<b>1</b>	<b>簡介</b>	<b>3</b>
1.1	可用性之標	3
1.1.1	WebAssembly 平台	4
1.1.2	行動平台	4
<b>2</b>	<b>建函式</b>	<b>7</b>
<b>3</b>	<b>建常數</b>	<b>35</b>
3.1	由 site module (模組) 所添增的常數	36
<b>4</b>	<b>建型</b>	<b>37</b>
4.1	真值檢測	37
4.2	Boolean (布林) 運算 --- and, or, not	37
4.3	比較運算	38
4.4	數值型 --- int, float, complex	38
4.4.1	整數型的位元運算	39
4.4.2	整數型的附加 methods	40
4.4.3	浮點數的附加 methods	42
4.4.4	數值型的雜	43
4.5	Boolean 型 - bool	44
4.6	代器型	45
4.6.1	Generator Types	45
4.7	Sequence Types --- list, tuple, range	45
4.7.1	Common Sequence Operations	45
4.7.2	Immutable Sequence Types	47
4.7.3	Mutable Sequence Types	47
4.7.4	List (串列)	48
4.7.5	Tuples	49
4.7.6	Ranges	50
4.8	Text Sequence Type --- str	51
4.8.1	String Methods	52
4.8.2	printf-style String Formatting	60
4.9	Binary Sequence Types --- bytes, bytearray, memoryview	62
4.9.1	Bytes Objects	62
4.9.2	Bytearray Objects	63
4.9.3	Bytes and Bytearray Operations	64
4.9.4	printf-style Bytes Formatting	75
4.9.5	Memory Views	77
4.10	Set Types --- set, frozenset	84
4.11	Mapping Types --- dict	86
4.11.1	字典視圖物件	90

4.12	情境管理器型 <code>Enum</code> . . . . .	91
4.13	型 <code>Enum</code> 釋的型 <code>Enum</code> --- 泛型 <code>Enum</code> 名 (Generic Alias)、聯合 (Union) . . . . .	92
4.13.1	泛型 <code>Enum</code> 名型 <code>Enum</code> . . . . .	92
4.13.2	聯合型 <code>Enum</code> (Union Type) . . . . .	95
4.14	Other Built-in Types . . . . .	97
4.14.1	模組 . . . . .	97
4.14.2	Classes and Class Instances . . . . .	97
4.14.3	函式 . . . . .	97
4.14.4	Methods . . . . .	98
4.14.5	程式碼物件 . . . . .	98
4.14.6	Type Objects . . . . .	98
4.14.7	Null 物件 . . . . .	98
4.14.8	The Ellipsis Object . . . . .	99
4.14.9	NotImplemented 物件 . . . . .	99
4.14.10	Internal Objects . . . . .	99
4.15	特殊屬性 . . . . .	99
4.16	Integer string conversion length limitation . . . . .	99
4.16.1	受影響的 API . . . . .	100
4.16.2	設定限制 . . . . .	101
4.16.3	建議的配置 . . . . .	101
<b>5</b>	<b><code>Enum</code> 建的例外</b> . . . . .	<b>103</b>
5.1	例外的情境 . . . . .	103
5.2	繼承自 <code>Enum</code> 建的例外 . . . . .	104
5.3	基底類 <code>Enum</code> (base classes) . . . . .	104
5.4	實體例外 . . . . .	105
5.4.1	作業系統例外 . . . . .	110
5.5	警告 . . . . .	111
5.6	例外群組 . . . . .	112
5.7	例外階層 . . . . .	113
<b>6</b>	<b>文本處理 (Text Processing) 服務</b> . . . . .	<b>117</b>
6.1	<code>string</code> --- 常見的字串操作 . . . . .	117
6.1.1	字串常數 . . . . .	117
6.1.2	自訂字串格式 . . . . .	118
6.1.3	格式化文字語法 . . . . .	119
6.1.4	模板字串 . . . . .	126
6.1.5	輔助函式 . . . . .	128
6.2	<code>re</code> --- 正規表示式 (regular expression) 操作 . . . . .	128
6.2.1	正規表示式語法 . . . . .	128
6.2.2	模組 <code>Enum</code> 容 . . . . .	135
6.2.3	Regular Expression Objects . . . . .	141
6.2.4	Match Objects . . . . .	142
6.2.5	Regular Expression Examples . . . . .	145
6.3	<code>difflib</code> --- 計算差 <code>Enum</code> 的輔助工具 . . . . .	150
6.3.1	SequenceMatcher 物件 . . . . .	154
6.3.2	SequenceMatcher 範例 . . . . .	157
6.3.3	Differ Objects . . . . .	157
6.3.4	Differ Example . . . . .	158
6.3.5	A command-line interface to difflib . . . . .	159
6.3.6	<code>ndiff</code> 範例: . . . . .	160
6.4	<code>textwrap</code> --- 文字包裝與填充 . . . . .	162
6.5	<code>unicodedata</code> --- Unicode 資料庫 . . . . .	165
6.6	<code>stringprep</code> --- 網際網路字串的準備 . . . . .	167
6.7	<code>readline</code> --- GNU <code>readline</code> 介面 . . . . .	168
6.7.1	Init file . . . . .	169
6.7.2	Line buffer . . . . .	169
6.7.3	History file . . . . .	169

6.7.4	History list . . . . .	170
6.7.5	Startup hooks . . . . .	170
6.7.6	Completion . . . . .	171
6.7.7	範例 . . . . .	171
6.8	rlcompleter --- GNU readline 的補全函式 . . . . .	173
<b>7</b>	<b>二進位資料服務</b>	<b>175</b>
7.1	struct --- 將位元組直譯☐打包起來的二進位資料 . . . . .	175
7.1.1	函式與例外 . . . . .	176
7.1.2	Format Strings . . . . .	176
7.1.3	Applications . . . . .	180
7.1.4	Classes . . . . .	181
7.2	codecs --- 編解碼器☐☐表和基底類☐ . . . . .	182
7.2.1	Codec Base Classes . . . . .	185
7.2.2	Encodings and Unicode . . . . .	191
7.2.3	Standard Encodings . . . . .	193
7.2.4	Python Specific Encodings . . . . .	195
7.2.5	encodings.idna --- Internationalized Domain Names in Applications . . . . .	197
7.2.6	encodings.mbcs --- Windows ANSI codepage . . . . .	198
7.2.7	encodings.utf_8_sig --- UTF-8 codec with BOM signature . . . . .	198
<b>8</b>	<b>資料型☐</b>	<b>199</b>
8.1	datetime --- 日期與時間的基本型☐ . . . . .	199
8.1.1	Aware and Naive Objects . . . . .	200
8.1.2	常數 . . . . .	200
8.1.3	Available Types . . . . .	200
8.1.4	timedelta 物件 . . . . .	201
8.1.5	date 物件 . . . . .	205
8.1.6	datetime 物件 . . . . .	209
8.1.7	time 物件 . . . . .	221
8.1.8	tzinfo 物件 . . . . .	224
8.1.9	timezone 物件 . . . . .	230
8.1.10	strftime() 與 strptime() 的行☐ . . . . .	231
8.2	zoneinfo --- IANA 時區支援 . . . . .	236
8.2.1	Using ZoneInfo . . . . .	236
8.2.2	Data sources . . . . .	237
8.2.3	The ZoneInfo class . . . . .	238
8.2.4	函式 . . . . .	240
8.2.5	Globals . . . . .	240
8.2.6	Exceptions and warnings . . . . .	241
8.3	calendar --- 日☐相關函式 . . . . .	241
8.3.1	命令列用法 . . . . .	247
8.4	collections --- 容器資料型態 . . . . .	248
8.4.1	ChainMap 物件 . . . . .	249
8.4.2	Counter 物件 . . . . .	251
8.4.3	deque 物件 . . . . .	254
8.4.4	defaultdict 物件 . . . . .	257
8.4.5	namedtuple() 擁有具名欄位之 tuple 的工廠函式 . . . . .	259
8.4.6	OrderedDict 物件 . . . . .	262
8.4.7	UserDict 物件 . . . . .	264
8.4.8	UserList 物件 . . . . .	264
8.4.9	UserString 物件 . . . . .	265
8.5	collections.abc --- 容器的抽象基底類☐ . . . . .	265
8.5.1	Collections Abstract Base Classes . . . . .	266
8.5.2	Collections Abstract Base Classes -- Detailed Descriptions . . . . .	268
8.5.3	Examples and Recipes . . . . .	270
8.6	heapq --- 堆積☐列 (heap queue) 演算法 . . . . .	271
8.6.1	基礎範例 . . . . .	272

8.6.2	優先 <code>__del__</code> 列實作細節	272
8.6.3	原理	273
8.7	<code>bisect</code> --- 陣列二分演算法 (Array bisection algorithm)	274
8.7.1	效能考量	275
8.7.2	搜尋一個已排序的 <code>list</code>	276
8.7.3	範例	276
8.8	<code>array</code> --- 高效率的數值型陣列	277
8.9	<code>weakref</code> --- 弱參照	280
8.9.1	弱參照物件	284
8.9.2	範例	285
8.9.3	最終化器物件	285
8.9.4	最終化器與 <code>__del__()</code> 方法的比較	286
8.10	<code>types</code> --- 動態型 <code>__del__</code> 建立與 <code>__del__</code> 建型 <code>__del__</code> 名稱	287
8.10.1	Dynamic Type Creation	287
8.10.2	Standard Interpreter Types	289
8.10.3	Additional Utility Classes and Functions	292
8.10.4	Coroutine Utility Functions	293
8.11	<code>copy</code> --- 淺層 (shallow) 和深層 (deep) <code>__del__</code> <code>__del__</code> 操作	293
8.12	<code>pprint</code> --- 資料美化列印器	294
8.12.1	函式	295
8.12.2	<code>PrettyPrinter</code> 物件	296
8.12.3	範例	297
8.13	<code>reprlib</code> --- <code>repr()</code> 的替代實作	300
8.13.1	<code>Repr</code> 物件	301
8.13.2	Subclassing <code>Repr</code> Objects	302
8.14	<code>enum</code> --- 對列舉的支援	303
8.14.1	模組 <code>__del__</code> 容	304
8.14.2	資料型 <code>__del__</code>	305
8.14.3	通用項目與裝飾器	316
8.14.4	備 <code>__del__</code>	317
8.15	<code>graphlib</code> --- 使用類圖 (graph-like) 結構進行操作的功能	317
8.15.1	例外	320
<b>9</b>	<b>數值與數學模組</b>	<b>321</b>
9.1	<code>numbers</code> --- 數值的抽象基底類 <code>__del__</code>	321
9.1.1	數值的階層	321
9.1.2	給型 <code>__del__</code> 實作者的 <code>__del__</code> 記	322
9.2	<code>math</code> --- 數學函式	324
9.2.1	數論函式	325
9.2.2	Floating point arithmetic	326
9.2.3	Floating point manipulation functions	327
9.2.4	Power, exponential and logarithmic functions	329
9.2.5	Summation and product functions	330
9.2.6	Angular conversion	331
9.2.7	Trigonometric functions	331
9.2.8	Hyperbolic functions	331
9.2.9	特殊函式	332
9.2.10	常數	332
9.3	<code>cmath</code> --- <code>__del__</code> 數的數學函式	333
9.3.1	轉 <code>__del__</code> 到極座標和從極座標做轉 <code>__del__</code>	333
9.3.2	<code>__del__</code> 函數和對數函數	334
9.3.3	三角函數	334
9.3.4	雙曲函數	335
9.3.5	分類函式	335
9.3.6	常數	336
9.4	<code>decimal</code> --- 十進位固定點和浮點運算	336
9.4.1	Quick-start Tutorial	338
9.4.2	Decimal objects	341

