once executed the *gzip* module keeps the input file(s).

在 3.8 版的變更: Add a new command line interface with a usage. By default, when you will execute the CLI, the default compression level is 6.

命令列選項

file
如果未指定 *file*，則從*sys.stdin* 讀取。

--fast
Indicates the fastest compression method (less compression).

--best
Indicates the slowest compression method (best compression).

-d, --decompress
解壓縮指定的檔案。

-h, --help
顯示幫助訊息。

13.3 bz2 --- bzip2 壓縮的支援

原始碼： Lib/bz2.py

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The *bz2* module contains:

- The *open()* function and *BZ2File* class for reading and writing compressed files.
- The *BZ2Compressor* and *BZ2Decompressor* classes for incremental (de)compression.
- The *compress()* and *decompress()* functions for one-shot (de)compression.

13.3.1 (De)compression of files

bz2.**open**(*filename*, *mode='rb'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)

Open a bzip2-compressed file in binary or text mode, returning a *file object*.

As with the constructor for *BZ2File*, the *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'w'`, `'wb'`, `'x'`, `'xb'`, `'a'` or `'ab'` for binary mode, or `'rt'`, `'wt'`, `'xt'`, or `'at'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 1 to 9, as for the *BZ2File* constructor.

For binary mode, this function is equivalent to the *BZ2File* constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *BZ2File* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

在 3.3 版被加入.

在 3.4 版的變更: The `'x'` (exclusive creation) mode was added.

在 3.6 版的變更: Accepts a *path-like object*.

class bz2.**BZ2File**(*filename*, *mode='r'*, *, *compresslevel=9*)

Open a bzip2-compressed file in binary mode.

If *filename* is a *str* or *bytes* object, open the named file directly. Otherwise, *filename* should be a *file object*, which will be used to read or write the compressed data.

The *mode* argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `'w'` does not truncate the file, and is instead equivalent to `'a'`.

If *mode* is `'w'` or `'a'`, *compresslevel* can be an integer between `1` and `9` specifying the level of compression: `1` produces the least compression, and `9` (default) produces the most compression.

If *mode* is `'r'`, the input file may be the concatenation of multiple compressed streams.

BZ2File provides all of the members specified by the *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the `with` statement are supported.

BZ2File also provides the following methods:

peek([*n*])

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

> **備F**
>
> While calling *peek()* does not change the file position of the *BZ2File*, it may change the position of the underlying file object (e.g. if the *BZ2File* was constructed by passing a file object for *filename*).

在 3.3 版被加入.

fileno()

Return the file descriptor for the underlying file.

在 3.3 版被加入.

readable()

Return whether the file was opened for reading.

在 3.3 版被加入.

seekable()

Return whether the file supports seeking.

在 3.3 版被加入.

writable()

Return whether the file was opened for writing.

在 3.3 版被加入.

read1(*size=-1*)

Read up to *size* uncompressed bytes, while trying to avoid making multiple reads from the underlying stream. Reads up to a buffer's worth of data if size is negative.

Returns `b''` if the file is at EOF.

在 3.3 版被加入.

readinto(*b*)

Read bytes into *b*.

Returns the number of bytes read (0 for EOF).

在 3.3 版被加入.

在 3.1 版的變更: Support for the `with` statement was added.

在 3.3 版的變更: Support was added for *filename* being a *file object* instead of an actual filename.

The `'a'` (append) mode was added, along with support for reading multi-stream files.

在 3.4 版的變更: The `'x'` (exclusive creation) mode was added.

在 3.5 版的變更: The *read()* method now accepts an argument of `None`.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.9 版的變更: The *buffering* parameter has been removed. It was ignored and deprecated since Python 3.0. Pass an open file object to control how the file is opened.

The *compresslevel* parameter became keyword-only.

在 3.10 版的變更: This class is thread unsafe in the face of multiple simultaneous readers or writers, just like its equivalent classes in *gzip* and *lzma* have always been.

13.3.2 Incremental (de)compression

class bz2.**BZ2Compressor**(*compresslevel=9*)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the *compress()* function instead.

compresslevel, if given, must be an integer between 1 and 9. The default is 9.

compress(*data*)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the *flush()* method to finish the compression process.

flush()

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

class bz2.**BZ2Decompressor**

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the *decompress()* function instead.

> **備🄵**
>
> This class does not transparently handle inputs containing multiple compressed streams, unlike *decompress()* and *BZ2File*. If you need to decompress a multi-stream input with *BZ2Decompressor*, you must use a new decompressor for each stream.

decompress(*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to *decompress()*. The returned data should be concatenated with the output of any previous calls to *decompress()*.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to False. In this case, the next call to *decompress()* may provide *data* as b'' to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to True.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

在 3.5 版的變更: 新增 *max_length* 參數。

eof

True if the end-of-stream marker has been reached.

在 3.3 版被加入.

unused_data

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be b''.

needs_input

`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

在 3.5 版被加入.

13.3.3 One-shot (de)compression

bz2.**compress**(*data*, *compresslevel=9*)

Compress *data*, a *bytes-like object*.

compresslevel, if given, must be an integer between `1` and `9`. The default is `9`.

For incremental compression, use a *BZ2Compressor* instead.

bz2.**decompress**(*data*)

Decompress *data*, a *bytes-like object*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a *BZ2Decompressor* instead.

在 3.3 版的變更: Support for multi-stream inputs was added.

13.3.4 用法范例

Below are some examples of typical usage of the *bz2* module.

Using *compress()* and *decompress()* to demonstrate round-trip compression:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> c = bz2.compress(data)
>>> len(data) / len(c)  # Data compression ratio
1.513595166163142
>>> d = bz2.decompress(c)
>>> data == d  # Check equality to original object after round-trip
True
```

Using *BZ2Compressor* for incremental compression:

```
>>> import bz2
>>> def gen_data(chunks=10, chunksize=1000):
...     """Yield incremental blocks of chunksize bytes."""
...     for _ in range(chunks):
...         yield b"z" * chunksize
...
>>> comp = bz2.BZ2Compressor()
>>> out = b""
>>> for chunk in gen_data():
```

(繼續下一頁)

(繼續上一頁)

```
...     # Provide data to the compressor object
...     out = out + comp.compress(chunk)
...
>>> # Finish the compression process.  Call this once you have
>>> # finished providing data to the compressor.
>>> out = out + comp.flush()
```

The example above uses a very "nonrandom" stream of data (a stream of `b"z"` chunks). Random data tends to compress poorly, while ordered, repetitive data usually yields a high compression ratio.

Writing and reading a bzip2-compressed file in binary mode:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> with bz2.open("myfile.bz2", "wb") as f:
...     # Write compressed data to file
...     unused = f.write(data)
...
>>> with bz2.open("myfile.bz2", "rb") as f:
...     # Decompress data from file
...     content = f.read()
...
>>> content == data  # Check equality to original object after round-trip
True
```

13.4 `lzma` --- 使用 LZMA 演算法進行壓縮

在 3.3 版被加入.

原始碼： Lib/lzma.py

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the `.xz` and legacy `.lzma` file formats used by the **xz** utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the *bz2* module. Note that *LZMAFile* and *bz2.BZ2File* are *not* thread-safe, so if you need to use a single *LZMAFile* instance from multiple threads, it is necessary to protect it with a lock.

exception lzma.**LZMAError**

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

13.4.1 Reading and writing compressed files

lzma.**open**(*filename*, *mode='rb'*, *, *format=None*, *check=-1*, *preset=None*, *filters=None*, *encoding=None*, *errors=None*, *newline=None*)

Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a `str`, `bytes` or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of `"r"`, `"rb"`, `"w"`, `"wb"`, `"x"`, `"xb"`, `"a"` or `"ab"` for binary mode, or `"rt"`, `"wt"`, `"xt"`, or `"at"` for text mode. The default is `"rb"`.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for `LZMADecompressor`. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for `LZMACompressor`.

For binary mode, this function is equivalent to the `LZMAFile` constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a `LZMAFile` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

在 3.4 版的變更: 新增 `"x"`、`"xb"` 和 `"xt"` 模式的支援。

在 3.6 版的變更: Accepts a *path-like object*.

class lzma.**LZMAFile**(*filename=None*, *mode='r'*, *, *format=None*, *check=-1*, *preset=None*, *filters=None*)

Open an LZMA-compressed file in binary mode.

An `LZMAFile` can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a `str`, `bytes` or *path-like* object). When wrapping an existing file object, the wrapped file will not be closed when the `LZMAFile` is closed.

The *mode* argument can be either `"r"` for reading (default), `"w"` for overwriting, `"x"` for exclusive creation, or `"a"` for appending. These can equivalently be given as `"rb"`, `"wb"`, `"xb"` and `"ab"` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `"w"` does not truncate the file, and is instead equivalent to `"a"`.

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for `LZMADecompressor`. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for `LZMACompressor`.

`LZMAFile` supports all the members specified by `io.BufferedIOBase`, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

The following method is also provided:

peek(*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

> **備F**
>
> While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

在 3.4 版的變更: 新增 "x" 和 "xb" 模式的支援。

在 3.5 版的變更: The *read()* method now accepts an argument of None.

在 3.6 版的變更: Accepts a *path-like object*.

13.4.2 Compressing and decompressing data in memory

class lzma.**LZMACompressor**(*format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see *compress()*.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT_XZ: The .xz container format.**
  This is the default format.
- **FORMAT_ALONE: The legacy .lzma container format.**
  This format is more limited than .xz -- it does not support integrity checks or multiple filters.
- **FORMAT_RAW: A raw data stream, not using any container format.**
  This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using FORMAT_AUTO (see *LZMADecompressor*).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- CHECK_NONE: No integrity check. This is the default (and the only acceptable value) for FORMAT_ALONE and FORMAT_RAW.
- CHECK_CRC32: 32-bit Cyclic Redundancy Check.
- CHECK_CRC64: 64-bit Cyclic Redundancy Check. This is the default for FORMAT_XZ.
- CHECK_SHA256: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an *LZMAError* is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant PRESET_EXTREME. If neither *preset* nor *filters* are given, the default behavior is to use PRESET_DEFAULT (preset level 6). Higher presets produce smaller output, but make the compression process slower.

> **備F**
>
> In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an *LZMACompressor* object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

compress(*data*)

Compress *data* (a `bytes` object), returning a `bytes` object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to `compress()` and `flush()`. The returned data should be concatenated with the output of any previous calls to `compress()`.

flush()

Finish the compression process, returning a `bytes` object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

class lzma.**LZMADecompressor**(*format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see `decompress()`.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an `LZMAError` if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

> **備🄵**
>
> This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `LZMAFile`. To decompress a multi-stream input with `LZMADecompressor`, you must create a new decompressor for each stream.

decompress(*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

在 3.5 版的變更: 新增 *max_length* 參數。

check

The ID of the integrity check used by the input stream. This may be `CHECK_UNKNOWN` until enough of the input has been decoded to determine what integrity check it uses.

eof

`True` if the end-of-stream marker has been reached.

unused_data

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b""`.

needs_input

`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

在 3.5 版被加入.

`lzma.`**compress**(*data*, *format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See *LZMACompressor* above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.`**decompress**(*data*, *format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See *LZMADecompressor* above for a description of the *format*, *memlimit* and *filters* arguments.

13.4.3 Miscellaneous

`lzma.`**is_check_supported**(*check*)

Return `True` if the given integrity check is supported on this system.

`CHECK_NONE` and `CHECK_CRC32` are always supported. `CHECK_CRC64` and `CHECK_SHA256` may be unavailable if you are using a version of **liblzma** that was compiled with a limited feature set.

13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key `"id"`, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- Compression filters:
  - `FILTER_LZMA1` (for use with `FORMAT_ALONE`)
  - `FILTER_LZMA2` (for use with `FORMAT_XZ` and `FORMAT_RAW`)
- Delta filter:
  - `FILTER_DELTA`
- Branch-Call-Jump (BCJ) filters:
  - `FILTER_X86`
  - `FILTER_IA64`
  - `FILTER_ARM`
  - `FILTER_ARMTHUMB`

- FILTER_POWERPC
- FILTER_SPARC

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- preset: A compression preset to use as a source of default values for options that are not specified explicitly.
- dict_size: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- lc: Number of literal context bits.
- lp: Number of literal position bits. The sum lc + lp must be at most 4.
- pb: Number of position bits; must be at most 4.
- mode: MODE_FAST or MODE_NORMAL.
- nice_len: What should be considered a "nice length" for a match. This should be 273 or less.
- mf: What match finder to use -- MF_HC3, MF_HC4, MF_BT2, MF_BT3, or MF_BT4.
- depth: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, dist. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, start_offset. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

13.4.5 范例

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

13.5 `zipfile` --- 處理 ZIP 封存檔案

原始碼： Lib/zipfile/

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in PKZIP Application Note.

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

exception zipfile.**BadZipFile**

The error raised for bad ZIP files.

在 3.2 版被加入.

exception zipfile.**BadZipfile**

Alias of *BadZipFile*, for compatibility with older Python versions.

在 3.2 版之後被🄴用.

exception zipfile.**LargeZipFile**

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

class zipfile.**ZipFile**

The class for reading and writing ZIP files. See section *ZipFile 物件* for constructor details.

class zipfile.**Path**

Class that implements a subset of the interface provided by `pathlib.Path`, including the full `importlib.resources.abc.Traversable` interface.

在 3.8 版被加入.

class zipfile.**PyZipFile**

Class for creating ZIP archives containing Python libraries.

class zipfile.**ZipInfo**(*filename='NoName'*, *date_time=(1980, 1, 1, 0, 0, 0)*)

Class used to represent information about a member of an archive. Instances of this class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Most users of the `zipfile` module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section *ZipInfo 物件*.

zipfile.**is_zipfile**(*filename*)

Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

在 3.1 版的變更: Support for file and file-like objects.

zipfile.**ZIP_STORED**

The numeric constant for an uncompressed archive member.

zipfile.**ZIP_DEFLATED**

The numeric constant for the usual ZIP compression method. This requires the `zlib` module.

zipfile.**ZIP_BZIP2**

The numeric constant for the BZIP2 compression method. This requires the `bz2` module.

在 3.3 版被加入.

zipfile.**ZIP_LZMA**

The numeric constant for the LZMA compression method. This requires the `lzma` module.

在 3.3 版被加入.

備🄵

The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

也參考

PKZIP Application Note
Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

Info-ZIP 首頁
Information about the Info-ZIP project's ZIP archive programs and development libraries.

13.5.1 ZipFile 物件

class zipfile.**ZipFile**(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *compresslevel=None*, ***, *strict_timestamps=True*, *metadata_encoding=None*)

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a *path-like object*.

The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, `'a'` to append to an existing file, or `'x'` to exclusively create and write a new file. If *mode* is `'x'` and *file* refers to an existing file, a *FileExistsError* will be raised. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is `'a'` and the file does not exist at all, it is created. If *mode* is `'r'` or `'a'`, the file should be seekable.

compression is the ZIP compression method to use when writing the archive, and should be *ZIP_STORED*, *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA*; unrecognized values will cause *NotImplementedError* to be raised. If *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA* is specified but the corresponding module (*zlib*, *bz2* or *lzma*) is not available, *RuntimeError* is raised. The default is *ZIP_STORED*.

If *allowZip64* is `True` (the default) zipfile will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is `false` *zipfile* will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using *ZIP_STORED* or *ZIP_LZMA* it has no effect. When using *ZIP_DEFLATED* integers `0` through `9` are accepted (see *zlib* for more information). When using *ZIP_BZIP2* integers `1` through `9` are accepted (see *bz2* for more information).

The *strict_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

When mode is `'r'`, *metadata_encoding* may be set to the name of a codec, which will be used to decode metadata such as the names of members and ZIP comments.

If the file is created with mode `'w'`, `'x'` or `'a'` and then *closed* without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

ZipFile is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished---even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

備🄵

metadata_encoding is an instance-wide setting for the ZipFile. It is not currently possible to set this on a per-member basis.

This attribute is a workaround for legacy implementations which produce archives with names in the current locale encoding or code page (mostly on Windows). According to the .ZIP standard, the encoding of metadata may be specified to be either IBM code page (default) or UTF-8 by a flag in the archive header. That flag takes precedence over *metadata_encoding*, which is a Python-specific extension.

在 3.2 版的變更: 新增*ZipFile* 作🄵情境管理器使用的能力。

在 3.3 版的變更: 新增對於*bzip2* 和*lzma* 壓縮的支援。

在 3.4 版的變更: ZIP64 extensions are enabled by default.

在 3.5 版的變更: Added support for writing to unseekable streams. Added support for the `'x'` mode.

在 3.6 版的變更: Previously, a plain *RuntimeError* was raised for unrecognized compression values.

在 3.6.2 版的變更: The *file* parameter accepts a *path-like object*.

在 3.7 版的變更: Add the *compresslevel* parameter.

在 3.8 版的變更: The *strict_timestamps* keyword-only parameter.

在 3.11 版的變更: Added support for specifying member name encoding for reading metadata in the zipfile's directory and file headers.

`ZipFile.`**`close`**`()`

Close the archive file. You must call *close()* before exiting your program or essential records will not be written.

`ZipFile.`**`getinfo`**`(`*name*`)`

Return a *ZipInfo* object with information about the archive member *name*. Calling *getinfo()* for a name not currently contained in the archive will raise a *KeyError*.

`ZipFile.`**`infolist`**`()`

Return a list containing a *ZipInfo* object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.`**`namelist`**`()`

Return a list of archive members by name.

`ZipFile.`**`open`**`(`*name*, *mode='r'*, *pwd=None*, ***, *force_zip64=False*`)`

Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a *ZipInfo* object. The *mode* parameter, if included, must be `'r'` (the default) or `'w'`. *pwd* is the password used to decrypt encrypted ZIP files as a *bytes* object.

open() is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With *mode* `'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: *read()*, *readline()*, *readlines()*, *seek()*, *tell()*, *__iter__()*, *__next__()*. These objects can operate independently of the ZipFile.

With `mode='w'`, a writable file handle is returned, which supports the *write()* method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a *ValueError*.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a *ZipInfo* object with *file_size* set, and use that as the *name* parameter.

備🄵

The *open()*, *read()* and *extract()* methods can take a filename or a *ZipInfo* object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

在 3.6 版的變更: Removed support of `mode='U'`. Use *io.TextIOWrapper* for reading compressed text files in *universal newlines* mode.

在 3.6 版的變更: *ZipFile.open()* can now be used to write files into the archive with the `mode='w'` option.

在 3.6 版的變更: Calling *open()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**extract**(*member*, *path=None*, *pwd=None*)

Extract a member from the archive to the current working directory; *member* must be its full name or a *ZipInfo* object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a *ZipInfo* object. *pwd* is the password used for encrypted files as a *bytes* object.

Returns the normalized path created (a directory or new file).

備🄵

If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../../foo../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

在 3.6 版的變更: Calling *extract()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

在 3.6.2 版的變更: The *path* parameter accepts a *path-like object*.

ZipFile.**extractall**(*path=None*, *members=None*, *pwd=None*)

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by *namelist()*. *pwd* is the password used for encrypted files as a *bytes* object.

警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`. This module attempts to prevent that. See *extract()* note.

在 3.6 版的變更: Calling *extractall()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

在 3.6.2 版的變更: The *path* parameter accepts a *path-like object*.

ZipFile.**printdir**()

Print a table of contents for the archive to `sys.stdout`.

ZipFile.**setpassword**(*pwd*)

Set *pwd* (a *bytes* object) as default password to extract encrypted files.

ZipFile.**read**(*name*, *pwd=None*)

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files as a *bytes* object and, if specified, overrides the default password set with *setpassword()*. Calling *read()* on a ZipFile that uses a compression method other than *ZIP_STORED*, *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA* will raise a *NotImplementedError*. An error will also be raised if the corresponding compression module is not available.

在 3.6 版的變更: Calling *read()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**testzip**()

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return None.

在 3.6 版的變更: Calling *testzip()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**write**(*filename*, *arcname=None*, *compress_type=None*, *compresslevel=None*)

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry. Similarly, *compresslevel* will override the constructor if given. The archive must be open with mode 'w', 'x' or 'a'.

備🄵

The ZIP file standard historically did not specify a metadata encoding, but strongly recommended CP437 (the original IBM PC encoding) for interoperability. Recent versions allow use of UTF-8 (only). In this module, UTF-8 will automatically be used to write the member names if they contain any non-ASCII characters. It is not possible to write member names in any encoding other than ASCII or UTF-8.

備🄵

Archive names should be relative to the archive root, that is, they should not start with a path separator.

備🄵

If arcname (or filename, if arcname is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

備🄵

A leading slash in the filename may lead to the archive being impossible to open in some zip programs on Windows systems.

在 3.6 版的變更: Calling *write()* on a ZipFile created with mode 'r' or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.**writestr**(*zinfo_or_arcname*, *data*, *compress_type=None*, *compresslevel=None*)

Write a file into the archive. The contents is *data*, which may be either a *str* or a *bytes* instance; if it is a *str*, it is encoded as UTF-8 first. *zinfo_or_arcname* is either the file name it will be given in the archive, or a *ZipInfo* instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode 'w', 'x' or 'a'.

If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo_or_arcname* (if that is a *ZipInfo* instance). Similarly, *compresslevel* will override the constructor if given.

備🄵

When passing a *ZipInfo* instance as the *zinfo_or_arcname* parameter, the compression method used will be that specified in the *compress_type* member of the given *ZipInfo* instance. By default, the *ZipInfo* constructor sets this member to *ZIP_STORED*.

在 3.2 版的變更: *compress_type* 引數。

在 3.6 版的變更: Calling *writestr()* on a ZipFile created with mode `'r'` or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

`ZipFile.`**`mkdir`**(*zinfo_or_directory*, *mode=511*)

Create a directory inside the archive. If *zinfo_or_directory* is a string, a directory is created inside the archive with the mode that is specified in the *mode* argument. If, however, *zinfo_or_directory* is a *ZipInfo* instance then the *mode* argument is ignored.

The archive must be opened with mode `'w'`, `'x'` or `'a'`.

在 3.11 版被加入.

The following data attributes are also available:

`ZipFile.`**`filename`**

Name of the ZIP file.

`ZipFile.`**`debug`**

The level of debug output to use. This may be set from `0` (the default, no output) to `3` (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.`**`comment`**

The comment associated with the ZIP file as a *bytes* object. If assigning a comment to a *ZipFile* instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

13.5.2 Path Objects

`class` `zipfile.`**`Path`**(*root*, *at=''*)

Construct a Path object from a `root` zipfile (which may be a *ZipFile* instance or `file` suitable for passing to the *ZipFile* constructor).

`at` specifies the location of this Path within the zipfile, e.g. 'dir/file.txt', 'dir/', or ''. Defaults to the empty string, indicating the root.

Path objects expose the following features of *pathlib.Path* objects:

Path objects are traversable using the `/` operator or `joinpath`.

`Path.`**`name`**

The final path component.

`Path.`**`open`**(*mode='r'*, ***, *pwd*, ****)

Invoke *ZipFile.open()* on the current path. Allows opening for read or write, text or binary through supported modes: 'r', 'w', 'rb', 'wb'. Positional and keyword arguments are passed through to *io.TextIOWrapper* when opened as text and ignored otherwise. `pwd` is the `pwd` parameter to *ZipFile.open()*.

在 3.9 版的變更: Added support for text and binary modes for open. Default mode is now text.

在 3.11.2 版的變更: The `encoding` parameter can be supplied as a positional argument without causing a *TypeError*. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all *io.TextIOWrapper* arguments, `encoding` included, as keywords.

Path.**iterdir**()

Enumerate the children of the current directory.

Path.**is_dir**()

Return `True` if the current context references a directory.

Path.**is_file**()

Return `True` if the current context references a file.

Path.**exists**()

Return `True` if the current context references a file or directory in the zip file.

Path.**suffix**

The file extension of the final component.

在 3.11 版被加入: 新增*Path.suffix* 特性。

Path.**stem**

The final path component, without its suffix.

在 3.11 版被加入: 新增*Path.stem* 特性。

Path.**suffixes**

A list of the path's file extensions.

在 3.11 版被加入: 新增*Path.suffixes* 特性。

Path.**read_text**(*, **)

Read the current file as unicode text. Positional and keyword arguments are passed through to *io.TextIOWrapper* (except `buffer`, which is implied by the context).

在 3.11.2 版的變更: The `encoding` parameter can be supplied as a positional argument without causing a *TypeError*. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all *io.TextIOWrapper* arguments, `encoding` included, as keywords.

Path.**read_bytes**()

Read the current file as bytes.

Path.**joinpath**(*other*)

Return a new Path object with each of the *other* arguments joined. The following are equivalent:

```
>>> Path(...).joinpath('child').joinpath('grandchild')
>>> Path(...).joinpath('child', 'grandchild')
>>> Path(...) / 'child' / 'grandchild'
```

在 3.10 版的變更: Prior to 3.10, `joinpath` was undocumented and accepted exactly one parameter.

The zipp project provides backports of the latest path object functionality to older Pythons. Use `zipp.Path` in place of `zipfile.Path` for early access to changes.

13.5.3 PyZipFile 物件

The *PyZipFile* constructor takes the same parameters as the *ZipFile* constructor, and one additional parameter, *optimize*.

class zipfile.**PyZipFile**(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *optimize=-1*)

在 3.2 版的變更: 新增 *optimize* 參數。

在 3.4 版的變更: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of *ZipFile* objects:

writepy(*pathname*, *basename=''*, *filterfunc=None*)

Search for files `*.py` and add the corresponding file to the archive.

If the *optimize* parameter to *PyZipFile* was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the *optimize* parameter to *PyZipFile* was `0`, `1` or `2`, only files with that optimization level (see *compile()*) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a *RuntimeError* will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

basename is intended for internal use only.

filterfunc, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in `test` directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
...
>>> zf.writepy('myprog', filterfunc=notests)
```

The *writepy()* method makes archives with file names like this:

```
string.pyc                      # Top level name
test/__init__.pyc               # Package directory
test/testall.pyc                # Module test.testall
test/bogus/__init__.pyc         # Subpackage directory
test/bogus/myfile.pyc           # Submodule test.bogus.myfile
```

在 3.4 版的變更: 新增 *filterfunc* 參數。

在 3.6.2 版的變更: The *pathname* parameter accepts a *path-like object*.

在 3.7 版的變更: Recursion sorts directory entries.

13.5.4 ZipInfo 物件

Instances of the *ZipInfo* class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a *ZipInfo* instance for a filesystem file:

classmethod ZipInfo.**from_file**(*filename*, *arcname=None*, *, *strict_timestamps=True*)

Construct a *ZipInfo* instance for a file on the filesystem, in preparation for adding it to a zip file.

filename should be the path to a file or directory on the filesystem.

If *arcname* is specified, it is used as the name within the archive. If *arcname* is not specified, the name will be the same as *filename*, but with any drive letter and leading path separators removed.

The *strict_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

在 3.6 版被加入.

在 3.6.2 版的變更: The *filename* parameter accepts a *path-like object*.

在 3.8 版的變更: 新增 *strict_timestamps* 僅限關鍵字參數。

Instances have the following methods and attributes:

ZipInfo.**is_dir**()

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

在 3.6 版被加入.

ZipInfo.**filename**

Name of the file in the archive.

ZipInfo.**date_time**

The time and date of the last modification to the archive member. This is a tuple of six values:

Index	Value
0	Year (>= 1980)
1	Month (one-based)
2	Day of month (one-based)
3	Hours (zero-based)
4	Minutes (zero-based)
5	Seconds (zero-based)

備🄵

The ZIP file format does not support timestamps before 1980.

ZipInfo.**compress_type**

Type of compression for the archive member.

ZipInfo.**comment**

Comment for the individual archive member as a *bytes* object.

ZipInfo.**extra**
: Expansion field data. The PKZIP Application Note contains some comments on the internal structure of the data contained in this *bytes* object.

ZipInfo.**create_system**
: System which created ZIP archive.

ZipInfo.**create_version**
: PKZIP version which created ZIP archive.

ZipInfo.**extract_version**
: PKZIP version needed to extract archive.

ZipInfo.**reserved**
: Must be zero.

ZipInfo.**flag_bits**
: ZIP flag bits.

ZipInfo.**volume**
: Volume number of file header.

ZipInfo.**internal_attr**
: Internal attributes.

ZipInfo.**external_attr**
: External file attributes.

ZipInfo.**header_offset**
: Byte offset to the file header.

ZipInfo.**CRC**
: CRC-32 of the uncompressed file.

ZipInfo.**compress_size**
: Size of the compressed data.

ZipInfo.**file_size**
: Size of the uncompressed file.

13.5.5 Command-Line Interface

The *zipfile* module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the *-c* option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the *-e* option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

Command-line options

-l <zipfile>
--list <zipfile>
List files in a zipfile.

-c <zipfile> <source1> ... <sourceN>
--create <zipfile> <source1> ... <sourceN>
Create zipfile from source files.

-e <zipfile> <output_dir>
--extract <zipfile> <output_dir>
Extract zipfile into target directory.

-t <zipfile>
--test <zipfile>
Test whether the zipfile is valid or not.

--metadata-encoding <encoding>
Specify encoding of member names for `-l`, `-e` and `-t`.

在 3.11 版被加入.

13.5.6 Decompression pitfalls

The extraction in zipfile module might fail due to some pitfalls listed below.

From file itself

Decompression may fail due to incorrect password / CRC checksum / ZIP format or unsupported compression method / decryption.

File System limitations

Exceeding limitations on different file systems can cause decompression failed. Such as allowable characters in the directory entries, length of the file name, length of the pathname, size of a single file, and number of files, etc.

Resources limitations

The lack of memory or disk volume would lead to decompression failed. For example, decompression bombs (aka ZIP bomb) apply to zipfile library that can cause disk volume exhaustion.

Interruption

Interruption during the decompression, such as pressing control-C or killing the decompression process may result in incomplete decompression of the archive.

Default behaviors of extraction

Not knowing the default extraction behaviors can cause unexpected decompression results. For example, when extracting the same archive twice, it overwrites files without asking.

13.6 `tarfile` --- 讀取與寫入 tar 封存檔案

原始碼： Lib/tarfile.py

The `tarfile` module makes it possible to read and write tar archives, including those using gzip, bz2 and lzma compression. Use the `zipfile` module to read or write `.zip` files, or the higher-level functions in *shutil*.

Some facts and figures:

- reads and writes `gzip`, `bz2` and `lzma` compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for all variants of the *sparse* extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

在 3.3 版的變更: Added support for `lzma` compression.

在 3.12 版的變更: Archives are extracted using a *filter*, which makes it possible to either limit surprising/dangerous features, or to acknowledge that they are expected and the archive is fully trusted. By default, archives are fully trusted, but this default is deprecated and slated to change in Python 3.14.

`tarfile.`**`open`**(*name=None*, *mode='r'*, *fileobj=None*, *bufsize=10240*, ***kwargs*)

Return a `TarFile` object for the pathname *name*. For detailed information on `TarFile` objects and the keyword arguments that are allowed, see *TarFile 物件*.

mode has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

mode	action
`'r'` 或 `'r:*'`	Open for reading with transparent compression (recommended).
`'r:'`	Open for reading exclusively without compression.
`'r:gz'`	Open for reading with gzip compression.
`'r:bz2'`	Open for reading with bzip2 compression.
`'r:xz'`	Open for reading with lzma compression.
`'x'` 或 `'x:'`	Create a tarfile exclusively without compression. Raise a *FileExistsError* exception if it already exists.
`'x:gz'`	Create a tarfile with gzip compression. Raise a *FileExistsError* exception if it already exists.
`'x:bz2'`	Create a tarfile with bzip2 compression. Raise a *FileExistsError* exception if it already exists.
`'x:xz'`	Create a tarfile with lzma compression. Raise a *FileExistsError* exception if it already exists.
`'a'` 或 `'a:'`	Open for appending with no compression. The file is created if it does not exist.
`'w'` 或 `'w:'`	Open for uncompressed writing.
`'w:gz'`	Open for gzip compressed writing.
`'w:bz2'`	Open for bzip2 compressed writing.
`'w:xz'`	Open for lzma compressed writing.

Note that `'a:gz'`, `'a:bz2'` or `'a:xz'` is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, *ReadError* is raised. Use *mode* `'r'` to avoid this. If a compression method is not supported, *CompressionError* is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes `'w:gz'`, `'x:gz'`, `'w|gz'`, `'w:bz2'`, `'x:bz2'`, `'w|bz2'`, *tarfile.open()* accepts the keyword argument *compresslevel* (default `9`) to specify the compression level of the file.

For modes `'w:xz'` and `'x:xz'`, *tarfile.open()* accepts the keyword argument *preset* to specify the compression level of the file.

For special purposes, there is a second format for *mode*: `'filemode|[compression]'`. *tarfile.open()* will return a *TarFile* object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a *read()* or *write()* method (depending on the *mode*) that works with bytes. *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin.buffer`, a socket *file object* or a tape device. However, such a *TarFile* object is limited in that it does not allow random access, see 範例. The currently possible modes:

Mode	Action
`'r|*'`	Open a *stream* of tar blocks for reading with transparent compression.
`'r|'`	Open a *stream* of uncompressed tar blocks for reading.
`'r|gz'`	Open a gzip compressed *stream* for reading.
`'r|bz2'`	Open a bzip2 compressed *stream* for reading.
`'r|xz'`	Open an lzma compressed *stream* for reading.
`'w|'`	Open an uncompressed *stream* for writing.
`'w|gz'`	Open a gzip compressed *stream* for writing.
`'w|bz2'`	Open a bzip2 compressed *stream* for writing.
`'w|xz'`	Open an lzma compressed *stream* for writing.

在 3.5 版的變更: The `'x'` (exclusive creation) mode was added.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

在 3.12 版的變更: The *compresslevel* keyword argument also works for streams.

class tarfile.**TarFile**

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See *TarFile 物件*.

tarfile.**is_tarfile**(*name*)

Return `True` if *name* is a tar archive file, that the `tarfile` module can read. *name* may be a `str`, file, or file-like object.

在 3.9 版的變更: Support for file and file-like objects.

The `tarfile` module defines the following exceptions:

exception tarfile.**TarError**

Base class for all `tarfile` exceptions.

exception tarfile.**ReadError**

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

exception tarfile.**CompressionError**

Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception tarfile.**StreamError**

Is raised for the limitations that are typical for stream-like `TarFile` objects.

exception tarfile.**ExtractError**

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel`== 2.

exception tarfile.**HeaderError**

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

exception tarfile.**FilterError**

Base class for members *refused* by filters.

tarinfo

Information about the member that the filter refused to extract, as *TarInfo*.

exception tarfile.**AbsolutePathError**

Raised to refuse extracting a member with an absolute path.

exception tarfile.**OutsideDestinationError**

Raised to refuse extracting a member outside the destination directory.

exception tarfile.**SpecialFileError**

Raised to refuse extracting a special file (e.g. a device or pipe).

exception tarfile.**AbsoluteLinkError**

Raised to refuse extracting a symbolic link with an absolute path.

exception tarfile.**LinkOutsideDestinationError**

Raised to refuse extracting a symbolic link pointing outside the destination directory.

The following constants are available at the module level:

tarfile.**ENCODING**
: The default character encoding: `'utf-8'` on Windows, the value returned by *sys.getfilesystemencoding()* otherwise.

tarfile.**REGTYPE**

tarfile.**AREGTYPE**
: A regular file *type*.

tarfile.**LNKTYPE**
: A link (inside tarfile) *type*.

tarfile.**SYMTYPE**
: A symbolic link *type*.

tarfile.**CHRTYPE**
: A character special device *type*.

tarfile.**BLKTYPE**
: A block special device *type*.

tarfile.**DIRTYPE**
: A directory *type*.

tarfile.**FIFOTYPE**
: A FIFO special device *type*.

tarfile.**CONTTYPE**
: A contiguous file *type*.

tarfile.**GNUTYPE_LONGNAME**
: A GNU tar longname *type*.

tarfile.**GNUTYPE_LONGLINK**
: A GNU tar longlink *type*.

tarfile.**GNUTYPE_SPARSE**
: A GNU tar sparse file *type*.

Each of the following constants defines a tar archive format that the *tarfile* module is able to create. See section *Supported tar formats* for details.

tarfile.**USTAR_FORMAT**
: POSIX.1-1988 (ustar) format.

tarfile.**GNU_FORMAT**
: GNU tar format.

tarfile.**PAX_FORMAT**
: POSIX.1-2001 (pax) format.

tarfile.**DEFAULT_FORMAT**
: The default format for creating archives. This is currently *PAX_FORMAT*.

  在 3.8 版的變更: The default format for new archives was changed to *PAX_FORMAT* from *GNU_FORMAT*.

Documentation for tar archive files, including GNU tar extensions.

13.6.1 TarFile 物件

The TarFile object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a TarInfo object, see *TarInfo 物件* for details.

A TarFile object can be used as a context manager in a with statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the 範例 section for a use case.

在 3.2 版被加入: Added support for the context management protocol.

class tarfile.**TarFile**(*name=None*, *mode='r'*, *fileobj=None*, *format=DEFAULT_FORMAT*, *tarinfo=TarInfo*, *dereference=False*, *ignore_zeros=False*, *encoding=ENCODING*, *errors='surrogateescape'*, *pax_headers=None*, *debug=0*, *errorlevel=1*)

All following arguments are optional and can be accessed as instance attributes as well.

name is the pathname of the archive. *name* may be a *path-like object*. It can be omitted if *fileobj* is given. In this case, the file object's name attribute is used if it exists.

mode is either 'r' to read from an existing archive, 'a' to append data to an existing file, 'w' to create a new file overwriting an existing one, or 'x' to create a new file only if it does not already exist.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s mode. *fileobj* will be used from position 0.

備𝔽

fileobj is not closed, when TarFile is closed.

format controls the archive format for writing. It must be one of the constants USTAR_FORMAT, GNU_FORMAT or PAX_FORMAT that are defined at module level. When reading, format will be automatically detected, even if different formats are present in a single archive.

The *tarinfo* argument can be used to replace the default TarInfo class with a different one.

If *dereference* is False, add symbolic and hard links to the archive. If it is True, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore_zeros* is False, treat an empty block as the end of the archive. If it is True, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to sys.stderr.

errorlevel controls how extraction errors are handled, see the corresponding attribute.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section *Unicode issues* for in-depth information.

The *pax_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is `PAX_FORMAT`.

在 3.2 版的變更: Use `'surrogateescape'` as the default for the *errors* argument.

在 3.5 版的變更: The `'x'` (exclusive creation) mode was added.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

classmethod TarFile.**open**(...)

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

TarFile.**getmember**(*name*)

Return a `TarInfo` object for member *name*. If *name* can not be found in the archive, `KeyError` is raised.

備🄵

If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

TarFile.**getmembers**()

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

TarFile.**getnames**()

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

TarFile.**list**(*verbose=True*, *, *members=None*)

Print a table of contents to `sys.stdout`. If *verbose* is `False`, only the names of the members are printed. If it is `True`, output similar to that of **`ls -l`** is produced. If optional *members* is given, it must be a subset of the list returned by `getmembers()`.

在 3.5 版的變更: 新增 *members* 參數。

TarFile.**next**()

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

TarFile.**extractall**(*path='.'*, *members=None*, *, *numeric_owner=False*, *filter=None*)

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric_owner* is `True`, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

The *filter* argument specifies how `members` are modified or rejected before extraction. See *Extraction filters* for details. It is recommended to set this explicitly depending on which *tar* features you need to support.

警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.

Set `filter='data'` to prevent the most dangerous security issues, and read the *Extraction filters* section for details.

在 3.5 版的變更: 新增 *numeric_owner* 參數。

在 3.6 版的變更: The *path* parameter accepts a *path-like object*.

在 3.12 版的變更: 新增 *filter* 參數。

`TarFile.`**`extract`**(*member*, *path=''*, *set_attrs=True*, ***, *numeric_owner=False*, *filter=None*)

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a `TarInfo` object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set_attrs* is false.

The *numeric_owner* and *filter* arguments are the same as for `extractall()`.

備🄵

The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

警告

參🄵`extractall()` 的警告。

Set `filter='data'` to prevent the most dangerous security issues, and read the *Extraction filters* section for details.

在 3.2 版的變更: 增加 *set_attrs* 參數。

在 3.5 版的變更: 新增 *numeric_owner* 參數。

在 3.6 版的變更: The *path* parameter accepts a *path-like object*.

在 3.12 版的變更: 新增 *filter* 參數。

`TarFile.`**`extractfile`**(*member*)

Extract a member from the archive as a file object. *member* may be a filename or a `TarInfo` object. If *member* is a regular file or a link, an `io.BufferedReader` object is returned. For all other existing members, `None` is returned. If *member* does not appear in the archive, `KeyError` is raised.

在 3.3 版的變更: Return an `io.BufferedReader` object.

`TarFile.`**`errorlevel`**`: int`

If *errorlevel* is `0`, errors are ignored when using `TarFile.extract()` and `TarFile.extractall()`. Nevertheless, they appear as error messages in the debug output when *debug* is greater than 0. If `1` (the default), all *fatal* errors are raised as `OSError` or `FilterError` exceptions. If `2`, all *non-fatal* errors are raised as `TarError` exceptions as well.

Some exceptions, e.g. ones caused by wrong argument types or data corruption, are always raised.

Custom *extraction filters* should raise `FilterError` for *fatal* errors and `ExtractError` for *non-fatal* ones.

Note that when an exception is raised, the archive may be partially extracted. It is the user's responsibility to clean up.

`TarFile.`**`extraction_filter`**

在 3.12 版被加入.

The *extraction filter* used as a default for the *filter* argument of `extract()` and `extractall()`.

The attribute may be `None` or a callable. String names are not allowed for this attribute, unlike the *filter* argument to `extract()`.

If `extraction_filter` is `None` (the default), calling an extraction method without a *filter* argument will raise a `DeprecationWarning`, and fall back to the `fully_trusted` filter, whose dangerous behavior matches previous versions of Python.

In Python 3.14+, leaving `extraction_filter=None` will cause extraction methods to use the `data` filter by default.

The attribute may be set on instances or overridden in subclasses. It also is possible to set it on the `TarFile` class itself to set a global default, although, since it affects all uses of *tarfile*, it is best practice to only do so in top-level applications or `site configuration`. To set a global default this way, a filter function needs to be wrapped in `staticmethod()` to prevent injection of a `self` argument.

`TarFile.`**`add`**(*name*, *arcname=None*, *recursive=True*, ***, *filter=None*)

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to `False`. Recursion adds entries in sorted order. If *filter* is given, it should be a function that takes a `TarInfo` object argument and returns the changed `TarInfo` object. If it instead returns `None` the `TarInfo` object will be excluded from the archive. See 範例 for an example.

在 3.2 版的變更: 新增 *filter* 參數。

在 3.7 版的變更: Recursion adds entries in sorted order.

`TarFile.`**`addfile`**(*tarinfo*, *fileobj=None*)

Add the `TarInfo` object *tarinfo* to the archive. If *fileobj* is given, it should be a *binary file*, and `tarinfo.size` bytes are read from it and added to the archive. You can create `TarInfo` objects directly, or by using `gettarinfo()`.

`TarFile.`**`gettarinfo`**(*name=None*, *arcname=None*, *fileobj=None*)

Create a `TarInfo` object from the result of `os.stat()` or equivalent on an existing file. The file is either named by *name*, or specified as a *file object* *fileobj* with a file descriptor. *name* may be a *path-like object*. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s `name` attribute, or the *name* argument. The name should be a text string.

You can modify some of the `TarInfo`'s attributes before you add it using `addfile()`. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as `size` may need modifying. This is the case for objects such as `GzipFile`. The `name` may also be modified, in which case *arcname* could be a dummy string.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

`TarFile.`**`close`**()

Close the `TarFile`. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.`**`pax_headers`**`: dict`

A dictionary containing key-value pairs of pax global headers.

13.6.2 TarInfo 物件

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettarinfo()*.

Modifying the objects returned by *getmember()* or *getmembers()* will affect all subsequent operations on the archive. For cases where this is unwanted, you can use *copy.copy()* or call the *replace()* method to create a modified copy in one step.

Several attributes can be set to `None` to indicate that a piece of metadata is unused or unknown. Different *TarInfo* methods handle `None` differently:

- The *extract()* or *extractall()* methods will ignore the corresponding metadata, leaving it set to a default.
- *addfile()* will fail.
- *list()* will print a placeholder string.

class tarfile.**TarInfo**(*name=''*)

Create a *TarInfo* object.

classmethod TarInfo.**frombuf**(*buf*, *encoding*, *errors*)

Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

classmethod TarInfo.**fromtarfile**(*tarfile*)

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

TarInfo.**tobuf**(*format=DEFAULT_FORMAT*, *encoding=ENCODING*, *errors='surrogateescape'*)

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

在 3.2 版的變更: Use `'surrogateescape'` as the default for the *errors* argument.

A `TarInfo` object has the following public data attributes:

TarInfo.**name**: ***str***

Name of the archive member.

TarInfo.**size**: ***int***

Size in bytes.

TarInfo.**mtime**: ***int*** | ***float***

Time of last modification in seconds since the *epoch*, as in *os.stat_result.st_mtime*.

在 3.12 版的變更: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**mode**: ***int***

Permission bits, as for *os.chmod()*.

在 3.12 版的變更: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**type**

File type. *type* is usually one of these constants: *REGTYPE*, *AREGTYPE*, *LNKTYPE*, *SYMTYPE*, *DIRTYPE*, *FIFOTYPE*, *CONTTYPE*, *CHRTYPE*, *BLKTYPE*, *GNUTYPE_SPARSE*. To determine the type of a *TarInfo* object more conveniently, use the `is*()` methods below.

TarInfo.**linkname**: *str*

Name of the target file name, which is only present in *TarInfo* objects of type *LNKTYPE* and *SYMTYPE*.

For symbolic links (SYMTYPE), the *linkname* is relative to the directory that contains the link. For hard links (LNKTYPE), the *linkname* is relative to the root of the archive.

TarInfo.**uid**: *int*

User ID of the user who originally stored this member.

在 3.12 版的變更: Can be set to None for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**gid**: *int*

Group ID of the user who originally stored this member.

在 3.12 版的變更: Can be set to None for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**uname**: *str*

User name.

在 3.12 版的變更: Can be set to None for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**gname**: *str*

Group name.

在 3.12 版的變更: Can be set to None for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

TarInfo.**chksum**: *int*

Header checksum.

TarInfo.**devmajor**: *int*

Device major number.

TarInfo.**devminor**: *int*

Device minor number.

TarInfo.**offset**: *int*

The tar header starts here.

TarInfo.**offset_data**: *int*

The file's data starts here.

TarInfo.**sparse**

Sparse member information.

TarInfo.**pax_headers**: *dict*

A dictionary containing key-value pairs of an associated pax extended header.

TarInfo.**replace**(*name=...*, *mtime=...*, *mode=...*, *linkname=...*, *uid=...*, *gid=...*, *uname=...*, *gname=...*, *deep=True*)

在 3.12 版被加入.

Return a *new* copy of the TarInfo object with the given attributes changed. For example, to return a TarInfo with the group name set to 'staff', use:

```
new_tarinfo = old_tarinfo.replace(gname='staff')
```

By default, a deep copy is made. If *deep* is false, the copy is shallow, i.e. `pax_headers` and any custom attributes are shared with the original `TarInfo` object.

A *TarInfo* object also provides some convenient query methods:

`TarInfo.`**`isfile`**`()`

Return *True* if the *TarInfo* object is a regular file.

`TarInfo.`**`isreg`**`()`

Same as *isfile()*.

`TarInfo.`**`isdir`**`()`

Return *True* if it is a directory.

`TarInfo.`**`issym`**`()`

Return *True* if it is a symbolic link.

`TarInfo.`**`islnk`**`()`

Return *True* if it is a hard link.

`TarInfo.`**`ischr`**`()`

Return *True* if it is a character device.

`TarInfo.`**`isblk`**`()`

Return *True* if it is a block device.

`TarInfo.`**`isfifo`**`()`

Return *True* if it is a FIFO.

`TarInfo.`**`isdev`**`()`

Return *True* if it is one of character device, block device or FIFO.

13.6.3 Extraction filters

在 3.12 版被加入.

The *tar* format is designed to capture all details of a UNIX-like filesystem, which makes it very powerful. Unfortunately, the features make it easy to create tar files that have unintended -- and possibly malicious -- effects when extracted. For example, extracting a tar file can overwrite arbitrary files in various ways (e.g. by using absolute paths, `..` path components, or symlinks that affect later members).

In most cases, the full functionality is not needed. Therefore, *tarfile* supports extraction filters: a mechanism to limit functionality, and thus mitigate some of the security issues.

也參考

PEP 706
Contains further motivation and rationale behind the design.

The *filter* argument to *TarFile.extract()* or *extractall()* can be:

- the string `'fully_trusted'`: Honor all metadata as specified in the archive. Should be used if the user trusts the archive completely, or implements their own complex verification.
- the string `'tar'`: Honor most *tar*-specific features (i.e. features of UNIX-like filesystems), but block features that are very likely to be surprising or malicious. See *tar_filter()* for details.

- the string `'data'`: Ignore or block most features specific to UNIX-like filesystems. Intended for extracting cross-platform data archives. See *data_filter()* for details.
- `None` (default): Use *TarFile.extraction_filter*.

  If that is also `None` (the default), raise a `DeprecationWarning`, and fall back to the `'fully_trusted'` filter, whose dangerous behavior matches previous versions of Python.

  In Python 3.14, the `'data'` filter will become the default instead. It's possible to switch earlier; see *TarFile.extraction_filter*.
- A callable which will be called for each extracted member with a *TarInfo* describing the member and the destination path to where the archive is extracted (i.e. the same path is used for all members):

```
filter(member: TarInfo, path: str, /) -> TarInfo | None
```

  The callable is called just before each member is extracted, so it can take the current state of the disk into account. It can:

  – return a *TarInfo* object which will be used instead of the metadata in the archive, or

  – return `None`, in which case the member will be skipped, or

  – raise an exception to abort the operation or skip the member, depending on *errorlevel*. Note that when extraction is aborted, *extractall()* may leave the archive partially extracted. It does not attempt to clean up.

Default named filters

The pre-defined, named filters are available as functions, so they can be reused in custom filters:

`tarfile.`**`fully_trusted_filter`**(*member*, *path*)

Return *member* unchanged.

This implements the `'fully_trusted'` filter.

`tarfile.`**`tar_filter`**(*member*, *path*)

Implements the `'tar'` filter.

- Strip leading slashes (`/` and *os.sep*) from filenames.
- *Refuse* to extract files with absolute paths (in case the name is absolute even after stripping slashes, e.g. `C:/foo` on Windows). This raises *AbsolutePathError*.
- *Refuse* to extract files whose absolute path (after following symlinks) would end up outside the destination. This raises *OutsideDestinationError*.
- Clear high mode bits (setuid, setgid, sticky) and group/other write bits (*S_IWGRP* | *S_IWOTH*).

Return the modified `TarInfo` member.

`tarfile.`**`data_filter`**(*member*, *path*)

Implements the `'data'` filter. In addition to what `tar_filter` does:

- *Refuse* to extract links (hard or soft) that link to absolute paths, or ones that link outside the destination.

  This raises *AbsoluteLinkError* or *LinkOutsideDestinationError*.

  Note that such files are refused even on platforms that do not support symbolic links.
- *Refuse* to extract device files (including pipes). This raises *SpecialFileError*.
- For regular files, including hard links:

  - Set the owner read and write permissions (*S_IRUSR* | *S_IWUSR*).
  - Remove the group & other executable permission (*S_IXGRP* | *S_IXOTH*) if the owner doesn't have it (*S_IXUSR*).
- For other files (directories), set `mode` to `None`, so that extraction methods skip applying permission bits.
- Set user and group info (`uid`, `gid`, `uname`, `gname`) to `None`, so that extraction methods skip setting it.

Return the modified `TarInfo` member.

Filter errors

When a filter refuses to extract a file, it will raise an appropriate exception, a subclass of *FilterError*. This will abort the extraction if *TarFile.errorlevel* is 1 or more. With `errorlevel=0` the error will be logged and the member will be skipped, but extraction will continue.

Hints for further verification

Even with `filter='data'`, *tarfile* is not suited for extracting untrusted files without prior inspection. Among other issues, the pre-defined filters do not prevent denial-of-service attacks. Users should do additional checks.

Here is an incomplete list of things to consider:

- Extract to a *new temporary directory* to prevent e.g. exploiting pre-existing links, and to make it easier to clean up after a failed extraction.
- When working with untrusted data, use external (e.g. OS-level) limits on disk, memory and CPU usage.
- Check filenames against an allow-list of characters (to filter out control characters, confusables, foreign path separators, etc.).
- Check that filenames have expected extensions (discouraging files that execute when you "click on them", or extension-less files like Windows special device names).
- Limit the number of extracted files, total size of extracted data, filename length (including symlink length), and size of individual files.
- Check for files that would be shadowed on case-insensitive filesystems.

Also note that:

- Tar files may contain multiple versions of the same file. Later ones are expected to overwrite any earlier ones. This feature is crucial to allow updating tape archives, but can be abused maliciously.
- *tarfile* does not protect against issues with "live" data, e.g. an attacker tinkering with the destination (or source) directory while extraction (or archiving) is in progress.

Supporting older Python versions

Extraction filters were added to Python 3.12, but may be backported to older versions as security updates. To check whether the feature is available, use e.g. `hasattr(tarfile, 'data_filter')` rather than checking the Python version.

The following examples show how to support Python versions with and without the feature. Note that setting `extraction_filter` will affect any subsequent operations.

- Fully trusted archive:

```
my_tarfile.extraction_filter = (lambda member, path: member)
my_tarfile.extractall()
```

- Use the `'data'` filter if available, but revert to Python 3.11 behavior (`'fully_trusted'`) if this feature is not available:

```
my_tarfile.extraction_filter = getattr(tarfile, 'data_filter',
                                       (lambda member, path: member))
my_tarfile.extractall()
```

- Use the `'data'` filter; *fail* if it is not available:

```
my_tarfile.extractall(filter=tarfile.data_filter)
```

or:

```
my_tarfile.extraction_filter = tarfile.data_filter
my_tarfile.extractall()
```

- Use the `'data'` filter; *warn* if it is not available:

```
if hasattr(tarfile, 'data_filter'):
    my_tarfile.extractall(filter='data')
else:
    # remove this when no longer needed
    warn_the_user('Extracting may be unsafe; consider updating Python')
    my_tarfile.extractall()
```

Stateful extraction filter example

While *tarfile*'s extraction methods take a simple *filter* callable, custom filters may be more complex objects with an internal state. It may be useful to write these as context managers, to be used like this:

```
with StatefulFilter() as filter_func:
    tar.extractall(path, filter=filter_func)
```

Such a filter can be written as, for example:

```
class StatefulFilter:
    def __init__(self):
        self.file_count = 0

    def __enter__(self):
        return self

    def __call__(self, member, path):
        self.file_count += 1
        return member

    def __exit__(self, *exc_info):
        print(f'{self.file_count} files extracted')
```

13.6.4 Command-Line Interface

在 3.4 版被加入.

The `tarfile` module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar  spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the `-e` option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar  other-dir/
```

For a list of the files in a tar archive, use the `-l` option:

```
$ python -m tarfile -l monty.tar
```

Command-line options

-l <tarfile>
--list <tarfile>
: List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>
--create <tarfile> <source1> ... <sourceN>
: Create tarfile from source files.

-e <tarfile> [<output_dir>]
--extract <tarfile> [<output_dir>]
: Extract tarfile into the current directory if *output_dir* is not specified.

-t <tarfile>
--test <tarfile>
: Test whether the tarfile is valid or not.

-v, --verbose
: Verbose output.

--filter <filtername>
: Specifies the *filter* for `--extract`. See *Extraction filters* for details. Only string names are accepted (that is, `fully_trusted`, `tar`, and `data`).

13.6.5 范例

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall(filter='data')
tar.close()
```

How to extract a subset of a tar archive with *TarFile.extractall()* using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is ", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in *TarFile.add()*:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
```

(繼續下一頁)

(繼續上一頁)

```
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

13.6.6 Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (`USTAR_FORMAT`). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (`GNU_FORMAT`). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (`PAX_FORMAT`). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. Modern tar implementations, including GNU tar, bsdtar/libarchive and star, fully support extended *pax* features; some old or unmaintained libraries may not, but should treat *pax* archives as if they were in the universally supported *ustar* format. It is the current default format for new archives.

  It extends the existing *ustar* format with extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

13.6.7 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-*ASCII* characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in `tarfile` are controlled by the *encoding* and *errors* keyword arguments of the `TarFile` class.

encoding defines the character encoding to use for the metadata in the archive. The default value is `sys.getfilesystemencoding()` or `'ascii'` as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is `'surrogateescape'` which Python also uses for its file system calls, see *File Names, Command Line Arguments, and Environment Variables*.

For *PAX_FORMAT* archives (the default), *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

CHAPTER 14

檔案格式

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

14.1 csv --- CSV 檔案讀取及寫入

原始碼： Lib/csv.py

所謂的 CSV (Comma Separated Values) 檔案格式是試算表及資料庫中最常見的匯入、匯出檔案格式。在嘗試以 **RFC 4180** 中的標準化方式來描述格式之前，CSV 格式已經使用了許多年。由於缺少一個完善定義的標準，意味著各個不同的應用程式會在資料F生及銷F時有微妙的差F。這些不同之處使得從不同資料來源處理 CSV 檔案時會非常擾人。F管如此，雖然分隔符號和引號字元有所不同，整體的格式非常相似，可以寫個單一模組來高效率的操作這樣的資料，讓程式設計師可以隱藏讀取及寫入資料的細節。

csv 模組實作透過 class 去讀取、寫入 CSV 格式的表格資料。它讓程式設計師可以F出：「以 Excel F首選F寫入該種格式的資料」或是「從 Excel F生的檔案來讀取資料」，且無需知道這是 Excel 所使用的 CSV 格式等精確的細節。程式設計師也可以描述其他應用程式所理解的 CSV 格式或他們自行定義具有特殊意義的 CSV 格式。

csv 模組的*reader* 及*writer* 物件可以讀取及寫入序列。程式設計師也可以透過*DictReader* 及*DictWriter* class（類F）使用 dictionary（字典）讀取及寫入資料。

也參考

PEP 305 - CSV 檔案 API
Python Enhancement Proposal (PEP) 所提出的 Python 附加功能。

14.1.1 模組🄵容

csv 模組定義了以下函式：

csv.**reader**(*csvfile*, *dialect='excel'*, ***fmtparams*)

回傳一個讀取器物件 *(reader object)* 🄵處理在指定的 *csvfile* 中的每一行，csvfile 必須是字串的可🄵代物件 (iterable of strings)，其中每個字串都要是讀取器所定義的 csv 格式，csvfile 通常是個類檔案物件或者 list。如果 *csvfile* 是個檔案物件，則需開🄵時使用 `newline=''`。[1] *dialect* 🄵一個可選填的參數，可以用🄵特定的 CSV dialect（方言）定義一組參數。它可能🄵*Dialect* 的一個子類🄵 (subclass) 的實例或是由 *list_dialects()* 函式回傳的多個字串中的其中之一。另一個可選填的關鍵字引數 *fmtparams* 可以在這個 dialect 中覆寫 (override) 個🄵的格式化參數 (formatting parameter)。關於 dialect 及格式化參數的完整🄵明，請見段落 *Dialect 與格式參數*。

從 CSV 檔案讀取的每一列會回傳🄵一個字串列表。除非格式選項 `QUOTE_NONNUMERIC` 有被指定（在這個情🄵之下，🄵有引號的欄位都會被轉🄵成浮點數），否則不會進行自動資料型🄵轉🄵。

一個簡短的用法範例：

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

csv.**writer**(*csvfile*, *dialect='excel'*, ***fmtparams*)

回傳一個寫入器物件 (writer object)，其負責在給定的類檔案物件 (file-like object) 上將使用者的資料轉🄵🄵分隔字串 (delimited string)。*csvfile* 可以🄵具有 *write()* method 的任何物件。若 *csvfile* 🄵一個檔案物件，它應該使用 `newline=''` 開🄵[1] 。*dialect* 🄵一個可選填的參數，可以用🄵特定的 CSV dialect 定義一組參數。它可能🄵*Dialect* 的一個子類🄵的實例或是由 *list_dialects()* 函式回傳的多個字串中的其中之一。另一個可選填的關鍵字引數 *fmtparams* 可以在這個 dialect 中覆寫個🄵的格式化參數。關於 dialect 及格式化參數的完整🄵明，請見段落 *Dialect 與格式參數*。🄵了更容易與有實作 DB API 的模組互相接合，*None* 值會被寫成空字串。雖然這不是一個可逆的變🄵，這使得 dump （傾印）SQL NULL 資料值到 CSV 檔案上就無需讓 `cursor.fetch*` 呼叫回傳的資料進行預處理 (preprocessing)。其余非字串的資料則會在寫入之前用 *str()* 函式進行字串化 (stringify)。

一個簡短的用法範例：

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                            quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

csv.**register_dialect**(*name*[, *dialect*[, ***fmtparams*]])

將 *dialect* 與 *name* 進行關聯 (associate)。*name* 必須🄵字串。這個 dialect 可以透過傳遞 *Dialect* 的子類🄵進行指定；或是關鍵字引數 *fmtparams*；或是以上兩者皆是，🄵透過關鍵字引數來覆寫 dialect 的參數。關於 dialect 及格式化參數的完整🄵明，請見段落 *Dialect 與格式參數*。

csv.**unregister_dialect**(*name*)

從 dialect 🄵🄵表 (registry) 中，🄵除與 *name* 關聯的 dialect。若 *name* 如果不是🄵🄵的 dialect 名稱，則會🄵生一個 *Error*。

[1] 如果 `newline=''` 🄵有被指定，則嵌入引號中的🄵行符號不會被正確直譯，使用 `\r\n` 行尾 (linending) 的平台會寫入額外的 `\r`。自從 csv 模組有自己 (統一的) 🄵行處理方式，因此指定 `newline=''` 會永遠是安全的。

csv.**get_dialect**(*name*)

回傳一個與 *name* 關聯的 dialect。若 *name* 如果不是🄵🄵的 dialect 名稱，則會🄵生一個*Error*。這個函式會回傳一個 immutable （不可變物件）*Dialect*。

csv.**list_dialects**()

回傳所有已🄵🄵的 dialect 名稱。

csv.**field_size_limit**([*new_limit*])

回傳當前的剖析器 (parser) 允許的最大字串大小。如果 *new_limit* 被給定，則會變成新的最大字串大小。

csv 模組定義了下列的類🄵:

class csv.**DictReader**(*f*, *fieldnames=None*, *restkey=None*, *restval=None*, *dialect='excel'*, **args*, ***kwds*)

建立一個物件，其運作上就像一般的讀取器，但可以將每一列資訊 map （對映）到*dict* 中，可以透過選填的參數 *fieldnames* 設定 key。

參數 *fieldnames* 是一個*sequence*。如果 *fieldnames* 被省略了，檔案 *f* 中第一列的值會被當作欄位標題，且於結果中會被省略。如果 *fieldname* 有提供，它們就會被使用，且第一列會被包含在結果中。不管欄位標題是如何🄵定的，dictionary 都會保留原始的排序。

如果一列資料中的欄位比欄位標題還多，其余的資料及以 *restkey* （預設🄵 `None`）特指的欄位標題會放入列表當中🄵儲存。如果一個非空的 (non-blank) 列中的欄位比欄位標題還少，缺少的值則會填入 *restval* （預設🄵 `None`）的值。

所有其他選填的引數或關鍵字引數皆會傳遞至下層的*reader* 實例。

如果傳遞至 *fieldnames* 的引數是個🄵代器，則會被迫成🄵一個*list*。

在 3.6 版的變更: 回傳的列已成🄵型🄵 `OrderedDict`。

在 3.8 版的變更: 回傳的列已成🄵型🄵*dict*。

一個簡短的用法範例:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
{'first_name': 'John', 'last_name': 'Cleese'}
```

class csv.**DictWriter**(*f*, *fieldnames*, *restval=''*, *extrasaction='raise'*, *dialect='excel'*, **args*, ***kwds*)

建立一個物件，其運作上就像一般的寫入器，但可以將 dictionary map 到輸出的列上。參數 *fieldnames* 是一個鍵值的*sequence* 且可以辨識 dictionary 中傳遞至*writerow()* method 寫入至檔案 *f* 中的值。如果 dictionary 中缺少了 *fieldnames* 的鍵值，則會寫入選填的參數 *restval* 的值。如果傳遞至*writerow()* method 的 dictionary 包含了一個 *fieldnames* 中不存在的鍵值，選填的參數 *extrasaction* 可以指出該執行的動作。如果它被設定🄵 `'raise'`，預設會觸發*ValueError*。如果它被設定🄵 `'ignore'`，dictionary 中額外的值會被忽略。其他選填的引數或關鍵字引數皆會傳遞至下層的*writer* 實例。

請記得這不像類🄵*DictReader*，在類🄵*DictWriter* 中，參數 *fieldnames* 🄵不是選填的。

如果傳遞至 *fieldnames* 的引數是個🄵代器，則會被迫成🄵一個*list*。

一個簡短的用法範例:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

class csv.**Dialect**

類🄵*Dialect* 是一個容器類🄵，其屬性 (attribute) 包含如何處理雙引號、空白、分隔符號等資訊。由於缺少一個嚴謹的 CSV 技術規範，不同的應用程式會🄵出有巧妙不同的 CSV 資料。*Dialect* 實例定義了*reader* 以及*writer* 的實例該如何表示。

所有可用的*Dialect* 名稱會透過*list_dialects()* 回傳，且它們可以透過特定*reader* 及*writer* 類🄵的初始器 (initializer, __init__) 函式進行🄵🄵，就像這樣：

```
import csv

with open('students.csv', 'w', newline='') as csvfile:
    writer = csv.writer(csvfile, dialect='unix')
```

class csv.**excel**

類🄵*excel* 定義了透過 Excel 🄵生的 CSV 檔案的慣用屬性。它被🄵🄵的 dialect 名稱🄵 `'excel'`。

class csv.**excel_tab**

類🄵*excel_tab* 定義了透過 Excel 🄵生🄵以 Tab 作🄵分隔的 CSV 檔案的慣用屬性。它被🄵🄵的 dialect 名稱🄵 `'excel-tab'`。

class csv.**unix_dialect**

類🄵*unix_dialect* 定義了透過 UNIX 系統🄵生的 CSV 檔案的慣用屬性，🄵句話🄵，使用 `'\n'` 作🄵🄵行符號且所有欄位都被引號包覆起來。它被🄵🄵的 dialect 名稱🄵 `'unix'`。

在 3.2 版被加入.

class csv.**Sniffer**

類🄵*Sniffer* 被用來推斷 CSV 檔案的格式。

類🄵*Sniffer* 提供了兩個 method：

sniff(*sample*, *delimiters=None*)

分析給定的 *sample* 且回傳一個*Dialect* 子類🄵，反應出找到的格式參數。如果給定選填的參數 *delimiters*，它會被解釋🄵一個字串且含有可能、有效的分隔字元。

has_header(*sample*)

如果第一列的文字顯示將作🄵一系列的欄位標題，會分析 sample 文字（假定他是 CSV 格式）🄵回傳*True*。檢查每一欄時，會考慮是否滿足兩個關鍵標准其中之一，判斷 sample 是否包含標題：

- 第二列至第 n 列包含數字
- 第二列到第 n 列包含的字串中至少有一個值的長度與該行的假定標題的長度不同。

對第一列之後的二十個列進行🄵樣；如果超過一半的行及列滿足條件，則返回*True*。

> **備🄵**
>
> 此方法是一個粗略的🄵發，可能會🄵生🄵陽性及🄵陰性 (false positives and negatives)。

一個*Sniffer*的使用範例：

```
with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

*csv*模組定義了以下常數：

csv.**QUOTE_ALL**

引導*writer*物件引用所有欄位。

csv.**QUOTE_MINIMAL**

引導*writer*物件只引用包含特殊字元的欄位，例如：分隔符號、引號、或是分行符號的其他字元。

csv.**QUOTE_NONNUMERIC**

引導*writer*物件引用所有非數字的欄位。

引導*reader*物件轉🄵所有非引用的欄位🄵 *float*。

csv.**QUOTE_NONE**

引導*writer*物件不得引用欄位。當前的分隔符號出現在輸出資料時，在他之前的字元是當前的 * 逸出字元 (escape character)*。如果🄵有設定 * 逸出字元 *，若遇到任何字元需要逸出，寫入器則會引發*Error*。

引導*reader*物件不對引號進行特🄵處理。

csv.**QUOTE_NOTNULL**

引導*writer*物件引用所有非 None 的欄位。這與*QUOTE_ALL*相似，除非如果欄位值🄵 None，該欄位則被寫成空（🄵有引號）字串。

引導*reader*物件將空（🄵有引號）欄位直譯 (interpret) 🄵 None，否則會和*QUOTE_ALL*有相同的表現方式。

在 3.12 版被加入.

csv.**QUOTE_STRINGS**

引導*writer*物件永遠在字串的欄位前後放置引號。這與*QUOTE_NONNUMERIC*相似，除非如果欄位值🄵 None，該欄位則被寫成空（🄵有引號）字串。

引導*reader*物件將空（🄵有引號）字串直譯🄵 None，否則會和*QUOTE_ALL*有相同的表現方式。

在 3.12 版被加入.

*csv*模組定義下列例外：

exception csv.**Error**

當偵測到錯誤時，任何函式都可以引發。

14.1.2 Dialect 與格式參數

□了讓指定輸入及輸出紀□的格式更方便，特定的格式化參數會被組成 dialect。一個 dialect 是*Dialect* class 的子類□，其包含多個描述 CSV 檔案格式的多個屬性。當建立*reader* 或*writer* 物件時，程式設計師可以指定一個字串或是一個*Dialect* 的子類□作□ dialect 參數。此外，或是作□替代，在 *dialect* 參數中，程式設計師可以指定個□的格式化參數，其與*Dialect* 類□定義的屬性具有相同的名字。

Dialect 支援下列屬性：

Dialect.**delimiter**

一個單一字元 (one-character) 的字串可已用來分割欄位。預設□ `','`。

Dialect.**doublequote**

控制 *quotechar* 的實例何時出現在欄位之中，□讓它們自己被放在引號之□。當屬性□*True*，字元會是雙引號。若□*False*，在 *quotechar* 之前會先使用 *escapechar* 作□前綴字。預設□*True*。

在輸出時，若 *doublequote* 是*False* 且逸出字元□有被設定，當一個引號在欄位中被發現時，*Error* 會被引發。

Dialect.**escapechar**

一個會被寫入器使用的單一字元的字串，當 *quoting* 設定□*QUOTE_NONE* 時逸出分隔符號；當 *doublequote* 設定□*False* 時逸出引號。在讀取時，逸出字元會移除後面的字元以及任何特殊意義。預設□*None*，表示禁止逸出。

在 3.11 版的變更: *escapechar* □空是不被接受的。

Dialect.**lineterminator**

由*writer* □生被用來分行的字串。預設□ `'\r\n'`。

備□

reader 是 hard-coded 辨□ `'\r'` or `'\n'` 作□行尾 (end-of-line)，□忽略分行符號。未來可能會改變這個行□。

Dialect.**quotechar**

一個單一字元的字串被用於引用包含特殊字元的欄位，像是 *delimiter*、*quotechar* 或是□行字元。預設□ `'"'`。

在 3.11 版的變更: *quotechar* □空是不被允許的。

Dialect.**quoting**

控制 writer 何時□生引號，以及 reader 如何辨識引號。他可以使用任何*QUOTE_* 常數*且預設□*QUOTE_MINIMAL*。

Dialect.**skipinitialspace**

若□*True*，在緊接著分隔符號後的空格會被忽略。預設□*False*。

Dialect.**strict**

若□ `True`，若有錯誤的 CSV 輸入則會引發*Error*。預設□ `False`。

14.1.3 讀取器物件

讀取器物件（*reader()* 函式回傳的*DictReader* 實例與物件）有下列公用方法 (public method)：

csvreader.**__next__**()

回傳一個列表F讀入器的可F代物件的下一列F容（若該物件是由*reader()* 回傳）或是一個 dict（若F*DictReader* 實例），會依據當前的*Dialect* 進行剖析。通常會用 `next(reader)` 來進行呼叫。

讀取器物件有下列公用屬性 (public attributes)：

csvreader.**dialect**

dialect 的唯讀F述，會被剖析器使用。

csvreader.**line_num**

來源F代器所讀取的行數。這與回傳的紀F數不同，因F可以進行跨行紀F。

DictReader 物件有下列公用屬性：

DictReader.**fieldnames**

若在建立物件時F有作F參數傳遞，這個屬性會在第一次存取之前或是第一筆資料被讀取之前進行初始化 (initialize)。

14.1.4 寫入器物件

writer 物件（*writer()* 函式回傳的*DictWriter* 實例與物件）有下列公用方法。對於*writer* 物件而言，一個列中必須F一個可F代的字串或是數字；對於*DictWriter* 物件而言，則必須F一個 dictionary，且可以對應欄位標題至字串或數字（會先透過*str()* 進行傳遞）。請注意，在寫入F數 (complex number) 時會用小括號 (parens) 包起來。這可能在其他程式讀取 CSV 檔案時導致某些問題（假設他們完全支援F雜數字）。

csvwriter.**writerow**(*row*)

將參數 *row* 寫入至寫入器的檔案物件中，F依照當前的*Dialect* 進行格式化。回傳下層檔案物件 *write* 方法的回傳值。

在 3.5 版的變更: 新增對任意可F代物件 (arbitrary iterables) 的支援。

csvwriter.**writerows**(*rows*)

將 *rows* 中所有元素（F上述的一個可F代的 *row* 物件）寫入至寫入器的檔案物件中，F依照當前的 dialect 進行格式化。

寫入器物件有下列公用屬性：

csvwriter.**dialect**

dialect 的唯讀F述，會被寫入器使用。

DictWriter 物件有下列公用方法：

DictWriter.**writeheader**()

將具欄位標題的一列（於建構函式 (constructor) 中指定的）寫入至寫入器的檔案物件中，F依照當前的 dialect 進行格式化。回傳F部呼叫*csvwriter.writerow()* 的回傳值。

在 3.2 版被加入.

在 3.8 版的變更: *writeheader()* 現在也會回傳F部呼叫*csvwriter.writerow()* 的回傳值。

14.1.5 范例

最簡單的讀取 CSV 檔案範例：

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

讀取一個其他格式的檔案：

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

相對最簡單、可行的寫入範例🄵：

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

當*open()* 被使用於開🄵🄵讀取一個 CSV 檔案，該檔案會預設使用系統預設的編碼格式（請見*locale.getencoding()*），🄵解碼🄵 unicode。若要使用不同編碼格式進行檔案解碼，請使用 open 函式的 `encoding` 引數：

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

同理可以應用到使用不同編碼格式進行寫入：當開🄵輸出檔案時，指定 `encoding` 引數。

🄵🄵一個新的 dialect：

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

稍微進階的讀取器用法 -- 🄵取及回報錯誤：

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print(row)
    except csv.Error as e:
        sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

而當模組無法直接支援剖析字串時，仍可以輕松的解🄵：

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

🄵解

14.2 configparser --- 設定檔剖析器

原始碼： Lib/configparser.py

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

備🄵

This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

也參考

***tomllib* 模組**
TOML is a well-specified format for application configuration files. It is specifically designed to be an improved version of INI.

***shlex* 模組**
Support for creating Unix shell-like mini-languages which can also be used for application configuration files.

***json* 模組**
The `json` module implements a subset of JavaScript syntax which is sometimes used for configuration, but does not support comments.

14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[forge.example]
User = hg

[topsecret.server.example]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. `configparser` classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                      'Compression': 'yes',
...                      'CompressionLevel': '9'}
>>> config['forge.example'] = {}
>>> config['forge.example']['User'] = 'hg'
>>> config['topsecret.server.example'] = {}
>>> topsecret = config['topsecret.server.example']
>>> topsecret['Port'] = '50022'     # mutates the parser
>>> topsecret['ForwardX11'] = 'no'  # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...   config.write(configfile)
...
```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['forge.example', 'topsecret.server.example']
>>> 'forge.example' in config
True
>>> 'python.org' in config
False
>>> config['forge.example']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.example']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['forge.example']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['forge.example']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default values for all other sections[1]. Note also that keys in sections are case-insensitive and stored in lowercase[1].

[1] Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the

It is possible to read several configurations into a single *ConfigParser*, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1
```

```
>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

This behaviour is equivalent to a *ConfigParser.read()* call with several files passed to the *filenames* parameter.

14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide *getboolean()*. This method is case-insensitive and recognizes Boolean values from `'yes'`/`'no'`, `'on'`/`'off'`, `'true'`/`'false'` and `'1'`/`'0'`[Page 630, 1]. For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['forge.example'].getboolean('ForwardX11')
True
>>> config.getboolean('forge.example', 'Compression')
True
```

Apart from *getboolean()*, config parsers also provide equivalent *getint()* and *getfloat()* methods. You can register your own converters and customize the provided ones.[Page 630, 1]

Customizing Parser Behaviour section.

14.2.3 Fallback Values

As with a dictionary, you can use a section's *get()* method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the `'CompressionLevel'` key was specified only in the `'DEFAULT'` section. If we try to get it from the section `'topsecret.server.example'`, we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level *get()* method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('forge.example', 'monster',
...            fallback='No such things as monsters')
'No such things as monsters'
```

The same `fallback` argument can be used with the *getint()*, *getfloat()* and *getboolean()* methods, for example:

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (= or `:` by default[Page 630, 1]). By default, section names are case sensitive but keys are not[Page 630, 1]. Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it[Page 630, 1], in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

By default, a valid section name can be any string that does not contain '\n'. To change this, see *ConfigParser.SECTCRE*.

Configuration files may include comments, prefixed by specific characters (`#` and `;` by default[Page 630, 1]). Comments may appear on their own on an otherwise empty line, possibly indented.[Page 630, 1]

For example:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
    I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.

    [Sections Can Be Indented]
        can_values_be_as_well = True
        does_that_mean_anything_special = False
        purpose = formatting for readability
        multiline_values = are
            handled just fine as
            long as they are indented
            deeper than the first line
            of a value
        # Did I mention we can indent comments, too?
```

14.2.5 Interpolation of values

On top of the core functionality, *ConfigParser* supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

class configparser.**BasicInterpolation**

The default implementation used by *ConfigParser*. It enables values to contain format strings which refer to other values in the same section, or values in the special default section[Page 630, 1]. Additional default values can be provided on initialization.

For example:

```
[Paths]
home_dir: /Users
```

(繼續下一頁)

(繼續上一頁)

```
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures

[Escape]
# use a %% to escape the % sign (% is the only character that needs to be␣
↪escaped):
gain: 80%%
```

In the example above, *ConfigParser* with *interpolation* set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With `interpolation` set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

class configparser.**ExtendedInterpolation**

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures

[Escape]
# use a $$ to escape the $ sign ($ is the only character that needs to be␣
↪escaped):
cost: $$80
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

14.2.6 Mapping Protocol Access

在 3.2 版被加入.

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of *configparser*, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

configparser objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner[Page 630, 1]. E.g. `for option in parser["section"]` yields only `optionxform`'ed option key names. This means lowercased keys by default. At the same time, for a section that holds the key `'a'`, both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a *KeyError*.
- `DEFAULTSECT` cannot be removed from the parser:
  - trying to delete it raises *ValueError*,
  - `parser.clear()` leaves it intact,
  - `parser.popitem()` never returns it.
- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic configparser API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section_name*, *section_proxy* pairs including the DEFAULTSECT). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option*, *value* pairs for a specified `section`, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

14.2.7 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. *configparser* goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

  This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

Hint: if you want to specify default values for a specific section, use *read_dict()* before you read the actual file.

- *dict_type*, default value: *dict*

  This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the standard dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

  An alternative dictionary type can be used for example to sort sections and options on write-back.

  Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys will be ordered. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                                'key2': 'value2',
...                                'key3': 'value3'},
...                   'section2': {'keyA': 'valueA',
...                                'keyB': 'valueB',
...                                'keyC': 'valueC'},
...                   'section3': {'foo': 'x',
...                                'bar': 'y',
...                                'baz': 'z'}
... })
>>> parser.sections()
['section1', 'section2', 'section3']
>>> [option for option in parser['section3']]
['foo', 'bar', 'baz']
```

- *allow_no_value*, default value: `False`

  Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by *configparser*. The *allow_no_value* parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser

>>> sample_config = """
... [mysqld]
...   user = mysql
...   pid-file = /var/run/mysqld/mysqld.pid
...   skip-external-locking
...   old_passwords = 1
...   skip-bdb
...   # we don't need ACID today
...   skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
```

(繼續下一頁)

(繼續上一頁)

```
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
  ...
KeyError: 'does-not-exist'
```

- *delimiters*, default value: `('=', ':')`

  Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

  See also the *space_around_delimiters* argument to *ConfigParser.write()*.

- *comment_prefixes*, default value: `('#', ';')`

- *inline_comment_prefixes*, default value: `None`

  Comment prefixes are strings that indicate the start of a valid comment within a config file. *comment_prefixes* are used only on otherwise empty lines (optionally indented) whereas *inline_comment_prefixes* can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and `'#'` and `';'` are used as prefixes for whole line comments.

  在 3.2 版的變更: In previous versions of *configparser* behaviour matched `comment_prefixes=('#',';')` and `inline_comment_prefixes=(';',)`.

  Please note that config parsers don't support escaping of comment prefixes so using *inline_comment_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline_comment_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...
... [hashes]
... shebang =
...   ${hash}!/usr/bin/env python
...   ${hash} -*- coding: utf-8 -*-
...
... extensions =
...   enabled_extension
...   another_extension
...   #disabled_by_comment
...   yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...   line #2
...   line #3
... """)
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])
```

(繼續下一頁)

(繼續上一頁)

```
enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3
```

- *strict*, default value: `True`

  When set to `True`, the parser will not allow for any section or option duplicates while reading from a single source (using *read_file()*, *read_string()* or *read_dict()*). It is recommended to use strict parsers in new applications.

  在 3.2 版的變更: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty_lines_in_values*, default value: `True`

  In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```
[Section]
key = multiline
  value with a gotcha

 this = is still a part of the multiline value of 'key'
```

  This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default_section*, default value: `configparser.DEFAULTSECT` (that is: `"DEFAULT"`)

  The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called `"DEFAULT"` but this can be customized to point to any other valid section name. Some typical values include: `"general"` or `"common"`. The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value: `configparser.BasicInterpolation`

  Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*. *RawConfigParser* has a default value of `None`.

- *converters*, default value: not set

  Config parsers provide option value getters that perform type conversion. By default *getint()*, *getfloat()*, and *getboolean()* are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add

`getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

`ConfigParser.`**`BOOLEAN_STATES`**

By default when using *`getboolean()`*, config parsers consider the following values `True`: `'1'`, `'yes'`, `'true'`, `'on'` and the following values `False`: `'0'`, `'no'`, `'false'`, `'off'`. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include `accept`/`reject` or `enabled`/`disabled`.

`ConfigParser.`**`optionxform`**(*option*)

This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']
```

備🄵

The optionxform function transforms option names to a canonical form. This should be an idempotent function:

if the name is already in canonical form, it should be returned unchanged.

`ConfigParser.`**`SECTCRE`**

A compiled regular expression used to parse section headers. The default matches `[section]` to the name `"section"`. Whitespace is considered part of the section name, thus `[ larch ]` will be read as a section of name `" larch "`. Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [  Section 2  ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', '  Section 2  ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

備🄵

While ConfigParser objects also use an `OPTCRE` attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options *allow_no_value* and *delimiters*.

14.2.8 Legacy API Examples

Mainly because of backwards compatibility concerns, *configparser* provides also a legacy API with explicit `get`/`set` methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-raw mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
```

(繼續下一頁)

(繼續上一頁)

```
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use *ConfigParser*:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False))  # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))   # -> "%(bar)s is %(baz)s!"

# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a fallback value
print(cfg.get('Section1', 'foo'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
      # -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
      # -> None
```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```
import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is hard!"
```

14.2.9 ConfigParser 物件

class configparser.**ConfigParser**(*defaults=None*, *dict_type=dict*, *allow_no_value=False*, *delimiters=('=', ':')*, *comment_prefixes=('#', ';')*, *inline_comment_prefixes=None*, *strict=True*, *empty_lines_in_values=True*, *default_section=configparser.DEFAULTSECT*, *interpolation=BasicInterpolation()*, *converters={}*)

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline_comment_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is `True` (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*. When *empty_lines_in_values* is `False` (default: `True`), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow_no_value* is `True` (default: `False`), options without values are accepted; the value held for these is `None` and they are serialized without the trailing delimiter.

When *default_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named `"DEFAULT"`). This value can be retrieved and changed at runtime using the `default_section` instance attribute. This won't re-evaluate an already parsed config file, but will be used when writing parsed settings to a new config file.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*.

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. For example, using the default implementation of *optionxform()* (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding `get*()` method on the parser object and section proxies.

It is possible to read several configurations into a single *ConfigParser*, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the

previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1
```

```
>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

在 3.1 版的變更: The default *dict_type* is *collections.OrderedDict*.

在 3.2 版的變更: *allow_no_value*, *delimiters*, *comment_prefixes*, *strict*, *empty_lines_in_values*, *default_section* and *interpolation* were added.

在 3.5 版的變更: 新增 *converters* 引數。

在 3.7 版的變更: The *defaults* argument is read with *read_dict()*, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

在 3.8 版的變更: The default *dict_type* is *dict*, since it now preserves insertion order.

defaults()

Return a dictionary containing the instance-wide defaults.

sections()

Return a list of the sections available; the *default section* is not included in the list.

add_section(*section*)

Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised. The name of the section must be a string; if not, *TypeError* is raised.

在 3.2 版的變更: Non-string section names raise *TypeError*.

has_section(*section*)

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

options(*section*)

Return a list of options available in the specified *section*.

has_option(*section*, *option*)

If the given *section* exists, and contains the given *option*, return *True*; otherwise return *False*. If the specified *section* is *None* or an empty string, DEFAULT is assumed.

read(*filenames*, *encoding=None*)

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string, a *bytes* object or a *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the *ConfigParser* instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using *read_file()* before calling *read()* for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

在 3.2 版的變更: Added the *encoding* parameter. Previously, all files were read using the default encoding for *open()*.

在 3.6.1 版的變更: The *filenames* parameter accepts a *path-like object*.

在 3.7 版的變更: The *filenames* parameter accepts a *bytes* object.

read_file(*f*, *source=None*)

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a `name` attribute, that is used for *source*; the default is `'<???>'`.

在 3.2 版被加入: 取代 `readfp()`。

read_string(*string*, *source='<string>'*)

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, `'<string>'` is used. This should commonly be a filesystem path or a URL.

在 3.2 版被加入.

read_dict(*dictionary*, *source='<dict>'*)

Load configuration from any object that provides a dict-like `items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is used.

This method can be used to copy state between parsers.

在 3.2 版被加入.

get(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *DEFAULTSECT* in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. `None` can be provided as a *fallback* value.

All the `'%'` interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

在 3.2 版的變更: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

getint(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to an integer. See *get()* for explanation of *raw*, *vars* and *fallback*.

getfloat(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a floating-point number. See `get()` for explanation of *raw*, *vars* and *fallback*.

getboolean(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are `'1'`, `'yes'`, `'true'`, and `'on'`, which cause this method to return `True`, and `'0'`, `'no'`, `'false'`, and `'off'`, which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise `ValueError`. See `get()` for explanation of *raw*, *vars* and *fallback*.

items(*raw=False*, *vars=None*)

items(*section*, *raw=False*, *vars=None*)

When *section* is not given, return a list of *section_name*, *section_proxy* pairs, including DEFAULTSECT.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the `get()` method.

在 3.8 版的變更: Items present in *vars* no longer appear in the result. The previous behaviour mixed actual parser options with variables provided for interpolation.

set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. *option* and *value* must be strings; if not, `TypeError` is raised.

write(*fileobject*, *space_around_delimiters=True*)

Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future `read()` call. If *space_around_delimiters* is true, delimiters between keys and values are surrounded by spaces.

> **備🄵**
>
> Comments in the original configuration file are not preserved when writing the configuration back. What is considered a comment, depends on the given values for *comment_prefix* and *inline_comment_prefix*.

remove_option(*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise `NoSectionError`. If the option existed to be removed, return `True`; otherwise return `False`.

remove_section(*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

optionxform(*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before `optionxform()` is called.

configparser.**MAX_INTERPOLATION_DEPTH**

The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

14.2.10 RawConfigParser 物件

class configparser.**RawConfigParser**(*defaults=None*, *dict_type=dict*, *allow_no_value=False*, ***, *delimiters=('=', ':')*, *comment_prefixes=('#', ';')*, *inline_comment_prefixes=None*, *strict=True*, *empty_lines_in_values=True*, *default_section=configparser.DEFAULTSECT*[, *interpolation*])

Legacy variant of the `ConfigParser`. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

在 3.8 版的變更: The default *dict_type* is `dict`, since it now preserves insertion order.

備🄵

Consider using `ConfigParser` instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

add_section(*section*)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

14.2.11 例外

exception configparser.**Error**

Base class for all other `configparser` exceptions.

exception configparser.**NoSectionError**

Exception raised when a specified section is not found.

exception configparser.**DuplicateSectionError**

Exception raised if *add_section()* is called with the name of a section that is already present or in strict parsers when a section if found more than once in a single input file, string or dictionary.

在 3.2 版的變更: Added the optional *source* and *lineno* attributes and parameters to `__init__()`.

exception configparser.**DuplicateOptionError**

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

exception configparser.**NoOptionError**

Exception raised when a specified option is not found in the specified section.

exception configparser.**InterpolationError**

Base class for exceptions raised when problems occur performing string interpolation.

exception configparser.**InterpolationDepthError**

Exception raised when string interpolation cannot be completed because the number of iterations exceeds *MAX_INTERPOLATION_DEPTH*. Subclass of *InterpolationError*.

exception configparser.**InterpolationMissingOptionError**

Exception raised when an option referenced from a value does not exist. Subclass of *InterpolationError*.

exception configparser.**InterpolationSyntaxError**

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of *InterpolationError*.

exception configparser.**MissingSectionHeaderError**

Exception raised when attempting to parse a file which has no section headers.

exception configparser.**ParsingError**

Exception raised when errors occur attempting to parse a file.

在 3.12 版的變更: The `filename` attribute and `__init__()` constructor argument were removed. They have been available using the name `source` since 3.2.

🄵解

14.3 tomllib --- 剖析 TOML 檔案

在 3.11 版被加入.

原始碼： Lib/tomllib

此模組提供了剖析 TOML (Tom's Obvious Minimal Language, https://toml.io) 的一個介面，此模組🄵不支援寫入 TOML。

也參考

Tomli-W 套件是一個 TOML 編寫器，可以與此模組結合使用，以提供標准函式庫中*marshal* 和*pickle* 模組之使用者所熟悉的寫入 API。

也參考

TOML 工具套件是一個保留風格且具有讀寫能力的 TOML 函式庫。若要編輯已存在的 TOML 文件，建議用它來替🄴此模組。

此模組定義了以下函式：

`tomllib.`**`load`**(*fp*, */*, *, *parse_float=float*)

讀取一個 TOML 檔案。第一個引數應🄵一個可讀取的二進位檔案物件。回傳一個*dict*。用這個轉🄵表將 TOML 型🄵轉🄵成 Python 的。

parse_float 會被呼叫於要解碼的每個 TOML 浮點數字串。預設情🄵下，這相當於 `float(num_str)`。若有使用另一種資料型🄴或剖析器的 TOML 浮點數（例如*decimal.Decimal*），這就派得上用場。可呼叫物件不得回傳*dict* 或*list*，否則會引發*ValueError*。

不合格的 TOML 文件會使得*TOMLDecodeError* 被引發。

`tomllib.`**`loads`**(*s*, */*, *, *parse_float=float*)

自一個*str* 物件載入成 TOML。回傳一個*dict*。用這個轉🄵表轉🄵 TOML 型🄵成 Python 的。*parse_float* 引數和*load()* 中的相同。

不合格的 TOML 文件會使得*TOMLDecodeError* 被引發。

以下🄵可用的例外：

exception `tomllib.`**`TOMLDecodeError`**

ValueError 的子類🄵。

14.3.1 范例

剖析一個 TOML 檔案：

```
import tomllib

with open("pyproject.toml", "rb") as f:
    data = tomllib.load(f)
```

剖析一個 TOML 字串：

```
import tomllib

toml_str = """
python-version = "3.11.0"
python-implementation = "CPython"
"""

data = tomllib.loads(toml_str)
```

14.3.2 轉🄵表

TOML	Python
TOML 文件	dict
string	str
integer	int
float	float（可透過 *parse_float* 調整）
boolean	bool
偏移日期時間 (offset date-time)	datetime.datetime（設定 `tzinfo` 屬性🄵 `datetime.timezone` 的實例）
本地日期時間 (local date-time)	datetime.datetime（設定 `tzinfo` 🄵 `None`）
本地日期 (local date)	datetime.date
本地時間 (local time)	datetime.time
array	list
table	dict
行🄵表格 (inline table)	dict
表格陣列 (array of tables)	dict 串列 (list of dicts)

14.4 `netrc` --- netrc 檔案處理

原始碼： Lib/netrc.py

---

netrc 類🄵能🄵剖析 (parse) 🄵封裝 (encapsulate) netrc 檔案格式，以供 Unix **ftp** 程式和其他 FTP 用🄵端使用。

class netrc.**netrc**([*file*])

netrc 實例或其子類🄵實例能🄵封裝來自 netrc 檔案的資料。可用初始化引數（如有給定）指定要剖析的檔案，如果未給定引數，則將讀取（由*os.path.expanduser()* 指定的）使用者主目🄵中的 `.netrc` 檔案，否則將引發*FileNotFoundError* 例外。剖析錯誤會引發*NetrcParseError*，其帶有包括檔案名稱、列號和終止 token 的診斷資訊。如果在 POSIX 系統上未指定引數，且若檔案所有權或權限不安全（擁有者與運行該行程的使用者不同，或者可供任何其他使用者讀取或寫入），存有密碼的 `.netrc` 檔案將會引發*NetrcParseError*。這實作了與 ftp 和其他使用 `.netrc` 程式等效的安全行🄵。

在 3.4 版的變更: 新增了 POSIX 權限檢查。

在 3.7 版的變更: 當未傳遞 *file* 引數時，*os.path.expanduser()* 可用於查找 `.netrc` 檔案的位置。

在 3.10 版的變更: *netrc* 在使用特定語言環境編碼前會先嘗試 UTF-8 編碼。netrc 檔案中的條目就不再需要包含所有 token，缺少的 token 值被預設🄵空字串。現在所有 token 及其值都可以包含任意字元，例如空格和非 ASCII 字元。如果登入名稱🄵匿名，就不會觸發安全檢查。

exception netrc.**NetrcParseError**

當原始文本中遇到語法錯誤時，*netrc* 類🄵會引發例外。此例外的實例提供了三個有趣的屬性:

msg

錯誤的文字解釋。

filename

原始檔案的名稱。

lineno

發現錯誤的列號。

14.4.1 netrc 物件

netrc 實例具有以下方法：

netrc.**authenticators**(*host*)

回傳 *host* 身份驗證器的三元素 tuple (login, account, password)。如果 netrc 檔案不包含給定主機的條目，則回傳與'default' 條目關聯的 tuple。如果🄵無匹配主機且預設條目也不可用則回傳 None。

netrc.**__repr__**()

將類🄵資料傾印 (dump) 🄵 netrc 檔案格式的字串。（這會將🄵解移除，🄵可能會對條目重新排序。）

netrc 的實例具有公開實例變數：

netrc.**hosts**

將主機名稱對映到 (login, account, password) tuple 的字典。'default' 條目（如存在）表示🄵該名稱對應到的🄵主機 (pseudo-host)。

netrc.**macros**

巨集 (macro) 名稱與字串 list（串列）的對映字典。

14.5 plistlib --- 🄵生和剖析 Apple .plist 檔案

原始碼： Lib/plistlib.py

This module provides an interface for reading and writing the "property list" files used by Apple, primarily on macOS and iOS. This module supports both binary and XML plist files.

The property list (.plist) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the *dump()* and *load()* functions.

To work with plist data in bytes objects, use *dumps()* and *loads()*.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), *bytes*, *bytearray* or *datetime.datetime* objects.

在 3.4 版的變更: New API, old API deprecated. Support for binary format plists added.

在 3.8 版的變更: Support added for reading and writing *UID* tokens in binary plists as used by NSKeyedArchiver and NSKeyedUnarchiver.

在 3.9 版的變更: Old API removed.

也參考

PList manual page
Apple's documentation of the file format.

This module defines the following functions:

plistlib.**load**(*fp*, *, *fmt=None*, *dict_type=dict*)

Read a plist file. *fp* should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The *fmt* is the format of the file and the following values are valid:

- *None*: Autodetect the file format
- *FMT_XML*: XML file format
- *FMT_BINARY*: Binary plist format

The *dict_type* is the type used for dictionaries that are read from the plist file.

XML data for the *FMT_XML* format is parsed using the Expat parser from *xml.parsers.expat* -- see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises `InvalidFileException` when the file cannot be parsed.

在 3.4 版被加入.

`plistlib.`**`loads`**(*data*, *, *fmt=None*, *dict_type=dict*)

Load a plist from a bytes object. See *load()* for an explanation of the keyword arguments.

在 3.4 版被加入.

`plistlib.`**`dump`**(*value*, *fp*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*)

Write *value* to a plist file. *Fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- *FMT_XML*: XML formatted plist file
- *FMT_BINARY*: Binary formatted plist file

When *sort_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises *TypeError* when a key of a dictionary is not a string, otherwise such keys are skipped.

A *TypeError* will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An *OverflowError* will be raised for integer values that cannot be represented in (binary) plist files.

在 3.4 版被加入.

`plistlib.`**`dumps`**(*value*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*)

Return *value* as a plist-formatted bytes object. See the documentation for *dump()* for an explanation of the keyword arguments of this function.

在 3.4 版被加入.

The following classes are available:

`class` `plistlib.`**`UID`**(*data*)

Wraps an *int*. This is used when reading or writing NSKeyedArchiver encoded data, which contains UID (see PList manual).

It has one attribute, `data`, which can be used to retrieve the int value of the UID. `data` must be in the range `0 <= data < 2**64`.

在 3.8 版被加入.

The following constants are available:

`plistlib.`**`FMT_XML`**

The XML format for plist files.

在 3.4 版被加入.

plistlib.**FMT_BINARY**

The binary format for plist files

在 3.4 版被加入.

14.5.1 范例

Generating a plist:

```
import datetime
import plistlib

pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.now()
)
print(plistlib.dumps(pl).decode())
```

Parsing a plist:

```
import plistlib

plist = b"""<plist version="1.0">
<dict>
    <key>foo</key>
    <string>bar</string>
</dict>
</plist>"""
pl = plistlib.loads(plist)
print(pl["foo"])
```

CHAPTER 15

加密服務

本章所描述的模組 (module) 實作了多種加密演算法。它們可以在安裝時選擇是否一同安裝。在 Unix 系統上，`crypt` 模組也有機會能🄵被使用。以下🄵概述：

15.1 `hashlib` --- 安全雜🄵與訊息摘要

原始碼： Lib/hashlib.py

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, SHA512, (defined in the FIPS 180-4 standard), the SHA-3 series (defined in the FIPS 202 standard) as well as RSA's MD5 algorithm (defined in internet **RFC 1321**). The terms "secure hash" and "message digest" are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

備🄵

If you want the adler32 or crc32 hash functions, they are available in the `zlib` module.

15.1.1 雜🄵演算法

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally `bytes`) using the `update` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

To allow multithreading, the Python *GIL* is released while computing a hash supplied more than 2047 bytes of data at once in its constructor or `.update` method.

Constructors for hash algorithms that are always present in this module are *sha1()*, *sha224()*, *sha256()*, *sha384()*, *sha512()*, *sha3_224()*, *sha3_256()*, *sha3_384()*, *sha3_512()*, *shake_128()*, *shake_256()*, *blake2b()*, and *blake2s()*. *md5()* is normally available as well, though it may be missing or blocked if you are using a rare "FIPS compliant" build of Python. These correspond to *algorithms_guaranteed*.

Additional algorithms may also be available if your Python distribution's *hashlib* was linked against a build of OpenSSL that provides others. Others *are not guaranteed available* on all installations and will only be accessible by name via *new()*. See *algorithms_available*.

警告

Some algorithms have known hash collision weaknesses (including MD5 and SHA1). Refer to Attacks on cryptographic hash algorithms and the *hashlib-seealso* section at the end of this document.

在 3.6 版被加入: SHA3 (Keccak) and SHAKE constructors *sha3_224()*, *sha3_256()*, *sha3_384()*, *sha3_512()*, *shake_128()*, *shake_256()* were added. *blake2b()* and *blake2s()* were added. 在 3.9 版的變更: All hashlib constructors take a keyword-only argument *usedforsecurity* with default value `True`. A false value allows the use of insecure and blocked hashing algorithms in restricted environments. `False` indicates that the hashing algorithm is not used in a security context, e.g. as a non-cryptographic one-way compression function.

在 3.9 版的變更: Hashlib now uses SHA3 and SHAKE from OpenSSL if it provides it.

在 3.12 版的變更: For any of the MD5, SHA1, SHA2, or SHA3 algorithms that the linked OpenSSL does not provide we fall back to a verified implementation from the HACL* project.

15.1.2 用法

To obtain the digest of the byte string `b"Nobody inspects the spammish repetition"`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd}Ae\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\xf7\xbcN\x84:\xa6\xaf\x0c\x95\
↪x0fK\x94\x06'
>>> m.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

More condensed:

```
>>> hashlib.sha256(b"Nobody inspects the spammish repetition").hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

15.1.3 建構函式

hashlib.**new**(*name*, [*data*,]*, *usedforsecurity=True*)

Is a generic constructor that takes the string *name* of the desired algorithm as its first parameter. It also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer.

Using *new()* with an algorithm name:

```
>>> h = hashlib.new('sha256')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

hashlib.**md5**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha1**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha224**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha256**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha384**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha512**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_224**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_256**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_384**([*data*,]*, *usedforsecurity=True*)

hashlib.**sha3_512**([*data*,]*, *usedforsecurity=True*)

Named constructors such as these are faster than passing an algorithm name to *new()*.

15.1.4 Attributes

Hashlib provides the following constant module attributes:

hashlib.**algorithms_guaranteed**

A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms. Note that 'md5' is in this list despite some upstream vendors offering an odd "FIPS compliant" Python build that excludes it.

在 3.2 版被加入.

hashlib.**algorithms_available**

A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to *new()*. *algorithms_guaranteed* will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

在 3.2 版被加入.

15.1.5 Hash Objects

The following values are provided as constant attributes of the hash objects returned by the constructors:

`hash.`**`digest_size`**

The size of the resulting hash in bytes.

`hash.`**`block_size`**

The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

`hash.`**`name`**

The canonical name of this hash, always lowercase and always suitable as a parameter to *`new()`* to create another hash of this type.

在 3.4 版的變更: The name attribute has been present in CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

`hash.`**`update`**(*data*)

Update the hash object with the *bytes-like object*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

`hash.`**`digest`**()

Return the digest of the data passed to the *`update()`* method so far. This is a bytes object of size *`digest_size`* which may contain bytes in the whole range from 0 to 255.

`hash.`**`hexdigest`**()

Like *`digest()`* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.`**`copy`**()

Return a copy ("clone") of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

15.1.6 SHAKE variable length digests

`hashlib.`**`shake_128`**([*data*,]*, *usedforsecurity=True*)

`hashlib.`**`shake_256`**([*data*,]*, *usedforsecurity=True*)

The *`shake_128()`* and *`shake_256()`* algorithms provide variable length digests with length_in_bits//2 up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

`shake.`**`digest`**(*length*)

Return the digest of the data passed to the *`update()`* method so far. This is a bytes object of size *length* which may contain bytes in the whole range from 0 to 255.

`shake.`**`hexdigest`**(*length*)

Like *`digest()`* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value in email or other non-binary environments.

範例:

```
>>> h = hashlib.shake_256(b'Nobody inspects the spammish repetition')
>>> h.hexdigest(20)
'44709d6fcb83d92a76dcb0b668c98e1b1d3dafe7'
```

15.1.7 File hashing

The hashlib module provides a helper function for efficient hashing of a file or file-like object.

hashlib.**file_digest**(*fileobj*, *digest*, */*)

Return a digest object that has been updated with contents of file object.

fileobj must be a file-like object opened for reading in binary mode. It accepts file objects from builtin *open()*, *BytesIO* instances, SocketIO objects from *socket.socket.makefile()*, and similar. The function may bypass Python's I/O and use the file descriptor from *fileno()* directly. *fileobj* must be assumed to be in an unknown state after this function returns or raises. It is up to the caller to close *fileobj*.

digest must either be a hash algorithm name as a *str*, a hash constructor, or a callable that returns a hash object.

範例：

```
>>> import io, hashlib, hmac
>>> with open(hashlib.__file__, "rb") as f:
...     digest = hashlib.file_digest(f, "sha256")
...
>>> digest.hexdigest()
'...'
```

```
>>> buf = io.BytesIO(b"somedata")
>>> mac1 = hmac.HMAC(b"key", digestmod=hashlib.sha512)
>>> digest = hashlib.file_digest(buf, lambda: mac1)
```

```
>>> digest is mac1
True
>>> mac2 = hmac.HMAC(b"key", b"somedata", digestmod=hashlib.sha512)
>>> mac1.digest() == mac2.digest()
True
```

在 3.11 版被加入.

15.1.8 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a salt.

hashlib.**pbkdf2_hmac**(*hash_name*, *password*, *salt*, *iterations*, *dklen=None*)

The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudorandom function.

The string *hash_name* is the desired name of the hash digest algorithm for HMAC, e.g. 'sha1' or 'sha256'. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. *os.urandom()*.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2022, hundreds of thousands of iterations of SHA-256 are suggested. For rationale as to why and how to choose what is best for

your application, read *Appendix A.2.2* of NIST-SP-800-132. The answers on the stackexchange pbkdf2 iterations question explain in detail.

dklen is the length of the derived key in bytes. If *dklen* is `None` then the digest size of the hash algorithm *hash_name* is used, e.g. 64 for SHA-512.

```
>>> from hashlib import pbkdf2_hmac
>>> our_app_iters = 500_000  # Application specific, read above.
>>> dk = pbkdf2_hmac('sha256', b'password', b'bad salt' * 2, our_app_iters)
>>> dk.hex()
'15530bba69924174860db778f2c6f8104d3aaf9d26241840c8c4a641c8d000a9'
```

Function only available when Python is compiled with OpenSSL.

在 3.4 版被加入.

在 3.12 版的變更: Function now only available when Python is built with OpenSSL. The slow pure Python implementation has been removed.

`hashlib.`**`scrypt`**(*password*, ***, *salt*, *n*, *r*, *p*, *maxmem=0*, *dklen=64*)

The function provides scrypt password-based key derivation function as defined in **RFC 7914**.

password and *salt* must be *bytes-like objects*. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. `os.urandom()`.

n is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MiB). *dklen* is the length of the derived key in bytes.

在 3.6 版被加入.

15.1.9 BLAKE2

BLAKE2 is a cryptographic hash function defined in **RFC 7693** that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for HMAC), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's `hashlib` objects.