9.4.3	Context objects	348
9.4.4	常數	354
9.4.5	Rounding modes	354
9.4.6	Signals	355
9.4.7	Floating-Point Notes	356
9.4.8	Working with threads	358
9.4.9	Recipes	358
9.4.10	Decimal FAQ	361
9.5	fractions --- 有理數	364
9.6	random --- 生成☐隨機數	367
9.6.1	簿記函式 (bookkeeping functions)	368
9.6.2	回傳位元組的函式	368
9.6.3	回傳整數的函式	369
9.6.4	回傳序列的函式	369
9.6.5	離散分布	370
9.6.6	實數分布	370
9.6.7	替代☐生器	371
9.6.8	關於 Reproducibility (復現性) 的注意事項	372
9.6.9	範例	372
9.6.10	使用方案	374
9.6.11	Command-line usage	375
9.6.12	Command-line example	376
9.7	statistics --- 數學統計函式	376
9.7.1	平均值與中央位置量數	377
9.7.2	離度 (spread) 的測量	377
9.7.3	兩個輸入之間的關☐統計	377
9.7.4	函式細節	378
9.7.5	例外	386
9.7.6	NormalDist 物件	386
9.7.7	範例與錦囊妙計	388
<b>10</b>	<b>函式編程模組</b>	<b>391</b>
10.1	itertools --- 建立☐生高效率☐圈之☐代器的函式	391
10.1.1	Itertools 函式	393
10.1.2	Itertools 應用技巧	402
10.2	functools --- 可呼叫物件上的高階函式與操作	407
10.2.1	partial 物件	416
10.3	operator --- 標準運算子替代函式	416
10.3.1	運算子與函式間的對映	421
10.3.2	原地 (in-place) 運算子	421
<b>11</b>	<b>檔案與目錄存取</b>	<b>425</b>
11.1	pathlib --- 物件導向檔案系統路徑	425
11.1.1	基本用法	426
11.1.2	例外	427
11.1.3	純路徑	427
11.1.4	實體路徑	436
11.1.5	模式語言 (pattern language)	446
11.1.6	與 glob 模組的比較	447
11.1.7	與 os 和 os.path 模組的比較	447
11.2	os.path --- 常見的路徑名操作	448
11.3	stat --- 直譯 stat() 的結果	455
11.4	filecmp --- 檔案與目錄比較	460
11.4.1	The dircmp class	461
11.5	tempfile --- 生成臨時檔案和目錄	463
11.5.1	範例	466
11.5.2	已☐用的函式和變數	467
11.6	glob --- Unix 風格的路徑名稱模式擴展	468

11.6.1	範例	469
11.7	fnmatch --- Unix 檔案名稱模式比對	470
11.8	linecache --- 隨機存取文字列	471
11.9	shutil --- 高階檔案操作	472
11.9.1	Directory and files operations	472
11.9.2	Archiving operations	478
11.9.3	Querying the size of the output terminal	481
<b>12</b>	<b>資料持久性 (Data Persistence)</b>	<b>483</b>
12.1	pickle --- Python 物件序列化	483
12.1.1	和其他 Python 模組的關	484
12.1.2	資料串流格式	484
12.1.3	模組介面	485
12.1.4	哪些物件能或不能被封裝、拆封?	488
12.1.5	Pickling 類	489
12.1.6	針對型、函式或特定物件定縮函式	494
12.1.7	帶外 (Out-of-band) 資料緩衝區	495
12.1.8	限制全域物件	496
12.1.9	效能	498
12.1.10	範例	498
12.2	copyreg --- pickle 支援函式	498
12.2.1	範例	499
12.3	shelve --- Python object persistence	499
12.3.1	Restrictions	500
12.3.2	範例	501
12.4	marshal --- 內部 Python 物件序列化	502
12.5	dbm --- Unix "databases" 的介面	503
12.5.1	dbm.sqlite3 --- SQLite backend for dbm	505
12.5.2	dbm.gnu --- GNU 資料庫管理器	505
12.5.3	dbm.ndbm --- 新資料庫管理器	507
12.5.4	dbm.dumb --- 可式 DBM 實作	508
12.6	sqlite3 --- SQLite 資料庫的 DB-API 2.0 介面	509
12.6.1	教學	510
12.6.2	Reference	512
12.6.3	How-to guides	532
12.6.4	解釋	539
<b>13</b>	<b>資料壓縮與保存</b>	<b>541</b>
13.1	zlib --- 相容於 gzip 的壓縮	541
13.2	gzip --- gzip 檔案的支援	544
13.2.1	用法範例	547
13.2.2	命令列介面	547
13.3	bz2 --- bzip2 壓縮的支援	548
13.3.1	(De)compression of files	548
13.3.2	Incremental (de)compression	550
13.3.3	One-shot (de)compression	551
13.3.4	用法範例	551
13.4	lzma --- 使用 LZMA 演算法進行壓縮	552
13.4.1	Reading and writing compressed files	552
13.4.2	Compressing and decompressing data in memory	554
13.4.3	Miscellaneous	556
13.4.4	Specifying custom filter chains	556
13.4.5	範例	557
13.5	zipfile --- 處理 ZIP 封存檔案	558
13.5.1	ZipFile 物件	559
13.5.2	Path Objects	564
13.5.3	PyZipFile 物件	565
13.5.4	ZipInfo 物件	566

13.5.5	Command-Line Interface	567
13.5.6	Decompression pitfalls	568
13.6	tarfile --- 讀取與寫入 tar 封存檔案	569
13.6.1	TarFile 物件	572
13.6.2	TarInfo 物件	576
13.6.3	Extraction filters	578
13.6.4	Command-Line Interface	581
13.6.5	範例	582
13.6.6	Supported tar formats	583
13.6.7	Unicode issues	583
<b>14</b>	<b>檔案格式</b>	<b>585</b>
14.1	csv --- CSV 檔案讀取及寫入	585
14.1.1	模組內容	585
14.1.2	Dialect 與格式參數	589
14.1.3	讀取器物件	590
14.1.4	寫入器物件	590
14.1.5	範例	591
14.2	configparser --- 設定檔剖析器	592
14.2.1	Quick Start	592
14.2.2	Supported Datatypes	594
14.2.3	Fallback Values	594
14.2.4	Supported INI File Structure	595
14.2.5	Unnamed Sections	596
14.2.6	Interpolation of values	596
14.2.7	Mapping Protocol Access	597
14.2.8	Customizing Parser Behaviour	598
14.2.9	Legacy API Examples	603
14.2.10	ConfigParser 物件	604
14.2.11	RawConfigParser 物件	608
14.2.12	例外	609
14.3	tomllib --- 剖析 TOML 檔案	609
14.3.1	範例	610
14.3.2	轉譯表	611
14.4	netrc --- netrc 檔案處理	611
14.4.1	netrc 物件	612
14.5	plistlib --- 產生和剖析 Apple .plist 檔案	612
14.5.1	範例	614
<b>15</b>	<b>加密服務</b>	<b>615</b>
15.1	hashlib --- 安全雜項與訊息摘要	615
15.1.1	雜項演算法	615
15.1.2	用法	616
15.1.3	建構函式	616
15.1.4	屬性	617
15.1.5	雜項物件	617
15.1.6	SHAKE 可變長度摘要	618
15.1.7	檔案雜項	618
15.1.8	密鑰的生成	619
15.1.9	BLAKE2	619
15.2	hmac --- 基於金鑰雜項的訊息驗證	626
15.3	secrets --- 產生用於管理機密的安全亂數	627
15.3.1	亂數	628
15.3.2	生成權杖 (token)	628
15.3.3	其他函式	629
15.3.4	應用技巧和典範實務 (best practices)	629
<b>16</b>	<b>通用作業系統服務</b>	<b>631</b>
16.1	os --- 各種作業系統介面	631

16.1.1	File Names, Command Line Arguments, and Environment Variables	632
16.1.2	Python UTF-8 模式	632
16.1.3	行程參數	633
16.1.4	File Object Creation	640
16.1.5	File Descriptor Operations	641
16.1.6	Files and Directories	653
16.1.7	行程管理	679
16.1.8	Interface to the scheduler	692
16.1.9	Miscellaneous System Information	693
16.1.10	Random numbers	695
16.2	io 一處理資料串流的核心工具	696
16.2.1	總覽	697
16.2.2	文字編碼	698
16.2.3	高階模組介面	698
16.2.4	類階層	699
16.2.5	Performance	709
16.3	time --- 時間存取與轉	709
16.3.1	函式	710
16.3.2	時鐘 ID 常數	719
16.3.3	時區常數	721
16.4	logging --- Python 的日誌工具	721
16.4.1	Logger 物件	722
16.4.2	Logging Levels	727
16.4.3	Handler Objects	728
16.4.4	Formatter Objects	729
16.4.5	Filter Objects	731
16.4.6	LogRecord 物件	731
16.4.7	LogRecord 屬性	732
16.4.8	LoggerAdapter 物件	734
16.4.9	執行緒安全	734
16.4.10	模組層級函式	734
16.4.11	模組層級屬性	738
16.4.12	Integration with the warnings module	739
16.5	logging.config --- 日誌配置	739
16.5.1	Configuration functions	740
16.5.2	Security considerations	742
16.5.3	Configuration dictionary schema	742
16.5.4	Configuration file format	748
16.6	logging.handlers --- 日誌處理器	751
16.6.1	StreamHandler	751
16.6.2	FileHandler	752
16.6.3	NullHandler	752
16.6.4	WatchedFileHandler	753
16.6.5	BaseRotatingHandler	753
16.6.6	RotatingFileHandler	755
16.6.7	TimedRotatingFileHandler	755
16.6.8	SocketHandler	756
16.6.9	DatagramHandler	757
16.6.10	SysLogHandler	758
16.6.11	NTEventLogHandler	760
16.6.12	SMTPHandler	761
16.6.13	MemoryHandler	761
16.6.14	HTTPHandler	762
16.6.15	QueueHandler	763
16.6.16	QueueListener	764
16.7	platform --- 對底層平臺識資料的存取	765
16.7.1	跨平台	765
16.7.2	Java 平台	767

16.7.3	Windows 平台	767
16.7.4	macOS 平台	767
16.7.5	iOS 平台	767
16.7.6	Unix 平台	768
16.7.7	Linux 平台	768
16.7.8	Android 平台	768
16.8	errno --- 標準 errno 系統符號	769
16.9	ctypes --- 用於 Python 的外部函式庫	777
16.9.1	ctypes 教學	777
16.9.2	ctypes reference	794
<b>17</b>	<b>命令列介面函式庫</b>	<b>811</b>
17.1	argparse --- 命令列選項、引數和子命令的剖析器	811
17.1.1	ArgumentParser 物件	812
17.1.2	add_argument() 方法	819
17.1.3	parse_args() 方法	829
17.1.4	Other utilities	832
17.1.5	例外	840
17.2	optparse --- 命令列選項剖析器	853
17.2.1	選擇一個命令列參數剖析函式庫	853
17.2.2	Introduction	854
17.2.3	背景	855
17.2.4	教學	857
17.2.5	Reference Guide	864
17.2.6	Option Callbacks	873
17.2.7	Extending optparse	877
17.2.8	例外	879
17.3	getpass --- 可圖式密碼輸入工具	880
17.4	fileinput --- 逐列圖代多個輸入串流	880
17.5	curses --- 字元儲存格顯示的終端處理	883
17.5.1	函式	883
17.5.2	Window Objects	890
17.5.3	Constants	896
17.6	curses.textpad --- Text input widget for curses programs	908
17.6.1	Textbox objects	908
17.7	curses.ascii --- ASCII 字元的工具程式	909
17.8	curses.panel --- curses 的面板堆圖擴充	913
17.8.1	函式	913
17.8.2	Panel Objects	913
<b>18</b>	<b>圖行執行 (Concurrent Execution)</b>	<b>915</b>
18.1	threading --- 基於執行緒的平行性	915
18.1.1	Thread-Local Data	918
18.1.2	Thread Objects	918
18.1.3	Lock 物件	921
18.1.4	RLock 物件	922
18.1.5	Condition Objects	923
18.1.6	Semaphore Objects	925
18.1.7	Event Objects	926
18.1.8	Timer Objects	927
18.1.9	Barrier Objects	927
18.1.10	Using locks, conditions, and semaphores in the with statement	928
18.2	multiprocessing --- 以行程圖基礎的平行性	929
18.2.1	簡介	929
18.2.2	Reference	935
18.2.3	Programming guidelines	963
18.2.4	範例	966
18.3	multiprocessing.shared_memory --- 對於共享記憶體跨行程直接存取	971