Creating hash objects

New hash objects are created by calling constructor functions:

`hashlib.`**`blake2b`**(*data=b''*, ***, *digest_size=64*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*, *usedforsecurity=True*)

`hashlib.`**`blake2s`**(*data=b''*, ***, *digest_size=32*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*, *usedforsecurity=True*)

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be *bytes-like object*. It can be passed only as positional argument.
- *digest_size*: size of output digest in bytes.

- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).
- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

Hash	digest_size	len(key)	len(salt)	len(person)
BLAKE2b	64	64	16	16
BLAKE2s	32	32	8	8

備🄵

BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module *constants* described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf_size*: maximal byte length of leaf (0 to `2**32-1`, 0 if unlimited or in sequential mode).
- *node_offset*: node offset (0 to `2**64-1` for BLAKE2b, 0 to `2**48-1` for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).
- *inner_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last_node*: boolean indicating whether the processed node is the last one (`False` for sequential mode).

See section 2.10 in BLAKE2 specification for comprehensive review of tree hashing.

常數

`blake2b.`**`SALT_SIZE`**

`blake2s.`**`SALT_SIZE`**

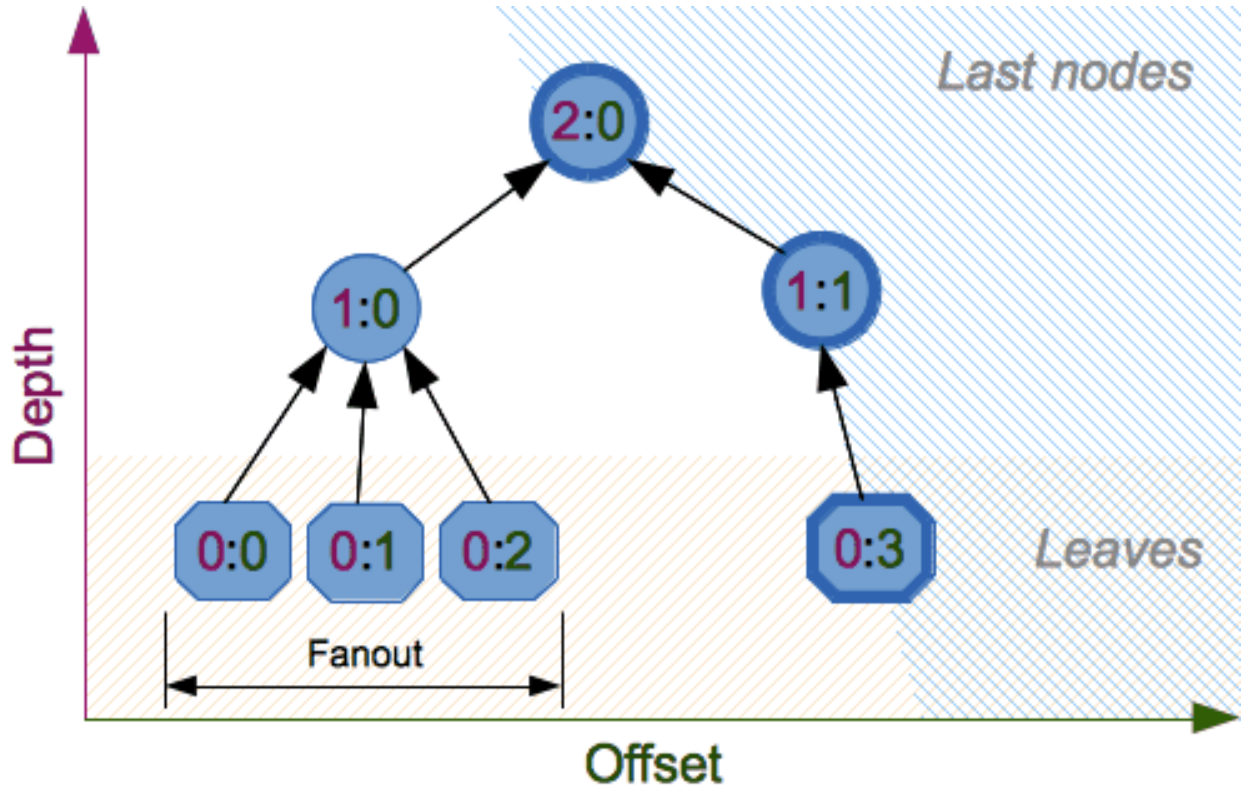
Salt length (maximum length accepted by constructors).

`blake2b.`**`PERSON_SIZE`**

`blake2s.`**`PERSON_SIZE`**

Personalization string length (maximum length accepted by constructors).

`blake2b.`**`MAX_KEY_SIZE`**



`blake2s.`**`MAX_KEY_SIZE`**

Maximum key size.

`blake2b.`**`MAX_DIGEST_SIZE`**

`blake2s.`**`MAX_DIGEST_SIZE`**

Maximum digest size that the hash function can output.

范例

Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (*`blake2b()`* or *`blake2s()`*), then update it with the data by calling *`update()`* on the object, and, finally, get the digest out of the object by calling *`digest()`* (or *`hexdigest()`* for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc
↪'
```

As a shortcut, you can pass the first chunk of data to update directly to the constructor as the positional argument:

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc
↪'
```

You can call *hash.update()* as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
...
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc
↪'
```

Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcfd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for Hash-based message authentication code (HMAC). BLAKE2 can be securely used in prefix-MAC mode thanks to the indifferentiability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0},{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with *hmac* module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'
```

Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

> Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring $1,000,000 to an account, rather than $10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process --- even if it is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.
>
> (NIST SP-800-106 "Randomized Hashing for Digital Signatures")

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

警告

Salted hashing (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See BLAKE2 FAQ for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

Personalization

Sometimes it is useful to force hash function to produce different digests for the same input for different purposes. Quoting the authors of the Skein hash function:

> We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.

(The Skein Hash Function Family, p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778de59f383a3'
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWPlYk1e/nWfu0WSEb0KRcjhDeP/o=
```

Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
  10
 /  \
00  01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=1, node_depth=0, last_node=True)
>>> # Root node
```

(繼續下一頁)

(繼續上一頁)

```
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=1, last_node=True)
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'
```

15.2 hmac --- 基於金鑰雜🄵的訊息驗証

原始碼： Lib/hmac.py

此模組 (module) 實現了 **RFC 2014** 所描述的 HMAC 演算法。

hmac.**new**(*key*, *msg=None*, *digestmod*)

回傳一個新的 hmac 物件。*key* 是一個指定密鑰的 bytes（位元組）或 bytearray 物件。如果提供了 *msg*，將會呼叫 `update(msg)` 方法。*digestmod* 🄵 HMAC 物件所用的摘要名稱、摘要建構函式 (constructor) 或模組。它可以是適用於*hashlib.new()* 的任何名稱。🄵管該引數的位置在後，但它🄵是必須的。

在 3.4 版的變更: 參數 *key* 可以🄵 bytes 或 bytearray 物件。參數 *msg* 可以🄵*hashlib* 所支援的任意型🄵。參數 *digestmod* 可以🄵雜🄵演算法的名稱。

在 3.8 版的變更: *digestmod* 引數現在是必須的。請將其作🄵關鍵字引數傳入以避免當你🄵有初始 *msg* 時導致的麻煩。

hmac.**digest**(*key*, *msg*, *digest*)

基於給定密鑰 *key* 和 *digest* 回傳 *msg* 的摘要。此函式等價於 `HMAC(key, msg, digest).digest()`，但使用了優化的 C 或行🄵實作（inline implementation），對放入記憶體的訊息能處理得更快。參數 *key*、*msg* 和 *digest* 在*new()* 中具有相同含義。

作🄵 CPython 的實現細節，C 的優化實作只有當 *digest* 🄵字串🄵且是一個 OpenSSL 所支持的摘要演算法的名稱時才會被使用。

在 3.7 版被加入.

HMAC 物件具有下列方法 (method)：

HMAC.**update**(*msg*)

用 *msg* 來更新 hmac 物件。重🄵呼叫相當於單次呼叫🄵傳入所有引數的拼接結果：`m.update(a); m.update(b)` 等價於 `m.update(a + b)`。

在 3.4 版的變更: 參數 *msg* 可以是*hashlib* 所支援的任何型🄵。

HMAC.**digest**()

回傳當前已傳給*update()* 方法的 bytes 摘要。這個 bytes 物件的長度會與傳給建構函式的摘要 *digest_size* 的長度相同。它可以包含 NUL bytes 以及 non-ASCII bytes。

警告

在一個例行的驗證事務運行期間，將*digest()* 的輸出與外部提供的摘要進行比較時，建議使用*compare_digest()* 函式而不是 == 運算子以🄵少被定時攻擊時的漏洞。

HMAC.**hexdigest**()

像是*digest()* 但摘要的回傳形式🄵兩倍長度的字串，且此字串只包含十六進位數位。這可以被用於在電子郵件或其他非二進位制環境中安全地交🄵數據。

警告

在一個例行的驗證事務運行期間，將*hexdigest()* 的輸出與外部提供的摘要進行比較時，建議使用*compare_digest()* 函式而不是 == 運算子以F少被定時攻擊時的漏洞。

HMAC.**copy**()
回傳 hmac 物件的拷貝 (”clone”)。這可以被用來有效率地計算那些共享相同初始子字串的字串的摘要。

一個 hash 物件具有以下屬性：

HMAC.**digest_size**
以 bytes 表示最終 HMAC 摘要的大小。

HMAC.**block_size**
以 bytes 表示雜F演算法的F部區塊大小。

在 3.4 版被加入.

HMAC.**name**
HMAC 的正准名稱總是F小寫形式，例如 `hmac-md5`。

在 3.4 版被加入.

在 3.10 版的變更: 未寫入文件的屬性 `HMAC.digest_cons`，`HMAC.inner` 和 `HMAC.outer` 已被移除。

這個模組還提供了下列輔助函式：

hmac.**compare_digest**(*a*, *b*)
回傳 `a == b`。此函式使用一種經專門設計的方式通過避免基於F容的短路行F來防止定時分析，使得它適合處理密碼學。*a* 和 *b* 必須F相同的型F：可以是*str*（僅限 ASCII，如*HMAC.hexdigest()* 的回傳值），或者是*bytes-like object*。

備F

如果 *a* 和 *b* 具有不同的長度，或者如果發生了錯誤，定時攻擊在理論上可以獲取有關 *a* 和 *b* 的型F和長度的訊息—但不能獲取他們的值。

在 3.3 版被加入.

在 3.10 版的變更: 此函式在可能的情F下會在F部使用 OpenSSL 的 `CRYPTO_memcmp()`。

也參考

***hashlib* 模組**
Python 模組提供安全的雜F函式。

15.3 secrets --- 🄵生用於管理機密的安全亂數

在 3.6 版被加入.

原始碼： Lib/secrets.py

---

secrets 模組可用於🄵生高加密🄵度的亂數，適合用來管理諸如密碼、帳號認證、安全性權杖（security tokens）這類資料，以及管理其他相關的機密資料。

尤其應優先使用*secrets* 作🄵預設來替代*random* 模組中的預設🄵亂數🄵生器（pseudo-random number generator），該模組被設計用於建模和模擬，而非用於安全性和加密。

也參考

PEP 506

15.3.1 亂數

secrets 模組使你得以存取作業系統所提供安全性最高的亂數🄵生器。

class secrets.**SystemRandom**

一個用來🄵生亂數的類🄵，用的是作業系統提供的最高品質來源。請參🄵*random.SystemRandom* 以獲取更多細節。

secrets.**choice**(*seq*)

從一非空序列中，回傳一個隨機選取的元素。

secrets.**randbelow**(*exclusive_upper_bound*)

回傳一個 [0, *exclusive_upper_bound*) 範圍之🄵的隨機整數。

secrets.**randbits**(*k*)

回傳一個具 *k* 個隨機位元的整數。

15.3.2 🄵生權杖（token）

secrets 模組提供了一些🄵生安全性權杖的函式，適合用於諸如重設密碼、難以猜測的 URL，或類似的應用。

secrets.**token_bytes**([*nbytes=None*])

回傳一個隨機位元組字串，其中含有 *nbytes* 位元組的數字。如果 *nbytes* 🄵 None 或未提供，則會使用一合理預設值。

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

secrets.**token_hex**([*nbytes=None*])

回傳一以十六進位表示的隨機字串。字串具有 *nbytes* 個隨機位元組，每個位元組會轉成兩個十六進位的數字。如果 *nbytes* 🄵 None 或未提供，則會使用一個合理的預設值。

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

secrets.**token_urlsafe**([*nbytes=None*])

回傳一個 URL 安全的隨機文本字串，包含 *nbytes* 個隨機位元組。文本將使用 Base64 編碼，因此平均來🄵每個位元組會對應到約 1.3 個字元。如果 *nbytes* 🄵 None 或未提供，則會使用一個合理的預設值。

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

權杖應當使用多少個位元組？

🄵了在面對暴力攻擊時能保證安全，權杖必須具有足🄵的隨機性。不幸的是，對隨機性是否足🄵的標准，會隨著電腦越來越🄵大🄵能🄵在更短時間🄵進行更多猜測而不斷提高。在 2015 年時，人們認🄵 32 位元組（256 位元）的隨機性對於 *secrets* 模組所預期的一般使用場景來🄵是足🄵的。

對於想自行管理權杖長度的使用者，你可以對各種 token_* 函式明白地指定 *int* 引數（argument）來指定權杖要使用的隨機性程度。該引數以位元組數來表示要使用的隨機性程度。

否則，如未提供引數，或者如果引數🄵 None，則 token_* 函式則會使用一個合理的預設值。

備🄵

該預設值可能在任何時候被改變，包括在維護版本更新的時候。

15.3.3 其他函式

secrets.**compare_digest**(*a*, *b*)

如果字串或類位元組串物件 *a* 與 *b* 相等則回傳 True，否則回傳 False，以”🄵定時間比較 (constant-time compare) ” 的處理方式可降低時序攻擊的風險。請參🄵*hmac.compare_digest()* 以了解更多細節。

15.3.4 應用技巧和典范實務（best practices）

本節展示了一些使用 *secrets* 來管理基本安全等級的應用技巧和典範實務。

🄵生八個字元長的字母數字密碼：

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
password = ''.join(secrets.choice(alphabet) for i in range(8))
```

備🄵

應用程式不能以可復原的格式存儲密碼，無論是用純文本還是經過加密。它們應當先加鹽（salt），再使用高加密🄵度的單向（不可逆）雜🄵函式來🄵生雜🄵值。

🄵生十個字元長的字母數字密碼，其中包含至少一個小寫字母，至少一個大寫字母以及至少三個數字：

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
```

(繼續下一頁)

(繼續上一頁)

```
while True:
    password = ''.join(secrets.choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
            and any(c.isupper() for c in password)
            and sum(c.isdigit() for c in password) >= 3):
        break
```

🄵生 XKCD 風格的 passphrase:

```
import secrets
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(secrets.choice(words) for i in range(4))
```

🄵生難以猜測的暫時性 URL，🄵含回復密碼時所用的一個安全性權杖:

```
import secrets
url = 'https://example.com/reset=' + secrets.token_urlsafe()
```

CHAPTER 16

通用作業系統服務

此章節所描述的模組 (module) 提供了作業系統特性的使用介面，例如檔案與時鐘，（幾乎）在所有作業系統上皆能使用。這些介面通常是參考 Unix 或 C 的介面來實作，不過在其他大多數系統上也能使用。以下🄵概述：

16.1 os --- 各種作業系統介面

原始碼： Lib/os.py

該模組提供了一種便利的方式來操作與作業系統相關的功能。如果你想讀取或寫入檔案，請參🄵*open()*，如果你想操作檔案路徑，請參🄵*os.path* 模組，如果你想透過命令列查看所有檔案中的所有🄵容，請查看*fileinput* 模組。要建立臨時檔案和目🄵，請參🄵*tempfile* 模組，要操作高級檔案和目🄵，請參🄵*shutil* 模組。

關於這些功能的可用性🄵明：

- Python 所有🄵建作業系統相關的模組設計是這樣：只要有相同的函式可使用，就會使用相同的介面（interface）。舉例來🄵，`os.stat(path)` 函式會以相同格式回傳關於 *path* 的統計資訊（這剛好來自於 POSIX 的介面。）。
- 對於特定的作業系統獨有的擴充功能也可以透過*os* 取得，但使用它們的時候對於可移植性無疑會是個問題。
- 所有接受檔案路徑和檔案名稱的函式皆接受位元組 (bytes) 和字串物件 (string objects)，且如果回傳檔案路徑或檔案名稱，則會🄵出相同型🄵的物件。
- 在 VxWorks, 不支援 os.popen、os.fork、os.execv 和 os.spawn*p*。
- 在 WebAssembly 平台 `wasm32-emscripten` 和 `wasm32-wasi` 上，大部分*os* 模組無法使用或行🄵不同。與行程（Process）（例如*fork()*、*execve()*）、訊號（例如*kill()*、*wait()*），與資源（例如*nice()*）相關的 API 不可使用。其他諸如*getuid()* 和*getpid()* 的相關 API 是 emulated 或 stubs。

備🄵

在檔案名稱和路徑找不到或無效的時候，或引數型🄵正確但作業系統不接受的時候，在此模組中的所有的函式都會引發*OSError*（或其子類🄵）。

exception os.**error**

🄵建例外*OSError* 的🄵名。

os.**name**

The name of the operating system dependent module imported. The following names have currently been registered: `'posix'`, `'nt'`, `'java'`.

也參考

sys.platform has a finer granularity. *os.uname()* gives system-dependent version information.

The *platform* module provides detailed checks for the system's identity.

16.1.1 File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the *filesystem encoding and error handler* to perform this conversion (see *sys.getfilesystemencoding()*).

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.1 版的變更: On some systems, conversion using the file system encoding may fail. In this case, Python uses the *surrogateescape encoding error handler*, which means that undecodable bytes are replaced by a Unicode character U+DC*xx* on decoding, and these are again translated to the original byte on encoding.

The *file system encoding* must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions can raise *UnicodeError*.

另請參🄵*locale encoding*。

16.1.2 Python UTF-8 模式

在 3.7 版被加入: 更多資訊請見 **PEP 540**。

Python 在 UTF-8 模式下會忽略*locale encoding* 🄵且🄵制使用 UTF-8 去編碼:

- Use UTF-8 as the *filesystem encoding*.
- *sys.getfilesystemencoding()* 回傳 `'utf-8'`。
- *locale.getpreferredencoding()* returns `'utf-8'` (the *do_setlocale* argument has no effect).
- *sys.stdin*, *sys.stdout*, and *sys.stderr* all use UTF-8 as their text encoding, with the `surrogateescape` *error handler* being enabled for *sys.stdin* and *sys.stdout* (*sys.stderr* continues to use `backslashreplace` as it does in the default locale-aware mode)
- On Unix, *os.device_encoding()* returns `'utf-8'` rather than the device encoding.

Note that the standard stream settings in UTF-8 mode can be overridden by `PYTHONIOENCODING` (just as they can be in the default locale-aware mode).

As a consequence of the changes in those lower level APIs, other higher level APIs also exhibit different default behaviours:

- Command line arguments, environment variables and filenames are decoded to text using the UTF-8 encoding.
- *`os.fsdecode()`* and *`os.fsencode()`* use the UTF-8 encoding.
- *`open()`*, *`io.open()`*, and *`codecs.open()`* use the UTF-8 encoding by default. However, they still use the strict error handler by default so that attempting to open a binary file in text mode is likely to raise an exception rather than producing nonsense data.

The *Python UTF-8 Mode* is enabled if the LC_CTYPE locale is `C` or `POSIX` at Python startup (see the `PyConfig_Read()` function).

It can be enabled or disabled using the `-X utf8` command line option and the `PYTHONUTF8` environment variable.

If the `PYTHONUTF8` environment variable is not set at all, then the interpreter defaults to using the current locale settings, *unless* the current locale is identified as a legacy ASCII-based locale (as described for `PYTHONCOERCECLOCALE`), and locale coercion is either disabled or fails. In such legacy locales, the interpreter will default to enabling UTF-8 mode unless explicitly instructed not to do so.

The Python UTF-8 Mode can only be enabled at the Python startup. Its value can be read from *`sys.flags.utf8_mode`*.

See also the UTF-8 mode on Windows and the *filesystem encoding and error handler*.

PEP 686
Python 3.15 預設使用*Python UTF-8 模式*

16.1.3 行程參數

These functions and data items provide information and operate on the current process and user.

`os.`**`ctermid`**`()`

Return the filename corresponding to the controlling terminal of the process.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`environ`**

A *mapping* object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the *`os`* module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in *`os.environ`*, except for changes made by modifying *`os.environ`* directly.

This mapping may be used to modify the environment as well as query the environment. *`putenv()`* will be called automatically when the mapping is modified.

On Unix, keys and values use *`sys.getfilesystemencoding()`* and `'surrogateescape'` error handler. Use *`environb`* if you would like to use a different encoding.

On Windows, the keys are converted to uppercase. This also applies when getting, setting, or deleting an item. For example, `environ['monty'] = 'python'` maps the key `'MONTY'` to the value `'python'`.

備🄵

Calling *putenv()* directly does not change *os.environ*, so it's better to modify *os.environ*.

備🄵

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

You can delete items in this mapping to unset environment variables. *unsetenv()* will be called automatically when an item is deleted from *os.environ*, and when one of the `pop()` or `clear()` methods is called.

在 3.9 版的變更: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

`os.`**`environb`**

Bytes version of *environ*: a *mapping* object where both keys and values are *bytes* objects representing the process environment. *environ* and *environb* are synchronized (modifying *environb* updates *environ*, and vice versa).

environb is only available if *supports_bytes_environ* is `True`.

在 3.2 版被加入.

在 3.9 版的變更: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

`os.`**`chdir`**(*path*)

`os.`**`fchdir`**(*fd*)

`os.`**`getcwd`**()

These functions are described in *Files and Directories*.

`os.`**`fsencode`**(*filename*)

Encode *path-like* *filename* to the *filesystem encoding and error handler*; return *bytes* unchanged.

fsdecode() is the reverse function.

在 3.2 版被加入.

在 3.6 版的變更: Support added to accept objects implementing the *os.PathLike* interface.

`os.`**`fsdecode`**(*filename*)

Decode the *path-like* *filename* from the *filesystem encoding and error handler*; return *str* unchanged.

fsencode() is the reverse function.

在 3.2 版被加入.

在 3.6 版的變更: Support added to accept objects implementing the *os.PathLike* interface.

`os.`**`fspath`**(*path*)

Return the file system representation of the path.

If *str* or *bytes* is passed in, it is returned unchanged. Otherwise *__fspath__()* is called and its value is returned as long as it is a *str* or *bytes* object. In all other cases, *TypeError* is raised.

在 3.6 版被加入.

class os.**PathLike**

An *abstract base class* for objects representing a file system path, e.g. *pathlib.PurePath*.

在 3.6 版被加入.

abstractmethod **__fspath__**()

Return the file system path representation of the object.

The method should only return a *str* or *bytes* object, with the preference being for *str*.

os.**getenv**(*key*, *default=None*)

Return the value of the environment variable *key* as a string if it exists, or *default* if it doesn't. *key* is a string. Note that since *getenv()* uses *os.environ*, the mapping of *getenv()* is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with *sys.getfilesystemencoding()* and `'surrogateescape'` error handler. Use *os.getenvb()* if you would like to use a different encoding.

適用： Unix、Windows。

os.**getenvb**(*key*, *default=None*)

Return the value of the environment variable *key* as bytes if it exists, or *default* if it doesn't. *key* must be bytes. Note that since *getenvb()* uses *os.environb*, the mapping of *getenvb()* is similarly also captured on import, and the function may not reflect future environment changes.

getenvb() is only available if *supports_bytes_environ* is `True`.

適用： Unix。

在 3.2 版被加入.

os.**get_exec_path**(*env=None*)

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is `None`, *environ* is used.

在 3.2 版被加入.

os.**getegid**()

Return the effective group id of the current process. This corresponds to the "set id" bit on the file being executed in the current process.

適用： Unix、非 Emscripten、非 WASI。

os.**geteuid**()

Return the current process's effective user id.

適用： Unix、非 Emscripten、非 WASI。

os.**getgid**()

Return the real group id of the current process.

適用： Unix。

The function is a stub on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**getgrouplist**(*user*, *group*, */*)

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**getgroups**()

Return list of supplemental group ids associated with the current process.

適用： Unix、非 Emscripten、非 WASI。

備🄵

On macOS, *getgroups()* behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of `10.5` or earlier, *getgroups()* returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to *setgroups()* if suitably privileged. If built with a deployment target greater than `10.5`, *getgroups()* returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to *setgroups()*, and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with *sysconfig.get_config_var()*.

os.**getlogin**()

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use *getpass.getuser()* since the latter checks the environment variables `LOGNAME` or `USERNAME` to find out who the user is, and falls back to `pwd.getpwuid(os.getuid())[0]` to get the login name of the current real user id.

適用： Unix、Windows、非 Emscripten、非 WASI。

os.**getpgid**(*pid*)

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

適用： Unix、非 Emscripten、非 WASI。

os.**getpgrp**()

Return the id of the current process group.

適用： Unix、非 Emscripten、非 WASI。

os.**getpid**()

Return the current process id.

The function is a stub on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**getppid**()

Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

適用： Unix、Windows、非 Emscripten、非 WASI。

在 3.2 版的變更: 新增對 Windows 的支援。

os.**getpriority**(*which*, *who*)

Get program scheduling priority. The value *which* is one of *PRIO_PROCESS*, *PRIO_PGRP*, or *PRIO_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO_PROCESS*, process group identifier for *PRIO_PGRP*, and a user ID for *PRIO_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**PRIO_PROCESS**

os.**PRIO_PGRP**

os.**PRIO_USER**

Parameters for the *getpriority()* and *setpriority()* functions.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**PRIO_DARWIN_THREAD**

os.**PRIO_DARWIN_PROCESS**

os.**PRIO_DARWIN_BG**

os.**PRIO_DARWIN_NONUI**

Parameters for the *getpriority()* and *setpriority()* functions.

適用： macOS

在 3.12 版被加入.

os.**getresuid**()

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

適用： Unix、非 Emscripten、非 WASI。

在 3.2 版被加入.

os.**getresgid**()

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

適用： Unix、非 Emscripten、非 WASI。

在 3.2 版被加入.

os.**getuid**()

Return the current process's real user id.

適用： Unix。

The function is a stub on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**initgroups**(*username*, *gid*, /)

Call the system initgroups() to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

適用： Unix、非 Emscripten、非 WASI。

在 3.2 版被加入.

os.**putenv**(*key*, *value*, /)

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with *os.system()*, *popen()* or *fork()* and *execv()*.

Assignments to items in *os.environ* are automatically translated into corresponding calls to *putenv()*; however, calls to *putenv()* don't update *os.environ*, so it is actually preferable to assign to items of *os.environ*. This also applies to *getenv()* and *getenvb()*, which respectively use *os.environ* and *os.environb* in their implementations.

備🄵

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

Raises an *auditing event* `os.putenv` with arguments `key`, `value`.

在 3.9 版的變更: The function is now always available.

`os.`**`setegid`**(*egid*, */*)

Set the current process's effective group id.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`seteuid`**(*euid*, */*)

Set the current process's effective user id.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`setgid`**(*gid*, */*)

Set the current process' group id.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`setgroups`**(*groups*, */*)

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

適用： Unix、非 Emscripten、非 WASI。

備🄵

On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for *`getgroups()`* for cases where it may not return the same group list set by calling setgroups().

`os.`**`setns`**(*fd*, *nstype=0*)

Reassociate the current thread with a Linux namespace. See the *`setns(2)`* and *`namespaces(7)`* man pages for more details.

If *fd* refers to a `/proc/pid/ns/` link, `setns()` reassociates the calling thread with the namespace associated with that link, and *nstype* may be set to one of the *CLONE_NEW* constants* to impose constraints on the operation (`0` means no constraints).

Since Linux 5.8, *fd* may refer to a PID file descriptor obtained from *`pidfd_open()`*. In this case, `setns()` reassociates the calling thread into one or more of the same namespaces as the thread referred to by *fd*. This is subject to any constraints imposed by *nstype*, which is a bit mask combining one or more of the *CLONE_NEW* constants*, e.g. `setns(fd, os.CLONE_NEWUTS | os.CLONE_NEWPID)`. The caller's memberships in unspecified namespaces are left unchanged.

fd can be any object with a *`fileno()`* method, or a raw file descriptor.

This example reassociates the thread with the `init` process's network namespace:

```
fd = os.open("/proc/1/ns/net", os.O_RDONLY)
os.setns(fd, os.CLONE_NEWNET)
os.close(fd)
```

適用： Linux 3.0 以上且具有 glibc 2.14 以上。

在 3.12 版被加入.

也參考

unshare() 函式。

os.**setpgrp**()

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

適用： Unix、非 Emscripten、非 WASI。

os.**setpgid**(*pid*, *pgrp*, */*)

Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

適用： Unix、非 Emscripten、非 WASI。

os.**setpriority**(*which*, *who*, *priority*)

Set program scheduling priority. The value *which* is one of *PRIO_PROCESS*, *PRIO_PGRP*, or *PRIO_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO_PROCESS*, process group identifier for *PRIO_PGRP*, and a user ID for *PRIO_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**setregid**(*rgid*, *egid*, */*)

Set the current process's real and effective group ids.

適用： Unix、非 Emscripten、非 WASI。

os.**setresgid**(*rgid*, *egid*, *sgid*, */*)

Set the current process's real, effective, and saved group ids.

適用： Unix、非 Emscripten、非 WASI。

在 3.2 版被加入.

os.**setresuid**(*ruid*, *euid*, *suid*, */*)

Set the current process's real, effective, and saved user ids.

適用： Unix、非 Emscripten、非 WASI。

在 3.2 版被加入.

os.**setreuid**(*ruid*, *euid*, */*)

Set the current process's real and effective user ids.

適用： Unix、非 Emscripten、非 WASI。

os.**getsid**(*pid*, */*)

Call the system call `getsid()`. See the Unix manual for the semantics.

適用： Unix、非 Emscripten、非 WASI。

os.**setsid**()

Call the system call `setsid()`. See the Unix manual for the semantics.

適用： Unix、非 Emscripten、非 WASI。

os.**setuid**(*uid*, /)

Set the current process's user id.

適用： Unix、非 Emscripten、非 WASI。

os.**strerror**(*code*, /)

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, *`ValueError`* is raised.

os.**supports_bytes_environ**

`True` if the native OS type of the environment is bytes (eg. `False` on Windows).

在 3.2 版被加入.

os.**umask**(*mask*, /)

Set the current numeric umask and return the previous umask.

The function is a stub on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**uname**()

Returns information identifying the current operating system. The return value is an object with five attributes:

- `sysname` - 作業系統名稱
- `nodename` - name of machine on network (implementation-defined)
- `release` - operating system release
- `version` - 作業系統版本
- `machine` - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing `sysname`, `nodename`, `release`, `version`, and `machine` in that order.

Some systems truncate `nodename` to 8 characters or to the leading component; a better way to get the hostname is *`socket.gethostname()`* or even `socket.gethostbyaddr(socket.gethostname())`.

適用： Unix。

在 3.3 版的變更: Return type changed from a tuple to a tuple-like object with named attributes.

os.**unsetenv**(*key*, /)

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with *`os.system()`*, *`popen()`* or *`fork()`* and *`execv()`*.

Deletion of items in *`os.environ`* is automatically translated into a corresponding call to *`unsetenv()`*; however, calls to *`unsetenv()`* don't update *`os.environ`*, so it is actually preferable to delete items of *`os.environ`*.

Raises an *auditing event* `os.unsetenv` with argument `key`.

在 3.9 版的變更: The function is now always available and is also available on Windows.

os.**unshare**(*flags*)

Disassociate parts of the process execution context, and move them into a newly created namespace. See the *`unshare(2)`* man page for more details. The *flags* argument is a bit mask, combining zero or more of the *CLONE_* constants*, that specifies which parts of the execution context should be unshared from their existing

associations and moved to a new namespace. If the *flags* argument is `0`, no changes are made to the calling process's execution context.

適用： Linux 2.6.16 以上。

在 3.12 版被加入.

也參考

`setns()` 函式。

Flags to the `unshare()` function, if the implementation supports them. See `unshare(2)` in the Linux manual for their exact effect and availability.

os.**CLONE_VM**

16.1.4 File Object Creation

These functions create new *file objects*. (See also `open()` for opening file descriptors.)

os.**fdopen**(*fd*, **args*, ***kwargs*)

Return an open file object connected to the file descriptor *fd*. This is an alias of the `open()` built-in function and accepts the same arguments. The only difference is that the first argument of `fdopen()` must always be an integer.

16.1.5 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name ”file descriptor” is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a *file object* when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

os.**close**(*fd*)

Close file descriptor *fd*.

備🄵

This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To close a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, use its *close()* method.

os.**closerange**(*fd_low*, *fd_high*, */*)

Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

os.**copy_file_range**(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Copy *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. If *offset_src* is `None`, then *src* is read from the current position; respectively for *offset_dst*.

In Linux kernel older than 5.3, the files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an *OSError* is raised with *errno* set to *errno.EXDEV*.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations, such as the use of reflinks (i.e., two or more inodes that share pointers to the same copy-on-write disk blocks; supported file systems include btrfs and XFS) and server-side copy (in the case of NFS).

The function copies bytes between two file descriptors. Text options, like the encoding and the line ending, are ignored.

The return value is the amount of bytes copied. This could be less than the amount requested.

備🄵

On Linux, *os.copy_file_range()* should not be used for copying a range of a pseudo file from a special filesystem like procfs and sysfs. It will always copy no bytes and return 0 as if the file was empty because of a known Linux kernel issue.

適用： Linux 4.5 以上且具有 glibc 2.27 以上。

在 3.8 版被加入.

os.**device_encoding**(*fd*)

Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return *None*.

On Unix, if the *Python UTF-8 Mode* is enabled, return `'UTF-8'` rather than the device encoding.

在 3.10 版的變更: On Unix, the function now implements the Python UTF-8 Mode.

os.**dup**(*fd*, /)

Return a duplicate of file descriptor *fd*. The new file descriptor is *non-inheritable*.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is *inheritable*.

適用： 非 WASI。

在 3.4 版的變更: The new file descriptor is now non-inheritable.

os.**dup2**(*fd*, *fd2*, *inheritable=True*)

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is *inheritable* by default or non-inheritable if *inheritable* is `False`.

適用： 非 WASI。

在 3.4 版的變更: Add the optional *inheritable* parameter.

在 3.7 版的變更: Return *fd2* on success. Previously, `None` was always returned.

os.**fchmod**(*fd*, *mode*)

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

適用： Unix。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**fchown**(*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See *chown()*. As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

適用： Unix。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

os.**fdatasync**(*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

適用： Unix。

備🄵

This function is not available on MacOS.

os.**fpathconf**(*fd*, *name*, /)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

適用： Unix。

os.**fstat**(*fd*)

Get the status of the file descriptor *fd*. Return a *stat_result* object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

也參考

The *stat()* function.

os.**fstatvfs**(*fd*, /)

Return information about the filesystem containing the file associated with file descriptor *fd*, like *statvfs()*. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

適用： Unix。

os.**fsync**(*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the MS `_commit()` function.

If you're starting with a buffered Python *file object* *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

適用： Unix、Windows。

os.**ftruncate**(*fd*, *length*, /)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Raises an *auditing event* `os.truncate` with arguments `fd`, `length`.

適用： Unix、Windows。

在 3.5 版的變更: 新增對 Windows 的支援

os.**get_blocking**(*fd*, /)

Get the blocking mode of the file descriptor: `False` if the *O_NONBLOCK* flag is set, `True` if the flag is cleared.

另請參🄵*set_blocking()* 與*socket.socket.setblocking()*。

適用： Unix、Windows。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

On Windows, this function is limited to pipes.

在 3.5 版被加入.

在 3.12 版的變更: 新增對 Windows 上的 pipe 支援。

os.**isatty**(*fd*, /)

Return `True` if the file descriptor *fd* is open and connected to a tty(-like) device, else `False`.

os.**lockf**(*fd*, *cmd*, *len*, /)

Apply, test or remove a POSIX lock on an open file descriptor. *fd* is an open file descriptor. *cmd* specifies the command to use - one of *F_LOCK*, *F_TLOCK*, *F_ULOCK* or *F_TEST*. *len* specifies the section of the file to lock.

Raises an *auditing event* `os.lockf` with arguments `fd`, `cmd`, `len`.

適用： Unix。

在 3.3 版被加入.

os.**F_LOCK**

os.**F_TLOCK**

os.**F_ULOCK**

os.**F_TEST**

Flags that specify what action *lockf()* will take.

適用： Unix。

在 3.3 版被加入.

os.**login_tty**(*fd*, /)

Prepare the tty of which fd is a file descriptor for a new login session. Make the calling process a session leader; make the tty the controlling tty, the stdin, the stdout, and the stderr of the calling process; close fd.

適用： Unix、非 Emscripten、非 WASI。

在 3.11 版被加入.

os.**lseek**(*fd*, *pos*, *whence*, /)

Set the current position of file descriptor *fd* to position *pos*, modified by *whence*, and return the new position in bytes relative to the start of the file. Valid values for *whence* are:

- *SEEK_SET* or 0 -- set *pos* relative to the beginning of the file
- *SEEK_CUR* or 1 -- set *pos* relative to the current file position
- *SEEK_END* or 2 -- set *pos* relative to the end of the file
- *SEEK_HOLE* -- set *pos* to the next data location, relative to *pos*
- *SEEK_DATA* -- set *pos* to the next data hole, relative to *pos*

在 3.3 版的變更: Add support for SEEK_HOLE and SEEK_DATA.

os.**SEEK_SET**

os.**SEEK_CUR**

os.**SEEK_END**

Parameters to the *lseek()* function and the *seek()* method on *file-like objects*, for whence to adjust the file position indicator.

SEEK_SET
Adjust the file position relative to the beginning of the file.

SEEK_CUR
Adjust the file position relative to the current file position.

SEEK_END
Adjust the file position relative to the end of the file.

Their values are 0, 1, and 2, respectively.

os.**SEEK_HOLE**

os.**SEEK_DATA**

Parameters to the *lseek()* function and the *seek()* method on *file-like objects*, for seeking file data and holes on sparsely allocated files.

SEEK_DATA
Adjust the file offset to the next location containing data, relative to the seek position.

SEEK_HOLE
Adjust the file offset to the next location containing a hole, relative to the seek position. A hole is defined as a sequence of zeros.

備🄵

These operations only make sense for filesystems that support them.

適用： Linux 3.1 以上、macOS、Unix。

在 3.3 版被加入.

os.**open**(*path*, *flags*, *mode=0o777*, *, *dir_fd=None*)

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like *O_RDONLY* and *O_WRONLY*) are defined in the *os* module. In particular, on Windows adding *O_BINARY* is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the *dir_fd* parameter.

Raises an *auditing event* `open` with arguments `path`, `mode`, `flags`.

在 3.4 版的變更: The new file descriptor is now non-inheritable.

備🄵

This function is intended for low-level I/O. For normal usage, use the built-in function *open()*, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file object, use *fdopen()*.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

在 3.6 版的變更: Accepts a *path-like object*.

The following constants are options for the *flags* parameter to the *open()* function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the *open(2)* manual page on Unix or the MSDN on Windows.

os.**O_RDONLY**
os.**O_WRONLY**
os.**O_RDWR**
os.**O_APPEND**
os.**O_CREAT**
os.**O_EXCL**
os.**O_TRUNC**

The above constants are available on Unix and Windows.

os.**O_DSYNC**
os.**O_RSYNC**
os.**O_SYNC**
os.**O_NDELAY**
os.**O_NONBLOCK**
os.**O_NOCTTY**

os.**O_CLOEXEC**

The above constants are only available on Unix.

在 3.3 版的變更: Add *O_CLOEXEC* constant.

os.**O_BINARY**

os.**O_NOINHERIT**

os.**O_SHORT_LIVED**

os.**O_TEMPORARY**

os.**O_RANDOM**

os.**O_SEQUENTIAL**

os.**O_TEXT**

The above constants are only available on Windows.

os.**O_EVTONLY**

os.**O_FSYNC**

os.**O_SYMLINK**

os.**O_NOFOLLOW_ANY**

The above constants are only available on macOS.

在 3.10 版的變更: Add *O_EVTONLY*, *O_FSYNC*, *O_SYMLINK* and *O_NOFOLLOW_ANY* constants.

os.**O_ASYNC**

os.**O_DIRECT**

os.**O_DIRECTORY**

os.**O_NOFOLLOW**

os.**O_NOATIME**

os.**O_PATH**

os.**O_TMPFILE**

os.**O_SHLOCK**

os.**O_EXLOCK**

The above constants are extensions and not present if they are not defined by the C library.

在 3.4 版的變更: Add *O_PATH* on systems that support it. Add *O_TMPFILE*, only available on Linux Kernel 3.11 or newer.

os.**openpty**()

Open a new pseudo-terminal pair. Return a pair of file descriptors `(master, slave)` for the pty and the tty, respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the *pty* module.

適用： Unix、非 Emscripten、非 WASI。

在 3.4 版的變更: The new file descriptors are now non-inheritable.

os.**pipe**()

Create a pipe. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

適用： Unix、Windows。

在 3.4 版的變更: The new file descriptors are now non-inheritable.

os.**pipe2**(*flags*, /)

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: *O_NONBLOCK*, *O_CLOEXEC*. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**posix_fallocate**(*fd*, *offset*, *len*, /)

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

適用： Unix、非 Emscripten。

在 3.3 版被加入.

os.**posix_fadvise**(*fd*, *offset*, *len*, *advice*, /)

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of *POSIX_FADV_NORMAL*, *POSIX_FADV_SEQUENTIAL*, *POSIX_FADV_RANDOM*, *POSIX_FADV_NOREUSE*, *POSIX_FADV_WILLNEED* or *POSIX_FADV_DONTNEED*.

適用： Unix。

在 3.3 版被加入.

os.**POSIX_FADV_NORMAL**

os.**POSIX_FADV_SEQUENTIAL**

os.**POSIX_FADV_RANDOM**

os.**POSIX_FADV_NOREUSE**

os.**POSIX_FADV_WILLNEED**

os.**POSIX_FADV_DONTNEED**

Flags that can be used in *advice* in *posix_fadvise()* that specify the access pattern that is likely to be used.

適用： Unix。

在 3.3 版被加入.

os.**pread**(*fd*, *n*, *offset*, /)

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

適用： Unix。

在 3.3 版被加入.

os.**preadv**(*fd*, *buffers*, *offset*, *flags=0*, /)

Read from a file descriptor *fd* at a position of *offset* into mutable *bytes-like objects* *buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_HIPRI*
- *RWF_NOWAIT*

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.readv()* and *os.pread()*.

適用： Linux 2.6.30 以上、FreeBSD 6.0 以上、OpenBSD 2.7 以上、AIX 7.1 以上。

Using flags requires Linux >= 4.6.

在 3.7 版被加入.

os.**RWF_NOWAIT**

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set errno to *errno.EAGAIN*.

適用： Linux 4.14 以上。

在 3.7 版被加入.

os.**RWF_HIPRI**

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the *O_DIRECT* flag.

適用： Linux 4.6 以上。

在 3.7 版被加入.

os.**pwrite**(*fd*, *str*, *offset*, /)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

適用： Unix。

在 3.3 版被加入.

os.**pwritev**(*fd*, *buffers*, *offset*, *flags=0*, /)

Write the *buffers* contents to file descriptor *fd* at an offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_DSYNC*
- *RWF_SYNC*
- *RWF_APPEND*

Return the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.writev()* and *os.pwrite()*.

適用： Linux 2.6.30 以上、FreeBSD 6.0 以上、OpenBSD 2.7 以上、AIX 7.1 以上。

Using flags requires Linux >= 4.6.

在 3.7 版被加入.

os.**RWF_DSYNC**

Provide a per-write equivalent of the *O_DSYNC* *os.open()* flag. This flag effect applies only to the data range written by the system call.

適用： Linux 4.7 以上。

在 3.7 版被加入.

os.**RWF_SYNC**

Provide a per-write equivalent of the *O_SYNC* *os.open()* flag. This flag effect applies only to the data range written by the system call.

適用： Linux 4.7 以上。

在 3.7 版被加入.

os.**RWF_APPEND**

Provide a per-write equivalent of the *O_APPEND* *os.open()* flag. This flag is meaningful only for *os.pwritev()*, and its effect applies only to the data range written by the system call. The *offset* argument does not affect the write operation; the data is always appended to the end of the file. However, if the *offset* argument is `-1`, the current file *offset* is updated.

適用： Linux 4.16 以上。

在 3.10 版被加入.

os.**read**(*fd*, *n*, */*)

Read at most *n* bytes from file descriptor *fd*.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

備🄵

This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To read a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdin*, use its `read()` or `readline()` methods.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**sendfile**(*out_fd*, *in_fd*, *offset*, *count*)

os.**sendfile**(*out_fd*, *in_fd*, *offset*, *count*, *headers=()*, *trailers=()*, *flags=0*)

Copy *count* bytes from file descriptor *in_fd* to file descriptor *out_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return `0`.

The first function notation is supported by all platforms that define *sendfile()*.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in_fd* and the position of *in_fd* is updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of `0` for *count* specifies to send until the end of *in_fd* is reached.

All platforms support sockets as *out_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

適用： Unix、非 Emscripten、非 WASI。

備🄵

For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

在 3.3 版被加入.

在 3.9 版的變更: Parameters *out* and *in* was renamed to *out_fd* and *in_fd*.

os.**SF_NODISKIO**

os.**SF_MNOWAIT**

os.**SF_SYNC**

Parameters to the `sendfile()` function, if the implementation supports them.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**SF_NOCACHE**

Parameter to the `sendfile()` function, if the implementation supports it. The data won't be cached in the virtual memory and will be freed afterwards.

適用： Unix、非 Emscripten、非 WASI。

在 3.11 版被加入.

os.**set_blocking**(*fd*, *blocking*, */*)

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if blocking is `False`, clear the flag otherwise.

另請參🄵`get_blocking()` 與`socket.socket.setblocking()`。

適用： Unix、Windows。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

On Windows, this function is limited to pipes.

在 3.5 版被加入.

在 3.12 版的變更: 新增對 Windows 上的 pipe 支援。

os.**splice**(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Transfer *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. At least one of the file descriptors must refer to a pipe. If *offset_src* is `None`, then *src* is read from the current position; respectively for *offset_dst*. The offset associated to the file descriptor that refers to a pipe must be `None`. The files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with `errno` set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

Upon successful completion, returns the number of bytes spliced to or from the pipe. A return value of 0 means end of input. If *src* refers to a pipe, then this means that there was no data to transfer, and it would not make sense to block because there are no writers connected to the write end of the pipe.

適用： Linux 2.6.17 以上且具有 glibc 2.5 以上

在 3.10 版被加入.

os.**SPLICE_F_MOVE**

os.**SPLICE_F_NONBLOCK**

os.**SPLICE_F_MORE**

在 3.10 版被加入.

os.**readv**(*fd*, *buffers*, /)

Read from a file descriptor *fd* into a number of mutable *bytes-like objects* *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

適用： Unix。

在 3.3 版被加入.

os.**tcgetpgrp**(*fd*, /)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*).

適用： Unix、非 WASI。

os.**tcsetpgrp**(*fd*, *pg*, /)

Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*) to *pg*.

適用： Unix、非 WASI。

os.**ttyname**(*fd*, /)

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

適用： Unix。

os.**write**(*fd*, *str*, /)

Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

備🄵

This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To write a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdout* or *sys.stderr*, use its `write()` method.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**writev**(*fd*, *buffers*, /)

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

適用： Unix。

在 3.3 版被加入.

Querying the size of a terminal

在 3.3 版被加入.

os.**get_terminal_size**(*fd=STDOUT_FILENO*, /)

Return the size of the terminal window as `(columns, lines)`, tuple of type *terminal_size*.

The optional argument `fd` (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an *OSError* is raised.

shutil.get_terminal_size() is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

適用： Unix、Windows。

class os.**terminal_size**

A subclass of tuple, holding `(columns, lines)` of the terminal window size.

columns

Width of the terminal window in characters.

lines

Height of the terminal window in characters.

Inheritance of File Descriptors

在 3.4 版被加入.

A file descriptor has an ”inheritable” flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using *spawn** functions, all inheritable handles and all inheritable file descriptors are inherited. Using the *subprocess* module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the *close_fds* parameter is `False`.

On WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`, the file descriptor cannot be modified.

os.**get_inheritable**(*fd*, /)

Get the ”inheritable” flag of the specified file descriptor (a boolean).

os.**set_inheritable**(*fd*, *inheritable*, /)

Set the ”inheritable” flag of the specified file descriptor.

os.**get_handle_inheritable**(*handle*, /)

Get the ”inheritable” flag of the specified handle (a boolean).

適用： Windows。

os.**set_handle_inheritable**(*handle*, *inheritable*, /)

Set the "inheritable" flag of the specified handle.

適用： Windows。

16.1.6 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the *os* module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`).)

  You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using *os.supports_fd*. If this functionality is unavailable, using it will raise a *NotImplementedError*.

  If the function also supports *dir_fd* or *follow_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

  You can check whether or not *dir_fd* is supported for a particular function on your platform using *os.supports_dir_fd*. If it's unavailable, using it will raise a *NotImplementedError*.

- **not following symlinks:** If *follow_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python will call the `l...` variant of the function.)

  You can check whether or not *follow_symlinks* is supported for a particular function on your platform using *os.supports_follow_symlinks*. If it's unavailable, using it will raise a *NotImplementedError*.

os.**access**(*path*, *mode*, *, *dir_fd=None*, *effective_ids=False*, *follow_symlinks=True*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be *F_OK* to test the existence of *path*, or it can be the inclusive OR of one or more of *R_OK*, *W_OK*, and *X_OK* to test permissions. Return *True* if access is allowed, *False* if not. See the Unix man page *access(2)* for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective_ids* is `True`, *access()* will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective_ids* may not be supported on your platform; you can check whether or not it is available using *os.supports_effective_ids*. If it is unavailable, using it will raise a *NotImplementedError*.

備🄵

Using *access()* to check if a user is authorized to e.g. open a file before actually doing so using *open()* creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

備🄵

I/O operations may fail even when *access()* indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

在 3.3 版的變更: 新增 *dir_fd*、*effective_ids* 與 *follow_symlinks* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

os.**F_OK**

os.**R_OK**

os.**W_OK**

os.**X_OK**

Values to pass as the *mode* parameter of *access()* to test the existence, readability, writability and executability of *path*, respectively.

os.**chdir**(*path*)

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

This function can raise *OSError* and subclasses such as *FileNotFoundError*, *PermissionError*, and *NotADirectoryError*.

Raises an *auditing event* `os.chdir` with argument `path`.

在 3.3 版的變更: Added support for specifying *path* as a file descriptor on some platforms.

在 3.6 版的變更: Accepts a *path-like object*.

os.**chflags**(*path*, *flags*, *, *follow_symlinks=True*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the *stat* module):

- *stat.UF_NODUMP*
- *stat.UF_IMMUTABLE*
- *stat.UF_APPEND*
- *stat.UF_OPAQUE*
- *stat.UF_NOUNLINK*
- *stat.UF_COMPRESSED*
- *stat.UF_HIDDEN*

- *stat.SF_ARCHIVED*
- *stat.SF_IMMUTABLE*
- *stat.SF_APPEND*
- *stat.SF_NOUNLINK*
- *stat.SF_SNAPSHOT*

This function can support *not following symlinks*.

Raises an *auditing event* `os.chflags` with arguments `path`, `flags`.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版的變更: 新增 *follow_symlinks* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`chmod`**(*path*, *mode*, *, *dir_fd=None*, *follow_symlinks=True*)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the *stat* module) or bitwise ORed combinations of them:

- *stat.S_ISUID*
- *stat.S_ISGID*
- *stat.S_ENFMT*
- *stat.S_ISVTX*
- *stat.S_IREAD*
- *stat.S_IWRITE*
- *stat.S_IEXEC*
- *stat.S_IRWXU*
- *stat.S_IRUSR*
- *stat.S_IWUSR*
- *stat.S_IXUSR*
- *stat.S_IRWXG*
- *stat.S_IRGRP*
- *stat.S_IWGRP*
- *stat.S_IXGRP*
- *stat.S_IRWXO*
- *stat.S_IROTH*
- *stat.S_IWOTH*
- *stat.S_IXOTH*

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

備🄵

Although Windows supports *chmod()*, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`chown`**(*path*, *uid*, *gid*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

See *shutil.chown()* for a higher-level function that accepts names in addition to numeric ids.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

適用： Unix。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

在 3.6 版的變更: Supports a *path-like object*.

`os.`**`chroot`**(*path*)

Change the root directory of the current process to *path*.

適用： Unix、非 Emscripten、非 WASI。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`fchdir`**(*fd*)

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Raises an *auditing event* `os.chdir` with argument `path`.

適用： Unix。

`os.`**`getcwd`**()

Return a string representing the current working directory.

`os.`**`getcwdb`**()

Return a bytestring representing the current working directory.

在 3.8 版的變更: The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see **PEP 529** for the rationale. The function is no longer deprecated on Windows.

`os.`**`lchflags`**(*path*, *flags*)

Set the flags of *path* to the numeric *flags*, like *chflags()*, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Raises an *auditing event* `os.chflags` with arguments `path`, `flags`.

適用： Unix、非 Emscripten、非 WASI。

在 3.6 版的變更: Accepts a *path-like object*.

`os.lchmod`(*path*, *mode*)

Change the mode of *path* to the numeric *mode*. If path is a symlink, this affects the symlink rather than the target. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

`lchmod()` is not part of POSIX, but Unix implementations may have it if changing the mode of symbolic links is supported.

Raises an *auditing event* `os.chmod` with arguments `path`, `mode`, `dir_fd`.