18.4	concurrent 套件	977
18.5	concurrent.futures --- 自動平行任務	977
18.5.1	Executor 物件	977
18.5.2	ThreadPoolExecutor	978
18.5.3	ProcessPoolExecutor	980
18.5.4	Future 物件	981
18.5.5	模組函式	982
18.5.6	例外類	983
18.6	subprocess --- 子行程管理	984
18.6.1	Using the subprocess Module	984
18.6.2	安全性注意事項	992
18.6.3	Popen Objects	993
18.6.4	Windows Popen Helpers	995
18.6.5	Older high-level API	997
18.6.6	Replacing Older Functions with the subprocess Module	999
18.6.7	Legacy Shell Invocation Functions	1002
18.6.8	解	1002
18.7	sched --- 事件排程器	1003
18.7.1	排程器物件	1004
18.8	queue --- 同步列 (synchronized queue) 類	1005
18.8.1	列物件	1006
18.8.2	SimpleQueue 物件	1007
18.9	contextvars --- 情境變數	1008
18.9.1	Context Variables	1008
18.9.2	Manual Context Management	1009
18.9.3	對 asyncio 的支援	1011
18.10	_thread --- 低階執行緒 API	1012

## 19 Networking and Interprocess Communication 1015

19.1	asyncio --- 非同步 I/O	1015
19.1.1	Runners (執行器)	1016
19.1.2	協程與任務	1018
19.1.3	串流	1037
19.1.4	同步化原始物件 (Synchronization Primitives)	1044
19.1.5	子行程	1050
19.1.6	列 (Queues)	1054
19.1.7	例外	1057
19.1.8	事件圈	1058
19.1.9	Futures	1080
19.1.10	傳輸與協定	1083
19.1.11	Policies	1096
19.1.12	平臺支援	1100
19.1.13	擴充	1101
19.1.14	高階 API 索引	1102
19.1.15	低階 API 索引	1105
19.1.16	使用 asyncio 開發	1109
19.2	socket --- Low-level networking interface	1112
19.2.1	Socket 系列家族	1113
19.2.2	模組容	1116
19.2.3	Socket 物件	1128
19.2.4	Notes on socket timeouts	1135
19.2.5	範例	1136
19.3	ssl --- socket 物件的 TLS/SSL 包裝器	1140
19.3.1	函式、常數與例外	1140
19.3.2	SSL Sockets	1151
19.3.3	SSL Contexts	1156
19.3.4	Certificates	1165
19.3.5	範例	1166

19.3.6	Notes on non-blocking sockets	1169
19.3.7	Memory BIO Support	1170
19.3.8	SSL session	1172
19.3.9	Security considerations	1172
19.3.10	TLS 1.3	1173
19.4	select --- 等待 I/O 完成	1174
19.4.1	/dev/poll Polling Objects	1176
19.4.2	Edge and Level Trigger Polling (epoll) Objects	1177
19.4.3	Polling Objects	1178
19.4.4	Kqueue Objects	1179
19.4.5	Kevent Objects	1179
19.5	selectors --- 高階 I/O 多工	1181
19.5.1	簡介	1181
19.5.2	Classes	1181
19.5.3	範例	1184
19.6	signal --- 設定非同步事件的處理函式	1184
19.6.1	一般規則	1184
19.6.2	模組內容	1185
19.6.3	範例	1191
19.6.4	關於 SIGPIPE 的說明	1192
19.6.5	訊號處理程式與例外的說明	1192
19.7	mmap --- 記憶體對映檔案的支援	1193
19.7.1	MADV_* 常數	1197
19.7.2	MAP_* 常數	1198
<b>20</b>	<b>網際網路資料處理</b>	<b>1199</b>
20.1	email --- 郵件和 MIME 處理套件	1199
20.1.1	email.message: 表示電子郵件訊息	1200
20.1.2	email.parser: 剖析電子郵件訊息	1208
20.1.3	email.generator: 生成 MIME 文件	1211
20.1.4	email.policy: Policy Objects	1214
20.1.5	email.errors: 例外和缺陷類別	1221
20.1.6	email.headerregistry: 自訂標頭物件	1222
20.1.7	email.contentmanager: 管理 MIME 內容	1228
20.1.8	email: 範例	1230
20.1.9	email.message.Message: Representing an email message using the compat32 API	1236
20.1.10	email.mime: 從頭開始建立電子郵件和 MIME 物件	1244
20.1.11	email.header: 國際化標頭	1247
20.1.12	email.charset: 字元集合的表示	1249
20.1.13	email.encoders: 編碼器	1251
20.1.14	email.utils: 雜項工具	1252
20.1.15	email.iterators: 迭代器	1254
20.2	json --- JSON 編碼器與解碼器	1255
20.2.1	基本用法	1257
20.2.2	編碼器與解碼器	1260
20.2.3	例外	1262
20.2.4	合規性與互通性 (Interoperability)	1262
20.2.5	命令列介面	1264
20.3	mailbox --- 以各種格式操作郵件信箱	1265
20.3.1	Mailbox 物件	1265
20.3.2	Message 物件	1274
20.3.3	例外	1282
20.3.4	範例	1282
20.4	mimetypes --- 將檔案名稱對映到 MIME 類型	1283
20.4.1	MimeTypes 物件	1285
20.5	base64 --- Base16、Base32、Base64、Base85 資料編碼	1286
20.5.1	安全性注意事項	1289
20.6	binascii --- 在二進位制和 ASCII 之間轉換	1290

20.7	quopri --- 編碼和解碼 MIME 可列印字元資料	1292
<b>21</b>	<b>Structured Markup Processing Tools</b>	<b>1293</b>
21.1	html --- 超連結標記語言 (HTML) 支援	1293
21.2	html.parser --- 簡單的 HTML 和 XHTML 剖析器	1293
21.2.1	HTML 剖析器應用程式範例	1294
21.2.2	HTMLParser 方法	1294
21.2.3	範例	1296
21.3	html.entities --- HTML 一般實體的定義	1298
21.4	XML 處理模組	1298
21.4.1	XML 漏洞	1299
21.4.2	defusedxml 套件	1299
21.5	xml.etree.cElementTree --- ElementTree XML API	1300
21.5.1	教學	1300
21.5.2	XPath 支援	1305
21.5.3	Reference	1306
21.5.4	XInclude support	1309
21.5.5	Reference	1310
21.6	xml.dom --- Document 物件模型 API	1318
21.6.1	模組內容	1319
21.6.2	Objects in the DOM	1320
21.6.3	Conformance	1327
21.7	xml.dom.minidom --- 最小的 DOM 實作	1328
21.7.1	DOM 物件	1329
21.7.2	DOM 範例	1330
21.7.3	minidom and the DOM standard	1331
21.8	xml.dom.pulldom --- 支援建置部分 DOM 樹	1332
21.8.1	DOMEventStream 物件	1333
21.9	xml.sax --- SAX2 剖析器支援	1334
21.9.1	SAXException 物件	1335
21.10	xml.sax.handler --- SAX 處理函式的基本類	1336
21.10.1	ContentHandler 物件	1338
21.10.2	DTDHandler 物件	1340
21.10.3	EntityResolver 物件	1340
21.10.4	ErrorHandler 物件	1340
21.10.5	LexicalHandler 物件	1340
21.11	xml.sax.saxutils --- SAX 工具程式	1341
21.12	xml.sax.xmlreader --- XML 剖析器的介面	1342
21.12.1	XMLReader 物件	1343
21.12.2	IncrementalParser 物件	1344
21.12.3	Locator Objects	1344
21.12.4	InputSource 物件	1344
21.12.5	The Attributes Interface	1345
21.12.6	The AttributesNS Interface	1345
21.13	xml.parsers.expat --- 使用 Expat 進行快速 XML 剖析	1346
21.13.1	XMLParser 物件	1347
21.13.2	ExpatError 例外	1351
21.13.3	範例	1351
21.13.4	Content Model Descriptions	1352
21.13.5	Expat error constants	1353
<b>22</b>	<b>網路協定 (Internet protocols) 及支援</b>	<b>1357</b>
22.1	webbrowser --- 方便的網頁瀏覽器控制器	1357
22.1.1	瀏覽器控制器物件	1359
22.2	wsgiref --- WSGI 工具與參考實作	1360
22.2.1	wsgiref.util -- WSGI 環境工具	1360
22.2.2	wsgiref.headers -- WSGI 回應標頭工具	1362
22.2.3	wsgiref.simple_server -- 一個簡單的 WSGI HTTP 伺服器	1362

22.2.4	wsgiref.validate	--- WSGI 符合性檢查	1363
22.2.5	wsgiref.handlers	-- 伺服器 / 閘道基本類	1364
22.2.6	wsgiref.types	-- 用於態型檢查的 WSGI 型	1367
22.2.7	範例		1368
22.3	urllib	--- URL 處理模組	1369
22.4	urllib.request	--- 用來開 URLs 的可擴充函式庫	1369
22.4.1	Request	物件	1374
22.4.2	OpenerDirector	物件	1376
22.4.3	BaseHandler	物件	1377
22.4.4	HTTPRedirectHandler	物件	1378
22.4.5	HTTPCookieProcessor	物件	1379
22.4.6	ProxyHandler	物件	1379
22.4.7	HTTPPasswordMgr	物件	1379
22.4.8	HTTPPasswordMgrWithPriorAuth	物件	1379
22.4.9	AbstractBasicAuthHandler	物件	1379
22.4.10	HTTPBasicAuthHandler	物件	1380
22.4.11	ProxyBasicAuthHandler	物件	1380
22.4.12	AbstractDigestAuthHandler	物件	1380
22.4.13	HTTPDigestAuthHandler	物件	1380
22.4.14	ProxyDigestAuthHandler	物件	1380
22.4.15	HTTPHandler	物件	1380
22.4.16	HTTPSHandler	物件	1380
22.4.17	FileHandler	物件	1380
22.4.18	DataHandler	物件	1380
22.4.19	FTPHandler	物件	1381
22.4.20	CacheFTPHandler	物件	1381
22.4.21	UnknownHandler	物件	1381
22.4.22	HTTPErrorProcessor	物件	1381
22.4.23	範例		1381
22.4.24	Legacy interface		1384
22.4.25	urllib.request Restrictions		1386
22.5	urllib.response	--- Response classes used by urllib	1386
22.6	urllib.parse	--- 將 URL 剖析成元件	1387
22.6.1	URL Parsing		1387
22.6.2	URL parsing security		1392
22.6.3	Parsing ASCII Encoded Bytes		1392
22.6.4	Structured Parse Results		1393
22.6.5	URL Quoting		1394
22.7	urllib.error	--- urllib.request 引發的例外類	1396
22.8	urllib.robotparser	--- robots.txt 的剖析器	1396
22.9	http	--- HTTP 模組	1397
22.9.1	HTTP 狀態碼		1398
22.9.2	HTTP 狀態分類		1399
22.9.3	HTTP 方法		1400
22.10	http.client	--- HTTP 協定用端	1401
22.10.1	HTTPConnection	物件	1403
22.10.2	HTTPResponse	物件	1406
22.10.3	範例		1407
22.10.4	HTTPMessage	物件	1408
22.11	ftplib	--- FTP 協定用端	1408
22.11.1	參考		1409
22.12	poplib	--- POP3 協定用端	1414
22.12.1	POP3 物件		1415
22.12.2	POP3 範例		1417
22.13	imaplib	--- IMAP4 協定客端	1417
22.13.1	IMAP4 物件		1419
22.13.2	IMAP4 範例		1423
22.14	smtplib	--- SMTP 協定用端	1424