適用： Unix、非 Linux、FreeBSD 1.3 以上、NetBSD 1.3 以上、非 OpenBSD。

在 3.6 版的變更: Accepts a *path-like object*.

`os.lchown`(*path*, *uid*, *gid*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Raises an *auditing event* `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

適用： Unix。

在 3.6 版的變更: Accepts a *path-like object*.

`os.link`(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*, *follow_symlinks=True*)

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

Raises an *auditing event* `os.link` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

適用： Unix、Windows、非 Emscripten。

在 3.2 版的變更: 新支援 Windows。

在 3.3 版的變更: 新增 *src_dir_fd*、*dst_dir_fd* 與 *follow_symlinks* 參數。

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

`os.listdir`(*path='.'*)

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an *auditing event* `os.listdir` with argument `path`.

備🄵

To encode `str` filenames to `bytes`, use *fsencode()*.

也參考

The *scandir()* function returns directory entries along with file attribute information, giving better performance for many common use cases.

在 3.2 版的變更: The *path* parameter became optional.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor.

在 3.6 版的變更: Accepts a *path-like object*.

os.**listdrives**()

Return a list containing the names of drives on a Windows system.

A drive name typically looks like `'C:\\'`. Not every drive name will be associated with a volume, and some may be inaccessible for a variety of reasons, including permissions, network connectivity or missing media. This function does not test for access.

May raise *OSError* if an error occurs collecting the drive names.

Raises an *auditing event* `os.listdrives` with no arguments.

適用： Windows。

在 3.12 版被加入.

os.**listmounts**(*volume*)

Return a list containing the mount points for a volume on a Windows system.

volume must be represented as a GUID path, like those returned by *os.listvolumes()*. Volumes may be mounted in multiple locations or not at all. In the latter case, the list will be empty. Mount points that are not associated with a volume will not be returned by this function.

The mount points return by this function will be absolute paths, and may be longer than the drive name.

Raises *OSError* if the volume is not recognized or if an error occurs collecting the paths.

Raises an *auditing event* `os.listmounts` with argument `volume`.

適用： Windows。

在 3.12 版被加入.

os.**listvolumes**()

Return a list containing the volumes in the system.

Volumes are typically represented as a GUID path that looks like `\\?\Volume{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}\`. Files can usually be accessed through a GUID path, permissions allowing. However, users are generally not familiar with them, and so the recommended use of this function is to retrieve mount points using *os.listmounts()*.

May raise *OSError* if an error occurs collecting the volumes.

Raises an *auditing event* `os.listvolumes` with no arguments.

適用： Windows。

在 3.12 版被加入.

os.**lstat**(*path*, *, *dir_fd=None*)

Perform the equivalent of an `lstat()` system call on the given path. Similar to *stat()*, but does not follow symbolic links. Return a *stat_result* object.

On platforms that do not support symbolic links, this is an alias for *stat()*.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

也參考

The `stat()` function.

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.8 版的變更: On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for `stat()`.

`os.`**`mkdir`**(*path*, *mode=0o777*, *, *dir_fd=None*)

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, `FileExistsError` is raised. If a parent directory in the path does not exist, `FileNotFoundError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

On Windows, a *mode* of `0o700` is specifically handled to apply access control to the new directory such that only the current user and administrators have access. Other values of *mode* are ignored.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

Raises an *auditing event* `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.12.4 版的變更: Windows now handles a *mode* of `0o700`.

`os.`**`makedirs`**(*name*, *mode=0o777*, *exist_ok=False*)

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to `mkdir()` for creating the leaf directory; see *the mkdir() description* for how it is interpreted. To set the file permission bits of any newly created parent directories you can set the umask before invoking `makedirs()`. The file permission bits of existing parent directories are not changed.

If *exist_ok* is `False` (the default), a `FileExistsError` is raised if the target directory already exists.

備🄵

`makedirs()` will become confused if the path elements to create include `pardir` (eg. ".." on UNIX systems).

This function handles UNC paths correctly.

Raises an *auditing event* `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

在 3.2 版的變更: 新增 *exist_ok* 參數。

在 3.4.1 版的變更: Before Python 3.4.1, if *exist_ok* was `True` and the directory existed, `makedirs()` would still raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See bpo-21082.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: The *mode* argument no longer affects the file permission bits of newly created intermediate-level directories.

`os.`**`mkfifo`**(*path*, *mode=0o666*, ***, *dir_fd=None*)

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between "client" and "server" type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn't open the FIFO --- it just creates the rendezvous point.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`mknod`**(*path*, *mode=0o600*, *device=0*, ***, *dir_fd=None*)

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`major`**(*device*, */*)

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.`**`minor`**(*device*, */*)

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.`**`makedev`**(*major*, *minor*, */*)

Compose a raw device number from the major and minor device numbers.

`os.`**`pathconf`**(*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

This function can support *specifying a file descriptor*.

適用： Unix。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`pathconf_names`**

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用： Unix。

`os.`**`readlink`**(*path*, *, *dir_fd=None*)

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a `PathLike` interface), the result will also be a string object, and the call may raise a UnicodeDecodeError. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

When trying to resolve a path that may contain links, use `realpath()` to properly handle recursion and platform differences.

適用： Unix、Windows。

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object* on Unix.

在 3.8 版的變更: Accepts a *path-like object* and a bytes object on Windows.

Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\` prefix) rather than the optional "print name" field that was previously returned.

`os.`**`remove`**(*path*, *, *dir_fd=None*)

Remove (delete) the file *path*. If *path* is a directory, an `OSError` is raised. Use `rmdir()` to remove directories. If the file does not exist, a `FileNotFoundError` is raised.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`removedirs`**(*name*)

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error

is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises *OSError* if the leaf directory could not be successfully removed.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`rename`**(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* exists, the operation will fail with an *OSError* subclass in a number of cases:

On Windows, if *dst* exists a *FileExistsError* is always raised. The operation may fail if *src* and *dst* are on different filesystems. Use *shutil.move()* to support moves to a different filesystem.

On Unix, if *src* is a file and *dst* is a directory or vice-versa, an *IsADirectoryError* or a *NotADirectoryError* will be raised respectively. If both are directories and *dst* is empty, *dst* will be silently replaced. If *dst* is a non-empty directory, an *OSError* is raised. If both are files, *dst* will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use *replace()*.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

在 3.3 版的變更: 新增 *src_dir_fd* 與 *dst_dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

`os.`**`renames`**(*old*, *new*)

Recursive directory or file renaming function. Works like *rename()*, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using *removedirs()*.

備🄵

This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

在 3.6 版的變更: Accepts a *path-like object* for *old* and *new*.

`os.`**`replace`**(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, *OSError* will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

Raises an *auditing event* `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

在 3.3 版被加入.

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

os.**rmdir**(*path*, *, *dir_fd=None*)

Remove (delete) the directory *path*. If the directory does not exist or is not empty, a *FileNotFoundError* or an *OSError* is raised respectively. In order to remove whole directory trees, *shutil.rmtree()* can be used.

This function can support *paths relative to directory descriptors*.

Raises an *auditing event* `os.rmdir` with arguments `path`, `dir_fd`.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

os.**scandir**(*path='.'*)

Return an iterator of *os.DirEntry* objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using *scandir()* instead of *listdir()* can significantly increase the performance of code that also needs file type or file attribute information, because *os.DirEntry* objects expose this information if the operating system provides it when scanning a directory. All *os.DirEntry* methods may perform a system call, but *is_dir()* and *is_file()* usually only require a system call for symbolic links; *os.DirEntry.stat()* always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the type of the *name* and *path* attributes of each *os.DirEntry* will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Raises an *auditing event* `os.scandir` with argument `path`.

The *scandir()* iterator supports the *context manager* protocol and has the following method:

scandir.**close**()

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the `with` statement.

在 3.6 版被加入.

The following example shows a simple use of *scandir()* to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

備🄵

On Unix-based systems, *scandir()* uses the system's opendir() and readdir() functions. On Windows, it uses the Win32 FindFirstFileW and FindNextFileW functions.

在 3.5 版被加入.

在 3.6 版的變更: Added support for the *context manager* protocol and the *close()* method. If a *scandir()* iterator is neither exhausted nor explicitly closed a *ResourceWarning* will be emitted in its destructor.

The function accepts a *path-like object*.

在 3.7 版的變更: Added support for *file descriptors* on Unix.

class os.**DirEntry**

Object yielded by *scandir()* to expose the file path and other file attributes of a directory entry.

scandir() will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling *scandir()*, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise *OSError*. If you need very fine-grained control over errors, you can catch *OSError* when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the *PathLike* interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the *scandir()* *path* argument.

The *name* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where *scandir_path* is the *scandir()* *path* argument. The path is only absolute if the *scandir()* *path* argument was absolute. If the *scandir()* *path* argument was a *file descriptor*, the *path* attribute is the same as the *name* attribute.

The *path* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir(*, *follow_symlinks=True*)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* along with *stat.S_ISDIR()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow_symlinks* is `False`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

is_file(*, *follow_symlinks=True*)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per *is_dir()*.

is_symlink()

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call *os.path.islink()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

is_junction()

Return `True` if this entry is a junction (even if broken); return `False` if the entry points to a regular directory, any kind of file, a symlink, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call *os.path.isjunction()* to fetch up-to-date information.

在 3.12 版被加入.

stat(*, *follow_symlinks=True*)

Return a *stat_result* object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if *follow_symlinks* is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the *stat_result* are always set to zero. Call *os.stat()* to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of *pathlib.Path*. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()`, `is_junction()`, and `stat()` methods.

在 3.5 版被加入.

在 3.6 版的變更: Added support for the *PathLike* interface. Added support for *bytes* paths on Windows.

在 3.12 版的變更: The `st_ctime` attribute of a stat result is deprecated on Windows. The file creation time is properly available as `st_birthtime`, and in the future `st_ctime` may be changed to return zero or the metadata change time, if available.

`os.`**stat**(*path*, *, *dir_fd=None*, *follow_symlinks=True*)

Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given path. *path* may be specified as either a string or bytes -- directly or indirectly through the *PathLike* interface -- or as an open file descriptor. Return a *stat_result* object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use *`lstat()`*.

This function can support *specifying a file descriptor* and *not following symlinks*.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the *`os.path.realpath()`* function to resolve the path name as far as possible and call *`lstat()`* on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

範例：

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

也參考

`fstat()` 和*`lstat()`* 函式。

在 3.3 版的變更: 新增 *dir_fd* 與 *follow_symlinks* 參數，指定一個檔案描述器而非路徑。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.8 版的變更: On Windows, all reparse points that can be resolved by the operating system are now followed, and passing `follow_symlinks=False` disables following all name surrogate reparse points. If the operating system reaches a reparse point that it is not able to follow, *stat* now returns the information for the original path as if `follow_symlinks=False` had been specified instead of raising an error.

class os.**stat_result**

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of *`os.stat()`*, *`os.fstat()`* and *`os.lstat()`*.

Attributes:

st_mode

File mode: file type and file mode bits (permissions).

st_ino

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the file index on Windows

st_dev

Identifier of the device on which this file resides.

st_nlink

Number of hard links.

st_uid

User identifier of the file owner.

st_gid

Group identifier of the file owner.

st_size

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime

Time of most recent access expressed in seconds.

st_mtime

Time of most recent content modification expressed in seconds.

st_ctime

Time of most recent metadata change expressed in seconds.

在 3.12 版的變更: `st_ctime` is deprecated on Windows. Use `st_birthtime` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

st_atime_ns

Time of most recent access expressed in nanoseconds as an integer.

在 3.3 版被加入.

st_mtime_ns

Time of most recent content modification expressed in nanoseconds as an integer.

在 3.3 版被加入.

st_ctime_ns

Time of most recent metadata change expressed in nanoseconds as an integer.

在 3.3 版被加入.

在 3.12 版的變更: `st_ctime_ns` is deprecated on Windows. Use `st_birthtime_ns` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

st_birthtime

Time of file creation expressed in seconds. This attribute is not always available, and may raise *AttributeError*.

在 3.12 版的變更: `st_birthtime` is now available on Windows.

st_birthtime_ns

Time of file creation expressed in nanoseconds as an integer. This attribute is not always available, and may raise *AttributeError*.

在 3.12 版被加入.

備🄵

The exact meaning and resolution of the *st_atime*, *st_mtime*, *st_ctime* and *st_birthtime* attributes depend on the operating system and the file system. For example, on Windows systems using the

FAT32 file systems, *st_mtime* has 2-second resolution, and *st_atime* has only 1-day resolution. See your operating system documentation for details.

Similarly, although *st_atime_ns*, *st_mtime_ns*, *st_ctime_ns* and *st_birthtime_ns* are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store *st_atime*, *st_mtime*, *st_ctime* and *st_birthtime* cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use *st_atime_ns*, *st_mtime_ns*, *st_ctime_ns* and *st_birthtime_ns*.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks

Number of 512-byte blocks allocated for file. This may be smaller than *st_size*/512 when the file has holes.

st_blksize

”Preferred” blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev

Type of device if an inode device.

st_flags

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen

File generation number.

On Solaris and derivatives, the following attributes may also be available:

st_fstype

String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

st_rsize

Real size of the file.

st_creator

Creator of the file.

st_type

File type.

On Windows systems, the following attributes are also available:

st_file_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` <stat.FILE_ATTRIBUTE_ARCHIVE> constants in the *stat* module.

在 3.5 版被加入.

st_reparse_tag

When *st_file_attributes* has the *FILE_ATTRIBUTE_REPARSE_POINT* set, this field contains the tag identifying the type of reparse point. See the *IO_REPARSE_TAG_** constants in the *stat* module.

The standard module *stat* defines functions and constants that are useful for extracting information from a stat structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a *stat_result* instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the stat structure, in the order *st_mode*, *st_ino*, *st_dev*, *st_nlink*, *st_uid*, *st_gid*, *st_size*, *st_atime*, *st_mtime*, *st_ctime*. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing *stat_result* as a tuple always returns integers.

在 3.5 版的變更: Windows now returns the file index as *st_ino* when available.

在 3.7 版的變更: Added the *st_fstype* member to Solaris/derivatives.

在 3.8 版的變更: 在 Windows 上新增*st_reparse_tag* 成員。

在 3.8 版的變更: On Windows, the *st_mode* member now identifies special files as S_IFCHR, S_IFIFO or S_IFBLK as appropriate.

在 3.12 版的變更: On Windows, *st_ctime* is deprecated. Eventually, it will contain the last metadata change time, for consistency with other platforms, but for now still contains creation time. Use *st_birthtime* for the creation time.

On Windows, *st_ino* may now be up to 128 bits, depending on the file system. Previously it would not be above 64 bits, and larger file identifiers would be arbitrarily packed.

On Windows, *st_rdev* no longer returns a value. Previously it would contain the same as *st_dev*, which was incorrect.

在 Windows 上新增*st_birthtime* 成員。

os.**statvfs**(*path*)

Perform a statvfs() system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the statvfs structure, namely: f_bsize, f_frsize, f_blocks, f_bfree, f_bavail, f_files, f_ffree, f_favail, f_flag, f_namemax, f_fsid.

Two module-level constants are defined for the f_flag attribute's bit-flags: if ST_RDONLY is set, the filesystem is mounted read-only, and if ST_NOSUID is set, the semantics of setuid/setgid bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are ST_NODEV (disallow access to device special files), ST_NOEXEC (disallow program execution), ST_SYNCHRONOUS (writes are synced at once), ST_MANDLOCK (allow mandatory locks on an FS), ST_WRITE (write on file/directory/symlink), ST_APPEND (append-only file), ST_IMMUTABLE (immutable file), ST_NOATIME (do not update access times), ST_NODIRATIME (do not update directory access times), ST_RELATIME (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

適用： Unix。

在 3.2 版的變更: 新增 ST_RDONLY 與 ST_NOSUID 常數。

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor.

在 3.4 版的變更: The ST_NODEV, ST_NOEXEC, ST_SYNCHRONOUS, ST_MANDLOCK, ST_WRITE, ST_APPEND, ST_IMMUTABLE, ST_NOATIME, ST_NODIRATIME, and ST_RELATIME constants were added.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增 f_fsid 屬性。

os.**supports_dir_fd**

A *set* object indicating which functions in the *os* module accept an open file descriptor for their *dir_fd* parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the *dir_fd* parameter is not available on all platforms Python supports. For consistency's sake, functions that may support *dir_fd* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for *dir_fd* is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its *dir_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if *os.stat()* accepts open file descriptors for *dir_fd* on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently *dir_fd* parameters only work on Unix platforms; none of them work on Windows.

在 3.3 版被加入.

os.**supports_effective_ids**

A *set* object indicating whether *os.access()* permits specifying `True` for its *effective_ids* parameter on the local platform. (Specifying `False` for *effective_ids* is always supported on all platforms.) If the local platform supports it, the collection will contain *os.access()*; otherwise it will be empty.

This expression evaluates to `True` if *os.access()* supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently *effective_ids* is only supported on Unix platforms; it does not work on Windows.

在 3.3 版被加入.

os.**supports_fd**

A *set* object indicating which functions in the *os* module permit specifying their *path* parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as *path* arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if *os.chdir()* accepts open file descriptors for *path* on your local platform:

```
os.chdir in os.supports_fd
```

在 3.3 版被加入.

os.**supports_follow_symlinks**

A *set* object indicating which functions in the *os* module accept `False` for their *follow_symlinks* parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement *follow_symlinks* is not available on all platforms Python supports. For consistency's sake, functions that may support *follow_symlinks* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for *follow_symlinks* is always supported on all platforms.)

To check whether a particular function accepts `False` for its *follow_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling *os.stat()* on the local platform:

```
os.stat in os.supports_follow_symlinks
```

在 3.3 版被加入.

os.**symlink**(*src*, *dst*, *target_is_directory=False*, *, *dir_fd=None*)

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

This function can support *paths relative to directory descriptors*.

> **備🄵**
>
> On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the *SeCreateSymbolicLinkPrivilege* privilege is required, or the process must be run as an administrator.
>
> *OSError* is raised when the function is called by an unprivileged user.

Raises an *auditing event* `os.symlink` with arguments `src`, `dst`, `dir_fd`.

適用： Unix、Windows。

The function is limited on Emscripten and WASI, see *WebAssembly 平台* for more information.

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: Added the *dir_fd* parameter, and now allow *target_is_directory* on non-Windows platforms.

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

在 3.8 版的變更: Added support for unelevated symlinks on Windows with Developer Mode.

os.**sync**()

Force write of everything to disk.

適用： Unix。

在 3.3 版被加入.

os.**truncate**(*path*, *length*)

Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

Raises an *auditing event* `os.truncate` with arguments `path`, `length`.

適用： Unix、Windows。

在 3.3 版被加入.

在 3.5 版的變更: 新增對 Windows 的支援

在 3.6 版的變更: Accepts a *path-like object*.

os.**unlink**(*path*, *, *dir_fd=None*)

Remove (delete) the file *path*. This function is semantically identical to *remove()*; the `unlink` name is its traditional Unix name. Please see the documentation for *remove()* for further information.

Raises an *auditing event* `os.remove` with arguments `path`, `dir_fd`.

在 3.3 版的變更: 新增 *dir_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

os.**utime**(*path*, *times=None*, *, [*ns*,]*dir_fd=None*, *follow_symlinks=True*)

Set the access and modified times of the file specified by *path*.

utime() takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent *stat()* call, depending on the resolution with which your operating system records access and modification times; see *stat()*. The best way to preserve exact times is to use the *st_atime_ns* and *st_mtime_ns* fields from the *os.stat()* result object with the *ns* parameter to *utime()*.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Raises an *auditing event* `os.utime` with arguments `path`, `times`, `ns`, `dir_fd`.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

在 3.6 版的變更: Accepts a *path-like object*.

os.**walk**(*top*, *topdown=True*, *onerror=None*, *followlinks=False*)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (including symlinks to directories, and excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and *walk()* will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform *walk()* about directories the caller creates or renames before it resumes *walk()* again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the *scandir()* call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an *OSError* instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, *walk()* will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

備𝔽

Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. *walk()* does not keep track of the directories it visited already.

備𝔽

If you pass a relative pathname, don't change the current working directory between resumptions of *walk()*. *walk()* never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS directories
```

In the next example (simple implementation of *shutil.rmtree()*), walking the tree bottom-up is essential, *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

Raises an *auditing event* `os.walk` with arguments `top`, `topdown`, `onerror`, `followlinks`.

在 3.5 版的變更: This function now calls *os.scandir()* instead of *os.listdir()*, making it faster by reducing the number of calls to *os.stat()*.

在 3.6 版的變更: Accepts a *path-like object*.

`os.`**`fwalk`**(*top='.'*, *topdown=True*, *onerror=None*, ***, *follow_symlinks=False*, *dir_fd=None*)

This behaves exactly like *walk()*, except that it yields a 4-tuple `(dirpath, dirnames, filenames, dirfd)`, and it supports `dir_fd`.

dirpath, *dirnames* and *filenames* are identical to *walk()* output, and *dirfd* is a file descriptor referring to the directory *dirpath*.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the *fwalk()* default value for *follow_symlinks* is `False`.

備𝔽

Since *fwalk()* yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with *dup()*) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/email'):
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end="")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

Raises an *auditing event* `os.fwalk` with arguments `top`, `topdown`, `onerror`, `follow_symlinks`, `dir_fd`.

適用： Unix。

在 3.3 版被加入.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增對*bytes* 路徑的支援。

`os.`**`memfd_create`**(*name*[, *flags=os.MFD_CLOEXEC*])

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is *non-inheritable*.

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

適用： Linux 3.17 以上且具有 glibc 2.27 以上。

在 3.8 版被加入.

`os.`**`MFD_CLOEXEC`**

`os.`**`MFD_ALLOW_SEALING`**

`os.`**`MFD_HUGETLB`**

`os.`**`MFD_HUGE_SHIFT`**

os.**MFD_HUGE_MASK**
os.**MFD_HUGE_64KB**
os.**MFD_HUGE_512KB**
os.**MFD_HUGE_1MB**
os.**MFD_HUGE_2MB**
os.**MFD_HUGE_8MB**
os.**MFD_HUGE_16MB**
os.**MFD_HUGE_32MB**
os.**MFD_HUGE_256MB**
os.**MFD_HUGE_512MB**
os.**MFD_HUGE_1GB**
os.**MFD_HUGE_2GB**
os.**MFD_HUGE_16GB**

這些旗標可以傳給*memfd_create()*。

適用： Linux 3.17 以上且具有 glibc 2.27 以上

MFD_HUGE* 旗標僅在 Linux 4.14 以上可用。

在 3.8 版被加入.

os.**eventfd**(*initval*[, *flags=os.EFD_CLOEXEC*])

Create and return an event file descriptor. The file descriptors supports raw *read()* and *write()* with a buffer size of 8, *select()*, *poll()* and similar. See man page *eventfd(2)* for more information. By default, the new file descriptor is *non-inheritable*.

initval is the initial value of the event counter. The initial value must be a 32 bit unsigned integer. Please note that the initial value is limited to a 32 bit unsigned int although the event counter is an unsigned 64 bit integer with a maximum value of 2^{64}-2.

flags can be constructed from *EFD_CLOEXEC*, *EFD_NONBLOCK*, and *EFD_SEMAPHORE*.

If *EFD_SEMAPHORE* is specified and the event counter is non-zero, *eventfd_read()* returns 1 and decrements the counter by one.

If *EFD_SEMAPHORE* is not specified and the event counter is non-zero, *eventfd_read()* returns the current event counter value and resets the counter to zero.

If the event counter is zero and *EFD_NONBLOCK* is not specified, *eventfd_read()* blocks.

eventfd_write() increments the event counter. Write blocks if the write operation would increment the counter to a value larger than 2^{64}-2.

範例：

```
import os

# semaphore with start value '1'
fd = os.eventfd(1, os.EFD_SEMAPHORE | os.EFC_CLOEXEC)
try:
    # acquire semaphore
    v = os.eventfd_read(fd)
    try:
        do_work()
    finally:
        # release semaphore
```

(繼續下一頁)

(繼續上一頁)

```
        os.eventfd_write(fd, v)
finally:
    os.close(fd)
```

適用： Linux 2.6.27 以上且具有 glibc 2.8 以上

在 3.10 版被加入.

os.**eventfd_read**(*fd*)

Read value from an `eventfd()` file descriptor and return a 64 bit unsigned int. The function does not verify that *fd* is an `eventfd()`.

適用： Linux 2.6.27 以上

在 3.10 版被加入.

os.**eventfd_write**(*fd*, *value*)

Add value to an `eventfd()` file descriptor. *value* must be a 64 bit unsigned int. The function does not verify that *fd* is an `eventfd()`.

適用： Linux 2.6.27 以上

在 3.10 版被加入.

os.**EFD_CLOEXEC**

Set close-on-exec flag for new `eventfd()` file descriptor.

適用： Linux 2.6.27 以上

在 3.10 版被加入.

os.**EFD_NONBLOCK**

設定新的`eventfd()` 檔案描述器的`O_NONBLOCK` 狀態旗標。

適用： Linux 2.6.27 以上

在 3.10 版被加入.

os.**EFD_SEMAPHORE**

Provide semaphore-like semantics for reads from an `eventfd()` file descriptor. On read the internal counter is decremented by one.

適用： Linux 2.6.30 以上

在 3.10 版被加入.

Linux extended attributes

在 3.3 版被加入.

These functions are all available on Linux only.

os.**getxattr**(*path*, *attribute*, *, *follow_symlinks=True*)

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the `PathLike` interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* `os.getxattr` with arguments `path`, `attribute`.

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

os.**listxattr**(*path=None*, *, *follow_symlinks=True*)

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is None, *listxattr()* will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* os.listxattr with argument path.

在 3.6 版的變更: Accepts a *path-like object*.

os.**removexattr**(*path*, *attribute*, *, *follow_symlinks=True*)

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the *PathLike* interface). If it is a string, it is encoded with the *filesystem encoding and error handler*.

This function can support *specifying a file descriptor* and *not following symlinks*.

Raises an *auditing event* os.removexattr with arguments path, attribute.

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

os.**setxattr**(*path*, *attribute*, *value*, *flags=0*, *, *follow_symlinks=True*)

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the *PathLike* interface). If it is a str, it is encoded with the *filesystem encoding and error handler*. *flags* may be *XATTR_REPLACE* or *XATTR_CREATE*. If *XATTR_REPLACE* is given and the attribute does not exist, ENODATA will be raised. If *XATTR_CREATE* is given and the attribute already exists, the attribute will not be created and EEXISTS will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

> **備🄵**
>
> A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

Raises an *auditing event* os.setxattr with arguments path, attribute, value, flags.

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

os.**XATTR_SIZE_MAX**

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

os.**XATTR_CREATE**

This is a possible value for the flags argument in *setxattr()*. It indicates the operation must create an attribute.

os.**XATTR_REPLACE**

This is a possible value for the flags argument in *setxattr()*. It indicates the operation must replace an existing attribute.

16.1.7 行程管理

These functions may be used to create and manage processes.

The various *exec** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the argv[0] passed to a program's main(). For example, os.execv('/bin/echo', ['foo', 'bar']) will only print bar on standard output; foo will seem to be ignored.

os.**abort**()

Generate a SIGABRT signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for SIGABRT with *signal.signal()*.

os.**add_dll_directory**(*path*)

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through *sys.path*), and also by *ctypes*.

Remove the directory by calling **close()** on the returned object or using it in a with statement.

See the Microsoft documentation for more information about how DLLs are loaded.

Raises an *auditing event* os.add_dll_directory with argument path.

適用： Windows。

在 3.8 版被加入: Previous versions of CPython would resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching PATH or the current working directory, and OS functions such as AddDllDirectory having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the porting notes for information on updating libraries.

os.**execl**(*path*, *arg0*, *arg1*, ...)

os.**execle**(*path*, *arg0*, *arg1*, ..., *env*)

os.**execlp**(*file*, *arg0*, *arg1*, ...)

os.**execlpe**(*file*, *arg0*, *arg1*, ..., *env*)

os.**execv**(*path*, *args*)

os.**execve**(*path*, *args*, *env*)

os.**execvp**(*file*, *args*)

os.**execvpe**(*file*, *args*, *env*)

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as *OSError* exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using sys.stdout.flush() or *os.fsync()* before calling an *exec** function.

The "l" and "v" variants of the *exec** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the execl*() functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a "p" near the end (*execlp()*, *execlpe()*, *execvp()*, and *execvpe()*) will use the PATH environment variable to locate the program *file*. When the environment is being replaced (using one of the *exec*e* variants, discussed in the next paragraph), the new environment is used as the source of the PATH variable. The other variants, *execl()*, *execle()*, *execv()*, and *execve()*, will not use the PATH variable to locate the executable; *path* must contain an appropriate absolute or relative path. Relative paths must include at least one slash, even on Windows, as plain names will not be resolved.

For *execle()*, *execlpe()*, *execve()*, and *execvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead

of the current process' environment); the functions *execl()*, *execlp()*, *execv()*, and *execvp()* all cause the new process to inherit the environment of the current process.

For *execve()* on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using *os.supports_fd*. If it is unavailable, using it will raise a *NotImplementedError*.

Raises an *auditing event* `os.exec` with arguments `path`, `args`, `env`.

適用： Unix、Windows、非 Emscripten、非 WASI。

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor for *execve()*.

在 3.6 版的變更: Accepts a *path-like object*.

`os._exit`(*n*)

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

備🄵

The standard way to exit is *sys.exit(n)*. `_exit()` should normally only be used in the child process after a *fork()*.

The following exit codes are defined and can be used with *_exit()*, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

備🄵

Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

`os.EX_OK`

Exit code that means no error occurred. May be taken from the defined value of `EXIT_SUCCESS` on some platforms. Generally has a value of zero.

適用： Unix、Windows。

`os.EX_USAGE`

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

適用： Unix、非 Emscripten、非 WASI。

`os.EX_DATAERR`

Exit code that means the input data was incorrect.

適用： Unix、非 Emscripten、非 WASI。

`os.EX_NOINPUT`

Exit code that means an input file did not exist or was not readable.

適用： Unix、非 Emscripten、非 WASI。

`os.EX_NOUSER`

Exit code that means a specified user did not exist.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_NOHOST**

Exit code that means a specified host did not exist.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_UNAVAILABLE**

Exit code that means that a required service is unavailable.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_SOFTWARE**

Exit code that means an internal software error was detected.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_OSERR**

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_OSFILE**

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_CANTCREAT**

Exit code that means a user specified output file could not be created.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_IOERR**

Exit code that means that an error occurred while doing I/O on some file.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_TEMPFAIL**

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_PROTOCOL**

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_NOPERM**

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

適用： Unix、非 Emscripten、非 WASI。

os.**EX_CONFIG**

Exit code that means that some kind of configuration error occurred.

適用： Unix、非 Emscripten、非 WASI。

os.**EX_NOTFOUND**

Exit code that means something like "an entry was not found".

適用： Unix、非 Emscripten、非 WASI。

os.**fork**()

Fork a child process. Return 0 in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using fork() from a thread.

Raises an *auditing event* os.fork with no arguments.

警告

If you use TLS sockets in an application calling fork(), see the warning in the *ssl* documentation.

警告

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

在 3.8 版的變更: Calling fork() in a subinterpreter is no longer supported (*RuntimeError* is raised).

在 3.12 版的變更: If Python is able to detect that your process has multiple threads, *os.fork()* now raises a *DeprecationWarning*.

We chose to surface this as a warning, when detectable, to better inform developers of a design problem that the POSIX platform specifically notes as not supported. Even in code that *appears* to work, it has never been safe to mix threading with *os.fork()* on POSIX platforms. The CPython runtime itself has always made API calls that are not safe for use in the child process when threads existed in the parent (such as malloc and free).

Users of macOS or users of libc or malloc implementations other than those typically found in glibc to date are among those already more likely to experience deadlocks running such code.

See this discussion on fork being incompatible with threads for technical details of why we're surfacing this long-standing platform compatibility problem to developers.

適用： POSIX、非 Emscripten、非 WASI。

os.**forkpty**()

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of (pid, fd), where *pid* is 0 in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

Raises an *auditing event* os.forkpty with no arguments.

警告

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

在 3.8 版的變更: Calling forkpty() in a subinterpreter is no longer supported (*RuntimeError* is raised).

在 3.12 版的變更: If Python is able to detect that your process has multiple threads, this now raises a *DeprecationWarning*. See the longer explanation on *os.fork()*.

適用： Unix、非 Emscripten、非 WASI。

os.**kill**(*pid*, *sig*, */*)

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL_C_EVENT* and *signal.CTRL_BREAK_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the TerminateProcess API, and the exit code will be set to *sig*. The Windows version of *kill()* additionally takes process handles to be killed.

另請參🄵*signal.pthread_kill()*。

Raises an *auditing event* os.kill with arguments pid, sig.

適用： Unix、Windows、非 Emscripten、非 WASI。

在 3.2 版的變更: 新支援 Windows。

os.**killpg**(*pgid*, *sig*, */*)

Send the signal *sig* to the process group *pgid*.

Raises an *auditing event* os.killpg with arguments pgid, sig.

適用： Unix、非 Emscripten、非 WASI。

os.**nice**(*increment*, */*)

Add *increment* to the process's "niceness". Return the new niceness.

適用： Unix、非 Emscripten、非 WASI。

os.**pidfd_open**(*pid*, *flags=0*)

Return a file descriptor referring to the process *pid* with *flags* set. This descriptor can be used to perform process management without races and signals.

更多細節請見 *pidfd_open(2)* 手🄵頁。

適用： Linux 5.3 以上

在 3.9 版被加入.

os.**PIDFD_NONBLOCK**

This flag indicates that the file descriptor will be non-blocking. If the process referred to by the file descriptor has not yet terminated, then an attempt to wait on the file descriptor using *waitid(2)* will immediately return the error *EAGAIN* rather than blocking.

適用： Linux 5.10 以上

在 3.12 版被加入.

os.**plock**(*op*, */*)

Lock program segments into memory. The value of *op* (defined in <sys/lock.h>) determines which segments are locked.

適用： Unix、非 Emscripten、非 WASI。

os.**popen**(*cmd*, *mode='r'*, *buffering=-1*)

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *buffering* argument have the same meaning as the corresponding argument to the built-in *open()* function. The returned file object reads or writes text strings rather than bytes.

The close method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of

the return code. (For example, the return value might be `- signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, *waitstatus_to_exitcode()* can be used to convert the `close` method result (exit status) into an exit code if it is not `None`. On Windows, the `close` method result is directly the exit code (or `None`).

This is implemented using *subprocess.Popen*; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

適用： 非 Emscripten、非 WASI。

備🄵

The *Python UTF-8 Mode* affects encodings used for *cmd* and pipe contents.

popen() is a simple wrapper around *subprocess.Popen*. Use *subprocess.Popen* or *subprocess.run()* to control options like encodings.

`os.`**`posix_spawn`**(*path*, *argv*, *env*, *, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the `posix_spawn()` C library API for use from Python.

Most users should use *subprocess.run()* instead of *posix_spawn()*.

The positional-only arguments *path*, *args*, and *env* are similar to *execve()*.

The *path* parameter is the path to the executable file. The *path* should contain a directory. Use *posix_spawnp()* to pass an executable file without directory.

The *file_actions* argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's `fork()` and `exec()` steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

`os.`**`POSIX_SPAWN_OPEN`**

(`os.POSIX_SPAWN_OPEN`, *fd*, *path*, *flags*, *mode*)

Performs `os.dup2(os.open(path, flags, mode), fd)`.

`os.`**`POSIX_SPAWN_CLOSE`**

(`os.POSIX_SPAWN_CLOSE`, *fd*)

Performs `os.close(fd)`.

`os.`**`POSIX_SPAWN_DUP2`**

(`os.POSIX_SPAWN_DUP2`, *fd*, *new_fd*)

Performs `os.dup2(fd, new_fd)`.

These tuples correspond to the C library `posix_spawn_file_actions_addopen()`, `posix_spawn_file_actions_addclose()`, and `posix_spawn_file_actions_adddup2()` API calls used to prepare for the `posix_spawn()` call itself.

The *setpgroup* argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of *setpgroup* is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library `POSIX_SPAWN_SETPGROUP` flag.

If the *resetids* argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override

the setting of the effective UID and GID. This argument corresponds to the C library `POSIX_SPAWN_RESETIDS` flag.

If the *setsid* argument is `True`, it will create a new session ID for `posix_spawn`. *setsid* requires `POSIX_SPAWN_SETSID` or `POSIX_SPAWN_SETSID_NP` flag. Otherwise, *NotImplementedError* is raised.

The *setsigmask* argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library `POSIX_SPAWN_SETSIGMASK` flag.

The *sigdef* argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library `POSIX_SPAWN_SETSIGDEF` flag.

The *scheduler* argument must be a tuple containing the (optional) scheduler policy and an instance of *sched_param* with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library `POSIX_SPAWN_SETSCHEDPARAM` and `POSIX_SPAWN_SETSCHEDULER` flags.

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

在 3.8 版被加入.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`posix_spawnp`**(*path*, *argv*, *env*, ***, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the `posix_spawnp()` C library API for use from Python.

Similar to *posix_spawn()* except that the system searches for the *executable* file in the list of directories specified by the `PATH` environment variable (in the same way as for `execvp(3)`).

Raises an *auditing event* `os.posix_spawn` with arguments `path`, `argv`, `env`.

在 3.8 版被加入.

適用： POSIX、非 Emscripten、非 WASI。

見*posix_spawn()* 文件。

`os.`**`register_at_fork`**(***, *before=None*, *after_in_parent=None*, *after_in_child=None*)

Register callables to be executed when a new child process is forked using *os.fork()* or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after_in_parent* is a function called from the parent process after forking a child process.
- *after_in_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical *subprocess* launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

適用： Unix、非 Emscripten、非 WASI。

在 3.7 版被加入.

os.**spawnl**(*mode*, *path*, *...*)

os.**spawnle**(*mode*, *path*, *...*, *env*)

os.**spawnlp**(*mode*, *file*, *...*)

os.**spawnlpe**(*mode*, *file*, *...*, *env*)

os.**spawnv**(*mode*, *path*, *args*)

os.**spawnve**(*mode*, *path*, *args*, *env*)

os.**spawnvp**(*mode*, *file*, *args*)

os.**spawnvpe**(*mode*, *file*, *args*, *env*)

Execute the program *path* in a new process.

(Note that the *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the *Replacing Older Functions with the subprocess Module* section.)

If *mode* is *P_NOWAIT*, this function returns the process id of the new process; if *mode* is *P_WAIT*, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the *waitpid()* function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises OSError exception.

The "l" and "v" variants of the *spawn** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second "p" near the end (*spawnlp()*, *spawnlpe()*, *spawnvp()*, and *spawnvpe()*) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the *spawn*e* variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, *spawnl()*, *spawnle()*, *spawnv()*, and *spawnve()*, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For *spawnle()*, *spawnlpe()*, *spawnve()*, and *spawnvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions *spawnl()*, *spawnlp()*, *spawnv()*, and *spawnvp()* all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of `127`.

As an example, the following calls to *spawnlp()* and *spawnvpe()* are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Raises an *auditing event* `os.spawn` with arguments `mode`, `path`, `args`, `env`.

適用： Unix、Windows、非 Emscripten、非 WASI。

spawnlp(), *spawnlpe()*, *spawnvp()* and *spawnvpe()* are not available on Windows. *spawnle()* and *spawnve()* are not thread-safe on Windows; we advise you to use the *subprocess* module instead.

在 3.6 版的變更: Accepts a *path-like object*.

os.**P_NOWAIT**

os.**P_NOWAITO**

Possible values for the *mode* parameter to the *spawn** family of functions. If either of these values is given, the *spawn** functions will return as soon as the new process has been created, with the process id as the return value.

適用： Unix、Windows。

os.**P_WAIT**

Possible value for the *mode* parameter to the *spawn** family of functions. If this is given as *mode*, the *spawn** functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

適用： Unix、Windows。

os.**P_DETACH**

os.**P_OVERLAY**

Possible values for the *mode* parameter to the *spawn** family of functions. These are less portable than those listed above. *P_DETACH* is similar to *P_NOWAIT*, but the new process is detached from the console of the calling process. If *P_OVERLAY* is used, the current process will be replaced; the *spawn** function will not return.

適用： Windows。

os.**startfile**(*path*[, *operation*][, *arguments*][, *cwd*][, *show_cmd*])

Start a file with its associated application.

When *operation* is not specified, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the **start** command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a "command verb" that specifies what should be done with the file. Common verbs documented by Microsoft are `'open'`, `'print'` and `'edit'` (to be used on files) as well as `'explore'` and `'find'` (to be used on directories).

When launching an application, specify *arguments* to be passed as a single string. This argument may have no effect when using this function to launch a document.

The default working directory is inherited, but may be overridden by the *cwd* argument. This should be an absolute path. A relative *path* will be resolved against this argument.

Use *show_cmd* to override the default window style. Whether this has any effect will depend on the application being launched. Values are integers as supported by the Win32 `ShellExecute()` function.

startfile() returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory or *cwd*. If you want to use an absolute path, make sure the first character is not a slash (`'/'`) Use *pathlib* or the *os.path.normpath()* function to ensure that paths are properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 `ShellExecute()` function is not resolved until this function is first called. If the function cannot be resolved, *NotImplementedError* will be raised.

Raises an *auditing event* `os.startfile` with arguments `path`, `operation`.

Raises an *auditing event* `os.startfile/2` with arguments `path`, `operation`, `arguments`, `cwd`, `show_cmd`.

適用： Windows。

在 3.10 版的變更: Added the *arguments*, *cwd* and *show_cmd* arguments, and the `os.startfile/2` audit event.

os.**system**(*command*)

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to *sys.stdin*, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for *wait()*.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable `COMSPEC`: it is usually **cmd.exe**, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the *Replacing Older Functions with the subprocess Module* section in the *subprocess* documentation for some helpful recipes.

On Unix, *waitstatus_to_exitcode()* can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

Raises an *auditing event* `os.system` with argument `command`.

適用： Unix、Windows、非 Emscripten、非 WASI。

os.**times**()

Returns the current global process times. The return value is an object with five attributes:

- `user` - 使用者時間
- `system` - 系統時間
- `children_user` - 所有子行程的使用者時間
- `children_system` - 所有子行程的系統時間
- `elapsed` - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing `user`, `system`, `children_user`, `children_system`, and `elapsed` in that order.

See the Unix manual page *times(2)* and times(3) manual page on Unix or the GetProcessTimes MSDN on Windows. On Windows, only `user` and `system` are known; the other attributes are zero.

適用： Unix、Windows。

在 3.3 版的變更: Return type changed from a tuple to a tuple-like object with named attributes.

os.**wait**()

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

If there are no children that could be waited for, *ChildProcessError* is raised.

waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

適用： Unix、非 Emscripten、非 WASI。

也參考

The other `wait*()` functions documented below can be used to wait for the completion of a specific child process and have more options. *waitpid()* is the only one also available on Windows.

os.**waitid**(*idtype*, *id*, *options*, /)

Wait for the completion of a child process.

idtype can be *P_PID*, *P_PGID*, *P_ALL*, or (on Linux) *P_PIDFD*. The interpretation of *id* depends on it; see their individual descriptions.

options is an OR combination of flags. At least one of *WEXITED*, *WSTOPPED* or *WCONTINUED* is required; *WNOHANG* and *WNOWAIT* are additional optional flags.

The return value is an object representing the data contained in the `siginfo_t` structure with the following attributes:

- `si_pid` (process ID)
- `si_uid` (real user ID of the child)
- `si_signo` (always *SIGCHLD*)
- `si_status` (the exit status or signal number, depending on `si_code`)
- `si_code` (see *CLD_EXITED* for possible values)

If *WNOHANG* is specified and there are no matching children in the requested state, `None` is returned. Otherwise, if there are no matching children that could be waited for, *ChildProcessError* is raised.

適用： Unix、非 Emscripten、非 WASI。

備🄵

This function is not available on macOS.

在 3.3 版被加入.

os.**waitpid**(*pid*, *options*, /)

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for *wait()*). The semantics of the call are affected by the value of the integer *options*, which should be `0` for normal operation.

If *pid* is greater than `0`, *waitpid()* requests status information for that specific process. If *pid* is `0`, the request is for the status of any child in the process group of the current process. If *pid* is `-1`, the request pertains to any child of the current process. If *pid* is less than `-1`, status is requested for any process in the process group `-pid` (the absolute value of *pid*).

options is an OR combination of flags. If it contains *WNOHANG* and there are no matching children in the requested state, `(0, 0)` is returned. Otherwise, if there are no matching children that could be waited for, *ChildProcessError* is raised. Other options that can be used are *WUNTRACED* and *WCONTINUED*.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to `0` has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The *spawn** functions called with *P_NOWAIT* return suitable process handles.

waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

適用： Unix、Windows、非 Emscripten、非 WASI。

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**wait3**(*options*)

Similar to *waitpid()*, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The *options* argument is the same as that provided to *waitpid()* and *wait4()*.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

適用： Unix、非 Emscripten、非 WASI。

os.**wait4**(*pid*, *options*)

Similar to *waitpid()*, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The arguments to *wait4()* are the same as those provided to *waitpid()*.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

適用： Unix、非 Emscripten、非 WASI。

os.**P_PID**

os.**P_PGID**

os.**P_ALL**

os.**P_PIDFD**

These are the possible values for *idtype* in *waitid()*. They affect how *id* is interpreted:

- P_PID - wait for the child whose PID is *id*.
- P_PGID - wait for any child whose progress group ID is *id*.
- P_ALL - wait for any child; *id* is ignored.
- P_PIDFD - wait for the child identified by the file descriptor *id* (a process file descriptor created with *pidfd_open()*).

適用： Unix、非 Emscripten、非 WASI。

備🄵

P_PIDFD is only available on Linux >= 5.4.

在 3.3 版被加入.

在 3.9 版被加入: The P_PIDFD constant.

os.**WCONTINUED**

This *options* flag for *waitpid()*, *wait3()*, *wait4()*, and *waitid()* causes child processes to be reported if they have been continued from a job control stop since they were last reported.

適用： Unix、非 Emscripten、非 WASI。

os.**WEXITED**

This *options* flag for *waitid()* causes child processes that have terminated to be reported.

The other wait* functions always report children that have terminated, so this option is not available for them.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**WSTOPPED**

This *options* flag for *waitid()* causes child processes that have been stopped by the delivery of a signal to be reported.

This option is not available for the other `wait*` functions.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

os.**WUNTRACED**

This *options* flag for *waitpid()*, *wait3()*, and *wait4()* causes child processes to also be reported if they have been stopped but their current state has not been reported since they were stopped.

This option is not available for *waitid()*.

適用： Unix、非 Emscripten、非 WASI。

os.**WNOHANG**

This *options* flag causes *waitpid()*, *wait3()*, *wait4()*, and *waitid()* to return right away if no child process status is available immediately.

適用： Unix、非 Emscripten、非 WASI。

os.**WNOWAIT**

This *options* flag causes *waitid()* to leave the child in a waitable state, so that a later `wait*()` call can be used to retrieve the child status information again.

This option is not available for the other `wait*` functions.

適用： Unix、非 Emscripten、非 WASI。

os.**CLD_EXITED**

os.**CLD_KILLED**

os.**CLD_DUMPED**

os.**CLD_TRAPPED**

os.**CLD_STOPPED**

os.**CLD_CONTINUED**

These are the possible values for `si_code` in the result returned by *waitid()*.

適用： Unix、非 Emscripten、非 WASI。

在 3.3 版被加入.

在 3.9 版的變更: Added *CLD_KILLED* and *CLD_STOPPED* values.

os.**waitstatus_to_exitcode**(*status*)

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where *signum* is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a *ValueError*.

On Windows, return *status* shifted right by 8 bits.

On Unix, if the process is being traced or if *waitpid()* was called with *WUNTRACED* option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

也參考

WIFEXITED(), *WEXITSTATUS()*, *WIFSIGNALED()*, *WTERMSIG()*, *WIFSTOPPED()*, *WSTOPSIG()* functions.

適用： Unix、Windows、非 Emscripten、非 WASI。

在 3.9 版被加入.

The following functions take a process status code as returned by *system()*, *wait()*, or *waitpid()* as a parameter. They may be used to determine the disposition of a process.

`os.`**`WCOREDUMP`**(*status*, /)

Return `True` if a core dump was generated for the process, otherwise return `False`.

This function should be employed only if *WIFSIGNALED()* is true.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`WIFCONTINUED`**(*status*)

Return `True` if a stopped child has been resumed by delivery of *SIGCONT* (if the process has been continued from a job control stop), otherwise return `False`.

參🄵*WCONTINUED* 選項。

適用： Unix、非 Emscripten、非 WASI。

`os.`**`WIFSTOPPED`**(*status*)

Return `True` if the process was stopped by delivery of a signal, otherwise return `False`.

WIFSTOPPED() only returns `True` if the *waitpid()* call was done using *WUNTRACED* option or when the process is being traced (see *ptrace(2)*).

適用： Unix、非 Emscripten、非 WASI。

`os.`**`WIFSIGNALED`**(*status*)

Return `True` if the process was terminated by a signal, otherwise return `False`.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`WIFEXITED`**(*status*)

Return `True` if the process exited terminated normally, that is, by calling `exit()` or `_exit()`, or by returning from `main()`; otherwise return `False`.

適用： Unix、非 Emscripten、非 WASI。

`os.`**`WEXITSTATUS`**(*status*)

Return the process exit status.

This function should be employed only if *WIFEXITED()* is true.

適用： Unix、非 Emscripten、非 WASI。

os.**WSTOPSIG**(*status*)

Return the signal which caused the process to stop.

This function should be employed only if *WIFSTOPPED()* is true.

適用： Unix、非 Emscripten、非 WASI。

os.**WTERMSIG**(*status*)

Return the number of the signal that caused the process to terminate.

This function should be employed only if *WIFSIGNALED()* is true.

適用： Unix、非 Emscripten、非 WASI。

16.1.8 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

在 3.3 版被加入.

The following scheduling policies are exposed if they are supported by the operating system.

os.**SCHED_OTHER**

The default scheduling policy.

os.**SCHED_BATCH**

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

os.**SCHED_IDLE**

Scheduling policy for extremely low priority background tasks.

os.**SCHED_SPORADIC**

Scheduling policy for sporadic server programs.

os.**SCHED_FIFO**

A First In First Out scheduling policy.

os.**SCHED_RR**

A round-robin scheduling policy.

os.**SCHED_RESET_ON_FORK**

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class os.**sched_param**(*sched_priority*)

This class represents tunable scheduling parameters used in *sched_setparam()*, *sched_setscheduler()*, and *sched_getparam()*. It is immutable.

At the moment, there is only one possible parameter:

sched_priority

The scheduling priority for a scheduling policy.

os.**sched_get_priority_min**(*policy*)

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_get_priority_max**(*policy*)

Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_setscheduler**(*pid*, *policy*, *param*, /)

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a *sched_param* instance.

os.**sched_getscheduler**(*pid*, /)

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

os.**sched_setparam**(*pid*, *param*, /)

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a *sched_param* instance.

os.**sched_getparam**(*pid*, /)

Return the scheduling parameters as a *sched_param* instance for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_rr_get_interval**(*pid*, /)

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_yield**()

Voluntarily relinquish the CPU.

os.**sched_setaffinity**(*pid*, *mask*, /)

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

os.**sched_getaffinity**(*pid*, /)

Return the set of CPUs the process with PID *pid* is restricted to.

If *pid* is zero, return the set of CPUs the calling thread of the current process is restricted to.

16.1.9 Miscellaneous System Information

os.**confstr**(*name*, /)

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

適用： Unix。

os.**confstr_names**

Dictionary mapping names accepted by *confstr()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用： Unix。

os.**cpu_count**()

Return the number of logical CPUs in the system. Returns None if undetermined.

This number is not equivalent to the number of logical CPUs the current process can use. len(os.sched_getaffinity(0)) gets the number of logical CPUs the calling thread of the current process is restricted to

在 3.4 版被加入.

os.**getloadavg**()

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises *OSError* if the load average was unobtainable.

適用： Unix。

os.**sysconf**(*name*, /)

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, -1 is returned. The comments regarding the *name* parameter for *confstr()* apply here as well; the dictionary that provides information on the known names is given by sysconf_names.

適用： Unix。

os.**sysconf_names**

Dictionary mapping names accepted by *sysconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用： Unix。

在 3.11 版的變更: Add 'SC_MINSIGSTKSZ' name.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

os.**curdir**

The constant string used by the operating system to refer to the current directory. This is '.' for Windows and POSIX. Also available via *os.path*.

os.**pardir**

The constant string used by the operating system to refer to the parent directory. This is '..' for Windows and POSIX. Also available via *os.path*.

os.**sep**

The character used by the operating system to separate pathname components. This is '/' for POSIX and '\\' for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames --- use *os.path.split()* and *os.path.join()* --- but it is occasionally useful. Also available via *os.path*.

os.**altsep**

An alternative character used by the operating system to separate pathname components, or None if only one separator character exists. This is set to '/' on Windows systems where sep is a backslash. Also available via *os.path*.

os.**extsep**

The character which separates the base filename from the extension; for example, the '.' in os.py. Also available via *os.path*.

os.**pathsep**

The character conventionally used by the operating system to separate search path components (as in PATH), such as ':' for POSIX or ';' for Windows. Also available via *os.path*.

os.**defpath**

The default search path used by *exec*p** and *spawn*p** if the environment doesn't have a 'PATH' key. Also available via *os.path*.

os.**linesep**

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as '\n' for POSIX, or multiple characters, for example, '\r\n' for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single '\n' instead, on all platforms.

os.**devnull**

The file path of the null device. For example: '/dev/null' for POSIX, 'nul' for Windows. Also available via *os.path*.

os.**RTLD_LAZY**

os.**RTLD_NOW**

os.**RTLD_GLOBAL**

os.**RTLD_LOCAL**

os.**RTLD_NODELETE**

os.**RTLD_NOLOAD**

os.**RTLD_DEEPBIND**

Flags for use with the *setdlopenflags()* and *getdlopenflags()* functions. See the Unix manual page *dlopen(3)* for what the different flags mean.

在 3.3 版被加入.

16.1.10 Random numbers

os.**getrandom**(*size*, *flags=0*)

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

getrandom() relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the /dev/random and /dev/urandom devices.

The flags argument is a bit mask that can contain zero or more of the following values ORed together: *os.GRND_RANDOM* and *GRND_NONBLOCK*.

See also the Linux getrandom() manual page.

適用： Linux 3.17 以上。

在 3.6 版被加入.

os.**urandom**(*size*, */*)

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the getrandom() syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the **PEP 524** for the rationale. On Linux, the *getrandom()* function can be used to get random bytes in non-blocking mode (using the *GRND_NONBLOCK* flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the *NotImplementedError* exception is raised.

On Windows, it will use `BCryptGenRandom()`.

也參考

The *secrets* module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see *random.SystemRandom*.

在 3.5 版的變更: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

在 3.5.2 版的變更: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

在 3.6 版的變更: On Linux, `getrandom()` is now used in blocking mode to increase the security.

在 3.11 版的變更: On Windows, `BCryptGenRandom()` is used instead of `CryptGenRandom()` which is deprecated.

`os.`**GRND_NONBLOCK**

By default, when reading from `/dev/random`, *getrandom()* blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the *GRND_NONBLOCK* flag is set, then *getrandom()* does not block in these cases, but instead immediately raises *BlockingIOError*.

在 3.6 版被加入.

`os.`**GRND_RANDOM**

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

在 3.6 版被加入.

16.2 io —處理資料串流的核心工具

原始碼： Lib/io.py

16.2.1 總覽

io 模組替 Python 提供處理各種類型 IO 的主要工具。有三種主要的 IO 類型：*文字 I/O (text I/O)*、*二進位 I/O (binary I/O)* 以及 *原始 I/O (raw I/O)*。這些均🄵泛用 (generic) 類型，且每種類型都可以使用各式後端儲存 (backing store)。任一種屬於這些類型的具體物件稱🄵*file object*。其它常見的名詞還有 *資料串流 (stream)* 以及 *類檔案物件 (file-like objects)*。

無論其類型🄵何，每個具體的資料串流物件也將具有各種能力：唯讀的、只接受寫入的、或者讀寫兼具的。它還允許任意的隨機存取（向前或向後尋找至任意位置），或者只能依順序存取（例如 socket 或 pipe 的情形下）。

所有的資料串流都會謹慎處理你所提供的資料的型🄵。舉例來🄵，提供一個*str* 物件給二進位資料串流的 `write()` 方法將會引發*TypeError*。同樣地，若提供一個*bytes* 物件給文字資料串流的 `write()` 方法，也會引發同樣的錯誤。

在 3.3 版的變更: 原本會引發*IOError* 的操作，現在將改成引發*OSError*。因🄵*IOError* 現在是*OSError* 的🄵名。

文字 I/O

文字 I/O 要求和🄵出*str* 物件。這意味著每當後端儲存🄵原生 bytes 時（例如在檔案的情形下），資料的編碼與解碼會以清楚易懂的方式進行，也可選擇同時轉🄵特定於平台的🄵行字元。

建立文字資料串流最簡單的方法是使用*open()*，可選擇性地指定編碼:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

記憶體🄵的文字資料串流也可以使用*StringIO* 物件建立:

```
f = io.StringIO("some initial text data")
```

文字資料串流 API 的詳細🄵明在*TextIOBase* 文件當中。

二進位 (Binary) I/O

二進位 I/O（也稱🄵緩衝 *I/O (buffered I/O)*）要求的是*類位元組物件 (bytes-like objects)* 且🄵生*bytes* 物件。不進行編碼、解碼或者🄵行字元轉🄵。這種類型的資料串流可用於各種非文字資料，以及需要手動控制對文字資料的處理時。

建立二進位資料串流最簡單的方法是使用*open()*，🄵在 mode 字串中加入 `'b'`:

```
f = open("myfile.jpg", "rb")
```

記憶體🄵的二進位資料串流也可以透過*BytesIO* 物件來建立:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

二進位資料串流 API 的詳細🄵明在*BufferedIOBase* 文件當中。

其它函式庫模組可能提供額外的方法來建立文字或二進位資料串流。例如*socket.socket.makefile()*。

原始 (Raw) I/O

原始 I/O（也稱🄵無緩衝 *I/O (unbuffered I/O)*）通常作🄵二進位以及文字資料串流的低階 building-block 使用；在使用者程式碼中直接操作原始資料串流很少有用。然而，你可以透過以無緩衝的二進位模式開🄵一個檔案來建立一個原始資料串流:

```
f = open("myfile.jpg", "rb", buffering=0)
```

原始串流 API 在*RawIOBase* 文件中有詳細描述。

16.2.2 文字編碼

TextIOWrapper 和*open()* 預設編碼是根據區域設定的 (locale-specific) (*locale.getencoding()*)。

然而，許多開發人員在開🄵以 UTF-8 編碼的文字檔案（例如：JSON、TOML、Markdown 等）時忘記指定編碼，因🄵多數 Unix 平台預設使用 UTF-8 區域設定。這會導致錯誤，因🄵對於大多數 Windows 使用者來🄵，預設地區編碼🄵非 UTF-8。舉例來🄵：

```
# May not work on Windows when non-ASCII characters in the file.
with open("README.md") as f:
    long_description = f.read()
```

因此，🄵烈建議在開🄵文字檔案時，明確指定編碼。若你想使用 UTF-8 編碼，請傳入 `encoding="utf-8"`。若想使用目前的地區編碼，Python 3.10 以後的版本支援使用 `encoding="locale"`。

也參考

Python UTF-8 模式
在 Python UTF-8 模式下，可以將預設編碼從特定地區編碼改🄵 UTF-8。

PEP 686
Python 3.15 將預設使用*Python UTF-8 模式*。

選擇性加入的編碼警告

在 3.10 版被加入: 更多資訊請見 **PEP 597**。

要找出哪些地方使用到預設的地區編碼，你可以🄵用 `-X warn_default_encoding` 命令列選項，或者設定環境變數 `PYTHONWARNDEFAULTENCODING`。當使用到預設編碼時，會引發*EncodingWarning*。

如果你正在提供一個使用*open()* 或*TextIOWrapper* 且傳遞 `encoding=None` 作🄵參數的 API，你可以使用*text_encoding()*。如此一來如果 API 的呼叫方🄵有傳遞 `encoding`，呼叫方就會發出一個*EncodingWarning*。然而，對於新的 API，請考慮預設使用 UTF-8（即 `encoding="utf-8"`）。

16.2.3 高階模組介面

`io.`**DEFAULT_BUFFER_SIZE**
一個包含模組中緩衝 I/O 類🄵所使用的預設緩衝區大小的整數。若可能的話，*open()* 會使用檔案的 blksize （透過*os.stat()* 取得）。

`io.`**open**(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)
這是🄵建函式*open()* 的🄵名。

此函式會引發一個帶有引數 *path*、*mode* 以及 *flags* 的稽核事件 *(auditing event)* `open`。*mode* 與 *flags* 引數可能已經被修改或者從原始呼叫中被推斷出來。

`io.`**open_code**(*path*)
以 `'rb'` 模式開🄵提供的檔案。此函式應用於意圖將🄵容視🄵可執行的程式碼的情🄵下。

path 應該要屬於*str* 類🄵，且是個🄵對路徑。

這個函式的行🄵可能會被之前對 `PyFile_SetOpenCodeHook()` 的呼叫覆寫。然而，假設 *path* 是個*str* 且🄵🄵對路徑，則 `open_code(path)` 總是與 `open(path, 'rb')` 有相同行🄵。覆寫這個行🄵是🄵了對檔案進行額外驗證或預處理。

在 3.8 版被加入.

io.**text_encoding**(*encoding*, *stacklevel=2*, */*)

這是個輔助函數，適用於使用*open()* 或*TextIOWrapper* 且具有 encoding=None 參數的可呼叫物件。

若 *encoding* 不🄵 None，此函式將回傳 *encoding*。否則，將根據*UTF-8 Mode* 回傳 "locale" 或 "utf-8"。

若*sys.flags.warn_default_encoding* 🄵 真，且 *encoding* 🄵 None，此函式會發出一個*EncodingWarning*。*stacklevel* 指定警告在哪層發出。範例：

```
def read_text(path, encoding=None):
    encoding = io.text_encoding(encoding)  # stacklevel=2
    with open(path, encoding) as f:
        return f.read()
```

在此範例中，對於 read_text() 的呼叫方會引發一個*EncodingWarning*。

更多資訊請見文字編碼。

在 3.10 版被加入.

在 3.11 版的變更: 當 UTF-8 模式🄵用且 *encoding* 🄵 None 時，*text_encoding()* 會回傳"utf-8"。

exception io.**BlockingIOError**

這是🄵建的*BlockingIOError* 例外的相容性🄵名。

exception io.**UnsupportedOperation**

當在資料串流上呼叫不支援的操作時，會引發繼承自*OSError* 與*ValueError* 的例外。

也參考

sys
包含標準的 IO 資料串流：*sys.stdin*、*sys.stdout* 以及*sys.stderr*。

16.2.4 類🄵階層

I/O 串流的實作是由多個類🄵組合成的階層結構所構成。首先是*abstract base classes* （抽象基底類🄵，ABCs），它們被用來規範各種不同類型的串流，接著具體類🄵會提供標準串流的實作。

備🄵

🄵了協助具體串流類🄵的實作，抽象基底類🄵提供了某些方法的預設實作。舉例來🄵，*BufferedIOBase* 提供未經最佳化的 readinto() 與 readline() 實作。

I/O 階層結構的最上層是抽象基底類🄵*IOBase*。它定義了串流的基礎的介面。然而，請注意，讀取串流與寫入串流之間🄵🄵有分離；若不支援給定的操作，實作是允許引發*UnsupportedOperation* 例外的。

抽象基底類🄵*RawIOBase* 繼承*IOBase*。此類🄵處理對串流的位元組讀寫。*FileIO* 則繼承*RawIOBase* 來提供一個介面以存取機器檔案系統🄵的檔案。

抽象基底類🄵*BufferedIOBase* 繼承*IOBase*。此類🄵緩衝原始二進位串流 (*RawIOBase*)。它的子類🄵*BufferedWriter*、*BufferedReader* 與*BufferedRWPair* 分🄵緩衝可寫、可讀、可讀也可寫的的原始二進位串流。類🄵*BufferedRandom* 則提供一個對可搜尋串流 (seekable stream) 的緩衝介面。另一個類🄵*BufferedIOBase* 的子類🄵*BytesIO*，是一個記憶體🄵位元組串流。

抽象基底類🄵*TextIOBase* 繼承*IOBase*。此類🄵處理文本位元組串流，🄵處理字串的編碼和解碼。類🄵*TextIOWrapper* 繼承自*TextIOBase*，這是個對緩衝原始串流 (*BufferedIOBase*) 的緩衝文本介面。最後，*StringIO* 是個文字記憶體🄵串流。

引數名稱不是規範的一部份，只有*open()* 的引數將作🄵關鍵字引數。

以下表格總結了*io* 模組提供的抽象基底類🄵 (ABC)：

抽象基底類🄵 (ABC)	繼承	Stub 方法	Mixin 方法與屬性
IOBase		fileno、seek 和 truncate	close、closed、__enter__、__exit__、flush、isatty、__iter__、__next__、readable、readline、readlines、seekable、tell、writable 與 writelines
RawIOBase	*IOBase*	readinto 和 write	繼承自*IOBase* 的方法，read 與 readall
BufferedIOBase	*IOBase*	detach、read、read1 和 write	繼承自*IOBase* 的方法，readinto 與 readinto1
TextIOBase	*IOBase*	detach、read、readline 和 write	繼承自*IOBase* 的方法，encoding、errors 與 newlines

I/O 基礎類🄵

class io.**IOBase**

所有 I/O 類🄵的抽象基礎類🄵。

🄵許多方法提供了空的抽象實作，衍生類🄵可以選擇性地覆寫這些方法；預設的實作代表一個無法讀取、寫入或搜尋的檔案。

即使*IOBase* 因🄵實作的簽名差🄵巨大而🄵有宣告 read() 或 write() 方法，實作與用🄵端應把這些方法視🄵介面的一部份。此外，當呼叫不被它們支援的操作時，可能會引發*ValueError*（或*UnsupportedOperation*）例外。

The basic type used for binary data read from or written to a file is *bytes*. Other *bytes-like objects* are accepted as method arguments too. Text I/O classes work with *str* data.

請注意，在一個已經關閉的串流上呼叫任何方法（即使只是查詢）都是未定義的。在這種情🄵下，實作可能會引發*ValueError* 例外。

IOBase (and its subclasses) supports the iterator protocol, meaning that an *IOBase* object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See *readline()* below.

IOBase 也是個情境管理器，因此支援 with 陳述式。在這個例子中，*file* 會在 with 陳述式執行完畢後關閉——即使發生了🄵常。

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

IOBase 提供這些資料屬性與方法：

close()

清除𝔽關閉這個串流。若檔案已經關閉，則此方法𝔽有作用。一旦檔案被關閉，任何對檔案的操作（例如讀取或寫入）將引發*ValueError* 𝔽常。

𝔽了方便起見，允許多次呼叫這個方法；然而，只有第一次呼叫會有效果。

closed

如果串流已關閉，則𝔽 `True`。

fileno()

如果串流存在，則回傳其底層的檔案描述器（一個整數）。如果 IO 物件不使用檔案描述器，則會引發一個*OSError* 例外。

flush()

如果適用，清空串流的寫入緩衝區。對於唯讀和非阻塞串流，此操作不會執行任何操作。

isatty()

如果串流是互動式的（即連接到終端機/tty 設備），則回傳 `True`。

readable()

如果串流可以被讀取，則回傳 `True`。如果是 `False`，`read()` 將會引發*OSError* 例外。

readline(*size=-1*, */*)

從串流讀取𝔽回傳一行。如果指定了 *size*，則最多讀取 *size* 個位元組。

對於二進位檔案，行結束符總是 `b'\n'`；對於文字檔案，可以使用*open()* 函式的 *newline* 引數來選擇識𝔽的行結束符號。

readlines(*hint=-1*, */*)

從串流讀取𝔽回傳一個含有一或多行的 list。可以指定 *hint* 來控制讀取的行數：如果到目前𝔽止所有行的總大小（以位元組/字元計）超過 *hint*，則不會再讀取更多行。

hint 值𝔽 `0` 或更小，以及 `None`，都被視𝔽𝔽有提供 hint。

請注意，已經可以使用 `for line in file: ...` 在檔案物件上進行𝔽代，而不一定需要呼叫 `file.readlines()`。

seek(*offset*, *whence=os.SEEK_SET*, */*)

將串流位置改變到給定的位元組 *offset*，此位置是相對於由 *whence* 指示的位置解釋的，𝔽回傳新的𝔽對位置。*whence* 的值可𝔽：

- *os.SEEK_SET* 或 `0` -- 串流的起點（預設值）；*offset* 應𝔽零或正數
- *os.SEEK_CUR* 或 `1` -- 目前串流位置；*offset* 可以是負數
- *os.SEEK_END* 或 `2` -- 串流的結尾；*offset* 通常是負數

在 3.1 版被加入: `SEEK_*` 常數。

在 3.3 版被加入: 某些作業系統可以支援額外的值，例如*os.SEEK_HOLE* 或*os.SEEK_DATA*。檔案的合法值取𝔽於它是以文字模式還是二進位模式開𝔽。

seekable()

如果串流支援隨機存取，則回傳 `True`。如果是 `False`，則*seek()*、*tell()* 和*truncate()* 會引發*OSError*。

tell()

回傳目前串流的位置。

truncate(*size=None*, /)

將串流的大小調整F指定的 *size* 位元組（如果F有指定 *size*，則調整F目前位置）。目前串流位置不會改變。這種調整可以擴展或縮F當前檔案大小。在擴展的情F下，新檔案區域的F容取F於平台（在大多數系統上，額外的位元組會被填充F零）。回傳新的檔案大小。

在 3.5 版的變更: Windows 現在在擴展時會對檔案進行零填充 (zero-fill)。

writable()

如果串流支援寫入，則回傳 `True`。如果是 `False`，`write()` 和*truncate()* 將會引發*OSError*。

writelines(*lines*, /)

將一個包含每一行的 list 寫入串流。這不會新增行分隔符號，因此通常提供的每一行末尾都有一個行分隔符號。

__del__()

F物件銷F做准備。*IOBase* 提供了這個方法的預設實作，該實作會呼叫實例的*close()* 方法。

class io.**RawIOBase**

原始二進位串流的基底類F。它繼承自*IOBase*。

原始二進位串流通常提供對底層作業系統設備或 API 的低階存取，F不嘗試將其封裝在高階基元 (primitive) 中（這項功能在緩衝二進位串流和文字串流中的更高階層級完成，後面的頁面會有描述）。

RawIOBase 除了*IOBase* 的方法外，還提供以下這些方法：

read(*size=-1*, /)

從物件中讀取最多 *size* 個位元組F回傳。方便起見，如果 *size* 未指定或F -1，則回傳直到檔案結尾 (EOF) 的所有位元組。否則，只會進行一次系統呼叫。如果作業系統呼叫回傳的位元組少於 *size*，則可能回傳少於 *size* 的位元組。

如果回傳了 0 位元組，且 *size* 不是 0，這表示檔案結尾 (end of file)。如果物件處於非阻塞模式且F有可用的位元組，則回傳 `None`。

預設的實作會遵守*readall()* 和*readinto()* 的實作。

readall()

讀取F回傳串流中直到檔案結尾的所有位元組，必要時使用多次對串流的呼叫。

readinto(*b*, /)

將位元組讀入一個預先分配的、可寫的*bytes-like object* （類位元組物件）*b* 中，F回傳讀取的位元組數量。例如，*b* 可能是一個*bytearray*。如果物件處於非阻塞模式且F有可用的位元組，則回傳 `None`。

write(*b*, /)

將給定的*bytes-like object* （類位元組物件），*b*，寫入底層的原始串流，F回傳寫入的位元組大小。根據底層原始串流的具體情F，這可能少於 *b* 的位元組長度，尤其是當它處於非阻塞模式時。如果原始串流設置F非阻塞且無法立即寫入任何單一位元組，則回傳 `None`。呼叫者在此方法回傳後可以釋放或變更 *b*，因此實作應該只在方法呼叫期間存取 *b*。

class io.**BufferedIOBase**

支援某種緩衝的二進位串流的基底類F。它繼承自*IOBase*。

與*RawIOBase* 的主要差F在於，*read()*、*readinto()* 及*write()* 方法將分F嘗試讀取所請求的盡可能多的輸入，或消耗所有給定的輸出，即使可能需要進行多於一次的系統呼叫。

此外，如果底層的原始串流處於非阻塞模式且無法提供或接收足F的資料，這些方法可能會引發*BlockingIOError* 例外；與*RawIOBase* 不同之處在於，它們永遠不會回傳 `None`。

此外，*read()* 方法不存在一個遵從*readinto()* 的預設實作。

一個典型的*BufferedIOBase*實作不應該繼承自一個*RawIOBase*的實作，而是應該改用包裝的方式，像*BufferedWriter*和*BufferedReader*那樣的作法。

*BufferedIOBase*除了提供或覆寫來自*IOBase*的資料屬性和方法以外，還包含了這些:

raw

底層的原始串流（一個*RawIOBase*實例），*BufferedIOBase*處理的對象。這不是*BufferedIOBase* API 的一部分，且在某些實作可能不存在。

detach()

將底層的原始串流從緩衝區中分離出來，🄵回傳它。

在原始串流被分離後，緩衝區處於一個不可用的狀態。

某些緩衝區，如*BytesIO*，🄵有單一原始串流的概念可從此方法回傳。它們會引發*UnsupportedOperation*。

在 3.1 版被加入.

read(*size=-1*, /)

讀取🄵回傳最多 *size* 個位元組。如果引數被省略、🄵 None 或🄵負值，將讀取🄵回傳資料直到達到 EOF 🄵止。如果串流已經處於 EOF，則回傳一個空的*bytes*物件。

如果引數🄵正數，且底層原始串流不是互動式的，可能會發出多次原始讀取來滿足位元組數量（除非首先達到 EOF）。但對於互動式原始串流，最多只會發出一次原始讀取，且短少的資料不表示 EOF 即將到來。

如果底層原始串流處於非阻塞模式，且當前🄵有可用資料，則會引發*BlockingIOError*。

read1(*size=-1*, /)

讀取🄵回傳最多 *size* 個位元組，最多呼叫一次底層原始串流的*read()* (或*readinto()*) 方法。如果你正在*BufferedIOBase*物件之上實作自己的緩衝區，這可能會很有用。

如果 *size* 🄵 `-1` （預設值），則會回傳任意數量的位元組（除非達到 EOF，否則會超過零）。

readinto(*b*, /)

讀取位元組到一個預先分配的、可寫的*bytes-like object* *b* 當中，🄵回傳讀取的位元組數量。例如，*b* 可能是一個*bytearray*。

類似於*read()*，除非後者是互動式的，否則可能會對底層原始串流發出多次讀取。

如果底層原始串流處於非阻塞模式，且當前🄵有可用資料，則會引發*BlockingIOError*。

readinto1(*b*, /)

讀取位元組到一個預先分配的、可寫的*bytes-like object* *b* 中，最多呼叫一次底層原始串流的*read()* (或*readinto()*) 方法。此方法回傳讀取的位元組數量。

如果底層原始串流處於非阻塞模式，且當前🄵有可用資料，則會引發*BlockingIOError*。

在 3.5 版被加入.

write(*b*, /)

寫入給定的*bytes-like object*，*b*，🄵回傳寫入的位元組數量（總是等於 *b* 的長度，以位元組計，因🄵如果寫入失敗將會引發*OSError*）。根據實際的實作，這些位元組可能會立即寫入底層串流，或出於性能和延遲的緣故而被留在緩衝區當中。

當處於非阻塞模式時，如果需要將資料寫入原始串流，但它無法接受所有資料而不阻塞，則會引發*BlockingIOError*。

呼叫者可以在此方法回傳後釋放或變更 *b*，因此實作應該僅在方法呼叫期間存取 *b*。

原始檔案 I/O

class io.**FileIO**(*name*, *mode='r'*, *closefd=True*, *opener=None*)

一個代表包含位元組資料的 OS 層級檔案的原始二進制串流。它繼承自*RawIOBase*。

name 可以是兩種事物之一:

- 代表將要打開的檔案路徑的一個字元串或*bytes* 物件。在這種情🄵下，closefd 必須是 `True` （預設值），否則將引發錯誤。
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access. When the FileIO object is closed this fd will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. *FileExistsError* will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The *read()* (when called with a positive argument), *readinto()* and *write()* methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

See the *open()* built-in function for examples on using the *opener* parameter.

在 3.3 版的變更: The *opener* parameter was added. The `'x'` mode was added.

在 3.4 版的變更: The file is now non-inheritable.

FileIO provides these data attributes in addition to those from *RawIOBase* and *IOBase*:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class io.**BytesIO**(*initial_bytes=b''*)

A binary stream using an in-memory bytes buffer. It inherits from *BufferedIOBase*. The buffer is discarded when the *close()* method is called.

The optional argument *initial_bytes* is a *bytes-like object* that contains initial data.

BytesIO provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

備🄵

As long as the view exists, the *BytesIO* object cannot be resized or closed.

在 3.2 版被加入.

getvalue()

Return *bytes* containing the entire contents of the buffer.

read1(*size=-1*, */*)

In *BytesIO*, this is the same as *read()*.

在 3.7 版的變更: The *size* argument is now optional.

readinto1(*b*, */*)

In *BytesIO*, this is the same as *readinto()*.

在 3.5 版被加入.

class io.**BufferedReader**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a readable, non seekable *RawIOBase* raw binary stream. It inherits from *BufferedIOBase*.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, *DEFAULT_BUFFER_SIZE* is used.

BufferedReader provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

peek(*size=0*, */*)

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

read(*size=-1*, */*)

Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1(*size=-1*, */*)

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

在 3.7 版的變更: The *size* argument is now optional.

class io.**BufferedWriter**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a writeable, non seekable *RawIOBase* raw binary stream. It inherits from *BufferedIOBase*.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying *RawIOBase* object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

flush()

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

write(*b*, /)

Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

class io.**BufferedRandom**(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a seekable `RawIOBase` raw binary stream. It inherits from `BufferedReader` and `BufferedWriter`.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRandom` is capable of anything `BufferedReader` or `BufferedWriter` can do. In addition, `seek()` and `tell()` are guaranteed to be implemented.

class io.**BufferedRWPair**(*reader*, *writer*, *buffer_size=DEFAULT_BUFFER_SIZE*, /)

A buffered binary stream providing higher-level access to two non seekable `RawIOBase` raw binary streams---one readable, the other writeable. It inherits from `BufferedIOBase`.

reader and *writer* are `RawIOBase` objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

警告

`BufferedRWPair` does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use `BufferedRandom` instead.

文字 I/O

class io.**TextIOBase**

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits from `IOBase`.

`TextIOBase` provides or overrides these data attributes and methods in addition to those from `IOBase`:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or `None`, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a *BufferedIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist in some implementations.

detach()

Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

在 3.1 版被加入.

read(*size=-1*, */*)

Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or `None`, reads until EOF.

readline(*size=-1*, */*)

Read until newline or EOF and return a single *str*. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek(*offset*, *whence=SEEK_SET*, */*)

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is `SEEK_SET`.

- `SEEK_SET` or `0`: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- `SEEK_CUR` or `1`: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- `SEEK_END` or `2`: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

在 3.1 版被加入: `SEEK_*` 常數。

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(*s*, */*)

Write the string *s* to the stream and return the number of characters written.

class io.**TextIOWrapper**(*buffer*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=False*, *write_through=False*)

A buffered text stream providing higher-level access to a *BufferedIOBase* buffered binary stream. It inherits from *TextIOBase*.

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getencoding()*. `encoding="locale"` can be used to specify the current locale's encoding explicitly. See 文字編碼 for more information.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a *ValueError* exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with *codecs.register_error()* is also valid.

newline controls how line endings are handled. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, *universal newlines* mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If *newline* is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, *os.linesep*. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *line_buffering* is `True`, *flush()* is implied when a call to write contains a newline character or a carriage return.

If *write_through* is `True`, calls to *write()* are guaranteed not to be buffered: any data written on the *TextIOWrapper* object is immediately handled to its underlying binary *buffer*.

在 3.3 版的變更: The *write_through* argument has been added.

在 3.3 版的變更: The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using *locale.setlocale()*, use the current locale encoding instead of the user preferred encoding.

在 3.10 版的變更: The *encoding* argument now supports the `"locale"` dummy encoding name.

TextIOWrapper provides these data attributes and methods in addition to those from *TextIOBase* and *IOBase*:

line_buffering

Whether line buffering is enabled.

write_through

Whether writes are passed immediately to the underlying binary buffer.

在 3.7 版被加入.

reconfigure(*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=None*, *write_through=None*)

Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line_buffering* and *write_through*.

Parameters not specified keep current settings, except `errors='strict'` is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

在 3.7 版被加入.

在 3.11 版的變更: The method supports `encoding="locale"` option.

seek(*cookie*, *whence=os.SEEK_SET*, */*)

Set the stream position. Return the new stream position as an *int*.

Four operations are supported, given by the following argument combinations:

- `seek(0, SEEK_SET)`: Rewind to the start of the stream.
- `seek(cookie, SEEK_SET)`: Restore a previous position; *cookie* **must be** a number returned by *tell()*.
- `seek(0, SEEK_END)`: Fast-forward to the end of the stream.
- `seek(0, SEEK_CUR)`: Leave the current stream position unchanged.

Any other argument combinations are invalid, and may raise exceptions.

也參考

os.SEEK_SET, *os.SEEK_CUR*, and *os.SEEK_END*.

tell()

Return the stream position as an opaque number. The return value of `tell()` can be given as input to *seek()*, to restore a previous stream position.

class io.**StringIO**(*initial_value=''*, *newline='\n'*)

A text stream using an in-memory text buffer. It inherits from *TextIOBase*.

The text buffer is discarded when the *close()* method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer which emulates opening an existing file in a `w+` mode, making it ready for an immediate write from the beginning or for a write that would overwrite the initial value. To emulate opening a file in an `a+` mode ready for appending, use `f.seek(0, io.SEEK_END)` to reposition the stream at the end of the buffer.

The *newline* argument works like that of *TextIOWrapper*, except that when writing output to the stream, if *newline* is `None`, newlines are written as `\n` on all platforms.

StringIO provides this method in addition to those from *TextIOBase* and *IOBase*:

getvalue()

Return a *str* containing the entire contents of the buffer. Newlines are decoded as if by *read()*, although the stream position is not changed.

使用範例:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()
```

(繼續下一頁)

(繼續上一頁)

```
# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.**IncrementalNewlineDecoder**

A helper codec that decodes newlines for *universal newlines* mode. It inherits from *codecs.IncrementalDecoder*.

16.2.5 Performance

This section discusses the performance of the provided concrete I/O implementations.

二進位 (Binary) I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

文字 I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, *tell()* and *seek()* are both quite slow due to the reconstruction algorithm used.

StringIO, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

Multi-threading

FileIO objects are thread-safe to the extent that the operating system calls (such as *read(2)* under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a *signal* handler. If a thread tries to re-enter a buffered object which it is already accessing, a *RuntimeError* is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the *open()* function will wrap a buffered object inside a *TextIOWrapper*. This includes standard streams and therefore affects the built-in *print()* function as well.

16.3 time --- 時間存取與轉[F]

這個模組提供了各種與時間相關的函式。若要查看相關功能，請參[F]*datetime* 和*calendar* 模組。

雖然這個模組隨時可用，但[F]非所有函式在所有平台上都可用。這個模組中定義的大多數函式都會呼叫 C 語言平台的函式庫中具有相同名稱的函式。由於這些函式的語義因平台而[F]，所以偶爾查[F]平台文件可能會有所幫助。

以下是對一些術語和慣例的[F]明。

- *epoch* 是起始的時間點，即 `time.gmtime(0)` 的回傳值。在所有平台上，它是 1970 年 1 月 1 日，00:00:00（UTC）。
- 術語 *seconds since the epoch*（紀元秒數）是指從 epoch（紀元）開始經過的總秒數，通常不包括 leap seconds。在所有符合 POSIX 標准的平台上，leap seconds （閏秒）都不計入這個總數。
- 這個模組中的函式可能無法處理*epoch* 之前或[F]遠未來的日期和時間。未來的臨界點由 C 函式庫[F]定；對於 32 位元系統來[F]通常是在 2038 年。
- 函式*strptime()* 在給定 `%y` 格式程式碼時可以解析兩位數的年份。當剖析兩位數的年份時，它們會根據 POSIX 和 ISO C 標准進行轉[F]：69--99 的值對映到 1969--1999，0--68 的值對映到 2000--2068。
- UTC 是 Coordinated Universal Time --- 世界協調時間（原稱[F]格林威治標准時間，或 GMT）。縮寫 UTC [F]不是寫錯，而是英文和法文之間折衷的結果。
- DST 是 Daylight Saving Time（日光節約時間），一年中的某些時段（通常）將會時區調整一小時。DST 的規則是根據當地法律[F]定的，且可能每年不同。C 函式庫有一個包含當地規則的表（通常會[F]了靈活性而從系統文件中讀取），在這方面是唯一的真正依據。
- 各種即時 (real-time) 函式的精確度可能低於其值或引數所表示的單位所建議的精確度。例如，在大多數 Unix 系統上，時鐘每秒只「跳」50 次或 100 次。
- On the other hand, the precision of *time()* and *sleep()* is better than their Unix equivalents: times are expressed as floating-point numbers, *time()* returns the most accurate time available (using Unix `gettimeofday()` where available), and *sleep()* will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- 由*gmtime()*、*localtime()* 和*strptime()* 回傳，[F]由*asctime()*、*mktime()* 和*strftime()* 接受的時間值，是一個 9 個整數的序列。*gmtime()*、*localtime()* 和*strptime()* 的回傳值也[F]各個欄位提供屬性名稱。

  關於這些物件的[F]述請見*struct_time*。

  在 3.3 版的變更：當平台支援對應的 `struct tm` 成員時，*struct_time* 型[F]被擴展以提供*tm_gmtoff* 和*tm_zone* 屬性。

  在 3.6 版的變更：*struct_time* 的屬性*tm_gmtoff* 和*tm_zone* 現在在所有平台上都可用。

- 使用以下函式在時間表示之間進行轉🄵：

轉🄵來源	轉🄵目標	使用
紀元秒數	世界協調時間的*struct_time*	*gmtime()*
紀元秒數	本地時間的*struct_time*	*localtime()*
世界協調時間的*struct_time*	紀元秒數	*calendar.timegm()*
本地時間的*struct_time*	紀元秒數	*mktime()*

16.3.1 函式

time.**asctime**([*t*])

將由*gmtime()* 或*localtime()* 回傳的元組或*struct_time* 表示的時間轉🄵🄵以下格式的字串：`'Sun Jun 20 23:21:05 1993'`。日期欄位🄵兩個字元長，如果日期是個位數，則用空格填充，例如：`'Wed Jun 9 04:26:40 1993'`。

如果🄵有提供 *t*，則使用由*localtime()* 回傳的當前時間。*asctime()* 不使用區域資訊。

備🄵

與同名的 C 函式不同，*asctime()* 不會添加結尾的🄵行字元。

time.**pthread_getcpuclockid**(*thread_id*)

🄵指定的 *thread_id* 回傳執行緒專用 CPU-time 時鐘的 *clk_id*。

使用*threading.get_ident()* 或*threading.Thread* 物件的*ident* 屬性來獲取適用於 *thread_id* 的值。

警告

傳遞無效或過期的 *thread_id* 可能會導致未定義的行🄵，例如分段錯誤 (segmentation fault)。

適用： Unix

若需更多資訊，請參🄵 *pthread_getcpuclockid(3)* 的🄵明文件。

在 3.7 版被加入.

time.**clock_getres**(*clk_id*)

回傳指定時鐘 *clk_id* 的解析度（精確度）。有關 *clk_id* 可接受的值的串列，請參🄵*Clock ID Constants*。

適用： Unix。

在 3.3 版被加入.

time.**clock_gettime**(*clk_id*) → *float*

回傳指定時鐘 *clk_id* 的時間。有關 *clk_id* 可接受的值的串列，請參🄵*Clock ID Constants*。

使用*clock_gettime_ns()* 以避免*float* 型🄵造成的精確度損失。

適用： Unix。

在 3.3 版被加入.

time.**clock_gettime_ns**(*clk_id*) → *int*

類似於*clock_gettime()*，但回傳以奈秒 (nanoseconds) 🄵單位的時間。

適用： Unix。

在 3.7 版被加入.

time.**clock_settime**(*clk_id*, *time:* float)

設定指定時鐘 *clk_id* 的時間。目前，*CLOCK_REALTIME* 是 *clk_id* 唯一可以接受的值。

使用*clock_settime_ns()* 以避免*float* 型🄵造成的精確度損失。

適用： Unix。

在 3.3 版被加入.

time.**clock_settime_ns**(*clk_id*, *time:* int)

類似於*clock_settime()*，但設定以奈秒🄵單位的時間。

適用： Unix。

在 3.7 版被加入.

time.**ctime**([*secs*])

將自*epoch* 起以秒表示的時間轉🄵🄵表示當地時間且符合以下格式的字串：`'Sun Jun 20 23:21:05 1993'`。日期欄位🄵兩個字元長，如果日期是個位數，則用空格填充，例如：`'Wed Jun 9 04:26:40 1993'`。

如果未提供 *secs* 或其🄵*None*，則使用由*time()* 回傳的當前時間。`ctime(secs)` 等同於 `asctime(localtime(secs))`。*ctime()* 不使用區域資訊。

time.**get_clock_info**(*name*)

獲取指定時鐘的資訊作🄵命名空間物件。支援的時鐘名稱及讀取他們的值的對應函式如下：

- `'monotonic'`: *time.monotonic()*
- `'perf_counter'`: *time.perf_counter()*
- `'process_time'`: *time.process_time()*
- `'thread_time'`: *time.thread_time()*
- `'time'`: *time.time()*

其結果具有以下屬性：

- *adjustable*: 如果時鐘可以自動（例如，透過 NTP 常駐程式）或由系統管理員手動更改，則🄵 `True`，否則🄵 `False`
- *implementation*: 用於獲取時鐘的值的底層 C 函式名稱。有關可能的值，請參🄵*Clock ID Constants*。
- *monotonic*: 如果時鐘不能倒轉，則🄵 `True`，否則🄵 `False`
- *resolution*: 以秒 (*float*) 🄵單位的時鐘的解析度

在 3.3 版被加入.

time.**gmtime**([*secs*])

將自*epoch* 起以秒表示的時間轉🄵🄵 UTC 中的*struct_time*，其中 dst 旗標始終🄵零。如果未提供 *secs* 或其🄵*None*，則使用由*time()* 回傳的當前時間。忽略秒的分數部分。關於*struct_time* 物件的描述，請參🄵上文。此函式的反運算請參🄵*calendar.timegm()*。

time.**localtime**([*secs*])

類似於*gmtime()*，但轉🄵🄵當地時間。如果未提供 *secs* 或其🄵*None*，則使用由*time()* 回傳的當前時間。當 DST 適用於給定時間時，dst 旗標會被設定🄵 1。

如果時間戳超出 C 平台的 localtime() 或 gmtime() 函式支援的範圍，*localtime()* 可能會引發*OverflowError*；在 localtime() 或 gmtime() 失敗時，會引發*OSError*。通常會把年份限制在 1970 年到 2038 年之間。

time.**mktime**(*t*)

This is the inverse function of *localtime()*. Its argument is the *struct_time* or full 9-tuple (since the dst flag is needed; use −1 as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating-point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

time.**monotonic**() → *float*

Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use *monotonic_ns()* to avoid the precision loss caused by the *float* type.

在 3.3 版被加入.

在 3.5 版的變更: The function is now always available and always system-wide.

在 3.10 版的變更: On macOS, the function is now system-wide.

time.**monotonic_ns**() → *int*

Similar to *monotonic()*, but return time as nanoseconds.

在 3.7 版被加入.

time.**perf_counter**() → *float*

Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use *perf_counter_ns()* to avoid the precision loss caused by the *float* type.

在 3.3 版被加入.

在 3.10 版的變更: On Windows, the function is now system-wide.

time.**perf_counter_ns**() → *int*

Similar to *perf_counter()*, but return time as nanoseconds.

在 3.7 版被加入.

time.**process_time**() → *float*

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use *process_time_ns()* to avoid the precision loss caused by the *float* type.

在 3.3 版被加入.

time.**process_time_ns**() → *int*

Similar to *process_time()* but return time as nanoseconds.

在 3.7 版被加入.

time.**sleep**(*secs*)

Suspend execution of the calling thread for the given number of seconds. The argument may be a floating-point number to indicate a more precise sleep time.

If the sleep is interrupted by a signal and no exception is raised by the signal handler, the sleep is restarted with a recomputed timeout.

The suspension time may be longer than requested by an arbitrary amount, because of the scheduling of other activity in the system.

On Windows, if *secs* is zero, the thread relinquishes the remainder of its time slice to any other thread that is ready to run. If there are no other threads ready to run, the function returns immediately, and the thread continues execution. On Windows 8.1 and newer the implementation uses a high-resolution timer which provides resolution of 100 nanoseconds. If *secs* is zero, `Sleep(0)` is used.

Unix implementation:

- Use `clock_nanosleep()` if available (resolution: 1 nanosecond);
- Or use `nanosleep()` if available (resolution: 1 nanosecond);
- Or use `select()` (resolution: 1 microsecond).

在 3.5 版的變更: The function now sleeps at least *secs* even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale).

在 3.11 版的變更: On Unix, the `clock_nanosleep()` and `nanosleep()` functions are now used if available. On Windows, a waitable timer is now used.

time.**strftime**(*format*[, *t*])

Convert a tuple or *struct_time* representing a time as returned by *gmtime()* or *localtime()* to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by *localtime()* is used. *format* must be a string. *ValueError* is raised if any field in *t* is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the *strftime()* result:

Directive	Meaning	F解
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%f	**Microseconds as a decimal number** [000000,999999].	(1)
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(2)
%S	Second as a decimal number [00,61].	(3)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(4)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(4)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%z	Time zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59].[1]	
%Z	Time zone name (no characters	

🄵解:

(1) The `%f` format directive only applies to *`strptime()`*, not to *`strftime()`*. However, see also *`datetime.datetime.strptime()`* and *`datetime.datetime.strftime()`* where the `%f` format directive *applies to microseconds*.

(2) When used with the *`strptime()`* function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.

(3) The range really is `0` to `61`; value `60` is valid in timestamps representing leap seconds and value `61` is supported for historical reasons.

(4) When used with the *`strptime()`* function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the **RFC 2822** Internet email standard.[1]

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the *`strftime(3)`* documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial `'%'` of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

`time.`**`strptime`**(*string*[, *format*])

Parse a string representing a time according to a format. The return value is a *`struct_time`* as returned by *`gmtime()`* or *`localtime()`*.

The *format* parameter uses the same directives as those used by *`strftime()`*; it defaults to `"%a %b %d %H:%M:%S %Y"` which matches the formatting returned by *`ctime()`*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *`ValueError`* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are `(1900, 1, 1, 0, 0, 0, 0, 1, -1)`. Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                 tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the `%Z` directive is based on the values contained in `tzname` and whether `daylight` is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because `strftime()` is implemented per platform it can sometimes offer more directives than those listed. But `strptime()` is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

[1] The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 **RFC 822** standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, **RFC 822** became obsolete and the 4-digit year has been first recommended by **RFC 1123** and then mandated by **RFC 2822**.

class time.**struct_time**

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface: values can be accessed by index and by attribute name. The following values are present:

Index	屬性	Values
0	**tm_year**	（例如 1993）
1	**tm_mon**	range [1, 12]
2	**tm_mday**	range [1, 31]
3	**tm_hour**	range [0, 23]
4	**tm_min**	range [0, 59]
5	**tm_sec**	range [0, 61]; see *Note (2)* in *strftime()*
6	**tm_wday**	range [0, 6]; Monday is 0
7	**tm_yday**	range [1, 366]
8	**tm_isdst**	0, 1 or -1; see below
N/A	**tm_zone**	abbreviation of timezone name
N/A	**tm_gmtoff**	offset east of UTC in seconds

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to *mktime()*, *tm_isdst* may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct_time*, or having elements of the wrong type, a *TypeError* is raised.

time.**time**() → *float*

Return the time in seconds since the *epoch* as a floating-point number. The handling of leap seconds is platform dependent. On Windows and most Unix systems, the leap seconds are not counted towards the time in seconds since the *epoch*. This is commonly referred to as Unix time.

Note that even though the time is always returned as a floating-point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower

value than a previous call if the system clock has been set back between the two calls.

The number returned by *time()* may be converted into a more common time format (i.e. year, month, day, hour, etc...) in UTC by passing it to *gmtime()* function or in local time by passing it to the *localtime()* function. In both cases a *struct_time* object is returned, from which the components of the calendar date may be accessed as attributes.

Use *time_ns()* to avoid the precision loss caused by the *float* type.

time.**time_ns**() → *int*

Similar to *time()* but returns time as an integer number of nanoseconds since the *epoch*.

在 3.7 版被加入.

time.**thread_time**() → *float*

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls in the same thread is valid.

Use *thread_time_ns()* to avoid the precision loss caused by the *float* type.

適用： Linux、Unix、Windows。

Unix systems supporting CLOCK_THREAD_CPUTIME_ID.

在 3.7 版被加入.

time.**thread_time_ns**() → *int*

Similar to *thread_time()* but return time as nanoseconds.

在 3.7 版被加入.

time.**tzset**()

Reset the time conversion rules used by the library routines. The environment variable TZ specifies how this is done. It will also set the variables tzname (from the TZ environment variable), timezone (non-DST seconds West of UTC), altzone (DST seconds west of UTC) and daylight (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

適用： Unix。

備🄵

Although in many cases, changing the TZ environment variable may affect the output of functions like *localtime()* without calling *tzset()*, this behavior should not be relied on.

The TZ environment variable should contain no whitespace.

The standard format of the TZ environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are:

std 和 dst
Three or more alphanumerics giving the timezone abbreviations. These will be propagated into time.tzname

offset
The offset has the form: ± hh[:mm[:ss]]. This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows dst, summer time is assumed to be one hour ahead of standard time.

start[/time], end[/time]
Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

Jn
The Julian day *n* (1 <= *n* <= 365). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

n
The zero-based Julian day (0 <= *n* <= 365). Leap days are counted, and it is possible to refer to February 29.

Mm.n.d
The *d*'th day (0 <= *d* <= 6) of week *n* of month *m* of the year (1 <= *n* <= 5, 1 <= *m* <= 12, where week 5 means "the last *d* day in month *m*" which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if time is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*tzfile(5)*) database to specify the timezone rules. To do this, set the `TZ` environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

16.3.2 Clock ID Constants

These constants are used as parameters for *clock_getres()* and *clock_gettime()*.

`time.`**CLOCK_BOOTTIME**
Identical to *CLOCK_MONOTONIC*, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of *CLOCK_REALTIME*, which may have discontinuities if the time is changed using `settimeofday()` or similar.

適用： Linux 2.6.39 以上。

在 3.7 版被加入.

time.**CLOCK_HIGHRES**

The Solaris OS has a CLOCK_HIGHRES timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. CLOCK_HIGHRES is the nonadjustable, high-resolution clock.

適用： Solaris。

在 3.3 版被加入.

time.**CLOCK_MONOTONIC**

Clock that cannot be set and represents monotonic time since some unspecified starting point.

適用： Unix。

在 3.3 版被加入.

time.**CLOCK_MONOTONIC_RAW**

Similar to *CLOCK_MONOTONIC*, but provides access to a raw hardware-based time that is not subject to NTP adjustments.

適用： Linux 2.6.28 以上、macOS 10.12 以上。

在 3.3 版被加入.

time.**CLOCK_PROCESS_CPUTIME_ID**

High-resolution per-process timer from the CPU.

適用： Unix。

在 3.3 版被加入.

time.**CLOCK_PROF**

High-resolution per-process timer from the CPU.

適用： FreeBSD、NetBSD 7 以上、OpenBSD。

在 3.7 版被加入.

time.**CLOCK_TAI**

International Atomic Time

The system must have a current leap second table in order for this to give the correct answer. PTP or NTP software can maintain a leap second table.

適用： Linux。

在 3.9 版被加入.

time.**CLOCK_THREAD_CPUTIME_ID**

Thread-specific CPU-time clock.

適用： Unix。

在 3.3 版被加入.

time.**CLOCK_UPTIME**

Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

適用： FreeBSD、OpenBSD 5.5 以上。

在 3.7 版被加入.

time.**CLOCK_UPTIME_RAW**

Clock that increments monotonically, tracking the time since an arbitrary point, unaffected by frequency or time adjustments and not incremented while the system is asleep.

適用： macOS 10.12 以上。

在 3.8 版被加入.

The following constant is the only parameter that can be sent to *clock_settime()*.

time.**CLOCK_REALTIME**

System-wide real-time clock. Setting this clock requires appropriate privileges.

適用： Unix。

在 3.3 版被加入.

16.3.3 Timezone Constants

time.**altzone**

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero. See note below.

time.**daylight**

Nonzero if a DST timezone is defined. See note below.

time.**timezone**

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

time.**tzname**

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

備🄵

For the above Timezone constants (*altzone*, *daylight*, *timezone*, and *tzname*), the value is determined by the timezone rules in effect at module load time or the last time *tzset()* is called and may be incorrect for times in the past. It is recommended to use the *tm_gmtoff* and *tm_zone* results from *localtime()* to obtain timezone information.

也參考

***datetime* 模組**
More object-oriented interface to dates and times.

***locale* 模組**
Internationalization services. The locale setting affects the interpretation of many format specifiers in *strftime()* and *strptime()*.

***calendar* 模組**
General calendar-related functions. *timegm()* is the inverse of *gmtime()* from this module.

🄵解

16.4 `argparse` --- Parser for command-line options, arguments and sub-commands

在 3.2 版被加入.

原始碼： Lib/argparse.py

教學

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the argparse tutorial.

The *argparse* module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and *argparse* will figure out how to parse those out of *sys.argv*. The *argparse* module also automatically generates help and usage messages. The module will also issue errors when users give the program invalid arguments.

16.4.1 Core Functionality

The *argparse* module's support for command-line interfaces is built around an instance of *argparse.ArgumentParser*. It is a container for argument specifications and has options that apply to the parser as whole:

```
parser = argparse.ArgumentParser(
                    prog='ProgramName',
                    description='What the program does',
                    epilog='Text at the bottom of help')
```

The *ArgumentParser.add_argument()* method attaches individual argument specifications to the parser. It supports positional arguments, options that accept values, and on/off flags:

```
parser.add_argument('filename')           # positional argument
parser.add_argument('-c', '--count')      # option that takes a value
parser.add_argument('-v', '--verbose',
                    action='store_true')  # on/off flag
```

The *ArgumentParser.parse_args()* method runs the parser and places the extracted data in a *argparse.Namespace* object:

```
args = parser.parse_args()
print(args.filename, args.count, args.verbose)
```

16.4.2 Quick Links for add_argument()

名懲	描述	數值
action	Specify how an argument should be handled	`'store'`, `'store_const'`, `'store_true'`, `'append'`, `'append_const'`, `'count'`, `'help'`, `'version'`
choices	Limit values to a specific set of choices	`['foo', 'bar']`, `range(1, 10)`, or *Container* instance
const	Store a constant value	
default	Default value used when an argument is not provided	Defaults to `None`
dest	Specify the attribute name used in the result namespace	
help	Help message for an argument	
metavar	Alternate display name for the argument as shown in help	
nargs	Number of times the argument can be used	*int*, `'?'`, `'*'`, or `'+'`
required	Indicate whether an argument is required or optional	`True` 或 `False`
type	Automatically convert an argument to the given type	*int*、*float*、`argparse.FileType('w')` 或可呼叫的函式

16.4.3 范例

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
                    help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
                    help='sum the integers (default: find the max)')

args = parser.parse_args()
print(args.accumulate(args.integers))
```

Assuming the above Python code is saved into a file called `prog.py`, it can be run at the command line and it provides useful help messages:

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
 N           an integer for the accumulator

options:
 -h, --help  show this help message and exit
 --sum       sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, an error will be displayed:

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

建立一個剖析器

The first step in using the *argparse* is creating an *ArgumentParser* object:

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

The *ArgumentParser* object will hold all the information necessary to parse the command line into Python data types.

增加引數

Filling an *ArgumentParser* with information about program arguments is done by making calls to the *add_argument()* method. Generally, these calls tell the *ArgumentParser* how to take the strings on the command line and turn them into objects. This information is stored and used when *parse_args()* is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                     const=sum, default=max,
...                     help='sum the integers (default: find the max)')
```

Later, calling *parse_args()* will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more integers, and the `accumulate` attribute will be either the *sum()* function, if `--sum` was specified at the command line, or the *max()* function if it was not.

剖析引數

ArgumentParser parses arguments through the *parse_args()* method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple *Namespace* object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, *parse_args()* will typically be called with no arguments, and the *ArgumentParser* will automatically determine the command-line arguments from *sys.argv*.

16.4.4 ArgumentParser 物件

class argparse.**ArgumentParser**(*prog=None*, *usage=None*, *description=None*, *epilog=None*, *parents=[]*, *formatter_class=argparse.HelpFormatter*, *prefix_chars='-'*, *fromfile_prefix_chars=None*, *argument_default=None*, *conflict_handler='error'*, *add_help=True*, *allow_abbrev=True*, *exit_on_error=True*)

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- *prog* - The name of the program (default: `os.path.basename(sys.argv[0])`)
- *usage* - The string describing the program usage (default: generated from arguments added to parser)
- *description* - Text to display before the argument help (by default, no text)
- *epilog* - Text to display after the argument help (by default, no text)
- *parents* - A list of `ArgumentParser` objects whose arguments should also be included
- *formatter_class* - A class for customizing the help output
- *prefix_chars* - The set of characters that prefix optional arguments (default: '-')
- *fromfile_prefix_chars* - The set of characters that prefix files from which additional arguments should be read (default: `None`)
- *argument_default* - The global default value for arguments (default: `None`)
- *conflict_handler* - The strategy for resolving conflicting optionals (usually unnecessary)
- *add_help* - Add a `-h/--help` option to the parser (default: `True`)
- *allow_abbrev* - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: `True`)
- *exit_on_error* - Determines whether or not ArgumentParser exits with error info when an error occurs. (default: `True`)

在 3.5 版的變更: 新增 *allow_abbrev* 參數。

在 3.8 版的變更: In previous versions, *allow_abbrev* also disabled grouping of short flags such as `-vv` to mean `-v -v`.

在 3.9 版的變更: 新增 *exit_on_error* 參數。

The following sections describe how each of these are used.

prog

By default, `ArgumentParser` objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

options:
 -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo of the myprogram program
```

usage

By default, *ArgumentParser* calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
 bar          bar help

options:
 -h, --help   show this help message and exit
 --foo [FOO]  foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
 bar           bar help

options:
 -h, --help    show this help message and exit
 --foo [FOO]   foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

描述

Most calls to the *ArgumentParser* constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

options:
 -h, --help  show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the *formatter_class* argument.

epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

options:
 -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the *description* argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the *formatter_class* argument to *ArgumentParser*.

parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to *ArgumentParser* can be used. The `parents=` argument takes a list of *ArgumentParser* objects, collects all the positional and optional actions from them, and adds these actions to the *ArgumentParser* object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the *ArgumentParser* will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

備🄵

You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

class argparse.**RawDescriptionHelpFormatter**

class argparse.**RawTextHelpFormatter**

class argparse.**ArgumentDefaultsHelpFormatter**

class argparse.**MetavarTypeHelpFormatter**

RawDescriptionHelpFormatter and *RawTextHelpFormatter* give more control over how textual descriptions are displayed. By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...             but that is okay''',
...     epilog='''
...             likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]
```

(繼續下一頁)

(繼續上一頁)

```
this description was indented weird but that is okay

options:
 -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines
```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         --------------------------------
...             I have indented it
...             exactly the way
...             I want it
...         '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
--------------------------------
   I have indented it
   exactly the way
   I want it

options:
 -h, --help  show this help message and exit
```

RawTextHelpFormatter maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

ArgumentDefaultsHelpFormatter automatically adds information about default values to each of the argument help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar ...]

positional arguments:
 bar         BAR! (default: [1, 2, 3])

options:
 -h, --help  show this help message and exit
 --foo FOO   FOO! (default: 42)
```

MetavarTypeHelpFormatter uses the name of the *type* argument for each argument as the display name for its values (rather than using the *dest* as the regular formatter does):

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

options:
  -h, --help  show this help message and exit
  --foo int
```

prefix_chars

Most command-line options will use - as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the ArgumentParser constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include - will cause `-f/--foo` options to be disallowed.

fromfile_prefix_chars

Sometimes, when dealing with a particularly long argument list, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the *`ArgumentParser`* constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w', encoding=sys.getfilesystemencoding()) as fp:
...     fp.write('-f\nbar')
...
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also *`convert_arg_line_to_args()`*) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

`ArgumentParser` uses *filesystem encoding and error handler* to read the file containing arguments.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

在 3.12 版的變更: *ArgumentParser* changed encoding and errors to read arguments files from default (e.g. *locale.getpreferredencoding(False)* and "strict") to *filesystem encoding and error handler*. Arguments file should be encoded in UTF-8 instead of ANSI Codepage on Windows.

argument_default

Generally, argument defaults are specified either by passing a default to *add_argument()* or by calling the *set_defaults()* methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to *ArgumentParser*. For example, to globally suppress attribute creation on *parse_args()* calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

allow_abbrev

Normally, when you pass an argument list to the *parse_args()* method of an *ArgumentParser*, it *recognizes abbreviations* of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

在 3.5 版被加入.

conflict_handler

ArgumentParser objects do not allow two actions with the same option string. By default, *ArgumentParser* objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
 ..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

options:
 -h, --help  show this help message and exit
 -f FOO      old foo help
 --foo FOO   new foo help
```

Note that *ArgumentParser* objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

add_help

By default, ArgumentParser objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the ArgumentParser help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

options:
 --foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

options:
  +h, ++help  show this help message and exit
```

exit_on_error

Normally, when you pass an invalid argument list to the *parse_args()* method of an *ArgumentParser*, it will exit with error info.

If the user would like to catch errors manually, the feature can be enabled by setting `exit_on_error` to `False`:

```
>>> parser = argparse.ArgumentParser(exit_on_error=False)
>>> parser.add_argument('--integers', type=int)
_StoreAction(option_strings=['--integers'], dest='integers', nargs=None, const=None,␣
↪default=None, type=<class 'int'>, choices=None, help=None, metavar=None)
>>> try:
...     parser.parse_args('--integers a'.split())
... except argparse.ArgumentError:
...     print('Catching an argumentError')
...
Catching an argumentError
```

16.4.5 The add_argument() method

`ArgumentParser.`**`add_argument`**(*name or flags...*[, *action*][, *nargs*][, *const*][, *default*][, *type*][, *choices*][, *required*][, *help*][, *metavar*][, *dest*])

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- *name or flags* - Either a name or a list of option strings, e.g. `foo` or `-f, --foo`.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line and if it is absent from the namespace object.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A sequence of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by *parse_args()*.

The following sections describe how each of these are used.

name or flags

The *add_argument()* method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to *add_argument()* must therefore be either a series of flags, or a simple argument name.

For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When *parse_args()* is called, optional arguments will be identified by the - prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

action

ArgumentParser objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by *parse_args()*. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo')
  >>> parser.parse_args('--foo 1'.split())
  Namespace(foo='1')
  ```

- `'store_const'` - This stores the value specified by the *const* keyword argument; note that the *const* keyword argument defaults to `None`. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', action='store_const', const=42)
  >>> parser.parse_args(['--foo'])
  Namespace(foo=42)
  ```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` used for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- `'append'` - This stores a list, and appends each argument value to the list. It is useful to allow an option to be specified multiple times. If the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- `'append_const'` - This stores a list, and appends the value specified by the *const* keyword argument to the list; note that the *const* keyword argument defaults to `None`. The `'append_const'` action is typically useful when multiple arguments need to store constants to the same list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- `'count'` - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count', default=0)
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

  Note, the *default* will be `None` unless explicitly set to *0*.

- `'help'` - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See *`ArgumentParser`* for details of how the output is created.

- `'version'` - This expects a `version=` keyword argument in the *`add_argument()`* call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='%(prog)s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

- `'extend'` - This stores a list, and extends each argument value to the list. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument("--foo", action="extend", nargs="+", type=str)
>>> parser.parse_args(["--foo", "f1", "--foo", "f2", "f3", "f4"])
Namespace(foo=['f1', 'f2', 'f3', 'f4'])
```

  在 3.8 版被加入.

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The `BooleanOptionalAction` is available in `argparse` and adds support for boolean actions such as `--foo` and `--no-foo`:

```
>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=argparse.BooleanOptionalAction)
>>> parser.parse_args(['--no-foo'])
Namespace(foo=False)
```

在 3.9 版被加入.

The recommended way to create a custom action is to extend *Action*, overriding the `__call__` method and optionally the `__init__` and `format_usage` methods.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super().__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

For more details, see *Action*.

nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. See also specifying-ambiguous-arguments. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', nargs=2)
  >>> parser.add_argument('bar', nargs=1)
  >>> parser.parse_args('c --foo a b'.split())
  Namespace(bar=['c'], foo=['a', 'b'])
  ```

  Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from *default* will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from *const* will be produced. Some examples to illustrate this:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')
```

One of the more common uses of `nargs='?'` is to allow optional input and output files:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='output.txt' encoding='UTF-8'>)
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' encoding='UTF-8'>)
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the *action*. Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced.

const

The `const` argument of *`add_argument()`* is used to hold constant values that are not read from the command line but are required for the various *`ArgumentParser`* actions. The two most common uses of it are:

- When *`add_argument()`* is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by *`parse_args()`*. See the *action* description for examples. If `const` is not provided to *`add_argument()`*, it will receive a default value of `None`.
- When *`add_argument()`* is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed to be `None` instead. See the *nargs* description for examples.

在 3.11 版的變更: `const=None` by default, including when `action='append_const'` or `action='store_const'`.

default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of *`add_argument()`*, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the target namespace already has an attribute set, the action *default* will not over write it:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args([], namespace=argparse.Namespace(foo=101))
Namespace(foo=101)
```

If the `default` value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *`Namespace`* return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the `default` value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, the parser reads command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, such as a *float* or *int*. The `type` keyword for *add_argument()* allows any necessary type-checking and type conversions to be performed.

If the *type* keyword is used with the *default* keyword, the type converter is only applied if the default is a string.

The argument to `type` can be any callable that accepts a single string. If the function raises *ArgumentTypeError*, *TypeError*, or *ValueError*, the exception is caught and a nicely formatted error message is displayed. No other exception types are handled.

Common built-in types and functions can be used as type converters:

```
import argparse
import pathlib

parser = argparse.ArgumentParser()
parser.add_argument('count', type=int)
parser.add_argument('distance', type=float)
parser.add_argument('street', type=ascii)
parser.add_argument('code_point', type=ord)
parser.add_argument('source_file', type=open)
parser.add_argument('dest_file', type=argparse.FileType('w', encoding='latin-1'))
parser.add_argument('datapath', type=pathlib.Path)
```

User defined functions can be used as well:

```
>>> def hyphenated(string):
...     return '-'.join([word[:4] for word in string.casefold().split()])
...
>>> parser = argparse.ArgumentParser()
>>> _ = parser.add_argument('short_title', type=hyphenated)
>>> parser.parse_args(['"The Tale of Two Cities"'])
Namespace(short_title='"the-tale-of-two-citi')
```

The *bool()* function is not recommended as a type converter. All it does is convert empty strings to `False` and non-empty strings to `True`. This is usually not what is desired.

In general, the `type` keyword is a convenience that should only be used for simple conversions that can only raise one of the three supported exceptions. Anything with more interesting error-handling or resource management should be done downstream after the arguments are parsed.

For example, JSON or YAML conversions have complex error cases that require better reporting than can be given by the `type` keyword. A *JSONDecodeError* would not be well formatted and a *FileNotFoundError* exception would not be handled at all.

Even *FileType* has its limitations for use with the `type` keyword. If one argument uses *FileType* and then a subsequent argument fails, an error is reported but the file is not automatically closed. In this case, it would be better to wait until after the parser has run and then use the `with`-statement to manage the files.

For type checkers that simply check against a fixed set of values, consider using the *choices* keyword instead.

choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a sequence object as the *choices* keyword argument to *add_argument()*. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* sequence is checked after any *type* conversions have been performed, so the type of the objects in the *choices* sequence should match the *type* specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)
```

Any sequence can be passed as the *choices* value, so *list* objects, *tuple* objects, and custom sequences are all supported.

Use of *enum.Enum* is not recommended because it is difficult to control its appearance in usage, help, and error messages.

Formatted choices override the default *metavar* which is normally derived from *dest*. This is usually what you want because the user never sees the *dest* parameter. If this display isn't desirable (perhaps because there are many choices), just specify an explicit *metavar*.

required

In general, the *argparse* module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
```

(繼續下一頁)

(繼續上一頁)

```
usage: [-h] --foo FOO
: error: the following arguments are required: --foo
```

As the example shows, if an option is marked as `required`, *parse_args()* will report an error if that option is not present at the command line.

備🄵

Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

幫助

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these `help` descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
...                     help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
 bar     one of the bars to be frobbled

options:
 -h, --help  show this help message and exit
 --foo   foo the bars before frobbling
```

The `help` strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to *add_argument()*, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                     help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
 bar     the bar to frobble (default: 42)

options:
 -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal `%` to appear in the help string, you must escape it as `%%`.

argparse supports silencing the help entry for certain options, by setting the `help` value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
```

(繼續下一頁)

(繼續上一頁)

```
usage: frobble [-h]

options:
  -h, --help  show this help message and exit
```

metavar

When *ArgumentParser* generates help messages, it needs some way to refer to each expected argument. By default, ArgumentParser objects use the *dest* value as the "name" of each object. By default, for positional argument actions, the *dest* value is used directly, and for optional argument actions, the *dest* value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo FOO] bar

positional arguments:
 bar

options:
 -h, --help  show this help message and exit
 --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo YYY] XXX

positional arguments:
 XXX

options:
 -h, --help  show this help message and exit
 --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the *parse_args()* object is still determined by the *dest* value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
```

(繼續下一頁)

(繼續上一頁)

```
usage: PROG [-h] [-x X X] [--foo bar baz]

options:
 -h, --help     show this help message and exit
 -x X X
 --foo bar baz
```

dest

Most *ArgumentParser* actions add some value as an attribute of the object returned by *parse_args()*. The name of this attribute is determined by the `dest` keyword argument of *add_argument()*. For positional argument actions, `dest` is normally supplied as the first argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. *ArgumentParser* generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to *add_argument()*.

class argparse.**Action**(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

Action objects are used by an ArgumentParser to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to *ArgumentParser.add_argument()* except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes "dest", "option_strings", "default", "type", "required", "help", etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters:

- `parser` - The ArgumentParser object which contains this action.
- `namespace` - The *`Namespace`* object that will be returned by *`parse_args()`*. Most actions add an attribute to this object using *`setattr()`*.
- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the *type* keyword argument to *`add_argument()`*.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__` method may perform arbitrary actions, but will typically set attributes on the `namespace` based on `dest` and `values`.

Action subclasses can define a `format_usage` method that takes no argument and return a string which will be used when printing the usage of the program. If such method is not provided, a sensible default will be used.

16.4.6 The parse_args() method

`ArgumentParser.`**`parse_args`**(*args=None*, *namespace=None*)

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to *`add_argument()`* determine exactly what objects are created and how they are assigned. See the documentation for *`add_argument()`* for details.

- *args* - List of strings to parse. The default is taken from *`sys.argv`*.
- *namespace* - An object to take the attributes. The default is a new empty *`Namespace`* object.

Option value syntax

The *`parse_args()`* method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using = to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single - prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, *parse_args()* checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing -

The *parse_args()* method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The *parse_args()* method is cautious here: positional arguments may only begin with - if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with - and don't look like negative numbers, you can insert the pseudo-argument `'--'` which tells *parse_args()* that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

See also the argparse howto on ambiguous arguments for more details.

Argument abbreviations (prefix matching)

The *parse_args()* method *by default* allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args('-bac MMM'.split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args('-bad WOOD'.split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args('-ba BA'.split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting *allow_abbrev* to `False`.

Beyond `sys.argv`

Sometimes it may be useful to have an ArgumentParser parse arguments other than those of *sys.argv*. This can be accomplished by passing a list of strings to *parse_args()*. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

The Namespace object

class argparse.**Namespace**

Simple class used by default by *parse_args()* to create an object holding attributes and return it.

This class is deliberately simple, just an *object* subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, *vars()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an *ArgumentParser* assign attributes to an already existing object, rather than a new *Namespace* object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

16.4.7 Other utilities

Sub-commands

ArgumentParser.**add_subparsers**([*title*][, *description*][, *prog*][, *parser_class*][, *action*][, *option_strings*][, *dest*][, *required*][, *help*][, *metavar*])

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. *ArgumentParser* supports the creation of such sub-commands with

the *add_subparsers()* method. The *add_subparsers()* method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any *ArgumentParser* constructor arguments, and returns an *ArgumentParser* object that can be modified as usual.

Description of parameters:

- title - title for the sub-parser group in help output; by default "subcommands" if description is provided, otherwise uses title for positional arguments
- description - description for the sub-parser group in help output, by default `None`
- prog - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- parser_class - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. ArgumentParser)
- *action* - the basic type of action to be taken when this argument is encountered at the command line
- *dest* - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- *required* - Whether or not a subcommand must be provided, by default `False` (added in 3.7)
- *help* - help for sub-parser group in help output, by default `None`
- *metavar* - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form {cmd1, cmd2, ..}

一些使用範例:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by *parse_args()* will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}   sub-command help
    a     a help
    b     b help

options:
  -h, --help  show this help message and exit
  --foo   foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar     bar help

options:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

options:
  -h, --help     show this help message and exit
  --baz {X,Y,Z}  baz help
```

The *add_subparsers()* method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                    description='valid subcommands',
...                                    help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...

options:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}   additional help
```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', aliases=['co'])
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

One particularly effective way of handling sub-commands is to combine the use of the *add_subparsers()* method with calls to *set_defaults()* so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('((%s))' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(required=True)
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let *parse_args()* do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the *add_subparsers()* call will work:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')
```

在 3.7 版的變更: New *required* keyword argument.

FileType 物件

class argparse.**FileType**(*mode='r'*, *bufsize=-1*, *encoding=None*, *errors=None*)

The *FileType* factory creates objects that can be passed to the type argument of *ArgumentParser.add_argument()*. Arguments that have *FileType* objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the *open()* function for more details):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType('wb', 0))
>>> parser.add_argument('out', type=argparse.FileType('w', encoding='UTF-8'))
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='w' encoding='UTF-8'>, raw=
↪<_io.FileIO name='raw.dat' mode='wb'>)
```

FileType objects understand the pseudo-argument `'-'` and automatically convert this into *sys.stdin* for readable *FileType* objects and *sys.stdout* for writable *FileType* objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>)
```

在 3.4 版的變更: Added the *encodings* and *errors* parameters.

Argument groups

ArgumentParser.**add_argument_group**(*title=None*, *description=None*)

By default, *ArgumentParser* groups command-line arguments into "positional arguments" and "options" when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the *add_argument_group()* method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar    bar help
  --foo FOO  foo help
```

The *add_argument_group()* method returns an argument group object which has an *add_argument()* method just like a regular *ArgumentParser*. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The *add_argument_group()* method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
```

(繼續下一頁)

(繼續上一頁)

```
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo    foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual "positional arguments" and "optional arguments" sections.

在 3.11 版的變更: Calling *add_argument_group()* on an argument group is deprecated. This feature was never supported and does not always work correctly. The function exists on the API by accident through inheritance and will be removed in the future.

Mutual exclusion

ArgumentParser.**add_mutually_exclusive_group**(*required=False*)

Create a mutually exclusive group. *argparse* will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The *add_mutually_exclusive_group()* method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of *add_argument_group()*. However, a mutually exclusive group can be added to an argument group that has a title and description. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_argument_group('Group title', 'Group description')
>>> exclusive_group = group.add_mutually_exclusive_group(required=True)
```

(繼續下一頁)

(繼續上一頁)

```
>>> exclusive_group.add_argument('--foo', help='foo help')
>>> exclusive_group.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [-h] (--foo FOO | --bar BAR)

options:
  -h, --help  show this help message and exit

Group title:
  Group description

  --foo FOO   foo help
  --bar BAR   bar help
```

在 3.11 版的變更: Calling *add_argument_group()* or *add_mutually_exclusive_group()* on a mutually exclusive group is deprecated. These features were never supported and do not always work correctly. The functions exist on the API by accident through inheritance and will be removed in the future.

Parser defaults

ArgumentParser.**set_defaults**(***kwargs*)

Most of the time, the attributes of the object returned by *parse_args()* will be fully determined by inspecting the command-line arguments and the argument actions. *set_defaults()* allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the *add_subparsers()* method for an example of this type.

ArgumentParser.**get_default**(*dest*)

Get the default value for a namespace attribute, as set by either *add_argument()* or by *set_defaults()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, *parse_args()* will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

ArgumentParser.**print_usage**(*file=None*)

Print a brief description of how the *ArgumentParser* should be invoked on the command line. If *file* is None, *sys.stdout* is assumed.

ArgumentParser.**print_help**(*file=None*)

Print a help message, including the program usage and information about the arguments registered with the *ArgumentParser*. If *file* is None, *sys.stdout* is assumed.

There are also variants of these methods that simply return a string instead of printing it:

ArgumentParser.**format_usage**()

Return a string containing a brief description of how the *ArgumentParser* should be invoked on the command line.

ArgumentParser.**format_help**()

Return a string containing a help message, including the program usage and information about the arguments registered with the *ArgumentParser*.

Partial parsing

ArgumentParser.**parse_known_args**(*args=None*, *namespace=None*)

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the *parse_known_args()* method can be useful. It works much like *parse_args()* except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

警告

Prefix matching rules apply to *parse_known_args()*. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

ArgumentParser.**convert_arg_line_to_args**(*arg_line*)

Arguments that are read from a file (see the *fromfile_prefix_chars* keyword argument to the *ArgumentParser* constructor) are read one argument per line. *convert_arg_line_to_args()* can be overridden for fancier reading.

This method takes a single argument *arg_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

Exiting methods

ArgumentParser.**exit**(*status=0*, *message=None*)

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that. The user can override this method to handle these steps differently:

```
class ErrorCatchingArgumentParser(argparse.ArgumentParser):
    def exit(self, status=0, message=None):
        if status:
            raise Exception(f'Exiting because of an error: {message}')
        exit(status)
```

ArgumentParser.**error**(*message*)

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

Intermixed parsing

ArgumentParser.**parse_intermixed_args**(*args=None*, *namespace=None*)

ArgumentParser.**parse_known_intermixed_args**(*args=None*, *namespace=None*)

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The *parse_intermixed_args()* and *parse_known_intermixed_args()* methods support this parsing style.

These parsers do not support all the argparse features, and will raise exceptions if unsupported features are used. In particular, subparsers, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between *parse_known_args()* and *parse_intermixed_args()*: the former returns `['2', '3']` as unparsed arguments, while the latter collects all the positionals into `rest`.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split())
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3'])
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.split())
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])
```

parse_known_intermixed_args() returns a two item tuple containing the populated namespace and the list of remaining argument strings. *parse_intermixed_args()* raises an error if there are any remaining unparsed argument strings.

在 3.7 版被加入.

16.4.8 Upgrading optparse code

Originally, the *argparse* module had attempted to maintain compatibility with *optparse*. However, *optparse* was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in *optparse* had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The *argparse* module improves on the standard library *optparse* module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like + and /.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom `type` and `action`.

A partial upgrade path from *optparse* to *argparse*:

- Replace all *optparse.OptionParser.add_option()* calls with *ArgumentParser.add_argument()* calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional *ArgumentParser.add_argument()* calls for the positional arguments. Keep in mind that what was previously called `options`, now in the *argparse* context is called `args`.
- Replace *optparse.OptionParser.disable_interspersed_args()* by using *parse_intermixed_args()* instead of *parse_args()*.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. int, float, complex, etc).
- Replace *optparse.Values* with *Namespace* and *optparse.OptionError* and *optparse.OptionValueError* with *ArgumentError*.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the OptionParser constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

16.4.9 Exceptions

exception argparse.**ArgumentError**

An error from creating or using an argument (optional or positional).

The string value of this exception is the message, augmented with information about the argument that caused it.

exception argparse.**ArgumentTypeError**

Raised when something goes wrong converting a command line string to a type.

16.5 getopt --- 用於命令列選項的 C 風格剖析器

原始碼： Lib/getopt.py

> **備🄵**
>
> The *getopt* module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the *argparse* module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form '-' and '--'). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.`**`getopt`**(*args*, *shortopts*, *longopts=[]*)

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (`':'`; i.e., the same format that Unix `getopt()` uses).

> **備🄵**
>
> Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading `'--'` characters should not be included in the option name. Long options which require an argument should be followed by an equal sign (`'='`). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is `['foo', 'frob']`, the option `--fo` will match as `--foo`, but `--f` will not match uniquely, so *GetoptError* will be raised.

The return value consists of two elements: the first is a list of `(option, value)` pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., `'-x'`) or two hyphens for long options (e.g., `'--long-option'`), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.`**`gnu_getopt`**(*args*, *shortopts*, *longopts=[]*)

This function works like *getopt()*, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The *getopt()* function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is `'+'`, or if the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

exception getopt.**GetoptError**

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

exception getopt.**error**

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err)  # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
```

(繼續下一頁)

(繼續上一頁)

```
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the *argparse* module:

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..
```

16.6 `logging` --- Python 的日🄵記🄵工具

原始碼： Lib/logging/__init__.py

Important

此頁面包含 API 參考訊息。有關教學流程和更進階的主題討論，請參🄵

- 基礎教學
- 進階教學
- 日🄵記🄵手🄵

這個模組定義了函式與類🄵 (class)，🄵應用程式和函式庫實作彈性的日🄵管理系統。

由標准函式庫模組提供的日🄵記🄵 API 的主要好處是，所有的 Python 模組都能參與日🄵記🄵，因此您的應用程式日🄵可以包含您自己的訊息，🄵與來自第三方模組的訊息整合在一起。

Here's a simple example of idiomatic usage:

```
# myapp.py
import logging
import mylib
logger = logging.getLogger(__name__)
```

(繼續下一頁)

(繼續上一頁)

```
def main():
    logging.basicConfig(filename='myapp.log', level=logging.INFO)
    logger.info('Started')
    mylib.do_something()
    logger.info('Finished')

if __name__ == '__main__':
    main()
```

```
# mylib.py
import logging
logger = logging.getLogger(__name__)

def do_something():
    logger.info('Doing something')
```

If you run *myapp.py*, you should see this in *myapp.log*:

```
INFO:__main__:Started
INFO:mylib:Doing something
INFO:__main__:Finished
```

The key feature of this idiomatic usage is that the majority of code is simply creating a module level logger with `getLogger(__name__)`, and using that logger to do any needed logging. This is concise, while allowing downstream code fine-grained control if needed. Logged messages to the module-level logger get forwarded to handlers of loggers in higher-level modules, all the way up to the highest-level logger known as the root logger; this approach is known as hierarchical logging.

For logging to be useful, it needs to be configured: setting the levels and destinations for each logger, potentially changing how specific modules log, often based on command-line arguments or application configuration. In most cases, like the one above, only the root logger needs to be so configured, since all the lower level loggers at module level eventually forward their messages to its handlers. *`basicConfig()`* provides a quick way to configure the root logger that handles many use cases.

這個模組提供了很多的功能性以及彈性。如果你對於 logging 不熟悉，熟悉它最好的方法就是去看教學（**請看右上方的連結**）。

The basic classes defined by the module, together with their attributes and methods, are listed in the sections below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- 格式器指定日🄵記🄵在最終輸出中的🄵局。

16.6.1 Logger 物件

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to *getLogger()* with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. In addition, all loggers are descendants of the root logger. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class logging.**Logger**

name

This is the logger's name, and is the value that was passed to *getLogger()* to obtain the logger.

> **備🄵**
>
> This attribute should be treated as read-only.

level

The threshold of this logger, as set by the *setLevel()* method.

> **備🄵**
>
> Do not set this attribute directly - always use *setLevel()*, which has checks for the level passed to it.

parent

The parent logger of this logger. It may change based on later instantiation of loggers which are higher up in the namespace hierarchy.

> **備🄵**
>
> This value should be treated as read-only.

propagate

如果此屬性評估🄵 true，則在此日🄵紀🄵器被記🄵的事件會被傳到更高階（上代）日🄵記🄵器的處理函式和所有附加在此日🄵記🄵器的任何處理器。訊息會直接傳到上代 loggers 的處理器 - 在問題中上代日🄵記🄵器的層級或是篩選器都不會被考慮。

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

Spelling it out with an example: If the propagate attribute of the logger named `A.B.C` evaluates to true, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to false, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

此建構函式將該屬性設🄵 `True`。

> **備🄵**
>
> If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

handlers

The list of handlers directly attached to this logger instance.

> **備🄵**
>
> This attribute should be treated as read-only; it is normally changed via the *addHandler()* and *removeHandler()* methods, which use locks to ensure thread-safe operation.

disabled

This attribute disables handling of any events. It is set to `False` in the initializer, and only changed by logging configuration code.

> **備🄵**
>
> This attribute should be treated as read-only.

setLevel(*level*)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

當一個日🄵記🄵器被建立時，記🄵層級會被設定成*NOTSET*（當此日🄵記🄵器是根日🄵記🄵器，或是代表父日🄵記🄵器的非根日🄵記🄵器時，會使所有訊息被處理）。請注意根日🄵記🄵器會以記🄵等級*WARNING*被建立。

The term 'delegation to the parent' means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

層級清單請見*Logging Levels*。

在 3.2 版的變更: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as *INFO*. Note, however, that levels are internally stored as integers, and methods such as e.g. *getEffectiveLevel()* and *isEnabledFor()* will return/expect to be passed integers.

isEnabledFor(*level*)

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger's effective level as determined by *getEffectiveLevel()*.

getEffectiveLevel()

Indicates the effective level for this logger. If a value other than *NOTSET* has been set using *setLevel()*, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than *NOTSET* is found, and that value is returned. The value returned is an integer, typically one of *logging.DEBUG*, *logging.INFO* etc.

getChild(*suffix*)

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

在 3.2 版被加入.

getChildren()

Returns a set of loggers which are immediate children of this logger. So for example `logging.getLogger().getChildren()` might return a set containing loggers named `foo` and `bar`, but a logger named `foo.bar` wouldn't be included in the set. Likewise, `logging.getLogger('foo').getChildren()` might return a set including a logger named `foo.bar`, but it wouldn't include one named `foo.bar.baz`.

在 3.12 版被加入.

debug(*msg*, **args*, ***kwargs*)

Logs a message with level *DEBUG* on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No % formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, *stacklevel* and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by *sys.exc_info()*) or an exception instance is provided, it is used; otherwise, *sys.exc_info()* is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to `1`. If greater than 1, the corresponding number of stack frames are skipped when computing the line number and function name set in the *LogRecord* created for the logging event. This can be used in logging helpers so that the function name, filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the *warnings* module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the __dict__ of the *LogRecord* created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protocol problem: connection␣
↪reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the section on *LogRecord attributes* for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the `Formatter` has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the `LogRecord`. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized `Formatter`s would be used with particular `Handler`s.

If no handler is attached to this logger (or any of its ancestors, taking into account the relevant `Logger.propagate` attributes), the message will be sent to the handler set on `lastResort`.

在 3.2 版的變更: 新增 *stack_info* 參數。

在 3.5 版的變更: The *exc_info* parameter can now accept exception instances.

在 3.8 版的變更: 新增 *stacklevel* 參數。

info(*msg*, **args*, ***kwargs*)

Logs a message with level `INFO` on this logger. The arguments are interpreted as for `debug()`.

warning(*msg*, **args*, ***kwargs*)

在此記🄵器上記🄵一條層級🄵`WARNING` 的訊息。這些引數被直譯的方式與`debug()` 相同。

備🄵

There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

error(*msg*, **args*, ***kwargs*)

Logs a message with level `ERROR` on this logger. The arguments are interpreted as for `debug()`.

critical(*msg*, **args*, ***kwargs*)

Logs a message with level `CRITICAL` on this logger. The arguments are interpreted as for `debug()`.

log(*level*, *msg*, **args*, ***kwargs*)

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for `debug()`.

exception(*msg*, **args*, ***kwargs*)

Logs a message with level `ERROR` on this logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This method should only be called from an exception handler.

addFilter(*filter*)

在該 logger F增加指定的 filter *filter*。

removeFilter(*filter*)

在該 logger F移除指定的 filter *filter*。

filter(*record*)

Apply this logger's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler(*hdlr*)

Adds the specified handler *hdlr* to this logger.

removeHandler(*hdlr*)

Removes the specified handler *hdlr* from this logger.

findCaller(*stack_info=False*, *stacklevel=1*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

The *stacklevel* parameter is passed from code calling the *debug()* and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

handle(*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using *filter()*.

makeRecord(*name*, *level*, *fn*, *lno*, *msg*, *args*, *exc_info*, *func=None*, *extra=None*, *sinfo=None*)

This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

hasHandlers()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

在 3.2 版被加入.

在 3.7 版的變更: Loggers can now be pickled and unpickled.

16.6.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

Level	Numeric value	What it means / When to use it
`logging.`**`NOTSET`**	0	When set on a logger, indicates that ancestor loggers are to be consulted to determine the effective level. If that still resolves to `NOTSET`, then all events are logged. When set on a handler, all events are handled.
`logging.`**`DEBUG`**	10	Detailed information, typically only of interest to a developer trying to diagnose a problem.
`logging.`**`INFO`**	20	Confirmation that things are working as expected.
`logging.`**`WARNING`**	30	An indication that something unexpected happened, or that a problem might occur in the near future (e.g. 'disk space low'). The software is still working as expected.
`logging.`**`ERROR`**	40	Due to a more serious problem, the software has not been able to perform some function.
`logging.`**`CRITICAL`**	50	A serious error, indicating that the program itself may be unable to continue running.

16.6.3 Handler Objects

Handlers have the following attributes and methods. Note that *`Handler`* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *`Handler.__init__()`*.

class logging.**Handler**

__init__(*level=NOTSET*)

Initializes the *`Handler`* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *`createLock()`*) for serializing access to an I/O mechanism.

createLock()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire()

Acquires the thread lock created with *`createLock()`*.

release()

Releases the thread lock acquired with *`acquire()`*.

setLevel(*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to *`NOTSET`* (which causes all messages to be processed).

層級清單請見*Logging Levels*。

在 3.2 版的變更: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as `INFO`.

setFormatter(*fmt*)

Sets the `Formatter` for this handler to *fmt*.

addFilter(*filter*)

Adds the specified filter *filter* to this handler.

removeFilter(*filter*)

Removes the specified filter *filter* from this handler.

filter(*record*)

Apply this handler's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when `shutdown()` is called. Subclasses should ensure that this gets called from overridden `close()` methods.

handle(*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError(*record*)

This method should be called from handlers when an exception is encountered during an `emit()` call. If the module-level attribute `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

format(*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

emit(*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

警告

This method is called after a handler-level lock is acquired, which is released after this method returns. When you override this method, note that you should be careful when calling anything that invokes other parts of the logging API which might do locking, because that might result in a deadlock. Specifically:

- Logging configuration APIs acquire the module-level lock, and then individual handler-level locks as those handlers are configured.
- Many logging APIs lock the module-level lock. If such an API is called from this method, it could cause a deadlock if a configuration call is made on another thread, because that thread will try to acquire the module-level lock *before* the handler-level lock, whereas this thread tries to acquire the

module-level lock *after* the handler-level lock (because in this method, the handler-level lock has already been acquired).

For a list of handlers included as standard, see *logging.handlers*.

16.6.4 Formatter Objects

class logging.**Formatter**(*fmt=None*, *datefmt=None*, *style='%'*, *validate=True*, ***, *defaults=None*)

Responsible for converting a *LogRecord* to an output string to be interpreted by a human or external system.

參數

- **fmt** (str) -- A format string in the given *style* for the logged output as a whole. The possible mapping keys are drawn from the *LogRecord* object's *LogRecord attributes*. If not specified, '%(message)s' is used, which is just the logged message.
- **datefmt** (str) -- A format string in the given *style* for the date/time portion of the logged output. If not specified, the default described in *formatTime()* is used.
- **style** (str) -- Can be one of '%', '{' or '$' and determines how the format string will be merged with its data: using one of *printf-style String Formatting* (%), *str.format()* ({) or *string.Template* ($). This only applies to *fmt* and *datefmt* (e.g. '%(message)s' versus '{message}'), not to the actual log messages passed to the logging methods. However, there are other ways to use {- and $-formatting for log messages.
- **validate** (bool) -- If True (the default), incorrect or mismatched *fmt* and *style* will raise a *ValueError*; for example, logging.Formatter('%(asctime)s - %(message)s', style='{').
- **defaults** (dict[str, *Any*]) -- A dictionary with default values to use in custom fields. For example, logging.Formatter('%(ip)s %(message)s', defaults={"ip": None})

在 3.2 版的變更: 新增 *style* 參數。

在 3.8 版的變更: 新增 *validate* 參數。

在 3.10 版的變更: 新增 *defaults* 參數。

format(*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using *msg % args*. If the formatting string contains '(asctime)', *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value (by setting the *exc_text* attribute to None) after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value, but recalculates it afresh.

If stack information is available, it's appended after the exception information, using *formatStack()* to transform it if necessary.

formatTime(*record*, *datefmt=None*)

This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior

is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format '%Y-%m-%d %H:%M:%S,uuu' is used, where the uuu part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is `2003-01-23 00:29:50,411`. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the `converter` attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

在 3.3 版的變更: Previously, the default format was hard-coded as in this example: `2010-09-06 22:38:15,292` where the part before the comma is handled by a strptime format string (`'%Y-%m-%d %H:%M:%S'`), and the part after the comma is a millisecond value. Because strptime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s,%03d'` --- and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the strptime format string) and `default_msec_format` (for appending the millisecond value).

在 3.9 版的變更: The `default_msec_format` can be `None`.

formatException(*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by *sys.exc_info()*) as a string. This default implementation just uses *traceback.print_exception()*. The resulting string is returned.

formatStack(*stack_info*)

Formats the specified stack information (a string as returned by *traceback.print_stack()*, but with the last newline removed) as a string. This default implementation just returns the input value.

class logging.**BufferingFormatter**(*linefmt=None*)

A base formatter class suitable for subclassing when you want to format a number of records. You can pass a *Formatter* instance which you want to use to format each line (that corresponds to a single record). If not specified, the default formatter (which just outputs the event message) is used as the line formatter.

formatHeader(*records*)

Return a header for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records, a title or a separator line.

formatFooter(*records*)

Return a footer for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records or a separator line.

format(*records*)

Return formatted text for a list of *records*. The base implementation just returns the empty string if there are no records; otherwise, it returns the concatenation of the header, each record formatted with the line formatter, and the footer.

16.6.5 Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all events are passed.

class logging.**Filter**(*name=''*)

Returns an instance of the *Filter* class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter(*record*)

Is the specified record to be logged? Returns false for no, true for yes. Filters can either modify log records in-place or return a completely different record instance which will replace the original log record in any future processing of the event.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using *debug()*, *info()*, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

在 3.2 版的變更: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its *filter()* method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by *filter()*.

在 3.12 版的變更: You can now return a *LogRecord* instance from filters to replace the log record rather than modifying it in place. This allows filters attached to a *Handler* to modify the log record before it is emitted, without having side effects on other handlers.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the *LogRecord* being processed. Obviously changing the LogRecord needs to be done with some care, but it does allow the injection of contextual information into logs (see filters-contextual).

16.6.6 LogRecord 物件

LogRecord instances are created automatically by the *Logger* every time something is logged, and can be created manually via *makeLogRecord()* (for example, from a pickled event received over the wire).

class logging.**LogRecord**(*name*, *level*, *pathname*, *lineno*, *msg*, *args*, *exc_info*, *func=None*, *sinfo=None*)

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the `message` attribute of the record.

參數

- **name** (`str`) -- The name of the logger used to log the event represented by this `LogRecord`. Note that the logger name in the `LogRecord` will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.

- **level** (int) -- The *numeric level* of the logging event (such as 10 for DEBUG, 20 for INFO, etc). Note that this is converted to *two* attributes of the LogRecord: levelno for the numeric value and levelname for the corresponding level name.
- **pathname** (str) -- The full string path of the source file where the logging call was made.
- **lineno** (int) -- The line number in the source file where the logging call was made.
- **msg** (Any) -- The event description message, which can be a %-format string with placeholders for variable data, or an arbitrary object (see arbitrary-object-messages).
- **args** (tuple | dict[str, Any]) -- Variable data to merge into the *msg* argument to obtain the event description.
- **exc_info** (tuple[type[BaseException], BaseException, types.TracebackType] | *None*) -- An exception tuple with the current exception information, as returned by *sys.exc_info()*, or None if no exception information is available.
- **func** (str | *None*) -- The name of the function or method from which the logging call was invoked.
- **sinfo** (str | *None*) -- A text string representing stack information from the base of the stack in the current thread, up to the logging call.

getMessage()

Returns the message for this *LogRecord* instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, *str()* is called on it to convert it to a string. This allows use of user-defined classes as messages, whose __str__ method can return the actual format string to be used.

在 3.2 版的變更: The creation of a *LogRecord* has been made more configurable by providing a factory which is used to create the record. The factory can be set using *getLogRecordFactory()* and *setLogRecordFactory()* (see this for the factory's signature).

This functionality can be used to inject your own values into a *LogRecord* at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

16.6.7 LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (*str.format()*), you can use `{attrname}` as the placeholder in the format string. If you are using $-formatting (*string.Template*), use the form `${attrname}`. In both cases, of course, replace `attrname` with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of `{msecs:03.0f}` would format a millisecond value of `4` as `004`. Refer to the *str.format()* documentation for full details on the options available to you.

Attribute name	格式	描述
args	你不應該需要自己格式化它。	The tuple of arguments merged into `msg` to produce `message`, or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	`%(asctime)s`	Human-readable time when the *LogRecord* was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).
created	`%(created)f`	Time when the *LogRecord* was created (as returned by *time.time()*).
exc_info	你不應該需要自己格式化它。	Exception tuple (à la `sys.exc_info`) or, if no exception has occurred, `None`.
filename	`%(filename)s`	Filename portion of `pathname`.
funcName	`%(funcName)s`	Name of function containing the logging call.
levelname	`%(levelname)s`	Text logging level for the message (`'DEBUG'`, `'INFO'`, `'WARNING'`, `'ERROR'`, `'CRITICAL'`).
levelno	`%(levelno)s`	Numeric logging level for the message (*DEBUG*, *INFO*, *WARNING*, *ERROR*, *CRITICAL*).
lineno	`%(lineno)d`	Source line number where the logging call was issued (if available).
message	`%(message)s`	The logged message, computed as `msg % args`. This is set when *Formatter.format()* is invoked.
模組	`%(module)s`	Module (name portion of `filename`).
msecs	`%(msecs)d`	Millisecond portion of the time when the *LogRecord* was created.
msg	你不應該需要自己格式化它。	The format string passed in the original logging call. Merged with `args` to produce `message`, or an arbitrary object (see arbitrary-object-messages).
name	`%(name)s`	Name of the logger used to log the call.
pathname	`%(pathname)s`	Full pathname of the source file where the logging call was issued (if available).
process	`%(process)d`	Process ID (if available).
processName	`%(processName)s`	Process name (if available).
relativeCreated	`%(relativeCreated)d`	Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.
stack_info	你不應該需要自己格式化它。	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	`%(thread)d`	Thread ID (if available).
threadName	`%(threadName)s`	Thread name (if available).
taskName	`%(taskName)s`	*asyncio.Task* name (if available).

在 3.1 版的變更: 新增 *processName*。

在 3.12 版的變更: 新增 *taskName*。

16.6.8 LoggerAdapter 物件

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class logging.**LoggerAdapter**(*logger*, *extra*)

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance and a dict-like object.

process(*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

manager

Delegates to the underlying `manager` on *logger*.

_log

Delegates to the underlying `_log()` method on *logger*.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()*, *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably.

在 3.2 版的變更: The *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()* methods were added to *LoggerAdapter*. These methods delegate to the underlying logger.

在 3.6 版的變更: Attribute `manager` and method `_log()` were added, which delegate to the underlying logger and allow adapters to be nested.

16.6.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

16.6.10 Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

logging.**getLogger**(*name=None*)

Return a logger with the specified name or, if name is `None`, return the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like *'a'*, *'a.b'* or *'a.b.c.d'*. Choice of these names is entirely up to the developer who is using logging, though it is recommended that `__name__` be used unless you have a specific reason for not doing that, as mentioned in *Logger 物件*.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.**getLoggerClass**()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.**getLogRecordFactory**()

Return a callable which is used to create a *LogRecord*.

在 3.2 版被加入: This function has been provided, along with *setLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See *setLogRecordFactory()* for more information about the how the factory is called.

logging.**debug**(*msg*, **args*, ***kwargs*)

This is a convenience function that calls *Logger.debug()*, on the root logger. The handling of the arguments is in every way identical to what is described in that method.

The only difference is that if the root logger has no handlers, then *basicConfig()* is called, prior to calling `debug` on the root logger.

For very short scripts or quick demonstrations of `logging` facilities, `debug` and the other module-level functions may be convenient. However, most programs will want to carefully and explicitly control the logging configuration, and should therefore prefer creating a module-level logger and calling *Logger.debug()* (or other level-specific methods) on it, as described at the beginnning of this documentation.

logging.**info**(*msg*, **args*, ***kwargs*)

Logs a message with level *INFO* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**warning**(*msg*, **args*, ***kwargs*)

Logs a message with level *WARNING* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

> **備🄵**
>
> There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

logging.**error**(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**critical**(*msg*, **args*, ***kwargs*)

Logs a message with level *CRITICAL* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**exception**(*msg*, **args*, ***kwargs*)

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for *debug()*. Exception info is added to the logging message. This function should only be called from an exception handler.

logging.**log**(*level*, *msg*, **args*, ***kwargs*)

Logs a message with level *level* on the root logger. The arguments and behavior are otherwise the same as for *debug()*.

logging.**disable**(*level=CRITICAL*)

Provides an overriding level *level* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *level* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the *level* parameter, but will have to explicitly supply a suitable value.

在 3.7 版的變更: The *level* parameter was defaulted to level `CRITICAL`. See bpo-28524 for more information about this change.

logging.**addLevelName**(*level*, *levelName*)

Associates level *level* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a *Formatter* formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

備🄵

If you are thinking of defining your own levels, please see the section on custom-levels.

logging.**getLevelNamesMapping**()

Returns a mapping from level names to their corresponding logging levels. For example, the string "CRITICAL" maps to *CRITICAL*. The returned mapping is copied from an internal mapping on each call to this function.

在 3.11 版被加入.

logging.**getLevelName**(*level*)

Returns the textual or numeric representation of logging level *level*.

If *level* is one of the predefined levels *CRITICAL*, *ERROR*, *WARNING*, *INFO* or *DEBUG* then you get the corresponding string. If you have associated levels with names using *addLevelName()* then the name you have associated with *level* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The *level* parameter also accepts a string representation of the level such as 'INFO'. In such cases, this functions returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string 'Level %s' % level is returned.

備🄵

Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see *LogRecord attributes*), and vice versa.

在 3.4 版的變更: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

logging.**getHandlerByName**(*name*)

Returns a handler with the specified *name*, or `None` if there is no handler with that name.

在 3.12 版被加入.

logging.**getHandlerNames**()

Returns an immutable set of all known handler names.

在 3.12 版被加入.

logging.**makeLogRecord**(*attrdict*)

Creates and returns a new *LogRecord* instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled *LogRecord* attribute dictionary, sent over a socket, and reconstituting it as a *LogRecord* instance at the receiving end.

logging.**basicConfig**(***kwargs*)

Does basic configuration for the logging system by creating a *StreamHandler* with a default *Formatter* and adding it to the root logger. The functions *debug()*, *info()*, *warning()*, *error()* and *critical()* will call *basicConfig()* automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured, unless the keyword argument *force* is set to `True`.

> **備🄵**
>
> This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

格式	描述
filename	Specifies that a `FileHandler` be created, using the specified filename, rather than a `StreamHandler`.
filemode	If *filename* is specified, open the file in this *mode*. Defaults to `'a'`.
format	Use the specified format string for the handler. Defaults to attributes `levelname`, `name` and `message` separated by colons.
datefmt	Use the specified date/time format, as accepted by `time.strftime()`.
style	If *format* is specified, use this style for the format string. One of `'%'`, `'{'` or `'$'` for *printf-style*, `str.format()` or `string.Template` respectively. Defaults to `'%'`.
level	Set the root logger level to the specified *level*.
stream	Use the specified stream to initialize the `StreamHandler`. Note that this argument is incompatible with *filename* - if both are present, a `ValueError` is raised.
handlers	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with *filename* or *stream* - if both are present, a `ValueError` is raised.
force	If this keyword argument is specified as true, any existing handlers attached to the root logger are removed and closed, before carrying out the configuration as specified by the other arguments.
encoding	If this keyword argument is specified along with *filename*, its value is used when the `FileHandler` is created, and thus used when opening the output file.
errors	If this keyword argument is specified along with *filename*, its value is used when the `FileHandler` is created, and thus used when opening the output file. If not specified, the value 'backslashreplace' is used. Note that if `None` is specified, it will be passed as such to `open()`, which means that it will be treated the same as passing 'errors'.

在 3.2 版的變更: 新增 *style* 引數。

在 3.3 版的變更: The *handlers* argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. *handlers* together with *stream* or *filename*, or *stream* together with *filename*).

在 3.8 版的變更: 新增 *force* 引數。

在 3.9 版的變更: 新增 *encoding* 與 *errors* 引數。

`logging.`**`shutdown`**`()`

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

When the logging module is imported, it registers this function as an exit handler (see `atexit`), so normally there's no need to do that manually.

`logging.`**`setLoggerClass`**`(`*klass*`)`

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the `logging.getLogger()` API to get your loggers.

`logging.`**`setLogRecordFactory`**`(`*factory*`)`

Set a callable which is used to create a `LogRecord`.

參數

`factory` -- The factory callable to be used to instantiate a log record.

在 3.2 版被加入: This function has been provided, along with *getLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

The factory has the following signature:

`factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None, **kwargs)`

name
The logger name.

level
The logging level (numeric).

fn
The full pathname of the file where the logging call was made.

lno
The line number in the file where the logging call was made.

msg
The logging message.

args
The arguments for the logging message.

exc_info
An exception tuple, or `None`.

func
The name of the function or method which invoked the logging call.

sinfo
A stack traceback such as is provided by *traceback.print_stack()*, showing the call hierarchy.

kwargs
額外的關鍵字引數。

16.6.11 Module-Level Attributes

`logging.`**`lastResort`**

A "handler of last resort" is available through this attribute. This is a *StreamHandler* writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that "no handlers could be found for logger XYZ". If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

在 3.2 版被加入.

`logging.`**`raiseExceptions`**

Used to see if exceptions during handling should be propagated.

Default: `True`.

If *raiseExceptions* is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors.

16.6.12 Integration with the warnings module

The *captureWarnings()* function can be used to integrate *logging* with the *warnings* module.

logging.**captureWarnings**(*capture*)

This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the *warnings* module will be redirected to the logging system. Specifically, a warning will be formatted using *warnings.formatwarning()* and the resulting string logged to a logger named `'py.warnings'` with a severity of *WARNING*.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- 進階教學
- Logging Cookbook

This section describes the API for configuring the logging module.

16.7.1 Configuration functions

The following functions configure the logging module. They are located in the *logging.config* module. Their use is optional --- you can configure the logging module using these functions or by making calls to the main API (defined in *logging* itself) and defining handlers which are declared either in *logging* or *logging.handlers*.

logging.config.**dictConfig**(*config*)

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a *ValueError*, *TypeError*, *AttributeError* or *ImportError* with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The *logging.config* module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

dictConfig() calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then *dictConfig()* could be called exactly as in the default, uncustomized state.

在 3.2 版被加入.

logging.config.**fileConfig**(*fname*, *defaults=None*, *disable_existing_loggers=True*, *encoding=None*)

Reads the logging configuration from a *configparser*-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

It will raise *FileNotFoundError* if the file doesn't exist and *RuntimeError* if the file is invalid or empty.

參數

- **fname** -- A filename, or a file-like object, or an instance derived from *RawConfigParser*. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a *ConfigParser* is instantiated, and the configuration read by it from the object passed in `fname`. If that has a *readline()* method, it is assumed to be a file-like object and read using *read_file()*; otherwise, it is assumed to be a filename and passed to *read()*.
- **defaults** -- Defaults to be passed to the `ConfigParser` can be specified in this argument.

- **disable_existing_loggers** -- If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.
- **encoding** -- The encoding used to open file when *fname* is filename.

在 3.4 版的變更: An instance of a subclass of *RawConfigParser* is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

在 3.10 版的變更: Added the *encoding* parameter.

在 3.12 版的變更: An exception will be thrown if the provided file doesn't exist or is invalid or empty.

`logging.config.`**listen**(*port=DEFAULT_LOGGING_CONFIG_PORT*, *verify=None*)

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by *dictConfig()* or *fileConfig()*. Returns a *Thread* instance on which you can call *start()* to start the server, and which you can *join()* when appropriate. To stop the server, call *stopListening()*.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

備🄵

Because portions of the configuration are passed through *eval()*, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls *listen()*. Specifically, if the process calling *listen()* runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's *listen()* socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to *listen()* to prevent unrecognised configurations from being applied.

在 3.4 版的變更: 新增 `verify` 引數。

備🄵

If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use *dictConfig()* for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

logging.config.**stopListening**()

Stops the listening server which was created with a call to *listen()*. This is typically called before calling join() on the return value from *listen()*.

16.7.2 Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in *User-defined objects*. However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

16.7.3 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the *logging* module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as sys.stderr. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to *dictConfig()* must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding *Formatter* instance.

  The configuring dict is searched for the following optional keys which correspond to the arguments passed to create a *Formatter* object:

  - format
  - datefmt
  - style
  - validate (since version >=3.8)
  - defaults (since version >=3.12)

  An optional class key indicates the name of the formatter's class (as a dotted module and class name). The instantiation arguments are as for *Formatter*, thus this key is most useful for instantiating a customised subclass of *Formatter*. For example, the alternative class might present exception tracebacks in an expanded or condensed format. If your formatter requires different or extra configuration keys, you should use *User-defined objects*.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a *logging.Filter* instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

  The configuring dict is searched for the following keys:

  - `class` (mandatory). This is the fully qualified name of the handler class.
  - `level` (optional). The level of the handler.
  - `formatter` (optional). The id of the formatter for this handler.
  - `filters` (optional). A list of ids of the filters for this handler.

    在 3.11 版的變更: `filters` can take filter instances in addition to ids.

  All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level   : INFO
    filters: [allow_foo]
    stream  : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

  the handler with id `console` is instantiated as a *logging.StreamHandler*, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a *logging.handlers.RotatingFileHandler* with the keyword arguments `filename='logconfig.log', maxBytes=1024, backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

  The configuring dict is searched for the following keys:

  - `level` (optional). The level of the logger.
  - `propagate` (optional). The propagation setting of the logger.
  - `filters` (optional). A list of ids of the filters for this logger.

    在 3.11 版的變更: `filters` can take filter instances in addition to ids.

  - `handlers` (optional). A list of ids of the handlers for this logger.

  The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.

- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing *fileConfig()* API.

If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- *disable_existing_loggers* - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
   # configuration of handler with id 'h1' goes here
   formatter: brief
  h2: #This is another id
   # configuration of handler with id 'h2' goes here
   formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a 'factory' - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here's a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
      (): my.package.customFormatterFactory
      bar: baz
      spam: 99.9
      answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard *`logging.Formatter`* instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a *`logging.Formatter`* initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

和:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key `'()'`, the instantiation is inferred from the context: as a result, standard *`logging.Formatter`* instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
```

(繼續下一頁)

(繼續上一頁)

```
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key `'()'`, which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

警告

The values for keys such as `bar`, `spam` and `answer` in the above example should not be configuration dictionaries or references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but passed to the callable as-is.

The key `'()'` has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The `'()'` also serves as a mnemonic that the corresponding value is a callable.

在 3.11 版的變更: The `filters` member of `handlers` and `loggers` can take filter instances in addition to ids.