22.14.1	SMTP 物件	1426
22.14.2	SMTP 範例	1430
22.15	uuid --- RFC 4122 定義的 UUID 物件	1430
22.15.1	命令列的用法	1433
22.15.2	範例	1434
22.15.3	命令列的範例	1434
22.16	socketserver --- 用於網路伺服器的框架	1435
22.16.1	Server Creation Notes	1435
22.16.2	Server Objects	1437
22.16.3	Request Handler Objects	1439
22.16.4	範例	1440
22.17	http.server --- HTTP 伺服器	1443
22.17.1	安全性注意事項	1449
22.18	http.cookies --- HTTP 狀態管理	1449
22.18.1	Cookie 物件	1450
22.18.2	Morsel 物件	1451
22.18.3	範例	1452
22.19	http.cookiejar --- HTTP 客戶端的 Cookie 處理	1453
22.19.1	CookieJar 與 FileCookieJar 物件	1454
22.19.2	FileCookieJar subclasses and co-operation with web browsers	1456
22.19.3	CookiePolicy 物件	1457
22.19.4	DefaultCookiePolicy 物件	1457
22.19.5	Cookie 物件	1459
22.19.6	範例	1460
22.20	xmlrpc --- XMLRPC 伺服器與用戶端模組	1461
22.21	xmlrpc.client --- XML-RPC 客戶端存取	1461
22.21.1	ServerProxy 物件	1463
22.21.2	日期時間物件	1464
22.21.3	Binary Objects	1465
22.21.4	Fault Objects	1465
22.21.5	ProtocolError 物件	1466
22.21.6	MultiCall 物件	1467
22.21.7	便捷的函式	1467
22.21.8	Example of Client Usage	1468
22.21.9	Example of Client and Server Usage	1468
22.22	xmlrpc.server --- 基本 XML-RPC 伺服器	1468
22.22.1	SimpleXMLRPCServer 物件	1469
22.22.2	CGIXMLRPCRequestHandler	1472
22.22.3	Documenting XMLRPC server	1473
22.22.4	DocXMLRPCServer 物件	1473
22.22.5	DocCGIXMLRPCRequestHandler	1474
22.23	ipaddress --- IPv4/IPv6 操作函式庫	1474
22.23.1	Convenience factory functions	1474
22.23.2	IP Addresses	1475
22.23.3	IP Network definitions	1479
22.23.4	Interface objects	1485
22.23.5	Other Module Level Functions	1486
22.23.6	Custom Exceptions	1487
<b>23</b>	<b>多媒體服務</b>	<b>1489</b>
23.1	wave --- 讀寫 WAV 檔案	1489
23.1.1	Wave_read 物件	1490
23.1.2	Wave_write 物件	1491
23.2	coloursys --- 顏色系統間的轉換	1492
<b>24</b>	<b>國際化</b>	<b>1493</b>
24.1	gettext --- 多語言國際化服務	1493
24.1.1	GNU gettext API	1493

24.1.2	Class-based API . . . . .	1494
24.1.3	Internationalizing your programs and modules . . . . .	1498
24.1.4	致謝 . . . . .	1500
24.2	locale --- 國際化服務 . . . . .	1501
24.2.1	Background, details, hints, tips and caveats . . . . .	1508
24.2.2	For extension writers and programs that embed Python . . . . .	1508
24.2.3	Access to message catalogs . . . . .	1508
<b>25</b>	<b>程式框架</b>	<b>1509</b>
25.1	turtle --- 龜圖學 (Turtle graphics) . . . . .	1509
25.1.1	介紹 . . . . .	1509
25.1.2	Get started . . . . .	1509
25.1.3	教學 . . . . .	1510
25.1.4	How to... . . . .	1512
25.1.5	Turtle graphics reference . . . . .	1513
25.1.6	Methods of RawTurtle/Turtle and corresponding functions . . . . .	1516
25.1.7	Methods of TurtleScreen/Screen and corresponding functions . . . . .	1532
25.1.8	Public classes . . . . .	1539
25.1.9	解釋 . . . . .	1540
25.1.10	Help and configuration . . . . .	1540
25.1.11	turtledemo --- Demo scripts . . . . .	1543
25.1.12	Changes since Python 2.6 . . . . .	1544
25.1.13	Changes since Python 3.0 . . . . .	1544
25.2	cmd --- 以列圖導向的指令直譯器支援 . . . . .	1544
25.2.1	Cmd 物件 . . . . .	1545
25.2.2	Cmd Example . . . . .	1546
25.3	shlex --- 簡單的語法分析 . . . . .	1549
25.3.1	shlex 物件 . . . . .	1551
25.3.2	Parsing Rules . . . . .	1553
25.3.3	Improved Compatibility with Shells . . . . .	1553
<b>26</b>	<b>以 Tk 打造圖形使用者介面 (Graphical User Interfaces)</b>	<b>1555</b>
26.1	tkinter --- Tcl/Tk 的 Python 介面 . . . . .	1555
26.1.1	Architecture . . . . .	1556
26.1.2	Tkinter Modules . . . . .	1557
26.1.3	Tkinter Life Preserver . . . . .	1558
26.1.4	Threading model . . . . .	1561
26.1.5	Handy Reference . . . . .	1562
26.1.6	File Handlers . . . . .	1567
26.2	tkinter.colorchooser --- 色選擇對話框 . . . . .	1568
26.3	tkinter.font --- Tkinter 字型包裝器 . . . . .	1568
26.4	Tkinter 對話框 . . . . .	1569
26.4.1	tkinter.simpledialog --- 標準 Tkinter 輸入對話框 . . . . .	1569
26.4.2	tkinter.filedialog --- File selection dialogs . . . . .	1570
26.4.3	tkinter.commondialog --- Dialog window templates . . . . .	1572
26.5	tkinter.messagebox --- Tkinter 訊息提示 . . . . .	1572
26.6	tkinter.scrolledtext --- 圖動文字小工具 . . . . .	1574
26.7	tkinter.dnd --- 拖放支援 . . . . .	1575
26.8	tkinter.ttk --- Tk 主題化小工具 . . . . .	1575
26.8.1	使用 Ttk . . . . .	1576
26.8.2	Ttk Widgets . . . . .	1576
26.8.3	Widget . . . . .	1577
26.8.4	Combobox . . . . .	1579
26.8.5	Spinbox . . . . .	1580
26.8.6	Notebook . . . . .	1581
26.8.7	Progressbar . . . . .	1583
26.8.8	Separator . . . . .	1583
26.8.9	Sizegrip . . . . .	1584

26.8.10	Treeview . . . . .	1584
26.8.11	Ttk Styling . . . . .	1589
26.9	IDLE --- Python editor and shell . . . . .	1594
26.9.1	目録 . . . . .	1594
26.9.2	Editing and Navigation . . . . .	1598
26.9.3	Startup and Code Execution . . . . .	1601
26.9.4	Help and Preferences . . . . .	1604
26.9.5	idlelib --- implementation of IDLE application . . . . .	1605
<b>27</b>	<b>開發工具</b>	<b>1607</b>
27.1	typing --- 支援型別提示 . . . . .	1607
27.1.1	Python 型別系統的技術規範 . . . . .	1608
27.1.2	型別名 . . . . .	1608
27.1.3	NewType . . . . .	1609
27.1.4	解釋 callable 物件 . . . . .	1610
27.1.5	泛型 . . . . .	1611
27.1.6	解釋元組 (tuple) . . . . .	1611
27.1.7	類別物件的型別 . . . . .	1612
27.1.8	Annotating generators and coroutines . . . . .	1613
27.1.9	使用者定義泛型型別 . . . . .	1614
27.1.10	Any 型別 . . . . .	1617
27.1.11	標稱 (nominal) 子型別 vs 結構子型別 . . . . .	1618
27.1.12	模組內容 . . . . .	1618
27.1.13	Deprecation Timeline of Major Features . . . . .	1657
27.2	pydoc --- 文件生成器與線上幫助系統 . . . . .	1657
27.3	Python 開發模式 . . . . .	1659
27.3.1	Python 開發模式的影響 . . . . .	1659
27.3.2	ResourceWarning 範例 . . . . .	1660
27.3.3	檔案描述器的錯誤範例 . . . . .	1661
27.4	doctest --- 測試互動式 Python 範例 . . . . .	1661
27.4.1	Simple Usage: Checking Examples in Docstrings . . . . .	1663
27.4.2	Simple Usage: Checking Examples in a Text File . . . . .	1664
27.4.3	How It Works . . . . .	1665
27.4.4	基礎 API . . . . .	1671
27.4.5	Unittest API . . . . .	1673
27.4.6	Advanced API . . . . .	1675
27.4.7	Debugging . . . . .	1680
27.4.8	Soapbox . . . . .	1683
27.5	unittest --- 單元測試框架 . . . . .	1684
27.5.1	簡單範例 . . . . .	1685
27.5.2	命令執行列介面 (Command-Line Interface) . . . . .	1686
27.5.3	Test Discovery (測試探索) . . . . .	1687
27.5.4	Organizing test code . . . . .	1688
27.5.5	Re-using old test code . . . . .	1690
27.5.6	Skipping tests and expected failures . . . . .	1690
27.5.7	Distinguishing test iterations using subtests . . . . .	1692
27.5.8	類別與函式 . . . . .	1693
27.5.9	Class and Module Fixtures . . . . .	1711
27.5.10	Signal Handling . . . . .	1713
27.6	unittest.mock --- mock 物件函式庫 . . . . .	1714
27.6.1	快速導引 . . . . .	1714
27.6.2	Mock 類別 . . . . .	1716
27.6.3	Patchers . . . . .	1732
27.6.4	MagicMock 以及魔術方法支援 . . . . .	1741
27.6.5	輔助函式 . . . . .	1744
27.6.6	side_effect、return_value 和 wraps 的優先順序 . . . . .	1751
27.7	unittest.mock --- 入門指南 . . . . .	1753
27.7.1	使用 Mock 的方式 . . . . .	1753