You can also specify a special key `'.'` whose value is a dictionary is a mapping of attribute names to values. If found, the specified attributes will be set on the user-defined object before it is returned. Thus, with the following configuration:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42,
  '.' {
    'foo': 'bar',
    'baz': 'bozz'
  }
}
```

the returned formatter will have attribute `foo` set to `'bar'` and attribute `baz` set to `'bozz'`.

警告

The values for attributes such as `foo` and `baz` in the above example should not be configuration dictionaries or references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but set as attribute values as-is.

Handler configuration order

Handlers are configured in alphabetical order of their keys, and a configured handler replaces the configuration dictionary in (a working copy of) the `handlers` dictionary in the schema. If you use a construct such as `cfg://handlers.foo`, then initially `handlers['foo']` points to the configuration dictionary for the handler named `foo`, and later (once that handler has been configured) it points to the configured handler instance. Thus, `cfg://handlers.foo` could resolve to either a dictionary or a handler instance. In general, it is wise to name handlers in a way such that dependent handlers are configured _after_ any handlers they depend on; that allows something like `cfg://handlers.foo` to be used in configuring a handler that depends on handler `foo`. If that dependent handler were named `bar`, problems would result, because the configuration of `bar` would be attempted before that of `foo`, and `foo` would not yet have been configured. However, if the dependent handler were named `foobar`, it would be configured after `foo`, with the result that `cfg://handlers.foo` would resolve to configured handler `foo`, and not its configuration dictionary.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a `level` in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the *`logging`* module. For example, consider *`logging.handlers.MemoryHandler`*, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]` would resolve to `'dev_team@domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin *`__import__()`* function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with *`staticmethod()`*. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with *`staticmethod()`* if you're setting the import callable on a configurator *instance*.

Configuring QueueHandler and QueueListener

If you want to configure a *`QueueHandler`*, noting that this is normally used in conjunction with a *`QueueListener`*, you can configure both together. After the configuration, the `QueueListener` instance will be available as the *`listener`* attribute of the created handler, and that in turn will be available to you using *`getHandlerByName()`* and passing the name you have used for the `QueueHandler` in your configuration. The dictionary schema for configuring the pair is shown in the example YAML snippet below.

```
handlers:
  qhand:
    class: logging.handlers.QueueHandler
    queue: my.module.queue_factory
    listener: my.package.CustomListener
```

(繼續下一頁)

(繼續上一頁)

```
    handlers:
      - hand_name_1
      - hand_name_2
      ...
```

The `queue` and `listener` keys are optional.

If the `queue` key is present, the corresponding value can be one of the following:

- An actual instance of *`queue.Queue`* or a subclass thereof. This is of course only possible if you are constructing or modifying the configuration dictionary in code.
- A string that resolves to a callable which, when called with no arguments, returns the *`queue.Queue`* instance to use. That callable could be a *`queue.Queue`* subclass or a function which returns a suitable queue instance, such as `my.module.queue_factory()`.
- A dict with a `'()'` key which is constructed in the usual way as discussed in *User-defined objects*. The result of this construction should be a *`queue.Queue`* instance.

If the `queue` key is absent, a standard unbounded *`queue.Queue`* instance is created and used.

If the `listener` key is present, the corresponding value can be one of the following:

- A subclass of *`logging.handlers.QueueListener`*. This is of course only possible if you are constructing or modifying the configuration dictionary in code.
- A string which resolves to a class which is a subclass of `QueueListener`, such as `'my.package.CustomListener'`.
- A dict with a `'()'` key which is constructed in the usual way as discussed in *User-defined objects*. The result of this construction should be a callable with the same signature as the `QueueListener` initializer.

If the `listener` key is absent, *`logging.handlers.QueueListener`* is used.

The values under the `handlers` key are the names of other handlers in the configuration (not shown in the above snippet) which will be passed to the queue listener.

Any custom queue handler and listener classes will need to be defined with the same initialization signatures as *`QueueHandler`* and *`QueueListener`*.

在 3.12 版被加入.

16.7.4 Configuration file format

The configuration file format understood by *`fileConfig()`* is based on *`configparser`* functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

備🄵

The *`fileConfig()`* API is older than the *`dictConfig()`* API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure *`Filter`* objects, which provide for filtering of messages beyond simple integer levels, using *`fileConfig()`*. If you need to have instances of *`Filter`* in your logging

configuration, you will need to use *dictConfig()*. Note that future enhancements to configuration functionality will be added to *dictConfig()*, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *evaluated* in the context of the `logging` package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by *eval()* in the `logging` package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when *evaluated* in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when *evaluated* in the context of the `logging` package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to `{}`.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args=(('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')
kwargs={'timeout': 10.0}

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s %(customfield)s
datefmt=
style=%
validate=True
defaults={'customfield': 'defaultvalue'}
class=logging.Formatter
```

The arguments for the formatter configuration are the same as the keys in the dictionary schema *formatters section*.

The `defaults` entry, when *evaluated* in the context of the `logging` package's namespace, is a dictionary of default values for custom formatting fields. If not provided, it defaults to `None`.

備🄵

Due to the use of *`eval()`* as described above, there are potential security risks which result from using the *`listen()`* to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the *`listen()`* documentation for more information.

16.8 `logging.handlers` --- 日🄵紀🄵處理器

原始碼： Lib/logging/handlers.py

Important

This page contains only reference information. For tutorials, please see

- 基礎教學
- 進階教學
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (*`StreamHandler`*, *`FileHandler`* and *`NullHandler`*) are actually defined in the *`logging`* module itself, but have been documented here along with the other handlers.

16.8.1 StreamHandler

The *StreamHandler* class, located in the core *logging* package, sends logging output to streams such as *sys.stdout*, *sys.stderr* or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

class logging.**StreamHandler**(*stream=None*)

Returns a new instance of the *StreamHandler* class. If *stream* is specified, the instance will use it for logging output; otherwise, *sys.stderr* will be used.

emit(*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream followed by *terminator*. If exception information is present, it is formatted using *traceback.print_exception()* and appended to the stream.

flush()

Flushes the stream by calling its *flush()* method. Note that the `close()` method is inherited from *Handler* and so does no output, so an explicit *flush()* call may be needed at times.

setStream(*stream*)

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

參數

stream -- The stream that the handler should use.

回傳

the old stream, if the stream was changed, or `None` if it wasn't.

在 3.7 版被加入.

terminator

String used as the terminator when writing a formatted record to a stream. Default value is `'\n'`.

If you don't want a newline termination, you can set the handler instance's `terminator` attribute to the empty string.

In earlier versions, the terminator was hardcoded as `'\n'`.

在 3.2 版被加入.

16.8.2 FileHandler

The *FileHandler* class, located in the core *logging* package, sends logging output to a disk file. It inherits the output functionality from *StreamHandler*.

class logging.**FileHandler**(*filename*, *mode='a'*, *encoding=None*, *delay=False*, *errors=None*)

Returns a new instance of the *FileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely. If *errors* is specified, it's used to determine how encoding errors are handled.

在 3.6 版的變更: As well as string values, *Path* objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

close()

Closes the file.

emit(*record*)

Outputs the record to the file.

Note that if the file was closed due to logging shutdown at exit and the file mode is 'w', the record will not be emitted (see bpo-42378).

16.8.3 NullHandler

在 3.1 版被加入.

The *NullHandler* class, located in the core *logging* package, does not do any formatting or output. It is essentially a 'no-op' handler for use by library developers.

class logging.**NullHandler**

Returns a new instance of the *NullHandler* class.

emit(*record*)

This method does nothing.

handle(*record*)

This method does nothing.

createLock()

This method returns None for the lock, since there is no underlying I/O to which access needs to be serialized.

See library-config for more information on how to use *NullHandler*.

16.8.4 WatchedFileHandler

The *WatchedFileHandler* class, located in the *logging.handlers* module, is a FileHandler which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as *newsyslog* and *logrotate* which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, *ST_INO* is not supported under Windows; *stat()* always returns zero for this value.

class logging.handlers.**WatchedFileHandler**(*filename*, *mode='a'*, *encoding=None*, *delay=False*, *errors=None*)

Returns a new instance of the *WatchedFileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

在 3.6 版的變更: As well as string values, *Path* objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

reopenIfNeeded()

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

在 3.6 版被加入.

emit(*record*)

Outputs the record to the file, but first calls *reopenIfNeeded()* to reopen the file if it has changed.

16.8.5 BaseRotatingHandler

The *BaseRotatingHandler* class, located in the *logging.handlers* module, is the base class for the rotating file handlers, *RotatingFileHandler* and *TimedRotatingFileHandler*. You should not need to instantiate this class, but it has attributes and methods you may need to override.

class logging.handlers.**BaseRotatingHandler**(*filename*, *mode*, *encoding=None*, *delay=False*, *errors=None*)

The parameters are as for `FileHandler`. The attributes are:

namer

If this attribute is set to a callable, the *rotation_filename()* method delegates to this callable. The parameters passed to the callable are those passed to *rotation_filename()*.

> **備🄵**
>
> The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.
>
> It's also worth noting that care should be taken when using a namer to preserve certain attributes in the filename which are used during rotation. For example, *RotatingFileHandler* expects to have a set of log files whose names contain successive integers, so that rotation works as expected, and *TimedRotatingFileHandler* deletes old log files (based on the `backupCount` parameter passed to the handler's initializer) by determining the oldest files to delete. For this to happen, the filenames should be sortable using the date/time portion of the filename, and a namer needs to respect this. (If a namer is wanted that doesn't respect this scheme, it will need to be used in a subclass of *TimedRotatingFileHandler* which overrides the *getFilesToDelete()* method to fit in with the custom naming scheme.)

在 3.3 版被加入.

rotator

If this attribute is set to a callable, the *rotate()* method delegates to this callable. The parameters passed to the callable are those passed to *rotate()*.

在 3.3 版被加入.

rotation_filename(*default_name*)

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the 'namer' attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is `None`), the name is returned unchanged.

參數

default_name -- The default name for the log file.

在 3.3 版被加入.

rotate(*source*, *dest*)

When rotating, rotate the current log.

The default implementation calls the 'rotator' attribute of the handler, if it's callable, passing the source and dest arguments to it. If the attribute isn't callable (the default is `None`), the source is simply renamed to the destination.

參數

- **source** -- The source filename. This is normally the base filename, e.g. 'test.log'.
- **dest** -- The destination filename. This is normally what the source is rotated to, e.g. 'test.log.1'.

在 3.3 版被加入.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of *RotatingFileHandler* and *TimedRotatingFileHandler*. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an `emit()` call, i.e. via the `handleError()` method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see cookbook-rotator-namer.

16.8.6 RotatingFileHandler

The *RotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files.

class logging.handlers.**RotatingFileHandler**(*filename*, *mode='a'*, *maxBytes=0*, *backupCount=0*, *encoding=None*, *delay=False*, *errors=None*)

Returns a new instance of the *RotatingFileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

You can use the *maxBytes* and *backupCount* values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly *maxBytes* in length; but if either of *maxBytes* or *backupCount* is zero, rollover never occurs, so you generally want to set *backupCount* to at least 1, and have a non-zero *maxBytes*. When *backupCount* is non-zero, the system will save old log files by appending the extensions '.1', '.2' etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

在 3.6 版的變更: As well as string values, *Path* objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

doRollover()

Does a rollover, as described above.

emit(*record*)

Outputs the record to the file, catering for rollover as described previously.

16.8.7 TimedRotatingFileHandler

The *TimedRotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files at certain timed intervals.

class logging.handlers.**TimedRotatingFileHandler**(*filename*, *when='h'*, *interval=1*, *backupCount=0*, *encoding=None*, *delay=False*, *utc=False*, *atTime=None*, *errors=None*)

Returns a new instance of the *TimedRotatingFileHandler* class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

Value	Type of interval	If/how *atTime* is used
'S'	Seconds	Ignored
'M'	Minutes	Ignored
'H'	Hours	Ignored
'D'	Days	Ignored
'W0'-'W6'	Weekday (0=Monday)	Used to compute initial rollover time
'midnight'	Roll over at midnight, if *atTime* not specified, else at time *atTime*	Used to compute initial rollover time

When using weekday-based rotation, specify 'W0' for Monday, 'W1' for Tuesday, and so on up to 'W6' for Sunday. In this case, the value passed for *interval* isn't used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to *emit()*.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen "at midnight" or "on a particular weekday". Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal interval calculation.

If *errors* is specified, it's used to determine how encoding errors are handled.

備🄵

Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of "every minute" is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution,

logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

在 3.4 版的變更: 新增 *atTime* 參數。

在 3.6 版的變更: As well as string values, `Path` objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

doRollover()

Does a rollover, as described above.

emit(*record*)

Outputs the record to the file, catering for rollover as described above.

getFilesToDelete()

Returns a list of filenames which should be deleted as part of rollover. These are the absolute paths of the oldest backup log files written by the handler.

16.8.8 SocketHandler

The `SocketHandler` class, located in the `logging.handlers` module, sends logging output to a network socket. The base class uses a TCP socket.

class logging.handlers.**SocketHandler**(*host*, *port*)

Returns a new instance of the `SocketHandler` class intended to communicate with a remote machine whose address is given by *host* and *port*.

在 3.4 版的變更: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a TCP socket is created.

close()

Closes the socket.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

handleError()

Handles an error which has occurred during `emit()`. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket()

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (`socket.SOCK_STREAM`).

makePickle(*record*)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket. The details of this operation are equivalent to:

```
data = pickle.dumps(record_attr_dict, 1)
datalen = struct.pack('>L', len(data))
return datalen + data
```

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send(*packet*)

Send a pickled byte-string *packet* to the socket. The format of the sent byte-string is as described in the documentation for *makePickle()*.

This function allows for partial sends, which can happen when the network is busy.

createSocket()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

16.8.9 DatagramHandler

The *DatagramHandler* class, located in the *logging.handlers* module, inherits from *SocketHandler* to support sending logging messages over UDP sockets.

class logging.handlers.**DatagramHandler**(*host*, *port*)

Returns a new instance of the *DatagramHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

備🄵

As UDP is not a streaming protocol, there is no persistent connection between an instance of this handler and *host*. For this reason, when using a network socket, a DNS lookup might have to be made each time an event is logged, which can introduce some latency into the system. If this affects you, you can do a lookup yourself and initialize this handler using the looked-up IP address rather than the hostname.

在 3.4 版的變更: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a UDP socket is created.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

makeSocket()

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK_DGRAM*).

send(*s*)

Send a pickled byte-string to a socket. The format of the sent byte-string is as described in the documentation for *SocketHandler.makePickle()*.

16.8.10 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

class logging.handlers.**SysLogHandler**(*address=('localhost', SYSLOG_UDP_PORT)*, *facility=LOG_USER*, *socktype=socket.SOCK_DGRAM*)

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a `(host, port)` tuple. If *address* is not specified, `('localhost', 514)` is used. The address is used to open a socket. An alternative to providing a `(host, port)` tuple is providing an address as a string, for example '/dev/log'. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, `LOG_USER` is used. The type of socket opened depends on the *socktype* argument, which defaults to *socket.SOCK_DGRAM* and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of *socket.SOCK_STREAM*.

Note that if your server is not listening on UDP port 514, *SysLogHandler* may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually '/dev/log' but on OS/X it's '/var/run/syslog'. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

備F

On macOS 12.x (Monterey), Apple has changed the behaviour of their syslog daemon - it no longer listens on a domain socket. Therefore, you cannot expect *SysLogHandler* to work on this system.

See gh-91070 for more information.

在 3.2 版的變更: 新增 *socktype*。

close()

Closes the socket to the remote host.

createSocket()

Tries to create a socket and, if it's not a datagram socket, connect it to the other end. This method is called during handler initialization, but it's not regarded as an error if the other end isn't listening at this point - the method will be called again when emitting an event, if there is no socket at that point.

在 3.11 版被加入.

emit(*record*)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

在 3.2.1 版的變更: (See: bpo-12168.) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification (**RFC 5424**). More recent versions of these daemons don't

expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

在 3.3 版的變更: (See: bpo-12419.) In earlier versions, there was no facility for an "ident" or "tag" prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to `""` to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident must be text, not bytes, and is prepended to the message exactly as is.

encodePriority(*facility*, *priority*)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in *SysLogHandler* and mirror the values defined in the `sys/syslog.h` header file.

Priorities

Name (string)	Symbolic value
`alert`	LOG_ALERT
`crit` 或 `critical`	LOG_CRIT
`debug`	LOG_DEBUG
`emerg` 或 `panic`	LOG_EMERG
`err` 或 `error`	LOG_ERR
`info`	LOG_INFO
`notice`	LOG_NOTICE
`warn` 或 `warning`	LOG_WARNING

Facilities

Name (string)	Symbolic value
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP
local0	LOG_LOCAL0
local1	LOG_LOCAL1
local2	LOG_LOCAL2
local3	LOG_LOCAL3
local4	LOG_LOCAL4
local5	LOG_LOCAL5
local6	LOG_LOCAL6
local7	LOG_LOCAL7

mapPriority(*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to 'warning'.

16.8.11 NTEventLogHandler

The *`NTEventLogHandler`* class, located in the *`logging.handlers`* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

class logging.handlers.**NTEventLogHandler**(*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *`NTEventLogHandler`* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, `'win32service.pyd'` is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of `'Application'`, `'System'` or `'Security'`, and defaults to `'Application'`.

close()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit(*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory(*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

getEventType(*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's typemap attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's *typemap* attribute.

getMessageID(*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

16.8.12 SMTPHandler

The *SMTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to an email address via SMTP.

class logging.handlers.**SMTPHandler**(*mailhost*, *fromaddr*, *toaddrs*, *subject*, *credentials=None*, *secure=None*, *timeout=1.0*)

Returns a new instance of the *SMTPHandler* class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the *smtplib.SMTP.starttls()* method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

在 3.3 版的變更: 新增 *timeout* 參數。

emit(*record*)

Formats the record and sends it to the specified addressees.

getSubject(*record*)

If you want to specify a subject line which is record-dependent, override this method.

16.8.13 MemoryHandler

The *MemoryHandler* class, located in the *logging.handlers* module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general *BufferingHandler*, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

class logging.handlers.**BufferingHandler**(*capacity*)

Initializes the handler with a buffer of the specified capacity. Here, *capacity* means the number of logging records buffered.

emit(*record*)

Append the record to the buffer. If `shouldFlush()` returns true, call `flush()` to process the buffer.

flush()

For a `BufferingHandler` instance, flushing means that it sets the buffer to an empty list. This method can be overwritten to implement more useful flushing behavior.

shouldFlush(*record*)

Return `True` if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.**MemoryHandler**(*capacity*, *flushLevel=ERROR*, *target=None*, *flushOnClose=True*)

Returns a new instance of the `MemoryHandler` class. The instance is initialized with a buffer size of *capacity* (number of records buffered). If *flushLevel* is not specified, `ERROR` is used. If no *target* is specified, the target will need to be set using `setTarget()` before this handler does anything useful. If *flushOnClose* is specified as `False`, then the buffer is *not* flushed when the handler is closed. If not specified or specified as `True`, the previous behaviour of flushing the buffer will occur when the handler is closed.

在 3.6 版的變更: 新增 *flushOnClose* 參數。

close()

Calls `flush()`, sets the target to `None` and clears the buffer.

flush()

For a `MemoryHandler` instance, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when buffered records are sent to the target. Override if you want different behavior.

setTarget(*target*)

Sets the target handler for this handler.

shouldFlush(*record*)

Checks for buffer full or a record at the *flushLevel* or higher.

16.8.14 HTTPHandler

The `HTTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to a web server, using either `GET` or `POST` semantics.

class logging.handlers.**HTTPHandler**(*host*, *url*, *method='GET'*, *secure=False*, *credentials=None*, *context=None*)

Returns a new instance of the `HTTPHandler` class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, `GET` is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify credentials, you should also specify secure=True so that your userid and password are not passed in cleartext across the wire.

在 3.5 版的變更: 新增 *context* 參數。

mapLogRecord(*record*)

Provides a dictionary, based on `record`, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of *LogRecord* is to be sent to the web server, or if more specific customization of what's sent to the server is required.

emit(*record*)

Sends the record to the web server as a URL-encoded dictionary. The *mapLogRecord()* method is used to convert the record to the dictionary to be sent.

> **備🄵**
>
> Since preparing a record for sending it to a web server is not the same as a generic formatting operation, using *setFormatter()* to specify a *Formatter* for a *HTTPHandler* has no effect. Instead of calling *format()*, this handler calls *mapLogRecord()* and then *urllib.parse.urlencode()* to encode the dictionary in a form suitable for sending to a web server.

16.8.15 QueueHandler

在 3.2 版被加入.

The *QueueHandler* class, located in the *logging.handlers* module, supports sending logging messages to a queue, such as those implemented in the *queue* or *multiprocessing* modules.

Along with the *QueueListener* class, *QueueHandler* can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via *SMTPHandler*) are done on a separate thread.

class logging.handlers.**QueueHandler**(*queue*)

Returns a new instance of the *QueueHandler* class. The instance is initialized with the queue to send messages to. The *queue* can be any queue-like object; it's used as-is by the *enqueue()* method, which needs to know how to send messages to it. The queue is not *required* to have the task tracking API, which means that you can use *SimpleQueue* instances for *queue*.

> **備🄵**
>
> If you are using *multiprocessing*, you should avoid using *SimpleQueue* and instead use *multiprocessing.Queue*.

emit(*record*)

Enqueues the result of preparing the LogRecord. Should an exception occur (e.g. because a bounded queue has filled up), the *handleError()* method is called to handle the error. This can result in the record silently being dropped (if *logging.raiseExceptions* is `False`) or a message printed to `sys.stderr` (if *logging.raiseExceptions* is `True`).

prepare(*record*)

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message, arguments, exception and stack information, if present. It also removes unpickleable items from the record in-place. Specifically, it overwrites the record's `msg` and `message` attributes with the merged message (obtained by calling the handler's *format()* method), and sets the `args`, `exc_info` and `exc_text` attributes to `None`.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

> **備🄵**
>
> The base implementation formats the message with arguments, sets the `message` and `msg` attributes to the formatted message and sets the `args` and `exc_text` attributes to `None` to allow pickling and to prevent further attempts at formatting. This means that a handler on the *`QueueListener`* side won't have the information to do custom formatting, e.g. of exceptions. You may wish to subclass `QueueHandler` and override this method to e.g. avoid setting `exc_text` to `None`. Note that the `message` / `msg` / `args` changes are related to ensuring the record is pickleable, and you might or might not be able to avoid doing that depending on whether your `args` are pickleable. (Note that you may have to consider not only your own code but also code in any libraries that you use.)

enqueue(*record*)

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

listener

When created via configuration using *`dictConfig()`*, this attribute will contain a *`QueueListener`* instance for use with this handler. Otherwise, it will be `None`.

在 3.12 版被加入.

16.8.16 QueueListener

在 3.2 版被加入.

The *`QueueListener`* class, located in the *`logging.handlers`* module, supports receiving logging messages from a queue, such as those implemented in the *`queue`* or *`multiprocessing`* modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While *`QueueListener`* is not itself a handler, it is documented here because it works hand-in-hand with *`QueueHandler`*.

Along with the *`QueueHandler`* class, *`QueueListener`* can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via *`SMTPHandler`*) are done on a separate thread.

class `logging.handlers.`**QueueListener**(*queue*, **handlers*, *respect_handler_level=False*)

Returns a new instance of the *`QueueListener`* class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the *`dequeue()`* method, which needs to know how to get messages from it. The queue is not *required* to have the task tracking API (though it's used if available), which means that you can use *`SimpleQueue`* instances for *queue*.

> **備🄵**
>
> If you are using *`multiprocessing`*, you should avoid using *`SimpleQueue`* and instead use *`multiprocessing.Queue`*.

If `respect_handler_level` is `True`, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

在 3.5 版的變更: 新增 `respect_handler_level` 引數。

dequeue(*block*)

Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

prepare(*record*)

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

handle(*record*)

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from *prepare()*.

start()

Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

stop()

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

enqueue_sentinel()

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

在 3.3 版被加入.

16.9 getpass --- 可🄵式密碼輸入工具

原始碼： Lib/getpass.py

Availability: not Emscripten, not WASI.

此模組在 WebAssembly 平台 `wasm32-emscripten` 和 `wasm32-wasi` 上無法作用或無法使用。有關更多資訊，請參🄵*WebAssembly 平台*。

getpass 模組 (module) 提供了兩個函式：

getpass.**getpass**(*prompt='Password: '*, *stream=None*)

提示使用者輸入一個密碼且不會有回音 (echo)。使用者會看到字串 *prompt* 作🄵提示，其預設值🄵 `'Password: '`。在 Unix 上，如有必要的話會使用替🄵錯誤處理函式 (replace error handler) 寫入到類檔案物件 (file-like object) *stream* 中。*stream* 預設🄵主控終端機 (controlling terminal) (`/dev/tty`)，如果不可用則🄵 `sys.stderr` (此引數在 Windows 上會被忽略)。

如果無回音輸入 (echo-free input) 無法使用則 getpass() 將回退🄵印出一條警告訊息到 *stream*，🄵從 `sys.stdin` 讀取且同時發出*GetPassWarning*。

備🄵

如果你從 IDLE 🄵部呼叫 getpass，輸入可能會在你🄵動 IDLE 的終端機中完成，而非在 IDLE 視窗中。

exception getpass.**GetPassWarning**

當密碼輸入可能被回音時會發出的*UserWarning* 子類🄵。

getpass.**getuser**()

回傳使用者的" 登入名稱"。

此函式會按順序檢查環境變數 `LOGNAME`、`USER`、`LNAME` 和 `USERNAME`，🄵回傳其中第一個被設定成非空字串的值。如果均未設定，則在支援*pwd* 模組的系統上將會回傳來自密碼資料庫的登入名稱，否則將引發一個例外。

大部分情🄵下，此函式應該要比*os.getlogin()* 優先使用。

16.10 curses --- 字元儲存格顯示的終端處理

原始碼： Lib/curses

The *curses* module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

備🄵

Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

curses-howto
Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

16.10.1 函式

The module *curses* defines the following exception:

exception curses.**error**
Exception raised when a curses library function returns an error.

備🄵

Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to *A_NORMAL*.

The module *curses* defines the following functions:

curses.**baudrate**()
Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

curses.**beep**()
Emit a short attention sound.

curses.**can_change_color**()
Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

curses.**cbreak**()
Enter cbreak mode. In cbreak mode (sometimes called "rare" mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first *raw()* then *cbreak()* leaves the terminal in cbreak mode.

curses.**color_content**(*color_number*)
Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between `0` and `COLORS - 1`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between `0` (no component) and `1000` (maximum amount of component).

curses.**color_pair**(*pair_number*)
Return the attribute value for displaying text in the specified color pair. Only the first 256 color pairs are supported. This attribute value can be combined with *A_STANDOUT*, *A_REVERSE*, and the other `A_*` attributes. *pair_number()* is the counterpart to this function.

curses.**curs_set**(*visibility*)
Set the cursor state. *visibility* can be set to `0`, `1`, or `2`, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the "visible" mode is an underline cursor and the "very visible" mode is a block cursor.

curses.**def_prog_mode**()

Save the current terminal mode as the "program" mode, the mode when the running program is using curses. (Its counterpart is the "shell" mode, for when the program is not in curses.) Subsequent calls to *reset_prog_mode()* will restore this mode.

curses.**def_shell_mode**()

Save the current terminal mode as the "shell" mode, the mode when the running program is not using curses. (Its counterpart is the "program" mode, when the program is using curses capabilities.) Subsequent calls to *reset_shell_mode()* will restore this mode.

curses.**delay_output**(*ms*)

Insert an *ms* millisecond pause in output.

curses.**doupdate**()

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The *doupdate()* ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a *noutrefresh()* call after write operations such as *addstr()* have been performed on a window. The normal *refresh()* call is simply `noutrefresh()` followed by `doupdate()`; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing `noutrefresh()` calls on all windows, followed by a single `doupdate()`.

curses.**echo**()

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

curses.**endwin**()

De-initialize the library, and return terminal to normal status.

curses.**erasechar**()

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.**filter**()

The *filter()* routine, if used, must be called before *initscr()* is called. The effect is that, during those calls, `LINES` is set to `1`; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the `home` string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

curses.**flash**()

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by *beep()*.

curses.**flushinp**()

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

curses.**getmouse**()

After *getch()* returns *KEY_MOUSE* to signal a mouse event, this method should be called to retrieve the queued mouse event, represented as a 5-tuple `(id, x, y, z, bstate)`. *id* is an ID value used to distinguish multiple devices, and *x*, *y*, *z* are the event's coordinates. (*z* is currently unused.) *bstate* is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where *n* is the button number from 1 to 5: *BUTTONn_PRESSED*, *BUTTONn_RELEASED*, *BUTTONn_CLICKED*, *BUTTONn_DOUBLE_CLICKED*, *BUTTONn_TRIPLE_CLICKED*, *BUTTON_SHIFT*, *BUTTON_CTRL*, *BUTTON_ALT*.

在 3.10 版的變更: The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

curses.**getsyx**()

Return the current coordinates of the virtual screen cursor as a tuple `(y, x)`. If *leaveok* is currently `True`, then return `(-1, -1)`.

curses.**getwin**(*file*)

Read window related data stored in the file by an earlier *window.putwin()* call. The routine then creates and initializes a new window using that data, returning the new window object.

curses.**has_colors**()

Return `True` if the terminal can display colors; otherwise, return `False`.

curses.**has_extended_color_support**()

Return `True` if the module supports extended colors; otherwise, return `False`. Extended color support allows more than 256 color pairs for terminals that support more than 16 colors (e.g. xterm-256color).

Extended color support requires ncurses version 6.1 or later.

在 3.10 版被加入.

curses.**has_ic**()

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.**has_il**()

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.**has_key**(*ch*)

Take a key value *ch*, and return `True` if the current terminal type recognizes a key with that value.

curses.**halfdelay**(*tenths*)

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between `1` and `255`. Use *nocbreak()* to leave half-delay mode.

curses.**init_color**(*color_number*, *r*, *g*, *b*)

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between `0` and `COLORS - 1`. Each of *r*, *g*, *b*, must be a value between `0` and `1000`. When *init_color()* is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if *can_change_color()* returns `True`.

curses.**init_pair**(*pair_number*, *fg*, *bg*)

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between `1` and `COLOR_PAIRS - 1` (the `0` color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between `0` and `COLORS - 1`, or, after calling *use_default_colors()*, `-1`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

curses.**initscr**()

Initialize the library. Return a *window* object which represents the whole screen.

備🄵

If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

curses.**is_term_resized**(*nlines*, *ncols*)

Return `True` if *resize_term()* would modify the window structure, `False` otherwise.

curses.**isendwin**()

Return `True` if *endwin()* has been called (that is, the curses library has been deinitialized).

curses.**keyname**(*k*)

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (`b'^'`) followed by the corresponding printable ASCII character. The name of an alt-key combination (128--255) is a bytes object consisting of the prefix `b'M-'` followed by the name of the corresponding ASCII character.

curses.**killchar**()

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.**longname**()

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to *initscr()*.

curses.**meta**(*flag*)

If *flag* is `True`, allow 8-bit characters to be input. If *flag* is `False`, allow only 7-bit chars.

curses.**mouseinterval**(*interval*)

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 milliseconds, or one fifth of a second.

curses.**mousemask**(*mousemask*)

Set the mouse events to be reported, and return a tuple `(availmask, oldmask)`. *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns `0`. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

curses.**napms**(*ms*)

Sleep for *ms* milliseconds.

curses.**newpad**(*nlines*, *ncols*)

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The *refresh()* and *noutrefresh()* methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

curses.**newwin**(*nlines*, *ncols*)

curses.**newwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a new *window*, whose left-upper corner is at `(begin_y, begin_x)`, and whose height/width is *nlines*/*ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

curses.**nl**()

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

curses.**nocbreak**()

Leave cbreak mode. Return to normal "cooked" mode with line buffering.

curses.**noecho**()

Leave echo mode. Echoing of input characters is turned off.

curses.**nonl**()

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

curses.**noqiflush**()

When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

curses.**noraw**()

Leave raw mode. Return to normal "cooked" mode with line buffering.

curses.**pair_content**(*pair_number*)

Return a tuple `(fg, bg)` containing the colors for the requested color pair. The value of *pair_number* must be between `0` and `COLOR_PAIRS - 1`.

curses.**pair_number**(*attr*)

Return the number of the color-pair set by the attribute value *attr*. *color_pair()* is the counterpart to this function.

curses.**putp**(*str*)

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of *putp()* always goes to standard output.

curses.**qiflush**([*flag*])

If *flag* is `False`, the effect is the same as calling *noqiflush()*. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

curses.**raw**()

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

curses.**reset_prog_mode**()

Restore the terminal to "program" mode, as previously saved by *def_prog_mode()*.

curses.**reset_shell_mode**()

Restore the terminal to "shell" mode, as previously saved by *def_shell_mode()*.

curses.**resetty**()

Restore the state of the terminal modes to what it was at the last call to *savetty()*.

curses.**resize_term**(*nlines*, *ncols*)

Backend function used by *resizeterm()*, performing most of the work; when resizing the windows, *resize_term()* blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The resize_term() function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

curses.**resizeterm**(*nlines*, *ncols*)

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

curses.**savetty**()

Save the current state of the terminal modes in a buffer, usable by *resetty()*.

curses.**get_escdelay**()

Retrieves the value set by *set_escdelay()*.

在 3.9 版被加入.

curses.**set_escdelay**(*ms*)

Sets the number of milliseconds to wait after reading an escape character, to distinguish between an individual escape character entered on the keyboard from escape sequences sent by cursor and function keys.

在 3.9 版被加入.

curses.**get_tabsize**()

Retrieves the value set by *set_tabsize()*.

在 3.9 版被加入.

curses.**set_tabsize**(*size*)

Sets the number of columns used by the curses library when converting a tab character to spaces as it adds the tab to a window.

在 3.9 版被加入.

curses.**setsyx**(*y*, *x*)

Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both -1, then *leaveok* is set True.

curses.**setupterm**(*term=None*, *fd=-1*)

Initialize the terminal. *term* is a string giving the terminal name, or None; if omitted or None, the value of the TERM environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or -1, the file descriptor for sys.stdout will be used.

curses.**start_color**()

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after *initscr()*.

start_color() initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the *curses* module, *COLORS* and *COLOR_PAIRS*, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

curses.**termattrs**()

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

curses.**termname**()

Return the value of the environment variable TERM, as a bytes object, truncated to 14 characters.

curses.**tigetflag**(*capname*)

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

curses.**tigetnum**(*capname*)

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

curses.**tigetstr**(*capname*)

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return `None` if *capname* is not a terminfo "string capability", or is canceled or absent from the terminal description.

curses.**tparm**(*str*[, ...])

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

curses.**typeahead**(*fd*)

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does "line-breakout optimization" by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until refresh or doupdate is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

curses.**unctrl**(*ch*)

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

curses.**ungetch**(*ch*)

Push *ch* so the next *getch()* will return it.

> **備𝔽**
>
> Only one *ch* can be pushed before `getch()` is called.

curses.**update_lines_cols**()

Update the *LINES* and *COLS* module variables. Useful for detecting manual screen resize.

在 3.5 版被加入.

curses.**unget_wch**(*ch*)

Push *ch* so the next *get_wch()* will return it.

> **備𝔽**
>
> Only one *ch* can be pushed before `get_wch()` is called.

在 3.3 版被加入.

curses.**ungetmouse**(*id*, *x*, *y*, *z*, *bstate*)

Push a *KEY_MOUSE* event onto the input queue, associating the given state data with it.

curses.**use_env**(*flag*)

If used, this function should be called before *initscr()* or newterm are called. When *flag* is False, the values of lines and columns specified in the terminfo database will be used, even if environment variables LINES and COLUMNS (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if LINES and COLUMNS are not set).

curses.**use_default_colors**()

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number -1. After calling this function, init_pair(x, curses.COLOR_RED, -1) initializes, for instance, color pair *x* to a red foreground color on the default background.

curses.**wrapper**(*func*, /, **args*, ***kwargs*)

Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to wrapper(). Before calling *func*, wrapper() turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

16.10.2 Window Objects

Window objects, as returned by *initscr()* and *newwin()* above, have the following methods and attributes:

window.**addch**(*ch*[, *attr*])

window.**addch**(*y*, *x*, *ch*[, *attr*])

Paint character *ch* at (y, x) with attributes *attr*, overwriting any character previously painted at that location. By default, the character position and attributes are the current settings for the window object.

> **備🄵**
>
> Writing outside the window, subwindow, or pad raises a *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

window.**addnstr**(*str*, *n*[, *attr*])

window.**addnstr**(*y*, *x*, *str*, *n*[, *attr*])

Paint at most *n* characters of the character string *str* at (y, x) with attributes *attr*, overwriting anything previously on the display.

window.**addstr**(*str*[, *attr*])

window.**addstr**(*y*, *x*, *str*[, *attr*])

Paint the character string *str* at (y, x) with attributes *attr*, overwriting anything previously on the display.

> **備🄵**
>
> - Writing outside the window, subwindow, or pad raises *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.

- A bug in ncurses, the backend for this Python module, can cause SegFaults when resizing windows. This is fixed in ncurses-6.1-20190511. If you are stuck with an earlier ncurses, you can avoid triggering this if you do not call `addstr()` with a *str* that has embedded newlines. Instead, call `addstr()` separately for each line.

`window.`**`attroff`**(*attr*)

Remove attribute *attr* from the ”background” set applied to all writes to the current window.

`window.`**`attron`**(*attr*)

Add attribute *attr* from the ”background” set applied to all writes to the current window.

`window.`**`attrset`**(*attr*)

Set the ”background” set of attributes to *attr*. This set is initially `0` (no attributes).

`window.`**`bkgd`**(*ch*[, *attr*])

Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.`**`bkgdset`**(*ch*[, *attr*])

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.`**`border`**([*ls*[, *rs*[, *ts*[, *bs*[, *tl*[, *tr*[, *bl*[, *br*]]]]]]]])

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

備🄵

A `0` value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

參數	描述	Default value
ls	Left side	`ACS_VLINE`
rs	Right side	`ACS_VLINE`
ts	Top	`ACS_HLINE`
bs	Bottom	`ACS_HLINE`
tl	Upper-left corner	`ACS_ULCORNER`
tr	Upper-right corner	`ACS_URCORNER`
bl	Bottom-left corner	`ACS_LLCORNER`
br	Bottom-right corner	`ACS_LRCORNER`

`window.`**`box`**([*vertch*, *horch*])

Similar to `border()`, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.`**`chgat`**(*attr*)

window.**chgat**(*num*, *attr*)

window.**chgat**(*y*, *x*, *attr*)

window.**chgat**(*y*, *x*, *num*, *attr*)

Set the attributes of *num* characters at the current cursor position, or at position `(y, x)` if supplied. If *num* is not given or is `-1`, the attribute will be set on all the characters to the end of the line. This function moves cursor to position `(y, x)` if supplied. The changed line will be touched using the *touchline()* method so that the contents will be redisplayed by the next window refresh.

window.**clear**()

Like *erase()*, but also cause the whole window to be repainted upon next call to *refresh()*.

window.**clearok**(*flag*)

If *flag* is `True`, the next call to *refresh()* will clear the window completely.

window.**clrtobot**()

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of *clrtoeol()* is performed.

window.**clrtoeol**()

Erase from cursor to the end of the line.

window.**cursyncup**()

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

window.**delch**([*y*, *x*])

Delete any character at `(y, x)`.

window.**deleteln**()

Delete the line under the cursor. All following lines are moved up by one line.

window.**derwin**(*begin_y*, *begin_x*)

window.**derwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

An abbreviation for "derive window", *derwin()* is the same as calling *subwin()*, except that *begin_y* and *begin_x* are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

window.**echochar**(*ch*[, *attr*])

Add character *ch* with attribute *attr*, and immediately call *refresh()* on the window.

window.**enclose**(*y*, *x*)

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

在 3.10 版的變更: Previously it returned `1` or `0` instead of `True` or `False`.

window.**encoding**

Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with *window.subwin()*. By default, current locale encoding is used (see *locale.getencoding()*).

在 3.3 版被加入.

window.**erase**()

Clear the window.

window.**getbegyx**()

Return a tuple `(y, x)` of coordinates of upper-left corner.

window.**getbkgd**()

Return the given window's current background character/attribute pair.

window.**getch**([*y*, *x*])

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

window.**get_wch**([*y*, *x*])

Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

在 3.3 版被加入.

window.**getkey**([*y*, *x*])

Get a character, returning a string instead of an integer, as *getch()* does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

window.**getmaxyx**()

Return a tuple `(y, x)` of the height and width of the window.

window.**getparyx**()

Return the beginning coordinates of this window relative to its parent window as a tuple `(y, x)`. Return `(-1, -1)` if this window has no parent.

window.**getstr**()

window.**getstr**(*n*)

window.**getstr**(*y*, *x*)

window.**getstr**(*y*, *x*, *n*)

Read a bytes object from the user, with primitive line editing capacity.

window.**getyx**()

Return a tuple `(y, x)` of current cursor position relative to the window's upper-left corner.

window.**hline**(*ch*, *n*)

window.**hline**(*y*, *x*, *ch*, *n*)

Display a horizontal line starting at `(y, x)` with length *n* consisting of the character *ch*.

window.**idcok**(*flag*)

If *flag* is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if *flag* is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

window.**idlok**(*flag*)

If *flag* is `True`, *curses* will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

window.**immedok**(*flag*)

If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call *refresh()* yourself. However, it may degrade performance considerably, due to repeated calls to wrefresh. This option is disabled by default.

window.**inch**([*y*, *x*])

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

window.**insch**(*ch*[, *attr*])

window.**insch**(*y*, *x*, *ch*[, *attr*])

Paint character *ch* at `(y, x)` with attributes *attr*, moving the line from position *x* right by one character.

window.**insdelln**(*nlines*)

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

window.**insertln**()

Insert a blank line under the cursor. All following lines are moved down by one line.

window.**insnstr**(*str*, *n*[, *attr*])

window.**insnstr**(*y*, *x*, *str*, *n*[, *attr*])

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.**insstr**(*str*[, *attr*])

window.**insstr**(*y*, *x*, *str*[, *attr*])

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.**instr**([*n*])

window.**instr**(*y*, *x*[, *n*])

Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, *instr()* returns a string at most *n* characters long (exclusive of the trailing NUL).

window.**is_linetouched**(*line*)

Return `True` if the specified line was modified since the last call to *refresh()*; otherwise return `False`. Raise a *curses.error* exception if *line* is not valid for the given window.

window.**is_wintouched**()

Return `True` if the specified window was modified since the last call to *refresh()*; otherwise return `False`.

window.**keypad**(*flag*)

If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by *curses*. If *flag* is `False`, escape sequences will be left as is in the input stream.

window.**leaveok**(*flag*)

If *flag* is `True`, cursor is left where it is on update, instead of being at "cursor position." This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at "cursor position" after an update.

window.**move**(*new_y*, *new_x*)

Move cursor to `(new_y, new_x)`.

window.**mvderwin**(*y*, *x*)

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

window.**mvwin**(*new_y*, *new_x*)

Move the window so its upper-left corner is at `(new_y, new_x)`.

window.**nodelay**(*flag*)

If *flag* is `True`, *getch()* will be non-blocking.

window.**notimeout**(*flag*)

If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

window.**noutrefresh**()

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call *doupdate()*.

window.**overlay**(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overlay()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

window.**overwrite**(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overwrite()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

window.**putwin**(*file*)

Write all data associated with the window into the provided file object. This information can be later retrieved using the *getwin()* function.

window.**redrawln**(*beg*, *num*)

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next *refresh()* call.

window.**redrawwin**()

Touch the entire window, causing it to be completely redrawn on the next *refresh()* call.

window.**refresh**([*pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*])

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with *newpad()*. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

window.**resize**(*nlines*, *ncols*)

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by *bkgdset()*) merged into them.

window.**scroll**([*lines=1*])

Scroll the screen or scrolling region upward by *lines* lines.

window.**scrollok**(*flag*)

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call *idlok()*.

window.**setscrreg**(*top*, *bottom*)

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window.**standend**()

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window.**standout**()

Turn on attribute *A_STANDOUT*.

window.**subpad**(*begin_y*, *begin_x*)

window.**subpad**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

window.**subwin**(*begin_y*, *begin_x*)

window.**subwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

window.**syncdown**()

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by *refresh()*, so it should almost never be necessary to call it manually.

window.**syncok**(*flag*)

If *flag* is `True`, then *syncup()* is called automatically whenever there is a change in the window.

window.**syncup**()

Touch all locations in ancestors of the window that have been changed in the window.

window.**timeout**(*delay*)

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and *getch()* will return `-1` if no input is waiting. If *delay* is positive, then *getch()* will block for *delay* milliseconds, and return `-1` if there is still no input at the end of that time.

window.**touchline**(*start*, *count*[, *changed*])

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=`True`) or unchanged (*changed*=`False`).

window.**touchwin**()

Pretend the whole window has been changed, for purposes of drawing optimizations.

window.**untouchwin**()

Mark all lines in the window as unchanged since the last call to *refresh()*.

window.**vline**(*ch*, *n*[, *attr*])

window.**vline**(*y*, *x*, *ch*, *n*[, *attr*])

Display a vertical line starting at `(y, x)` with length *n* consisting of the character *ch* with attributes *attr*.

16.10.3 Constants

The *curses* module defines the following data members:

curses.**ERR**

Some curses routines that return an integer, such as *getch()*, return *ERR* upon failure.

curses.**OK**

Some curses routines that return an integer, such as *napms()*, return *OK* upon success.

curses.**version**

curses.**__version__**

A bytes object representing the current version of the module.

curses.**ncurses_version**

A named tuple containing the three components of the ncurses library version: *major*, *minor*, and *patch*. All values are integers. The components can also be accessed by name, so `curses.ncurses_version[0]` is equivalent to `curses.ncurses_version.major` and so on.

Availability: if the ncurses library is used.

在 3.8 版被加入.

curses.**COLORS**

The maximum number of colors the terminal can support. It is defined only after the call to *start_color()*.

curses.**COLOR_PAIRS**

The maximum number of color pairs the terminal can support. It is defined only after the call to *start_color()*.

curses.**COLS**

The width of the screen, i.e., the number of columns. It is defined only after the call to *initscr()*. Updated by *update_lines_cols()*, *resizeterm()* and *resize_term()*.

curses.**LINES**

The height of the screen, i.e., the number of lines. It is defined only after the call to *initscr()*. Updated by *update_lines_cols()*, *resizeterm()* and *resize_term()*.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

Attribute	Meaning
curses.**A_ALTCHARSET**	Alternate character set mode
curses.**A_BLINK**	Blink mode
curses.**A_BOLD**	Bold mode
curses.**A_DIM**	Dim mode
curses.**A_INVIS**	Invisible or blank mode
curses.**A_ITALIC**	Italic mode
curses.**A_NORMAL**	Normal attribute
curses.**A_PROTECT**	Protected mode
curses.**A_REVERSE**	Reverse background and foreground colors
curses.**A_STANDOUT**	Standout mode
curses.**A_UNDERLINE**	Underline mode
curses.**A_HORIZONTAL**	Horizontal highlight
curses.**A_LEFT**	Left highlight
curses.**A_LOW**	Low highlight
curses.**A_RIGHT**	Right highlight
curses.**A_TOP**	Top highlight
curses.**A_VERTICAL**	Vertical highlight

在 3.7 版被加入: A_ITALIC was added.

Several constants are available to extract corresponding attributes returned by some methods.

Bit-mask	Meaning
curses.**A_ATTRIBUTES**	Bit-mask to extract attributes
curses.**A_CHARTEXT**	Bit-mask to extract a character
curses.**A_COLOR**	Bit-mask to extract color-pair field information

Keys are referred to by integer constants with names starting with KEY_. The exact keycaps available are system dependent.

Key constant	Key
curses.**KEY_MIN**	Minimum key value
curses.**KEY_BREAK**	Break key (unreliable)
curses.**KEY_DOWN**	Down-arrow
curses.**KEY_UP**	Up-arrow
curses.**KEY_LEFT**	Left-arrow
curses.**KEY_RIGHT**	Right-arrow
curses.**KEY_HOME**	Home key (upward+left arrow)
curses.**KEY_BACKSPACE**	Backspace (unreliable)
curses.**KEY_F0**	Function keys. Up to 64 function keys are supported.
curses.**KEY_Fn**	Value of function key *n*

curses.**KEY_RESIZE**	Terminal resize event
curses.**KEY_MAX**	Maximum key value

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (*KEY_F1*, *KEY_F2*, *KEY_F3*, *KEY_F4*) available, and the arrow keys mapped to *KEY_UP*, *KEY_DOWN*, *KEY_LEFT* and *KEY_RIGHT* in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

Keycap	Constant
Insert	KEY_IC
Delete	KEY_DC
Home	KEY_HOME
End	KEY_END
Page Up	KEY_PPAGE
Page Down	KEY_NPAGE

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

備🄵

These are available only after *initscr()* has been called.

ACS code	Meaning
curses.**ACS_BBSS**	alternate name for upper right corner
curses.**ACS_BLOCK**	solid square block
curses.**ACS_BOARD**	board of squares
curses.**ACS_BSBS**	alternate name for horizontal line
curses.**ACS_BSSB**	alternate name for upper left corner
curses.**ACS_BSSS**	alternate name for top tee
curses.**ACS_BTEE**	bottom tee
curses.**ACS_BULLET**	bullet
curses.**ACS_CKBOARD**	checker board (stipple)
curses.**ACS_DARROW**	arrow pointing down

curses.**ACS_SSSS**	alternate name for crossover or big plus
curses.**ACS_STERLING**	pound sterling
curses.**ACS_TTEE**	top tee
curses.**ACS_UARROW**	up arrow
curses.**ACS_ULCORNER**	upper left corner
curses.**ACS_URCORNER**	upper right corner
curses.**ACS_VLINE**	vertical line

The following table lists mouse button constants used by *getmouse()*:

Mouse button constant	Meaning
curses.**BUTTONn_PRESSED**	Mouse button *n* pressed
curses.**BUTTONn_RELEASED**	Mouse button *n* released
curses.**BUTTONn_CLICKED**	Mouse button *n* clicked
curses.**BUTTONn_DOUBLE_CLICKED**	Mouse button *n* double clicked
curses.**BUTTONn_TRIPLE_CLICKED**	Mouse button *n* triple clicked
curses.**BUTTON_SHIFT**	Shift was down during button state change
curses.**BUTTON_CTRL**	Control was down during button state change
curses.**BUTTON_ALT**	Control was down during button state change

在 3.10 版的變更: The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

The following table lists the predefined colors:

Constant	🄵色
curses.**COLOR_BLACK**	黑
curses.**COLOR_BLUE**	藍
curses.**COLOR_CYAN**	Cyan (light greenish blue)
curses.**COLOR_GREEN**	🄵
curses.**COLOR_MAGENTA**	Magenta (purplish red)
curses.**COLOR_RED**	紅
curses.**COLOR_WHITE**	白
curses.**COLOR_YELLOW**	Yellow

16.11 curses.textpad --- Text input widget for curses programs

The *curses.textpad* module provides a *Textbox* class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module *curses.textpad* defines the following function:

curses.textpad.**rectangle**(*win*, *uly*, *ulx*, *lry*, *lrx*)

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

16.11.1 Textbox objects

You can instantiate a *Textbox* object as follows:

class curses.textpad.**Textbox**(*win*)

Return a textbox widget object. The *win* argument should be a curses *window* object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates `(0, 0)`. The instance's *stripspaces* flag is initially on.

Textbox objects have the following methods:

edit([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

do_command(*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

Keystroke	Action
`Control-A`	Go to left edge of window.
`Control-B`	Cursor left, wrapping to previous line if appropriate.
`Control-D`	Delete character under cursor.
`Control-E`	Go to right edge (stripspaces off) or end of line (stripspaces on).
`Control-F`	Cursor right, wrapping to next line when appropriate.
`Control-G`	Terminate, returning the window contents.
`Control-H`	Delete character backward.
`Control-J`	Terminate if the window is 1 line, otherwise insert newline.
`Control-K`	If line is blank, delete it, otherwise clear to end of line.
`Control-L`	Refresh screen.
`Control-N`	Cursor down; move down one line.
`Control-O`	Insert a blank line at cursor location.
`Control-P`	Cursor up; move up one line.