27.7.2	Patch 裝飾器	1758
27.7.3	更多範例	1759
27.8	test --- Python 的回歸測試 (regression tests) 套件	1771
27.8.1	撰寫 test 套件的單元測試	1771
27.8.2	使用命令列介面執行測試	1773
27.9	test.support --- Python 測試套件的工具	1773
27.10	test.support.socket_helper --- 用於 socket 測試的工具	1782
27.11	test.support.script_helper --- 用於 Python 執行測試的工具	1783
27.12	test.support.bytecode_helper --- 用於測試位元組碼能正確 <sup>①</sup> 生的支援工具	1784
27.13	test.support.threading_helper --- Utilities for threading tests	1784
27.14	test.support.os_helper --- 用於 os 測試的工具	1785
27.15	test.support.import_helper --- 用於 import 測試的工具	1787
27.16	test.support.warnings_helper --- 用於 warnings 測試的工具	1788
<b>28</b>	<b>除錯與效能分析</b>	<b>1791</b>
28.1	稽核事件表	1791
28.2	bdb --- 偵錯器框架	1795
28.3	faulthandler --- 傾印 Python 回溯	1800
28.3.1	Dumping the traceback	1801
28.3.2	Fault handler state	1801
28.3.3	Dumping the tracebacks after a timeout	1801
28.3.4	Dumping the traceback on a user signal	1802
28.3.5	Issue with file descriptors	1802
28.3.6	範例	1802
28.4	pdb --- Python 偵錯器	1802
28.4.1	偵錯器命令	1805
28.5	Python 的分析器	1811
28.5.1	Introduction to the profilers	1811
28.5.2	Instant User's Manual	1811
28.5.3	profile and cProfile Module Reference	1813
28.5.4	The Stats Class	1815
28.5.5	What Is Deterministic Profiling?	1817
28.5.6	限制	1817
28.5.7	校正	1818
28.5.8	Using a custom timer	1818
28.6	timeit --- 測量小量程式片段的執行時間	1819
28.6.1	基礎範例	1819
28.6.2	Python 介面	1819
28.6.3	命令列介面	1821
28.6.4	範例	1822
28.7	trace --- 追 <sup>①</sup> 或追查 Python 陳述式執行	1823
28.7.1	Command-Line Usage	1824
28.7.2	Programmatic Interface	1825
28.8	tracemalloc --- 追 <sup>①</sup> 記憶體配置	1826
28.8.1	範例	1826
28.8.2	API	1830
<b>29</b>	<b>軟體封裝與發布</b>	<b>1837</b>
29.1	ensurepip --- pip 安裝器的初始建置 (bootstrapping)	1837
29.1.1	命令列介面	1838
29.1.2	模組 API	1838
29.2	venv --- 建立 <sup>①</sup> 擬環境	1839
29.2.1	建立 <sup>①</sup> 擬環境	1839
29.2.2	<sup>①</sup> 擬環境如何運作	1841
29.2.3	API	1842
29.2.4	一個擴展 EnvBuilder 的範例	1845
29.3	zipapp --- 管理可執行的 Python zip 封存檔案	1848
29.3.1	基本範例	1848

29.3.2	命令執行列介面	1848
29.3.3	Python API	1849
29.3.4	範例	1850
29.3.5	Specifying the Interpreter	1851
29.3.6	Creating Standalone Applications with zipapp	1851
29.3.7	The Python Zip Application Archive Format	1851
<b>30</b>	<b>Python Runtime 服務</b>	<b>1853</b>
30.1	sys --- 系統特定的參數與函式	1853
30.2	sys.monitoring --- 執行事件監控	1879
30.2.1	工具識器	1879
30.2.2	事件	1880
30.2.3	開和關閉事件	1881
30.2.4	回呼函式	1882
30.3	sysconfig --- 提供 Python 設定資訊的存取	1883
30.3.1	Configuration variables	1883
30.3.2	Installation paths	1884
30.3.3	User scheme	1885
30.3.4	Home scheme	1885
30.3.5	Prefix scheme	1886
30.3.6	安裝路徑函式	1887
30.3.7	其他函式	1888
30.3.8	將 sysconfig 作本使用	1889
30.4	builtins --- 物件	1889
30.5	__main__ --- 頂層程式碼環境	1890
30.5.1	__name__ == '__main__'	1890
30.5.2	Python 套件中的 __main__.py	1892
30.5.3	import __main__	1893
30.6	warnings --- 警告控制	1894
30.6.1	Warning Categories	1895
30.6.2	The Warnings Filter	1896
30.6.3	Temporarily Suppressing Warnings	1898
30.6.4	Testing Warnings	1898
30.6.5	Updating Code For New Versions of Dependencies	1899
30.6.6	Available Functions	1899
30.6.7	Available Context Managers	1901
30.7	dataclasses --- Data Classes	1901
30.7.1	模組容	1902
30.7.2	Post-init processing	1908
30.7.3	類變數	1909
30.7.4	Init-only variables	1909
30.7.5	凍結實例	1909
30.7.6	繼承	1909
30.7.7	Re-ordering of keyword-only parameters in __init__()	1910
30.7.8	預設工廠函式	1910
30.7.9	可變預設值	1910
30.7.10	Descriptor-typed fields	1911
30.8	contextlib --- Utilities for with-statement contexts	1912
30.8.1	Utilities	1912
30.8.2	Examples and Recipes	1921
30.8.3	Single use, reusable and reentrant context managers	1924
30.9	abc --- 抽象基底類	1926
30.10	atexit --- 退出處理函式	1931
30.10.1	atexit 範例	1931
30.11	traceback --- 列印或取得堆回溯 (stack traceback)	1932
30.11.1	Module-Level Functions	1933
30.11.2	TracebackException 物件	1935
30.11.3	StackSummary 物件	1937

30.11.4	FrameSummary 物件	1937
30.11.5	Examples of Using the Module-Level Functions	1938
30.11.6	TracebackException 的使用範例	1940
30.12	__future__ --- Future 陳述式定義	1941
30.12.1	模組☞容	1942
30.13	gc --- 垃圾回收器介面 (Garbage Collector interface)	1943
30.14	inspect --- 檢視活動物件	1946
30.14.1	Types and members	1947
30.14.2	取得原始碼	1951
30.14.3	Introspecting callables with the Signature object	1952
30.14.4	類☞與函式	1957
30.14.5	直譯器堆☞	1959
30.14.6	Fetching attributes statically	1961
30.14.7	Current State of Generators, Coroutines, and Asynchronous Generators	1962
30.14.8	Code Objects Bit Flags	1963
30.14.9	Buffer flags	1964
30.14.10	命令列介面	1965
30.15	site --- Site-specific configuration hook	1965
30.15.1	sitecustomize	1966
30.15.2	usercustomize	1966
30.15.3	Readline configuration	1967
30.15.4	模組☞容	1967
30.15.5	命令列介面	1968
<b>31</b>	<b>自訂 Python 直譯器</b>	<b>1969</b>
31.1	code --- 直譯器基底類☞	1969
31.1.1	Interactive Interpreter Objects	1970
31.1.2	Interactive Console Objects	1970
31.2	codeop --- 編譯 Python 程式碼	1971
<b>32</b>	<b>引入模組</b>	<b>1973</b>
32.1	zipimport --- 從 Zip 封存檔案匯入模組	1973
32.1.1	zipimporter 物件	1974
32.1.2	範例	1975
32.2	pkgutil --- 套件擴充工具程式	1975
32.3	modulefinder --- 搜尋☞本所使用的模組	1978
32.3.1	ModuleFinder 的用法範例	1979
32.4	runpy --- 定位☞執行 Python 模組	1979
32.5	importlib --- import 的實作	1982
32.5.1	簡介	1982
32.5.2	函式	1983
32.5.3	importlib.abc -- Abstract base classes related to import	1984
32.5.4	importlib.machinery -- Importers and path hooks	1990
32.5.5	importlib.util -- Utility code for importers	1996
32.5.6	範例	1999
32.6	importlib.resources -- 套件資源的讀取、開☞與存取	2001
32.6.1	Functional API	2002
32.7	importlib.resources.abc -- 資源的抽象基底類☞	2004
32.8	importlib.metadata -- 存取套件的元資料	2006
32.8.1	Overview	2007
32.8.2	Functional API	2007
32.8.3	Distributions	2011
32.8.4	Distribution Discovery	2011
32.8.5	Extending the search algorithm	2011
32.9	sys.path 模組搜尋路徑的初始化	2013
32.9.1	☞擬環境	2014
32.9.2	_pth 檔案	2014
32.9.3	Embedded Python	2014

<b>33 Python 語言服務</b>	<b>2015</b>
33.1 ast --- 抽象語法樹 (Abstract Syntax Trees)	2015
33.1.1 抽象文法 (Abstract Grammar)	2015
33.1.2 節點 (Node) 類	2018
33.1.3 ast 輔助程式	2045
33.1.4 編譯器旗標	2049
33.1.5 命令列用法	2049
33.2 symtable --- 存取編譯器的符號表	2050
33.2.1 生成符號表	2050
33.2.2 檢查符號表	2050
33.2.3 命令列用法	2053
33.3 token --- 與 Python 剖析樹一起使用的常數	2053
33.4 keyword --- 檢驗 Python 關鍵字	2057
33.5 tokenize --- Tokenizer for Python source	2058
33.5.1 Tokenizing Input	2058
33.5.2 Command-Line Usage	2059
33.5.3 範例	2060
33.6 tabnanny --- 偵測不良縮排	2061
33.7 pycbr --- Python 模組瀏覽器支援	2062
33.7.1 函式物件	2063
33.7.2 Class Objects	2063
33.8 py_compile --- 編譯 Python 來源檔案	2064
33.8.1 Command-Line Interface	2065
33.9 compileall --- 位元組編譯 Python 函式庫	2066
33.9.1 Command-line use	2066
33.9.2 Public functions	2067
33.10 dis --- Python bytecode 的反組譯器	2069
33.10.1 Command-line interface	2070
33.10.2 Bytecode analysis	2071
33.10.3 Analysis functions	2072
33.10.4 Python Bytecode Instructions	2074
33.10.5 Opcode collections	2090
33.11 pickletools --- pickle 開發者的工具	2091
33.11.1 命令列用法	2091
33.11.2 程式化介面	2092
<b>34 MS Windows 特有服務</b>	<b>2093</b>
34.1 msvcrt --- MS VC++ runtime 提供的有用例程	2093
34.1.1 File Operations	2093
34.1.2 Console I/O	2094
34.1.3 Other Functions	2094
34.2 winreg --- Windows 表存取	2096
34.2.1 函式	2096
34.2.2 常數	2101
34.2.3 Registry Handle Objects	2103
34.3 winsound --- Windows 的聲音播放介面	2104
<b>35 Unix 特有服務</b>	<b>2107</b>
35.1 posix --- 最常見的 POSIX 系統呼叫	2107
35.1.1 對大檔案 (Large File) 的支援	2107
35.1.2 值得注意的模組內容	2108
35.2 pwd --- 密碼資料庫	2108
35.3 grp --- 群組資料庫	2109
35.4 termios --- POSIX 風格 tty 控制	2109
35.4.1 範例	2111
35.5 tty --- 終端機控制函式	2111
35.6 pty --- 終端工具	2112
35.6.1 範例	2113

35.7	fcntl --- fcntl 和 ioctl 系統呼叫	2113
35.8	resource --- 資源使用資訊	2116
35.8.1	Resource Limits	2116
35.8.2	Resource Usage	2119
35.9	syslog --- Unix syslog 函式庫例程	2120
35.9.1	範例	2122
<b>36</b>	<b>模組命令列介面</b>	<b>2125</b>
<b>37</b>	<b>已被取代的模組</b>	<b>2127</b>
37.1	getopt --- 用於命令列選項的 C 風格剖析器	2127
<b>38</b>	<b>已移除的模組</b>	<b>2131</b>
38.1	aifc --- 讀寫 AIFF 與 AIFC 檔案	2131
38.2	asynchat --- 非同步 socket 指令/回應處理函式	2131
38.3	asyncore --- 非同步 socket 處理函式	2131
38.4	audioop --- 操作原始聲音檔案	2132
38.5	cgi --- 通用閘道器介面支援	2132
38.6	cgitb --- CGI 腳本的回溯管理器 (traceback manager)	2132
38.7	chunk --- 讀取 IFF 分塊資料	2132
38.8	crypt --- 用於檢查 Unix 密碼的函式	2132
38.9	distutils --- 建置與安裝 Python 模組	2132
38.10	imghdr --- 判定圖片種類	2133
38.11	imp --- 存取引入系統層	2133
38.12	mailcap --- Mailcap 檔案處理	2133
38.13	msilib --- 讀寫 Microsoft Installer 檔案	2133
38.14	nis --- Sun NIS (Yellow Pages) 介面	2133
38.15	nntplib --- NNTP 協定客戶端	2133
38.16	ossaudiodev --- 對 OSS 相容聲音裝置的存取	2134
38.17	pipes --- shell pipelines 介面	2134
38.18	smtpd --- SMTP 伺服器	2134
38.19	sndhdr --- 判定聲音檔案的種類	2134
38.20	spwd --- shadow 密碼資料庫	2134
38.21	sunau --- 讀寫 Sun AU 檔案	2134
38.22	telnetlib --- Telnet 客戶端	2135
38.23	uu --- uuencode 檔案的編碼與解碼	2135
38.24	xdrllib --- XDR 資料的編碼與解碼	2135

<b>D</b>	<b>版權宣告</b>	<b>2175</b>
	<b>Bibliography</b>	<b>2177</b>
	<b>Python 模組索引</b>	<b>2179</b>
	<b>索引</b>	<b>2183</b>

[reference-index](#) 說明 Python 這門語言確切的文法及語意，而這份函式庫參考手冊則是說明隨著 Python 一起發行的標準函式庫，除此之外，其內容也包含一些時常出現在 Python 發行版本中的非必要套件。

Python 的標準函式庫是非常龐大的，其提供了如下所述極多且涵蓋用途極廣的許多模組。包含一些用 C 語言撰寫，可以操作像是檔案讀寫等系統相關功能的內建模組，當然也有用 Python 撰寫，使用標準解法解決許多常見問題的模組。其中有些模組則是特別針對 Python 的可移植性去設計的，因此特地將一些平台特殊相依性的功能抽象化成可跨平台的 API。

Python 的 Windows 安裝檔基本上包含整個標準函式庫，且通常也包含許多附加的組件；而在類 Unix 作業系統方面，Python 通常是以一系列的套件被安裝，因此對於某些或全部的可選組件，可能都必須使用該作業系統提供的套件管理工具來安裝。

在標準函式庫之外，還有成千上萬且不斷增加的組件（從個別的程式、模組、套件到完整的應用程式開發框架），可以從 [Python 套件索引 \(Python Package Index\)](#) 中取得。

「Python 函式庫」包含了許多不同的部分。

函式庫中包括被視爲程式語言「核心」部分的資料型態，像是數字 (number) 或是串列 (list)。對於這些型別，Python 核心對這些字面值 (literal) 的形式做定義，對它們的語意制定了一些限制，但在此同時不把文字對應的語意完全定義。(另一方面，Python 在語法面上有確實的定義，例如拼字或是運算元次序)

Python 函式庫也囊括了建置函式與例外處理——這些物件都可以不用透過 `import` 陳述式來引入 Python 程式中就能使用。函式庫中有部份是被 Python 核心所定義的，但在這僅解釋最核心的語意部分。

整個函式庫中包含了許多模組，有許多方法可以從函式庫中取用這些模組。有些模組是以 C 語言撰寫建置於 Python 編譯器之中，其他的是由 Python 撰寫以源碼的方式 (source form) 引入。有些模組提供的功能是專屬於 Python 的，像是把 stack trace 印出來；有些則是針對特定作業系統，去試著存取特定硬體；還有些提供對特定應用的功能與操作介面，像是 World Wide Web。模組的使用情況會因機器與 Python 的版本而不同，部分模組是開放所有版本以及 Port 的 Python 來使用的，但有些會因系統支援或需求在某些版本或系統下無法使用，甚至有些僅限在特定的設定環境下才能使用。

這個手冊會「深入淺出」地介紹 Python 函式庫。它會先介紹一些建置函式、資料型態、和一些例外處理，再來一章章的主題式介紹相關模組。

這代表如果你從這個手冊的最開始讀起，在感到無聊時跳到下一個章節，你仍然可以得到一個對 Python 函式庫所支援的模組與其合理應用的概觀。當然，你不必像是在讀一本小說一樣讀這本手冊——你可以快速瀏覽目錄 (在手冊的最前頭)、或是你可以利用最後面的索引來查詢特定的函式或模組。最後，如果你享受讀一些隨機的主題，你可以選擇一個隨機的數字開始讀 (見 `random` 模組)。不管你想要以什麼順序來讀這個手冊，建置函式會是一個很好的入門，因手冊中其他章節都預設你已經對這個章節有一定的熟悉程度。

讓我們開始吧！

## 1.1 可用性之標

- 如果出現「適用：Unix」標，則代表該函式普遍存在於 Unix 系統中，但這不保證其存在於某特定作業系統。
- 如果有分標的話，有標明「適用：Unix」標的所有函式也都於 macOS、iOS 和 Android 上支援，因其建於 Unix 核心之上。
- If an availability note contains both a minimum Kernel version and a minimum libc version, then both conditions must hold. For example a feature with note *Availability: Linux >= 3.17 with glibc >= 2.27* requires both Linux 3.17 or newer and glibc 2.27 or newer.

### 1.1.1 WebAssembly 平台

The [WebAssembly](#) platforms `wasm32-emscripten` ([Emscripten](#)) and `wasm32-wasi` ([WASI](#)) provide a subset of POSIX APIs. WebAssembly runtimes and browsers are sandboxed and have limited access to the host and external resources. Any Python standard library module that uses processes, threading, networking, signals, or other forms of inter-process communication (IPC), is either not available or may not work as on other Unix-like systems. File I/O, file system, and Unix permission-related functions are restricted, too. Emscripten does not permit blocking I/O. Other blocking operations like `sleep()` block the browser event loop.

The properties and behavior of Python on WebAssembly platforms depend on the [Emscripten-SDK](#) or [WASI-SDK](#) version, WASM runtimes (browser, NodeJS, [wasmtime](#)), and Python build time flags. WebAssembly, Emscripten, and WASI are evolving standards; some features like networking may be supported in the future.

For Python in the browser, users should consider [Pyodide](#) or [PyScript](#). PyScript is built on top of Pyodide, which itself is built on top of CPython and Emscripten. Pyodide provides access to browsers' JavaScript and DOM APIs as well as limited networking capabilities with JavaScript's `XMLHttpRequest` and `Fetch` APIs.

- Process-related APIs are not available or always fail with an error. That includes APIs that spawn new processes (`fork()`, `execve()`), wait for processes (`waitpid()`), send signals (`kill()`), or otherwise interact with processes. The `subprocess` is importable but does not work.
- The `socket` module is available, but is limited and behaves differently from other platforms. On Emscripten, sockets are always non-blocking and require additional JavaScript code and helpers on the server to proxy TCP through WebSockets; see [Emscripten Networking](#) for more information. WASI snapshot preview 1 only permits sockets from an existing file descriptor.
- Some functions are stubs that either don't do anything and always return hardcoded values.
- Functions related to file descriptors, file permissions, file ownership, and links are limited and don't support some operations. For example, WASI does not permit symlinks with absolute file names.

### 1.1.2 行動平台

Android and iOS are, in most respects, POSIX operating systems. File I/O, socket handling, and threading all behave as they would on any POSIX operating system. However, there are several major differences:

- Mobile platforms can only use Python in "embedded" mode. There is no Python REPL, and no ability to use separate executables such as `python` or `pip`. To add Python code to your mobile app, you must use the Python embedding API. For more details, see [using-android](#) and [using-ios](#).
- Subprocesses:
  - On Android, creating subprocesses is possible but **officially unsupported**. In particular, Android does not support any part of the System V IPC API, so `multiprocessing` is not available.
  - An iOS app cannot use any form of subprocessing, multiprocessing, or inter-process communication. If an iOS app attempts to create a subprocess, the process creating the subprocess will either lock up, or crash. An iOS app has no visibility of other applications that are running, nor any ability to communicate with other running applications, outside of the iOS-specific APIs that exist for this purpose.
- Mobile apps have limited access to modify system resources (such as the system clock). These resources will often be *readable*, but attempts to modify those resources will usually fail.
- Console input and output:
  - On Android, the native `stdout` and `stderr` are not connected to anything, so Python installs its own streams which redirect messages to the system log. These can be seen under the tags `python.stdout` and `python.stderr` respectively.
  - iOS apps have a limited concept of console output. `stdout` and `stderr` *exist*, and content written to `stdout` and `stderr` will be visible in logs when running in Xcode, but this content *won't* be recorded in the system log. If a user who has installed your app provides their app logs as a diagnostic aid, they will not include any detail written to `stdout` or `stderr`.
  - Mobile apps have no usable `stdin` at all. While apps can display an on-screen keyboard, this is a software feature, not something that is attached to `stdin`.

As a result, Python modules that involve console manipulation (such as *curses* and *readline*) are not available on mobile platforms.

## CHAPTER 2

---

### ☐ 建函式

---

Python 直譯器有☐建多個可隨時使用的函式和型☐。以下按照英文字母排序列出。

## 建函式

<b>A</b>	<b>E</b>	<b>L</b>	<b>R</b>
<code>abs()</code>	<code>enumerate()</code>	<code>len()</code>	<code>range()</code>
<code>aiter()</code>	<code>eval()</code>	<code>list()</code>	<code>repr()</code>
<code>all()</code>	<code>exec()</code>	<code>locals()</code>	<code>reversed()</code>
<code>anext()</code>			<code>round()</code>
<code>any()</code>	<b>F</b>	<b>M</b>	
<code>ascii()</code>	<code>filter()</code>	<code>map()</code>	<b>S</b>
<b>B</b>	<code>float()</code>	<code>max()</code>	<code>set()</code>
<code>bin()</code>	<code>format()</code>	<code>memoryview()</code>	<code>setattr()</code>
<code>bool()</code>	<code>frozenset()</code>	<code>min()</code>	<code>slice()</code>
<code>breakpoint()</code>	<b>G</b>	<b>N</b>	<code>sorted()</code>
<code>bytearray()</code>	<code>getattr()</code>	<code>next()</code>	<code>staticmethod()</code>
<code>bytes()</code>	<code>globals()</code>	<b>O</b>	<code>str()</code>
<b>C</b>	<b>H</b>	<code>object()</code>	<code>sum()</code>
<code>callable()</code>	<code>hasattr()</code>	<code>oct()</code>	<code>super()</code>
<code>chr()</code>	<code>hash()</code>	<code>open()</code>	<b>T</b>
<code>classmethod()</code>	<code>help()</code>	<code>ord()</code>	<code>tuple()</code>
<code>compile()</code>	<code>hex()</code>	<b>P</b>	<code>type()</code>
<code>complex()</code>	<b>I</b>	<code>pow()</code>	<b>V</b>
<b>D</b>	<code>id()</code>	<code>print()</code>	<code>vars()</code>
<code>delattr()</code>	<code>input()</code>	<code>property()</code>	<b>Z</b>
<code>dict()</code>	<code>int()</code>		<code>zip()</code>
<code>dir()</code>	<code>isinstance()</code>		
<code>divmod()</code>	<code>issubclass()</code>		
	<code>iter()</code>		<code>__import__()</code>

**abs**(*x*)

回傳一個數的絕對值，引數可以是整數、浮點數或有實現 `__abs__()` 的物件。如果引數是一個數，回傳它的純量（大小）。

**aiter**(*async\_iterable*)

回傳非同步代器做非同步可代物件。相當於呼叫 `x.__aiter__()`。

注意：與 `iter()` 不同，`aiter()` 有兩個引數的變體。

在 3.10 版被加入。

**all**(*iterable*)

如果 *iterable* 的所有元素皆真（或 *iterable* 空）則回傳 `True`。等價於：

```
def all(iterable):
    for element in iterable:
        if not element:
            return False
    return True
```

**awaitable anext**(*async\_iterator*)

**awaitable** `anext` (*async\_iterator*, *default*)

當進入 `await` 時，從給定的 *asynchronous iterator* 中回傳下一個項目 (item)，代完畢則回傳 *default*。這是 `next()` 的非同步版本，其行類似於：

呼叫 *async\_iterator* 的 `__anext__()` 方法，回傳 *awaitable*。等待返回代器的下一個值。如果指定 *default*，當代器結束時會返回該值，否則會引發 `StopAsyncIteration`。