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

Constant	Keystroke
KEY_LEFT	`Control-B`
KEY_RIGHT	`Control-F`
KEY_UP	`Control-P`
KEY_DOWN	`Control-N`
KEY_BACKSPACE	`Control-h`

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()

Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

16.12 curses.ascii --- ASCII 字元的工具程式

原始碼： Lib/curses/ascii.py

The *curses.ascii* module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

Name	Meaning
curses.ascii.**NUL**	
curses.ascii.**SOH**	Start of heading, console interrupt
curses.ascii.**STX**	Start of text
curses.ascii.**ETX**	End of text
curses.ascii.**EOT**	End of transmission
curses.ascii.**ENQ**	Enquiry, goes with *ACK* flow control
curses.ascii.**ACK**	Acknowledgement
curses.ascii.**BEL**	Bell
curses.ascii.**BS**	Backspace
curses.ascii.**TAB**	Tab
curses.ascii.**HT**	Alias for *TAB*: ”Horizontal tab”

繼續下一頁

表格 3 – 繼續上一頁

Name	Meaning
curses.ascii.**LF**	Line feed
curses.ascii.**NL**	Alias for *LF*: ”New line”
curses.ascii.**VT**	Vertical tab
curses.ascii.**FF**	Form feed
curses.ascii.**CR**	Carriage return
curses.ascii.**SO**	Shift-out, begin alternate character set
curses.ascii.**SI**	Shift-in, resume default character set
curses.ascii.**DLE**	Data-link escape
curses.ascii.**DC1**	XON, for flow control
curses.ascii.**DC2**	Device control 2, block-mode flow control
curses.ascii.**DC3**	XOFF, for flow control
curses.ascii.**DC4**	Device control 4
curses.ascii.**NAK**	Negative acknowledgement
curses.ascii.**SYN**	Synchronous idle
curses.ascii.**ETB**	End transmission block

繼續下一頁

表格 3 – 繼續上一頁

Name	Meaning
curses.ascii.**CAN**	Cancel
curses.ascii.**EM**	End of medium
curses.ascii.**SUB**	Substitute
curses.ascii.**ESC**	Escape
curses.ascii.**FS**	File separator
curses.ascii.**GS**	Group separator
curses.ascii.**RS**	Record separator, block-mode terminator
curses.ascii.**US**	Unit separator
curses.ascii.**SP**	Space
curses.ascii.**DEL**	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

curses.ascii.**isalnum**(*c*)

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c) or isdigit(c)`.

curses.ascii.**isalpha**(*c*)

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c) or islower(c)`.

curses.ascii.**isascii**(*c*)

Checks for a character value that fits in the 7-bit ASCII set.

curses.ascii.**isblank**(*c*)

Checks for an ASCII whitespace character; space or horizontal tab.

curses.ascii.**iscntrl**(*c*)

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

curses.ascii.**isdigit**(*c*)

Checks for an ASCII decimal digit, `'0'` through `'9'`. This is equivalent to `c in string.digits`.

curses.ascii.**isgraph**(*c*)

Checks for ASCII any printable character except space.

curses.ascii.**islower**(*c*)

Checks for an ASCII lower-case character.

curses.ascii.**isprint**(*c*)

Checks for any ASCII printable character including space.

curses.ascii.**ispunct**(*c*)

Checks for any printable ASCII character which is not a space or an alphanumeric character.

curses.ascii.**isspace**(*c*)

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

curses.ascii.**isupper**(*c*)

Checks for an ASCII uppercase letter.

curses.ascii.**isxdigit**(*c*)

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

curses.ascii.**isctrl**(*c*)

Checks for an ASCII control character (ordinal values 0 to 31).

curses.ascii.**ismeta**(*c*)

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function *ord()*.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

curses.ascii.**ascii**(*c*)

Return the ASCII value corresponding to the low 7 bits of *c*.

curses.ascii.**ctrl**(*c*)

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

curses.ascii.**alt**(*c*)

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

curses.ascii.**unctrl**(*c*)

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00--0x1f) the string consists of a caret (`'^'`) followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is `'^?'`. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and `'!'` prepended to the result.

curses.ascii.**controlnames**

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

16.13 `curses.panel` --- curses 的面板堆🄵擴充

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

16.13.1 函式

The module *curses.panel* defines the following functions:

curses.panel.**bottom_panel**()

Returns the bottom panel in the panel stack.

curses.panel.**new_panel**(*win*)

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

curses.panel.**top_panel**()

Returns the top panel in the panel stack.

curses.panel.**update_panels**()

Updates the virtual screen after changes in the panel stack. This does not call *curses.doupdate()*, so you'll have to do this yourself.

16.13.2 Panel Objects

Panel objects, as returned by *new_panel()* above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

Panel.**above**()

Returns the panel above the current panel.

Panel.**below**()

Returns the panel below the current panel.

Panel.**bottom**()

Push the panel to the bottom of the stack.

Panel.**hidden**()

Returns `True` if the panel is hidden (not visible), `False` otherwise.

Panel.**hide**()

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

Panel.**move**(*y*, *x*)

Move the panel to the screen coordinates `(y, x)`.

Panel.**replace**(*win*)

Change the window associated with the panel to the window *win*.

Panel.**set_userptr**(*obj*)

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

Panel.**show**()

Display the panel (which might have been hidden).

Panel.**top**()

Push panel to the top of the stack.

Panel.**userptr**()

Returns the user pointer for the panel. This might be any Python object.

Panel.**window**()

Returns the window object associated with the panel.

16.14 `platform` --- 對底層平台識🄵資料的存取

原始碼： Lib/platform.py

備🄵

特定平臺清單🄵按字母順序排列，Linux 包括在 Unix 小節之中。

16.14.1 跨平台

platform.**architecture**(*executable=sys.executable*, *bits=''*, *linkage=''*)

查詢給定的可執行檔案（預設🄵 Python 直譯器二進位制檔案）來獲取各種架構資訊。

回傳一個 tuple（元組）`(bits, linkage)`，其中包含可執行檔案所使用的位元架構和連結格式資訊。這兩個值均以字串形式回傳。

無法確定的值將回傳參數所給定之預先設置值。如果給定的位元🄵 `''`，則會使用 `sizeof(pointer)`（或者當 Python 版本 < 1.5.2 時🄵 `sizeof(long)`）作🄵所支援指標大小的指示器 (indicator)。

此函式依賴於系統的 `file` 命令來執行實際的操作。這在幾乎所有 Unix 平臺和某些非 Unix 平臺上，只有當可執行檔案指向 Python 直譯器時才可使用。當以上要求不滿足時將會使用合理的預設值。

備🄵

在 macOS（也許還有其他平臺）上，可執行檔案可能是包含多種架構的通用檔案。

要獲取當前直譯器的"64 位元性 (64-bitness)"，更可靠的做法是查詢*`sys.maxsize`* 屬性：

```
is_64bits = sys.maxsize > 2**32
```

platform.**machine**()

回傳機器種類，例如 'AMD64'。如果該值無法確定則會回傳一個空字串。

platform.**node**()

回傳電腦的網路名稱（可能不是完整名稱!）。如果該值無法確定則會回傳一個空字串。

platform.**platform**(*aliased=False*, *terse=False*)

會🄵可能附帶有用資訊地回傳一個標識底層平臺的字串。

輸出應🄵人類易讀的 *(human readable)*，而非機器易剖析的 (machine parseable)。它在不同平臺上看起來可能不一致，這是有意🄵之的。

如果 *aliased* 🄵真值，此函式將使用各種不同於平臺通用名稱的🄵名來回報系統名稱，例如 SunOS 將被回報🄵 Solaris。*system_alias()* 函式被用於實作此功能。

將 *terse* 設🄵真值將導致此函式只回傳標識平臺所需的最小量資訊。

在 3.8 版的變更: 在 macOS 上，如果*mac_ver()* 回傳的釋出版字串非空字串，此函式現在會使用它以獲取 macOS 版本而非 darwin 版本。

platform.**processor**()

回傳（真實的）處理器名稱，例如 'amdk6'。

如果該值無法確定則將回傳空字串。請注意，許多平臺都不提供此資訊或是簡單地回傳與*machine()* 相同的值。NetBSD 則會提供此資訊。

platform.**python_build**()

回傳一個 tuple (buildno, builddate)，表示字串形式的 Python 建置編號和日期。

platform.**python_compiler**()

回傳一個標識用於編譯 Python 的編譯器的字串。

platform.**python_branch**()

回傳一個標識 Python 實作 SCM 分支的字串。

platform.**python_implementation**()

回傳一個標識 Python 實作的字串。可能的回傳值有：'CPython'、'IronPython'、'Jython'、'PyPy'。

platform.**python_revision**()

回傳一個標識 Python 實作 SCM 修訂版的字串。

platform.**python_version**()

將 Python 版本以字串 'major.minor.patchlevel' 形式回傳。

請注意此回傳值不同於 Python sys.version，它總是會包括 patchlevel（預設🄵 '0'）。

platform.**python_version_tuple**()

將 Python 版本以字串 tuple (major, minor, patchlevel) 形式回傳。

請注意此回傳值不同於 Python sys.version，它總是會包括 patchlevel（預設🄵 '0'）。

platform.**release**()

回傳系統的釋出版本，例如 '2.2.0' 或 'NT'，如果該值無法確定則將回傳一個空字串。

platform.**system**()

回傳系統/OS 的名稱，例如 'Linux'、'Darwin'、'Java'、'Windows'。如果該值無法確定則回傳一個空字串。

platform.**system_alias**(*system*, *release*, *version*)

回傳做🄵某些系統所使用的常見行銷名稱之🄵名的 (system, release, version)。它還會在可能導致混淆的情🄵下對資訊進行一些重新排序。

platform.**version**()

回傳系統的釋出版本資訊，例如 '#3 on degas'。如果該值無法確定則將回傳一個空字串。

platform.**uname**()

具有高可🄵性 (portable) 的 uname 介面。回傳包含六個屬性的*namedtuple()*：*system*、*node*、*release*、*version*、*machine* 和*processor*。

processor 會延遲解析，有需求時才會解析

注意：前兩個屬性名稱與*os.uname()* 提供的名稱不同，它們分🄵命名🄵 sysname 和 nodename。

無法確定的條目會被設🄵 ''。

在 3.3 版的變更: 將結果從 tuple 改🄵*namedtuple()*。

在 3.9 版的變更: *processor* 會延遲解析，🄵非立即解析。

16.14.2 Java 平台

platform.**java_ver**(*release=''*, *vendor=''*, *vminfo=('', '', '')*, *osinfo=('', '', '')*)

Jython 的版本介面。

回傳一個 tuple (release, vendor, vminfo, osinfo)，其中 *vminfo* 🄵 tuple (vm_name, vm_release, vm_vendor) 而 *osinfo* 🄵 tuple (os_name, os_version, os_arch)。無法確定的值將被設🄵由參數所給定的預設值（預設均🄵 ''）。

16.14.3 Windows 平台

platform.**win32_ver**(*release=''*, *version=''*, *csd=''*, *ptype=''*)

從 Windows 登🄵檔 (Window Registry) 獲取額外的版本資訊🄵回傳一個 tuple (release, version, csd, ptype)，它代表 OS 發行版、版本號、CSD 級🄵 (service pack) 和 OS 類型（多個/單個處理器）。

一點提示：*ptype* 在單個處理器的 NT 機器上🄵 'Uniprocessor Free'，而在多個處理器的機器上🄵 'Multiprocessor Free'。'Free' 是指該 OS 版本🄵有除錯程式。它也可能以 'Checked' 表示，代表該 OS 版本使用了除錯程式，即檢查引數、範圍等的程式。

platform.**win32_edition**()

回傳一個代表當前 Windows 版本的字串。可能的值包括但不限於 'Enterprise'、'IoTUAP'、'ServerStandard' 和 'nanoserver'。

在 3.8 版被加入.

platform.**win32_is_iot**()

如果*win32_edition()* 回傳的 Windows 版本被識🄵🄵 IoT 版則回傳 True。

在 3.8 版被加入.

16.14.4 macOS 平台

platform.**mac_ver**(*release=''*, *versioninfo=('', '', '')*, *machine=''*)

獲取 Mac OS 版本資訊🄵將其回傳🄵 tuple (release, versioninfo, machine)，其中 *versioninfo* 是一個 tuple (version, dev_stage, non_release_version)。

無法確定的條目會被設🄵 ''。所有 tuple 條目均🄵字串。

16.14.5 Unix 平台

platform.**libc_ver**(*executable=sys.executable*, *lib=''*, *version=''*, *chunksize=16384*)

嘗試確認可執行檔案（預設🄵 Python 直譯器）所連結到的 libc 版本。回傳一個字串 tuple (lib, version)，當查詢失敗時其預設值將被設🄵給定的參數值。

請注意，此函式對於不同 libc 版本如何🄵可執行檔案新增符號的方式有深層的關聯，可能僅適用於以 **gcc** 編譯出來的可執行檔案。

檔案會以 *chunksize* 位元組大小的分塊 (chunk) 來讀取和掃描。

16.14.6 Linux 平台

platform.**freedesktop_os_release**()

從 os-release 檔案獲取作業系統標識，🄵將其作🄵一個字典回傳。os-release 檔案🄵 freedesktop.org 標准、🄵在大多數 Linux 發行版上可用。一個重要的例外是 Android 和基於 Android 的發行版。

當 /etc/os-release 與 /usr/lib/os-release 均無法被讀取時將引發 *OSError* 或其子類🄵。

成功時，該函式將回傳一個字典，其中鍵和值均🄵字串。值當中的特殊字元例如 " 和 $ 會被移除引號 (unquoted)。欄位 NAME、ID 和 PRETTY_NAME 總會按照標准來定義。所有其他欄位都是可選的。根據不同廠商可能會包括額外的欄位。

請注意 NAME、VERSION 和 VARIANT 等欄位是適用於向使用者展示的字串。程式應當使用 ID、ID_LIKE、VERSION_ID 或 VARIANT_ID 等欄位來標識 Linux 發行版。

範例：

```
def get_like_distro():
    info = platform.freedesktop_os_release()
    ids = [info["ID"]]
    if "ID_LIKE" in info:
        # ids are space separated and ordered by precedence
        ids.extend(info["ID_LIKE"].split())
    return ids
```

在 3.10 版被加入.

16.15 errno --- 標準 errno 系統符號

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be all-inclusive.

`errno.`**`errorcode`**

Dictionary providing a mapping from the errno value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use *os.strerror()*.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.`**`EPERM`**

Operation not permitted. This error is mapped to the exception *PermissionError*.

`errno.`**`ENOENT`**

No such file or directory. This error is mapped to the exception *FileNotFoundError*.

`errno.`**`ESRCH`**

No such process. This error is mapped to the exception *ProcessLookupError*.

`errno.`**`EINTR`**

Interrupted system call. This error is mapped to the exception *InterruptedError*.

`errno.`**`EIO`**

I/O error

`errno.`**`ENXIO`**

No such device or address

`errno.`**`E2BIG`**

Arg list too long

`errno.`**`ENOEXEC`**

Exec format error

`errno.`**`EBADF`**

Bad file number

`errno.`**`ECHILD`**

No child processes. This error is mapped to the exception *ChildProcessError*.

`errno.`**`EAGAIN`**

Try again. This error is mapped to the exception *BlockingIOError*.

`errno.`**`ENOMEM`**

Out of memory

`errno.`**`EACCES`**

Permission denied. This error is mapped to the exception *PermissionError*.

`errno.`**`EFAULT`**

Bad address

errno.**ENOTBLK**
Block device required

errno.**EBUSY**
Device or resource busy

errno.**EEXIST**
File exists. This error is mapped to the exception *FileExistsError*.

errno.**EXDEV**
Cross-device link

errno.**ENODEV**
No such device

errno.**ENOTDIR**
Not a directory. This error is mapped to the exception *NotADirectoryError*.

errno.**EISDIR**
Is a directory. This error is mapped to the exception *IsADirectoryError*.

errno.**EINVAL**
Invalid argument

errno.**ENFILE**
File table overflow

errno.**EMFILE**
Too many open files

errno.**ENOTTY**
Not a typewriter

errno.**ETXTBSY**
Text file busy

errno.**EFBIG**
File too large

errno.**ENOSPC**
No space left on device

errno.**ESPIPE**
Illegal seek

errno.**EROFS**
Read-only file system

errno.**EMLINK**
Too many links

errno.**EPIPE**
Broken pipe. This error is mapped to the exception *BrokenPipeError*.

errno.**EDOM**
Math argument out of domain of func

errno.**ERANGE**
Math result not representable

errno.**EDEADLK**
Resource deadlock would occur

errno.**ENAMETOOLONG**
File name too long

errno.**ENOLCK**
No record locks available

errno.**ENOSYS**
Function not implemented

errno.**ENOTEMPTY**
Directory not empty

errno.**ELOOP**
Too many symbolic links encountered

errno.**EWOULDBLOCK**
Operation would block. This error is mapped to the exception *BlockingIOError*.

errno.**ENOMSG**
No message of desired type

errno.**EIDRM**
Identifier removed

errno.**ECHRNG**
Channel number out of range

errno.**EL2NSYNC**
Level 2 not synchronized

errno.**EL3HLT**
Level 3 halted

errno.**EL3RST**
Level 3 reset

errno.**ELNRNG**
Link number out of range

errno.**EUNATCH**
Protocol driver not attached

errno.**ENOCSI**
No CSI structure available

errno.**EL2HLT**
Level 2 halted

errno.**EBADE**
Invalid exchange

errno.**EBADR**
Invalid request descriptor

errno.**EXFULL**
Exchange full

errno.**ENOANO**
No anode

errno.**EBADRQC**
Invalid request code

errno.**EBADSLT**
Invalid slot

errno.**EDEADLOCK**
File locking deadlock error

errno.**EBFONT**
Bad font file format

errno.**ENOSTR**
Device not a stream

errno.**ENODATA**
No data available

errno.**ETIME**
Timer expired

errno.**ENOSR**
Out of streams resources

errno.**ENONET**
Machine is not on the network

errno.**ENOPKG**
Package not installed

errno.**EREMOTE**
Object is remote

errno.**ENOLINK**
Link has been severed

errno.**EADV**
Advertise error

errno.**ESRMNT**
Srmount error

errno.**ECOMM**
Communication error on send

errno.**EPROTO**
Protocol error

errno.**EMULTIHOP**
Multihop attempted

errno.**EDOTDOT**
RFS specific error

errno.**EBADMSG**
Not a data message

errno.**EOVERFLOW**
Value too large for defined data type

errno.**ENOTUNIQ**
Name not unique on network

errno.**EBADFD**
File descriptor in bad state

errno.**EREMCHG**
Remote address changed

errno.**ELIBACC**
Can not access a needed shared library

errno.**ELIBBAD**
Accessing a corrupted shared library

errno.**ELIBSCN**
.lib section in a.out corrupted

errno.**ELIBMAX**
Attempting to link in too many shared libraries

errno.**ELIBEXEC**
Cannot exec a shared library directly

errno.**EILSEQ**
Illegal byte sequence

errno.**ERESTART**
Interrupted system call should be restarted

errno.**ESTRPIPE**
Streams pipe error

errno.**EUSERS**
Too many users

errno.**ENOTSOCK**
Socket operation on non-socket

errno.**EDESTADDRREQ**
Destination address required

errno.**EMSGSIZE**
Message too long

errno.**EPROTOTYPE**
Protocol wrong type for socket

errno.**ENOPROTOOPT**
Protocol not available

errno.**EPROTONOSUPPORT**
Protocol not supported

errno.**ESOCKTNOSUPPORT**
Socket type not supported

errno.**EOPNOTSUPP**
Operation not supported on transport endpoint

errno.**ENOTSUP**
Operation not supported

在 3.2 版被加入.

errno.**EPFNOSUPPORT**
Protocol family not supported

errno.**EAFNOSUPPORT**
Address family not supported by protocol

errno.**EADDRINUSE**
Address already in use

errno.**EADDRNOTAVAIL**
Cannot assign requested address

errno.**ENETDOWN**
Network is down

errno.**ENETUNREACH**
Network is unreachable

errno.**ENETRESET**
Network dropped connection because of reset

errno.**ECONNABORTED**
Software caused connection abort. This error is mapped to the exception *ConnectionAbortedError*.

errno.**ECONNRESET**
Connection reset by peer. This error is mapped to the exception *ConnectionResetError*.

errno.**ENOBUFS**
No buffer space available

errno.**EISCONN**
Transport endpoint is already connected

errno.**ENOTCONN**
Transport endpoint is not connected

errno.**ESHUTDOWN**
Cannot send after transport endpoint shutdown. This error is mapped to the exception *BrokenPipeError*.

errno.**ETOOMANYREFS**
Too many references: cannot splice

errno.**ETIMEDOUT**
Connection timed out. This error is mapped to the exception *TimeoutError*.

errno.**ECONNREFUSED**
Connection refused. This error is mapped to the exception *ConnectionRefusedError*.

errno.**EHOSTDOWN**
Host is down

errno.**EHOSTUNREACH**
No route to host

errno.**EALREADY**
Operation already in progress. This error is mapped to the exception *BlockingIOError*.

errno.**EINPROGRESS**
Operation now in progress. This error is mapped to the exception *BlockingIOError*.

errno.**ESTALE**
Stale NFS file handle

errno.**EUCLEAN**
Structure needs cleaning

errno.**ENOTNAM**
Not a XENIX named type file

errno.**ENAVAIL**
No XENIX semaphores available

errno.**EISNAM**
Is a named type file

errno.**EREMOTEIO**
Remote I/O error

errno.**EDQUOT**
Quota exceeded

errno.**EQFULL**
Interface output queue is full

在 3.11 版被加入.

errno.**ENOTCAPABLE**
Capabilities insufficient. This error is mapped to the exception *PermissionError*.

適用： WASI, FreeBSD

在 3.11.1 版被加入.

errno.**ECANCELED**
Operation canceled

在 3.2 版被加入.

errno.**EOWNERDEAD**

Owner died

在 3.2 版被加入.

errno.**ENOTRECOVERABLE**

State not recoverable

在 3.2 版被加入.

16.16 ctypes --- 用於 Python 的外部函式庫

原始碼： Lib/ctypes

---

ctypes is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

16.16.1 ctypes tutorial

Note: The code samples in this tutorial use *doctest* to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or macOS, they contain doctest directives in comments.

Note: Some code samples reference the ctypes *c_int* type. On platforms where `sizeof(long) == sizeof(int)` it is an alias to *c_long*. So, you should not be confused if *c_long* is printed if you would expect *c_int* --- they are actually the same type.

Loading dynamic link libraries

ctypes exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. *cdll* loads libraries which export functions using the standard `cdecl` calling convention, while *windll* libraries call functions using the `stdcall` calling convention. *oledll* also uses the `stdcall` calling convention, and assumes the functions return a Windows `HRESULT` error code. The error code is used to automatically raise an *OSError* exception when the function call fails.

在 3.3 版的變更: Windows errors used to raise *WindowsError*, which is now an alias of *OSError*.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the cdecl calling convention:

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

備🄵

Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the *`LoadLibrary()`* method of the dll loaders should be used, or you should load the library by creating an instance of CDLL by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with a `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use *`getattr()`* to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

Calling functions

You can call these functions like any other Python callable. This example uses the `rand()` function, which takes no arguments and returns a pseudo-random integer:

```
>>> print(libc.rand())
1804289383
```

On Windows, you can call the `GetModuleHandleA()` function, which returns a win32 module handle (passing `None` as single argument to call it with a `NULL` pointer):

```
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

`ValueError` is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>>

>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, *`ctypes`* uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with *`ctypes`*, so you should be careful anyway. The *`faulthandler`* module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

None, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. None is passed as a C NULL pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (char* or wchar_t*). Python integers are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about *ctypes* data types.

Fundamental data types

ctypes defines a number of primitive C compatible data types:

ctypes type	C type	Python type
c_bool	_Bool	bool (1)
c_char	char	1-character bytes object
c_wchar	wchar_t	1-character string
c_byte	char	int
c_ubyte	unsigned char	int
c_short	short	int
c_ushort	unsigned short	int
c_int	int	int
c_uint	unsigned int	int
c_long	long	int
c_ulong	unsigned long	int
c_longlong	__int64 或 long long	int
c_ulonglong	unsigned __int64 或 unsigned long long	int
c_size_t	size_t	int
c_ssize_t	ssize_t 或 Py_ssize_t	int
c_time_t	time_t	int
c_float	float	float
c_double	double	float
c_longdouble	long double	float
c_char_p	char* (NUL terminated)	bytes object or None
c_wchar_p	wchar_t* (NUL terminated)	字串或 None
c_void_p	void*	int or None

(1) The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
```

(繼續下一頁)

(繼續上一頁)

```
>>> i.value = -99
>>> print(i.value)
-99
>>>
```

Assigning a new value to instances of the pointer types *c_char_p*, *c_wchar_p*, and *c_void_p* changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python bytes objects are immutable):

```
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s)              # the memory location has changed
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)                # first object is unchanged
Hello, World
>>>
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a *create_string_buffer()* function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```
>>> from ctypes import *
>>> p = create_string_buffer(3)            # create a 3 byte buffer, initialized to␣
↪NUL bytes
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")     # create a buffer containing a NUL␣
↪terminated string
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10 byte buffer
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00\x00'
>>>
```

The *create_string_buffer()* function replaces the old `c_buffer()` function (which is still available as an alias). To create a mutable memory block containing unicode characters of the C type `wchar_t`, use the *create_unicode_buffer()* function.

Calling functions, continued

Note that printf prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```
>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: Don't know how to convert parameter 2
>>>
```

As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding `ctypes` type, so that they can be converted to the required C data type:

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

Calling variadic functions

On a lot of platforms calling variadic functions through ctypes is exactly the same as calling functions with a fixed number of parameters. On some platforms, and in particular ARM64 for Apple Platforms, the calling convention for variadic functions is different than that for regular functions.

On those platforms it is required to specify the `argtypes` attribute for the regular, non-variadic, function arguments:

```
libc.printf.argtypes = [ctypes.c_char_p]
```

Because specifying the attribute does not inhibit portability it is advised to always specify `argtypes` for all variadic functions.

Calling functions with your own custom data types

You can also customize `ctypes` argument conversion to allow instances of your own classes be used as function arguments. `ctypes` looks for an `_as_parameter_` attribute and uses this as the function argument. The attribute must be an integer, string, bytes, a `ctypes` instance, or an object with an `_as_parameter_` attribute:

```
>>> class Bottles:
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
```

(繼續下一頁)

(繼續上一頁)

```
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a *property* which makes the attribute available on request.

Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the *argtypes* attribute.

argtypes must be a sequence of C data types (the `printf()` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a *from_param()* class method for them to be able to use them in the *argtypes* sequence. The *from_param()* class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a *ctypes* instance, or an object with an `_as_parameter_` attribute.

Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the *restype* attribute of the function object.

The C prototype of `time()` is `time_t time(time_t *)`. Because `time_t` might be of a different type than the default return type `int`, you should specify the `restype` attribute:

```
>>> libc.time.restype = c_time_t
```

The argument types can be specified using *argtypes*:

```
>>> libc.time.argtypes = (POINTER(c_time_t),)
```

To call the function with a `NULL` pointer as first argument, use `None`:

```
>>> print(libc.time(None))
1150640792
```

Here is a more advanced example, it uses the `strchr()` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p    # c_char_p is a pointer to a string
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the *ord("x")* calls above, you can set the *argtypes* attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr(b"abcdef", b"d")
b'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
ctypes.ArgumentError: argument 2: TypeError: one character bytes, bytearray or␣
↪integer expected
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
b'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the *restype* attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be found.
>>>
```

`WinError` is a function which will call Windows `FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls

GetLastError() to retrieve it.

Please note that a much more powerful error checking mechanism is available through the *errcheck* attribute; see the reference manual for details.

Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

ctypes exports the *byref()* function which is used to pass parameters by reference. The same effect can be achieved with the *pointer()* function, although *pointer()* does a lot more work since it constructs a real pointer object, so it is faster to use *byref()* if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc.sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>
```

Structures and unions

Structures and unions must derive from the *Structure* and *Union* base classes which are defined in the *ctypes* module. Each subclass must define a *_fields_* attribute. _fields_ must be a list of *2-tuples*, containing a *field name* and a *field type*.

The field type must be a *ctypes* type like *c_int*, or any other derived *ctypes* type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named *x* and *y*, and also shows how to initialize a structure in the constructor:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways:

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field *descriptor*s can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```
>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>
```

警告

ctypes does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a *_pack_* class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

ctypes uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the *BigEndianStructure*, *LittleEndianStructure*, *BigEndianUnion*, and *LittleEndianUnion* base classes. These classes cannot contain pointer fields.

Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the *_fields_* tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
```

(繼續下一頁)

(繼續上一頁)

```
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of `0 0` lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

Pointers

Pointer instances are created by calling the *pointer()* function on a *ctypes* type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a *contents* attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that *ctypes* does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another *c_int* instance to the pointer's contents attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the *pointer()* function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the *POINTER()* function, which accepts any *ctypes* type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
```

(繼續下一頁)

(繼續上一頁)

```
<class 'ctypes.LP_c_long'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a `NULL` pointer. `NULL` pointers have a `False` boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

ctypes checks for `NULL` when dereferencing pointers (but dereferencing invalid non-`NULL` pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>
```

Type conversions

Usually, ctypes does strict type checking. This means, if you have `POINTER(c_int)` in the *argtypes* list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where ctypes accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, ctypes accepts an array of c_int:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in *argtypes*, an object of the pointed type (`c_int` in this case) can be passed to the function. ctypes will apply the required *byref()* conversion in this case automatically.

To set a POINTER type field to NULL, you can assign None:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. *ctypes* provides a *cast()* function which can be used in the same way. The Bar structure defined above accepts POINTER(c_int) pointers or *c_int* arrays for its values field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the *cast()* function is handy.

The *cast()* function can be used to cast a ctypes instance into a pointer to a different ctypes data type. *cast()* takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, *cast()* can be used to assign to the values field of Bar the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

Incomplete Types

Incomplete Types are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new `class cell` is not available in the class statement itself. In *ctypes*, we can define the `cell` class and set the *_fields_* attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Let's try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = b"foo"
>>> c2 = cell()
>>> c2.name = b"bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>
```

Callback functions

ctypes allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The *CFUNCTYPE()* factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the *WINFUNCTYPE()* factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, that is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

The result:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Now we can actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

As we can easily check, our array is sorted now:

```
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>
```

The function factories can be used as decorator factories, so we may as well write:

```
>>> @CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
... def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), py_cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
```

(繼續下一頁)

(繼續上一頁)

```
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

備🄵

Make sure you keep references to *CFUNCTYPE()* objects as long as they are used from C code. *ctypes* doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), ctypes creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with *threading.local* will *not* survive across different callbacks, even when those calls are made from the same C thread.

Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_Version`, Python runtime version number encoded in a single constant integer.

ctypes can access values like this with the *in_dll()* class methods of the type. *pythonapi* is a predefined symbol giving access to the Python C api:

```
>>> version = ctypes.c_int.in_dll(ctypes.pythonapi, "Py_Version")
>>> print(hex(version.value))
0x30c00a0
```

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the docs for that value:

> This pointer is initialized to point to an array of `_frozen` records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with *ctypes*:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int),
...                 ("get_code", POINTER(c_ubyte)),  # Function pointer
...                ]
...
>>>
```

We have defined the `_frozen` data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "_PyImport_FrozenBootstrap")
>>>
```

Since `table` is a `pointer` to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the `NULL` entry:

```
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
zipimport 12345
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative `size` member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

Surprises

There are some edges in *ctypes* where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print `3 4 1 2`. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc` 's buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave differently from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = b"abc def ghi"
>>> s.value
b'abc def ghi'
>>> s.value is s.value
False
>>>
```

備🄵

Objects instantiated from *c_char_p* can only have their value set to bytes or integers.

Why is it printing `False`? ctypes instances are objects containing a memory block plus some *descriptor*s accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the `contents` of the object is stored. Accessing the contents again constructs a new Python object each time!

Variable-sized data types

ctypes provides some support for variable-sized arrays and structures.

The *resize()* function can be used to resize the memory buffer of an existing ctypes object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a *ValueError* is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
Traceback (most recent call last):
    ...
ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
    ...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with *ctypes* is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

16.16.2 ctypes reference

Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the *find_library()* function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.`**`find_library`**(*name*)

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, *find_library()* tries to run external programs (`/sbin/ldconfig`, `gcc`, `objdump` and `ld`) to find the library file. It returns the filename of the library file.

在 3.6 版的變更: On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.

以下是一些範例:

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On macOS, *find_library()* tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>
```

On Windows, *find_library()* searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with *ctypes*, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using *find_library()* to locate the library at runtime.

Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

class ctypes.**CDLL**(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*, *winmode=None*)

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

On Windows creating a *CDLL* instance may fail even if the DLL name exists. When a dependent DLL of the loaded DLL is not found, a *OSError* error is raised with the message *"[WinError 126] The specified module could not be found"*. This error message does not contain the name of the missing DLL because the Windows API does not return this information making this error hard to diagnose. To resolve this error and determine which DLL is not found, you need to find the list of dependent DLLs and determine which one is not found using Windows debugging and tracing tools.

在 3.12 版的變更: The *name* parameter can now be a *path-like object*.

也參考

Microsoft DUMPBIN tool -- A tool to find DLL dependents.

class ctypes.**OleDLL**(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*, *winmode=None*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific *HRESULT* code. *HRESULT* values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an *OSError* is automatically raised.

在 3.3 版的變更: *WindowsError* used to be raised, which is now an alias of *OSError*.

在 3.12 版的變更: The *name* parameter can now be a *path-like object*.

class ctypes.**WinDLL**(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*, *winmode=None*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

在 3.12 版的變更: The *name* parameter can now be a *path-like object*.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

class ctypes.**PyDLL**(*name*, *mode=DEFAULT_MODE*, *handle=None*)

Instances of this class behave like *CDLL* instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

在 3.12 版的變更: The *name* parameter can now be a *path-like object*.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen()` or `LoadLibrary()` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the *dlopen(3)* manpage. On Windows, *mode* is ignored. On posix systems, RTLD_NOW is always added, and is not configurable.

The *use_errno* parameter, when set to true, enables a ctypes mechanism that allows accessing the system *errno* error number in a safe way. *ctypes* maintains a thread-local copy of the systems *errno* variable; if you call foreign functions created with `use_errno=True` then the *errno* value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function *ctypes.get_errno()* returns the value of the ctypes private copy, and the function *ctypes.set_errno()* changes the ctypes private copy to a new value and returns the former value.

The *use_last_error* parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the *GetLastError()* and `SetLastError()` Windows API functions; *ctypes.get_last_error()* and *ctypes.set_last_error()* are used to request and change the ctypes private copy of the windows error code.

The *winmode* parameter is used on Windows to specify how the library is loaded (since *mode* is ignored). It takes any value that is valid for the Win32 API `LoadLibraryEx` flags parameter. When omitted, the default is to use the flags that result in the most secure DLL load, which avoids issues such as DLL hijacking. Passing the full path to the DLL is the safest way to ensure the correct library and dependencies are loaded.

在 3.8 版的變更: 新增 *winmode* 參數。

`ctypes.`**RTLD_GLOBAL**

Flag to use as *mode* parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.`**RTLD_LOCAL**

Flag to use as *mode* parameter. On platforms where this is not available, it is the same as *RTLD_GLOBAL*.

`ctypes.`**DEFAULT_MODE**

The default mode which is used to load shared libraries. On OSX 10.3, this is *RTLD_GLOBAL*, otherwise it is the same as *RTLD_LOCAL*.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6")  # On Linux
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

`PyDLL.`**_handle**

The system handle used to access the library.

`PyDLL.`**_name**

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the *LibraryLoader* class, either by calling the *LoadLibrary()* method, or by retrieving the library as attribute of the loader instance.

class `ctypes.`**LibraryLoader**(*dlltype*)

Class which loads shared libraries. *dlltype* should be one of the *CDLL*, *PyDLL*, *WinDLL*, or *OleDLL* types.

`__getattr__()` has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

LoadLibrary(*name*)

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

ctypes.**cdll**

Creates *CDLL* instances.

ctypes.**windll**

Windows only: Creates *WinDLL* instances.

ctypes.**oledll**

Windows only: Creates *OleDLL* instances.

ctypes.**pydll**

Creates *PyDLL* instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

ctypes.**pythonapi**

An instance of *PyDLL* that exposes Python C API functions as attributes. Note that all these functions are assumed to return C `int`, which is of course not always the truth, so you have to assign the correct `restype` attribute to use these functions.

Loading a library through any of these objects raises an *auditing event* `ctypes.dlopen` with string argument `name`, the name used to load the library.

Accessing a function on a loaded library raises an auditing event `ctypes.dlsym` with arguments `library` (the library object) and `name` (the symbol's name as a string or integer).

In cases when only the library handle is available rather than the object, accessing a function raises an auditing event `ctypes.dlsym/handle` with arguments `handle` (the raw library handle) and `name`.

Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

class ctypes.**_FuncPtr**

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

restype

Assign a ctypes type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing further processing or error

checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as `restype` and assign a callable to the *errcheck* attribute.

argtypes

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the *from_param()* class method of the items in the *argtypes* tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a *c_char_p* item in the *argtypes* tuple will convert a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in argtypes which are not ctypes types, but each item must have a *from_param()* method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

errcheck

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

callable(*result*, *func*, *arguments*)

result is what the foreign function returns, as specified by the `restype` attribute.

func is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

arguments is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

exception ctypes.**ArgumentError**

This exception is raised when a foreign function call cannot convert one of the passed arguments.

On Windows, when a foreign function call raises a system exception (for example, due to an access violation), it will be captured and replaced with a suitable Python exception. Further, an auditing event `ctypes.set_exception` with argument `code` will be raised, allowing an audit hook to replace the exception with its own.

Some ways to invoke foreign function calls may raise an auditing event `ctypes.call_function` with arguments `function pointer` and `arguments`.

Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function, and can be used as decorator factories, and as such, be applied to functions through the `@wrapper` syntax. See *Callback functions* for examples.

ctypes.**CFUNCTYPE**(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use_errno* is set to true, the ctypes private copy of the system *errno* variable

is exchanged with the real `errno` value before and after the call; *use_last_error* does the same for the Windows error code.

`ctypes.`**`WINFUNCTYPE`**(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention. The function will release the GIL during the call. *use_errno* and *use_last_error* have the same meaning as above.

`ctypes.`**`PYFUNCTYPE`**(*restype*, **argtypes*)

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

`prototype`(*address*)

Returns a foreign function at the specified address which must be an integer.

`prototype`(*callable*)

Create a C callable function (a callback function) from a Python *callable*.

`prototype`(*func_spec*[, *paramflags*])

Returns a foreign function exported by a shared library. *func_spec* must be a 2-tuple `(name_or_ordinal, library)`. The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

`prototype`(*vtbl_index*, *name*[, *paramflags*[, *iid*]])

Returns a foreign function that will call a COM method. *vtbl_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the `argtypes` tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

paramflags must be a tuple of the same length as `argtypes`.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1

Specifies an input parameter to the function.

2

Output parameter. The foreign function fills in a value.

4

Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

The following example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", "Hello from ctypes
↪"), (1, "flags", 0)
>>> MessageBox = prototype(("MessageBoxW", windll.user32), paramflags)
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
     HWND hWnd,
     LPRECT lpRect);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the GetWindowRect function now returns a RECT instance, when called.

Output parameters can be combined with the *errcheck* protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

If the *errcheck* function returns the argument tuple it receives unchanged, *ctypes* continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

Utility functions

ctypes.**addressof**(*obj*)

Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

Raises an *auditing event* `ctypes.addressof` with argument `obj`.

ctypes.**alignment**(*obj_or_type*)

Returns the alignment requirements of a ctypes type. *obj_or_type* must be a ctypes type or instance.

ctypes.**byref**(*obj*[, *offset*])

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
(((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

ctypes.**cast**(*obj*, *type*)

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

ctypes.**create_string_buffer**(*init_or_size*, *size=None*)

This function creates a mutable character buffer. The returned object is a ctypes array of *c_char*.

init_or_size must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

Raises an *auditing event* `ctypes.create_string_buffer` with arguments `init`, `size`.

ctypes.**create_unicode_buffer**(*init_or_size*, *size=None*)

This function creates a mutable unicode character buffer. The returned object is a ctypes array of *c_wchar*.

init_or_size must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

Raises an *auditing event* `ctypes.create_unicode_buffer` with arguments `init`, `size`.

ctypes.**DllCanUnloadNow**()

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the _ctypes extension dll exports.

ctypes.**DllGetClassObject**()

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllGetClassObject function that the `_ctypes` extension dll exports.

ctypes.util.**find_library**(*name*)

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

ctypes.util.**find_msvcrt**()

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

ctypes.**FormatError**([*code*])

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function GetLastError.

ctypes.**GetLastError**()

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

ctypes.**get_errno**()

Returns the current value of the ctypes-private copy of the system *errno* variable in the calling thread.

Raises an *auditing event* `ctypes.get_errno` with no arguments.

ctypes.**get_last_error**()

Windows only: returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

Raises an *auditing event* `ctypes.get_last_error` with no arguments.

ctypes.**memmove**(*dst*, *src*, *count*)

Same as the standard C memmove library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

ctypes.**memset**(*dst*, *c*, *count*)

Same as the standard C memset library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

ctypes.**POINTER**(*type*, */*)

Create and return a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

ctypes.**pointer**(*obj*, */*)

Create a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

ctypes.**resize**(*obj*, *size*)

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

ctypes.**set_errno**(*value*)

Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

Raises an *auditing event* `ctypes.set_errno` with argument `errno`.

ctypes.**set_last_error**(*value*)

Windows only: set the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

Raises an *auditing event* `ctypes.set_last_error` with argument `error`.

ctypes.**sizeof**(*obj_or_type*)

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

ctypes.**string_at**(*ptr*, *size=-1*)

Return the byte string at *void *ptr*. If *size* is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

Raises an *auditing event* `ctypes.string_at` with arguments `ptr`, `size`.

ctypes.**WinError**(*code=None*, *descr=None*)

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of *OSError*. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, *FormatError()* is called to get a textual description of the error.

在 3.3 版的變更: An instance of *WindowsError* used to be created, which is now an alias of *OSError*.

ctypes.**wstring_at**(*ptr*, *size=-1*)

Return the wide-character string at *void *ptr*. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Raises an *auditing event* `ctypes.wstring_at` with arguments `ptr`, `size`.

Data types

class ctypes.**_CData**

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the *addressof()* helper function. Another instance variable is exposed as *_objects*; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

from_buffer(*source*[, *offset*])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

Raises an *auditing event* `ctypes.cdata/buffer` with arguments `pointer`, `size`, `offset`.

from_buffer_copy(*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

Raises an *auditing event* `ctypes.cdata/buffer` with arguments `pointer`, `size`, `offset`.

from_address(*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

This method, and others that indirectly call this method, raises an *auditing event* `ctypes.cdata` with argument `address`.

from_param(*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's *argtypes* tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

in_dll(*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

_b_base_

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The *_b_base_* read-only member is the root ctypes object that owns the memory block.

_b_needsfree_

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

_objects

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

Fundamental data types

class ctypes.**_SimpleCData**

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. *_SimpleCData* is a subclass of *_CData*, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

value

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a ctypes instance, usually a new object is returned each time. *ctypes* does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a *restype* of *c_char_p*, you will always receive a Python bytes object, *not* a *c_char_p* instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of *c_void_p*, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

class ctypes.**c_byte**

Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_char**

Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.**c_char_p**

Represents the C `char*` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

class ctypes.**c_double**

Represents the C `double` datatype. The constructor accepts an optional float initializer.

class ctypes.**c_longdouble**

Represents the C `long double` datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to *c_double*.

class ctypes.**c_float**

Represents the C `float` datatype. The constructor accepts an optional float initializer.

class ctypes.**c_int**

Represents the C `signed int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to *c_long*.

class ctypes.**c_int8**

Represents the C 8-bit `signed int` datatype. Usually an alias for *c_byte*.

class ctypes.**c_int16**

Represents the C 16-bit `signed int` datatype. Usually an alias for *c_short*.

class ctypes.**c_int32**

Represents the C 32-bit `signed int` datatype. Usually an alias for *c_int*.

class ctypes.**c_int64**

Represents the C 64-bit `signed int` datatype. Usually an alias for *c_longlong*.

class ctypes.**c_long**

Represents the C `signed long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_longlong**

Represents the C `signed long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_short**

Represents the C `signed short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_size_t**

Represents the C `size_t` datatype.

class ctypes.**c_ssize_t**

Represents the C `ssize_t` datatype.

在 3.2 版被加入.

class ctypes.**c_time_t**

Represents the C `time_t` datatype.

在 3.12 版被加入.

class ctypes.**c_ubyte**

Represents the C `unsigned char` datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_uint**

Represents the C `unsigned int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for *c_ulong*.

class ctypes.**c_uint8**

Represents the C 8-bit `unsigned int` datatype. Usually an alias for *c_ubyte*.

class ctypes.**c_uint16**

Represents the C 16-bit `unsigned int` datatype. Usually an alias for *c_ushort*.

class ctypes.**c_uint32**

Represents the C 32-bit `unsigned int` datatype. Usually an alias for *c_uint*.

class ctypes.**c_uint64**

Represents the C 64-bit `unsigned int` datatype. Usually an alias for *c_ulonglong*.

class ctypes.**c_ulong**

Represents the C `unsigned long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_ulonglong**

Represents the C `unsigned long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_ushort**

Represents the C `unsigned short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.**c_void_p**

Represents the C `void*` type. The value is represented as integer. The constructor accepts an optional integer initializer.

class ctypes.**c_wchar**

Represents the C `wchar_t` datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.**c_wchar_p**

Represents the C `wchar_t*` datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class ctypes.**c_bool**

Represent the C `bool` datatype (more accurately, `_Bool` from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

class ctypes.**HRESULT**

Windows only: Represents a `HRESULT` value, which contains success or error information for a function or method call.

class ctypes.**py_object**

Represents the C `PyObject*` datatype. Calling this without an argument creates a `NULL` `PyObject*` pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

Structured data types

class ctypes.**Union**(**args*, ***kw*)

Abstract base class for unions in native byte order.

class ctypes.**BigEndianUnion**(**args*, ***kw*)

Abstract base class for unions in *big endian* byte order.

在 3.11 版被加入.

class ctypes.**LittleEndianUnion**(**args*, ***kw*)

Abstract base class for unions in *little endian* byte order.

在 3.11 版被加入.

class ctypes.**BigEndianStructure**(**args*, ***kw*)

Abstract base class for structures in *big endian* byte order.

class ctypes.**LittleEndianStructure**(**args*, ***kw*)

Abstract base class for structures in *little endian* byte order.

Structures and unions with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class ctypes.**Structure**(**args*, ***kw*)

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a *_fields_* class variable. *ctypes* will create *descriptor*s which allow reading and writing the fields by direct attribute accesses. These are the

fields

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like *c_int*, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the *_fields_* class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List._fields_ = [("pnext", POINTER(List)),
                 ...
                ]
```

The *_fields_* class variable must, however, be defined before the type is first used (an instance is created, *sizeof()* is called on it, and so on). Later assignments to the *_fields_* class variable will raise an AttributeError.

It is possible to define sub-subclasses of structure types, they inherit the fields of the base class plus the *_fields_* defined in the sub-subclass, if any.

pack

An optional small integer that allows overriding the alignment of structure fields in the instance. *_pack_* must already be defined when *_fields_* is assigned, otherwise it will have no effect. Setting this attribute to 0 is the same as not setting it at all.

anonymous

An optional sequence that lists the names of unnamed (anonymous) fields. *_anonymous_* must be already defined when *_fields_* is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. *ctypes* will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    _fields_ = [("lptdesc", POINTER(TYPEDESC)),
                ("lpadesc", POINTER(ARRAYDESC)),
                ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    _anonymous_ = ("u",)
    _fields_ = [("u", _U),
                ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the TYPEDESC instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to define sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate *_fields_* variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in *_fields_*. Keyword arguments in the constructor

are interpreted as attribute assignments, so they will initialize *_fields_* with the same name, or create new attributes for names not present in *_fields_*.

Arrays and pointers

class ctypes.**Array**(**args*)

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any *ctypes* data type with a non-negative integer. Alternatively, you can subclass this type and define *_length_* and *_type_* class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an *Array*.

length

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an *IndexError*. Will be returned by *len()*.

type

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class ctypes.**_Pointer**

Private, abstract base class for pointers.

Concrete pointer types are created by calling *POINTER()* with the type that will be pointed to; this is done automatically by *pointer()*.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so *len()* will raise *TypeError*. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

type

Specifies the type pointed to.

contents

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

CHAPTER 17

🄵行執行 (Concurrent Execution)

本章節描述的模組在程式的🄵行執行上提供支援。選擇要使用哪一個工具則取🄵於是執行什🄵樣的任務（CPU 密集或 IO 密集）與偏好的開發風格（事件驅動協作式多工處理或搶占式多工處理）。以下🄵此章節總覽：

17.1 `threading` --- 基於執行緒的平行性

原始碼： Lib/threading.py

This module constructs higher-level threading interfaces on top of the lower level *`_thread`* module.

在 3.7 版的變更: This module used to be optional, it is now always available.

也參考

`concurrent.futures.ThreadPoolExecutor` offers a higher level interface to push tasks to a background thread without blocking execution of the calling thread, while still being able to retrieve their results when needed.

`queue` provides a thread-safe interface for exchanging data between running threads.

`asyncio` offers an alternative approach to achieving task level concurrency without requiring the use of multiple operating system threads.

備🄵

In the Python 2.x series, this module contained `camelCase` names for some methods and functions. These are deprecated as of Python 3.10, but they are still supported for compatibility with Python 2.5 and lower.

CPython 實作細節： In CPython, due to the *Global Interpreter Lock*, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to

make better use of the computational resources of multi-core machines, you are advised to use *multiprocessing* or *concurrent.futures.ProcessPoolExecutor*. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

Availability: not Emscripten, not WASI.

此模組在 WebAssembly 平台 wasm32-emscripten 和 wasm32-wasi 上無法作用或無法使用。有關更多資訊，請參🄵*WebAssembly 平台*。

This module defines the following functions:

threading.**active_count**()

Return the number of *Thread* objects currently alive. The returned count is equal to the length of the list returned by *enumerate()*.

The function activeCount is a deprecated alias for this function.

threading.**current_thread**()

Return the current *Thread* object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the *threading* module, a dummy thread object with limited functionality is returned.

The function currentThread is a deprecated alias for this function.

threading.**excepthook**(*args*, /)

Handle uncaught exception raised by *Thread.run()*.

The *args* argument has the following attributes:

- *exc_type*: Exception type.
- *exc_value*: Exception value, can be None.
- *exc_traceback*: Exception traceback, can be None.
- *thread*: Thread which raised the exception, can be None.

If *exc_type* is *SystemExit*, the exception is silently ignored. Otherwise, the exception is printed out on *sys.stderr*.

If this function raises an exception, *sys.excepthook()* is called to handle it.

threading.excepthook() can be overridden to control how uncaught exceptions raised by *Thread.run()* are handled.

Storing *exc_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *thread* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *thread* after the custom hook completes to avoid resurrecting objects.

也參考

sys.excepthook() handles uncaught exceptions.

在 3.8 版被加入.

threading.**__excepthook__**

Holds the original value of *threading.excepthook()*. It is saved so that the original value can be restored in case they happen to get replaced with broken or alternative objects.

在 3.10 版被加入.

threading.**get_ident**()

Return the 'thread identifier' of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

在 3.3 版被加入.

threading.**get_native_id**()

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

Availability: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD.

在 3.8 版被加入.

threading.**enumerate**()

Return a list of all *Thread* objects currently active. The list includes daemonic threads and dummy thread objects created by *current_thread()*. It excludes terminated threads and threads that have not yet been started. However, the main thread is always part of the result, even when terminated.

threading.**main_thread**()

Return the main *Thread* object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

在 3.4 版被加入.

threading.**settrace**(*func*)

Set a trace function for all threads started from the *threading* module. The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

threading.**settrace_all_threads**(*func*)

Set a trace function for all threads started from the *threading* module and all Python threads that are currently executing.

The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

在 3.12 版被加入.

threading.**gettrace**()

Get the trace function as set by *settrace()*.

在 3.10 版被加入.

threading.**setprofile**(*func*)

Set a profile function for all threads started from the *threading* module. The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

threading.**setprofile_all_threads**(*func*)

Set a profile function for all threads started from the *threading* module and all Python threads that are currently executing.

The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

在 3.12 版被加入.

threading.**getprofile**()

Get the profiler function as set by *setprofile()*.

在 3.10 版被加入.

threading.**stack_size**([*size*])

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a *RuntimeError* is raised. If the specified stack size is invalid, a *ValueError* is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information).

適用： Windows, pthreads。

Unix platforms with POSIX threads support.

This module also defines the following constant:

threading.**TIMEOUT_MAX**

The maximum value allowed for the *timeout* parameter of blocking functions (*Lock.acquire()*, *RLock.acquire()*, *Condition.wait()*, etc.). Specifying a timeout greater than this value will raise an *OverflowError*.

在 3.2 版被加入.

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's *Thread* class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

17.1.1 Thread-Local Data

Thread-local data is data whose values are thread specific. To manage thread-local data, just create an instance of *local* (or a subclass) and store attributes on it:

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

class threading.**local**

A class that represents thread-local data.

For more details and extensive examples, see the documentation string of the _threading_local module: Lib/_threading_local.py.

17.1.2 Thread Objects

The *Thread* class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the *run()* method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and *run()* methods of this class.

Once a thread object is created, its activity must be started by calling the thread's *start()* method. This invokes the *run()* method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its *run()* method terminates -- either normally, or by raising an unhandled exception. The *is_alive()* method tests whether the thread is alive.

Other threads can call a thread's *join()* method. This blocks the calling thread until the thread whose *join()* method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the *name* attribute.

If the *run()* method raises an exception, *threading.excepthook()* is called to handle it. By default, *threading.excepthook()* ignores silently *SystemExit*.

A thread can be flagged as a "daemon thread". The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the *daemon* property or the *daemon* constructor argument.

備🄵

Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an *Event*.

There is a "main thread" object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that "dummy thread objects" are created. These are thread objects corresponding to "alien threads", which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be *joined*. They are never deleted, since it is impossible to detect the termination of alien threads.

class `threading.`**Thread**(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*, *, *daemon=None*)

This constructor should always be called with keyword arguments. Arguments are:

group should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

target is the callable object to be invoked by the *run()* method. Defaults to `None`, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form "Thread-*N*" where *N* is a small decimal number, or "Thread-*N* (target)" where "target" is `target.__name__` if the *target* argument is specified.

args is a list or tuple of arguments for the target invocation. Defaults to `()`.

kwargs is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If not `None`, *daemon* explicitly sets whether the thread is daemonic. If `None` (the default), the daemonic property is inherited from the current thread.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

在 3.3 版的變更: 新增 *daemon* 參數。

在 3.10 版的變更: Use the *target* name if *name* argument is omitted.

start()

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's *run()* method to be invoked in a separate thread of control.

This method will raise a *RuntimeError* if called more than once on the same thread object.

run()

Method representing the thread's activity.

You may override this method in a subclass. The standard *run()* method invokes the callable object passed to the object's constructor as the *target* argument, if any, with positional and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

Using list or tuple as the *args* argument which passed to the *Thread* could achieve the same effect.

舉例來🄵:

```
>>> from threading import Thread
>>> t = Thread(target=print, args=[1])
>>> t.run()
1
>>> t = Thread(target=print, args=(1,))
>>> t.run()
1
```

join(*timeout=None*)

Wait until the thread terminates. This blocks the calling thread until the thread whose *join()* method is called terminates -- either normally or through an unhandled exception -- or until the optional timeout occurs.