在 3.10 版被加入。

**any** (*iterable*)

如果 *iterable* 的任一元素為真，回傳 `True`。如果 *iterable* 是空的，則回傳 `False`。等價於：

```
def any(iterable):
    for element in iterable:
        if element:
            return True
    return False
```

**ascii** (*object*)

就像函式 `repr()`，回傳一個表示物件的字串，但是 `repr()` 回傳的字串中非 ASCII 編碼的字元會被跳 (escape)，像是 `\x`、`\u` 和 `\U`。這個函式生成的字串和 Python 2 的 `repr()` 回傳的結果相似。

**bin** (*x*)

將一個整數轉變為一個前綴為 `"0b"` 的二進位制字串。結果是一個有效的 Python 運算式。如果 *x* 不是 Python 的 `int` 物件，那它需要定義 `__index__()` method 回傳一個整數。舉例來：

```
>>> bin(3)
'0b11'
>>> bin(-10)
'-0b1010'
```

如果不一定需要 `"0b"` 前綴，還可以使用如下的方法。

```
>>> format(14, '#b'), format(14, 'b')
('0b11110', '11110')
>>> f'{14:#b}', f'{14:b}'
('0b11110', '11110')
```

可參考 `format()` 獲取更多資訊。

**class bool** (*object=False*, / (*Positional-only parameter separator (PEP 570)*))

回傳一個布林值，即 `True` 或者 `False`。引數會使用標準的真值測試程序來轉。如果引數為假或者被省略，則回傳 `False`；其他情況回傳 `True`。`bool` class (類) 是 `int` 的 subclass (子類) (參見數值型 `int`、`float`、`complex`)，其他 class 不能繼承自它。它只有 `False` 和 `True` 兩個實例 (參見 `Boolean` 型 - `bool`)。

在 3.7 版的變更：現在僅限位置參數。

**breakpoint** (*\*args*, *\*\*kws*)

這個函式將呼叫 `sys.breakpointhook()` 函式，將 *args* 和 *kws* 傳遞給它。這將有效地讓你在特定的呼叫點進入除錯器。預設情況下，`sys.breakpointhook()` 呼叫 `pdb.set_trace()` 不須帶任何引數。這樣的設計是為了方便使用者，讓他們不需要額外地導入 `pdb` 模組或輸入太多程式就可以進入除錯器。然而，可以將 `sys.breakpointhook()` 設置為其他函式，且 `breakpoint()` 將自動呼叫該函式，讓你進入所選擇的除錯器。如果無法存取 `sys.breakpointhook()` 這個函式，則此函式將引發 `RuntimeError`。

預設情況下，`breakpoint()` 的行可以透過 `PYTHONBREAKPOINT` 環境變數來更改。有關使用詳情，請參考 `sys.breakpointhook()`。

請注意，如果 `sys.breakpointhook()` 被替換了，則無法保證此功能。

引發一個附帶引數 `breakpointhook` 的稽核事件 `builtins.breakpoint`。

在 3.7 版被加入。

```
class bytearray (source=b")
```

```
class bytearray (source, encoding)
```

```
class bytearray (source, encoding, errors)
```

回傳一個新的 bytes 陣列。 `bytearray` class 是一個可變的整數序列，包含範圍  $0 \leq x < 256$  的整數。它有可變序列大部分常見的 method（如在 *Mutable Sequence Types* 中所述），同時也有 `bytes` 型大部分的 method，參見 *Bytes and bytearray Operations*。

選擇性參數 `source` 可以被用來以不同的方式初始化陣列：

- 如果是一個 *string*，你必須提供 `encoding` 參數（以及選擇性地提供 `errors`）； `bytearray()` 會使用 `str.encode()` method 來將 *string* 轉變成 bytes。
- 如果是一個 *integer*，陣列則會有該數值的長度，以 `null bytes` 來當作初始值。
- 如果是一個符合 *buffer* 介面的物件，該物件的唯讀 *buffer* 會被用來初始化 bytes 陣列。
- 如果是一個 *iterable*，它的元素必須是範圍  $0 \leq x < 256$  的整數，且會被用作陣列的初始值。

如果 `l` 有引數，則建立長度 `l` 的陣列。

可參考 *Binary Sequence Types --- bytes, bytearray, memoryview* 和 *Bytearray Objects*。

```
class bytes (source=b")
```

```
class bytes (source, encoding)
```

```
class bytes (source, encoding, errors)
```

回傳一個新的 "bytes" 物件，會是一個元素是範圍  $0 \leq x < 256$  整數的不可變序列。 `bytes` 是 `bytearray` 的不可變版本——它的同樣具備不改變物件的 method，也有相同的索引和切片操作。

因此，建構函式的引數和 `bytearray()` 相同。

Bytes 物件還可以用文字建立，參見 *strings*。

可參考 *Binary Sequence Types --- bytes, bytearray, memoryview*、*Bytes Objects* 和 *Bytes and bytearray Operations*。

```
callable (object)
```

如果引數 `object` 是可呼叫的，回傳 `True`，否則回傳 `False`。如果回傳 `True`，呼叫仍可能會失敗；但如果回傳 `False`，則呼叫 `object` 肯定會失敗。注意 `class` 是可呼叫的（呼叫 `class` 會回傳一個新的實例）；如果實例的 `class` 有定義 `__call__()` method，則它是可呼叫的。

在 3.2 版被加入：這個函式一開始在 Python 3.0 被移除，但在 Python 3.2 又被重新加入。

```
chr (i)
```

回傳代表字元之 Unicode 編碼位置 `i` 的整數的字串。例如，`chr(97)` 回傳字串 `'a'`，而 `chr(8364)` 回傳字串 `'€'`。這是 `ord()` 的逆函式。

引數的有效範圍是 0 到 1,114,111（16 進制表示 `0x10FFFF`）。如果 `i` 超過這個範圍，會引發 `ValueError`。

```
@classmethod
```

把一個 method 封裝成 class method（類方法）。

一個 class method 把自己的 class 作第一個引數，就像一個實例 method 把實例自己作第一個引數。請用以下慣例來宣告 class method：

```
class C:
    @classmethod
    def f(cls, arg1, arg2): ...
```

`@classmethod` 語法是一個函式 *decorator* — 參見 *function* 中關於函式定義的詳細介紹。

一個 class method 可以在 class（如 `C.f()`）或實例（如 `C().f()`）上呼叫。實例除了它的 class 資訊，其他都會被忽略。如果一個 class method 在 subclass 上呼叫，subclass 會作第一個引數傳入。

Class method 和 C++ 與 Java 的 static method 是有區別的。如果你想了解 static method，請看本節的 `staticmethod()`。關於 class method 的更多資訊，請參考 `types`。

在 3.9 版的變更: Class methods 現在可以包裝其他描述器，例如 `property()`

在 3.10 版的變更: Class method 現在繼承了 method 屬性 (`__module__`、`__name__`、`__qualname__`、`__doc__` 和 `__annotations__`)，擁有一個新的 `__wrapped__` 屬性。

Deprecated since version 3.11, removed in version 3.13: Class methods 不能再包裝其他的描述器，例如 `property()`。

**compile** (*source, filename, mode, flags=0, dont\_inherit=False, optimize=-1*)

將 *source* 編譯成程式碼或 AST 物件。程式碼物件可以被 `exec()` 或 `eval()` 執行。*source* 可以是一般的字串、bytes 字串、或者 AST 物件。參見 `ast` module (模組) 的說明文件了解如何使用 AST 物件。

*filename* 引數必須是程式碼的檔名；如果程式碼不是從檔案中讀取，可以傳入一些可辨識的值（經常會使用 '<string>' 來替代）。

*mode* 引數指定了編譯程式碼時必須用的模式。如果 *source* 是一系列的陳述式，可以是 'exec'；如果是單一運算式，可以是 'eval'；如果是單個互動式陳述式，可以是 'single'（在最後一種情況下，如果運算式執行結果不是 None 則會被印出來）。

可選引數 *flags* 和 *dont\_inherit* 控制用哪個編譯器選項以及允許哪個未來功能。如果兩者都不存在（或兩者都為零），則會呼叫與 `compile()` 相同旗標的程式碼來編譯。如果給定 *flags* 引數而未給定 *dont\_inherit*\*（或為零）則無論如何都會使用由 \**flags* 引數所指定的編譯器選項和未來陳述式。如果 *dont\_inherit* 是一個非零整數，則使用 *flags* 引數 - 周圍程式碼中的旗標（未來功能和編譯器選項）將被忽略。

編譯器選項和 future 陳述式使用 bits 來表示，可以一起被位元操作 OR 來表示數個選項。需要被具體定義特徵的位元域可以透過 `__future__` module 中 `Feature` 實例中的 `compiler_flag` 屬性來獲得。編譯器旗標可以在 `ast` module 中搜尋有 `PyCF_` 前綴的名稱。

引數 *optimize* 用來指定編譯器的最佳化級別；預設值 -1 選擇與直譯器的 -O 選項相同的最佳化級別。其他級別 0（有最佳化；`__debug__` 為真值）、1（assert 被刪除，`__debug__` 為假值）或 2（說明字串 (docstring) 也被刪除）。

如果編譯的原始碼無效，此函式會引發 `SyntaxError`，如果原始碼包含 null bytes，則會引發 `ValueError`。

如果你想解析 Python 程式碼成 AST 運算式，請參見 `ast.parse()`。

引發一個附帶引數 *source*、*filename* 的稽核事件 `compile`。此事件也可能由隱式編譯 (implicit compilation) 所引發。

### 備註

在 'single' 或 'eval' 模式編譯多行程式碼時，輸入必須以至少一個換行符結尾。這使 `code` module 更容易檢測陳述式的完整性。

### 警告

如果編譯足夠大或者足夠複雜的字串成 AST 物件時，Python 直譯器會因為 Python AST 編譯器的 stack 深度限制而崩潰。

在 3.2 版的變更: 允許使用 Windows 和 Mac 的換行符號。此外，在 'exec' 模式不需要以換行符號結尾。增加了 *optimize* 參數。

在 3.5 版的變更: 在之前的版本，*source* 中包含 null bytes 會引發 `TypeError`。

在 3.8 版被加入: `ast.PyCF_ALLOW_TOP_LEVEL_AWAIT` 現在可以傳遞旗標以啟用對頂層 `await`、`async for` 和 `async with` 的支援。

**class complex** (*number=0, /*)

```
class complex(string, /)
```

```
class complex(real=0, imag=0)
```

Convert a single string or number to a complex number, or create a complex number from real and imaginary parts.

例如：

```
>>> complex('+1.23')
(1.23+0j)
>>> complex('-4.5j')
-4.5j
>>> complex('-1.23+4.5j')
(-1.23+4.5j)
>>> complex('\t ( -1.23+4.5j ) \n')
(-1.23+4.5j)
>>> complex('-Infinity+NaNj')
(-inf+nanj)
>>> complex(1.23)
(1.23+0j)
>>> complex(imag=-4.5)
-4.5j
>>> complex(-1.23, 4.5)
(-1.23+4.5j)
```

If the argument is a string, it must contain either a real part (in the same format as for `float()`) or an imaginary part (in the same format but with a 'j' or 'J' suffix), or both real and imaginary parts (the sign of the imaginary part is mandatory in this case). The string can optionally be surrounded by whitespaces and the round parentheses '(' and ')', which are ignored. The string must not contain whitespace between '+', '-', the 'j' or 'J' suffix, and the decimal number. For example, `complex('1+2j')` is fine, but `complex('1 + 2j')` raises `ValueError`. More precisely, the input must conform to the `complexvalue` production rule in the following grammar, after parentheses and leading and trailing whitespace characters are removed:

```
complexvalue ::= floatvalue |
               floatvalue ("j" | "J") |
               floatvalue sign absfloatvalue ("j" | "J")
```

如果引數是一個數字，則建構函式會像 `int` 和 `float` 一樣進行數值轉。對於一個普通的 Python 物件 `x`，`complex(x)` 會委派給 `x.__complex__()`。如果 `__complex__()` 未定義，則會回退 (fall back) 到 `__float__()`。如果 `__float__()` 未定義，則會再回退到 `__index__()`。

If two arguments are provided or keyword arguments are used, each argument may be any numeric type (including complex). If both arguments are real numbers, return a complex number with the real component `real` and the imaginary component `imag`. If both arguments are complex numbers, return a complex number with the real component `real.real-imag.imag` and the imaginary component `real.imag+imag.real`. If one of arguments is a real number, only its real component is used in the above expressions.

If all arguments are omitted, returns `0j`.

數型在數值型 --- `int`、`float`、`complex` 中有相關描述。

在 3.6 版的變更：可以使用底將程式碼文字中的數字進行分組。

在 3.8 版的變更：如果 `__complex__()` 和 `__float__()` 未定義，則會回退到 `__index__()`。

```
delattr(object, name)
```

這是 `setattr()` 相關的函式。引數是一個物件和一個字串，該字串必須是物件中某個屬性名稱。如果物件允許，該函式將除指定的屬性。例如 `delattr(x, 'foobar')` 等價於 `del x.foobar`。 `name` 不必是個 Python 識符 (identifier) (請見 `setattr()`)。

```
class dict(**kwarg)
```

```
class dict(mapping, **kwarg)
```

**class dict** (*iterable*, *\*\*kwargs*)

建立一個新的 dictionary (字典)。dict 物件是一個 dictionary class。參見 *dict* 和 *Mapping Types --- dict* 來解這個 class。

其他容器型，請參見建的 *list*、*set* 和 *tuple* class，以及 *collections* module。

**dir()**

**dir(object)**

如果 `dir()` 有引數，則回傳當前區域作用域 (local scope) 中的名稱列表。如果有引數，它會嘗試回傳該物件的有效屬性列表。

如果物件有一個名 `__dir__()` 的 method，那該 method 將被呼叫，且必須回傳一個屬性列表。這允許實現自定義 `__getattr__()` 或 `__getattribute__()` 函式的物件能自定義 `dir()` 來報告它們的屬性。

如果物件不提供 `__dir__()`，這個函式會嘗試從物件已定義的 `__dict__` 屬性和型物件收集資訊。結果列表不總是完整的，如果物件有自定義 `__getattr__()`，那結果可能不準確。

預設的 `dir()` 機制對不同型的物件有不同行，它會試圖回傳最相關而非最完整的資訊：

- 如果物件是 module 物件，則列表包含 module 的屬性名稱。
- 如果物件是型或 class 物件，則列表包含它們的屬性名稱，且遞查詢其基礎的所有屬性。
- 否則，包含物件的屬性名稱列表、它的 class 屬性名稱，且遞查詢它的 class 的所有基礎 class 的屬性。

回傳的列表按字母表排序，例如：

```
>>> import struct
>>> dir() # show the names in the module namespace
['__builtins__', '__name__', 'struct']
>>> dir(struct) # show the names in the struct module
['Struct', '__all__', '__builtins__', '__cached__', '__doc__', '__file__',
 '__initializing__', '__loader__', '__name__', '__package__',
 '_clearcache', 'calcsize', 'error', 'pack', 'pack_into',
 'unpack', 'unpack_from']
>>> class Shape:
...     def __dir__(self):
...         return ['area', 'perimeter', 'location']
...
>>> s = Shape()
>>> dir(s)
['area', 'location', 'perimeter']
```

#### 備

因 `dir()` 主要是為了便於在互動式提示字元時使用，所以它會試圖回傳人們感興趣的名稱集合，而不是試圖保證結果的嚴格性或一致性，它具體的行也可能在不同版本之間改變。例如，當引數是一個 class 時，metaclass 的屬性不包含在結果列表中。

**divmod** (*a*, *b*)

它將兩個 (非數) 數字作引數，在執行整數除法時回傳一對商和余數。對於混合運算元型，適用二進位算術運算子的規則。對於整數，運算結果和 (`a // b`, `a % b`) 一致。對於浮點數，運算結果是 (`q`, `a % b`)，`q` 通常是 `math.floor(a / b)` 但可能會比 1 小。在任何情況下，`q * b + a % b` 和 `a` 基本相等，如果 `a % b` 非零，則它的符號和 `b` 一樣，且  $0 \leq \text{abs}(a \% b) < \text{abs}(b)$ 。

**enumerate** (*iterable*, *start=0*)

回傳一個列舉 (enumerate) 物件。iterable 必須是一個序列、iterator 或其他支援代的物件。enumerate() 回傳之 iterator 的 `__next__()` method 回傳一個 tuple (元組)，面包含一個計數值 (從 `start` 開始，預設 0) 和透過代 iterable 獲得的值。

```
>>> seasons = ['Spring', 'Summer', 'Fall', 'Winter']
>>> list(enumerate(seasons))
[(0, 'Spring'), (1, 'Summer'), (2, 'Fall'), (3, 'Winter')]
>>> list(enumerate(seasons, start=1))
[(1, 'Spring'), (2, 'Summer'), (3, 'Fall'), (4, 'Winter')]
```

等價於：

```
def enumerate(iterable, start=0):
    n = start
    for elem in iterable:
        yield n, elem
        n += 1
```

`eval` (*source*, */*, *globals=None*, *locals=None*)

### 參數

- **source** (*str* | code object) -- A Python expression.
- **globals** (*dict* | None) -- The global namespace (default: None).
- **locals** (*mapping* | None) -- The local namespace (default: None).

### 回傳

The result of the evaluated expression.

### 引發

Syntax errors are reported as exceptions.

### 警告

This function executes arbitrary code. Calling it with user-supplied input may lead to security vulnerabilities.

*expression* 引數會被視作一條 Python 運算式（技術上而言，是條件列表）來剖析及求值，而 *globals* 和 *locals* 對映分作全域和區域命名空間。如果 *globals* dictionary 存在但缺少 `__builtins__` 的鍵值，那 *expression* 被剖析之前，將該鍵插入對 `builtins` module dictionary 的引用。這一來，在將 `__builtins__` dictionary 傳入 `eval()` 之前，你可以透過將它插入 *globals* 來控制你需要哪些 `builtins` 來執行程式碼。如果 *locals* 對映被省略，那它的預設值是 *globals* dictionary。如果兩個對映都被省略，則以在 `eval()` 被呼叫的環境中的 *globals* 和 *locals* 執行運算式。請注意，`eval()` 在封閉 (enclosing) 環境中無法存取巢狀作用域 (non-locals)，除非呼叫 `eval()` 的作用域已經有參照它們（例如透過 `nonlocal` 陳述式）。

範例：

```
>>> x = 1
>>> eval('x+1')
2
```

這個函式也可以用來執行任意程式碼物件（如被 `compile()` 建立的那些）。這種情況下，傳入的引數是程式碼物件而不是字串。如果編譯該物件時的 *mode* 引數是 `'exec'`，那 `eval()` 回傳值 `None`。

提示：`exec()` 函式支援動態執行陳述式。`globals()` 和 `locals()` 函式分回傳當前的全域性和局部性 dictionary，它們對於將引數傳遞給 `eval()` 或 `exec()` 可能會方便許多。

如果給定來源是一個字串，那其前後的空格和定位字元會被移除。

另外可以參 `ast.literal_eval()`，該函式可以安全執行僅包含文字的運算式字串。

引發一個附帶程式碼物件引數的稽核事件 `exec`。也可能會引發程式碼編譯事件。

在 3.13 版的變更：The *globals* and *locals* arguments can now be passed as keywords.

在 3.13 版的變更: The semantics of the default *locals* namespace have been adjusted as described for the *locals()* builtin.

`exec(source, /, globals=None, locals=None, * (Keyword-only parameters separator (PEP 3102)), closure=None)`

### 警告

This function executes arbitrary code. Calling it with user-supplied input may lead to security vulnerabilities.

這個函式支援動態執行 Python 程式碼。*source* 必須是字串或者程式碼物件。如果是字串，那該字串將被剖析一系列 Python 陳述式執行（除非發生語法錯誤）。<sup>1</sup>如果是程式碼物件，它將被直接執行。無論哪種情況，被執行的程式碼都需要和檔案輸入一樣是有效的（可參閱語言參考手冊中關於 *file-input* 的章節）。請注意，即使在傳遞給 *exec()* 函式的程式碼的上下文中，*nonlocal*、*yield* 和 *return* 陳述式也不能在函式之外使用。該函式回傳值是 *None*。

無論哪種情況，如果省略了選擇性的部分，程式碼將在當前作用域執行。如果只提供了 *globals* 引數，就必須是字典型（且不能是字典的子類），而且會被用作全域和區域變數。如果同時提供了 *globals* 和 *locals*，它們分別被用作全域和區域變數。如果提供了 *locals*，則它可以是任何對映物件。請記住在 *module* 層級中全域和區域變數是相同的字典。

### 備註

When *exec* gets two separate objects as *globals* and *locals*, the code will be executed as if it were embedded in a class definition. This means functions and classes defined in the executed code will not be able to access variables assigned at the top level (as the "top level" variables are treated as class variables in a class definition).

如果 *globals* dictionary 不包含 `__builtins__` 鍵值，則將該鍵插入對 *builtins* module dictionary 的引用。這一來，在將 `__builtins__` dictionary 傳入 *exec()* 之前，你可以透過將它插入 *globals* 來控制你需要哪些函式來執行程式碼。

*closure* 引數會指定一個閉包 (closure) — 它是一個 cellvar (格變數) 的 tuple。只有在 *object* 是一個含有自由 (閉包) 變數 (*free (closure) variables*) 的程式碼物件時，它才有效。Tuple 的長度必須與程式碼物件的 `co_freevars` 屬性完全匹配。

引發一個附帶程式碼物件引數的稽核事件 *exec*。也可能會引發程式碼編譯事件。

### 備註

函式 *globals()* 和 *locals()* 各自回傳當前的全域和區域命名空間，因此可以將它們傳遞給 *exec()* 的第二個和第三個引數以供後續使用。

### 備註

預設情況下，*locals* 的行如下面 *locals()* 函式描述的一樣。如果你想在 *exec()* 函式回傳時知道程式碼對 *locals* 的變動，請明確地傳遞 *locals* dictionary。

在 3.11 版的變更: 增加了 *closure* 參數。

在 3.13 版的變更: The *globals* and *locals* arguments can now be passed as keywords.

在 3.13 版的變更: The semantics of the default *locals* namespace have been adjusted as described for the *locals()* builtin.

<sup>1</sup> 剖析器只接受 Unix 風格的行結束符。如果你從檔案中讀取程式碼，請確保用行符號轉 Windows 或 Mac 風格的行符號。

**filter** (*function, iterable*)

用 *iterable* 中函式 *function* 為 True 的那些元素，構建一個新的 iterator。*iterable* 可以是一個序列、一個支援迭代的容器、或一個 iterator。如果 *function* 是 None，則會假設它是一個識別性函式，即 *iterable* 中所有假值元素會被移除。

請注意，`filter(function, iterable)` 相當於一個生成器運算式，當 *function* 不是 None 的時候 `(item for item in iterable if function(item))`；*function* 是 None 的時候 `(item for item in iterable if item)`。

請參閱 `itertools.filterfalse()`，只有 *function* 為 false 時才選取 *iterable* 中元素的互補函式。

**class float** (*number=0.0, /*)

**class float** (*string, /*)

回傳從數字或字串生成的浮點數。

例如：

```
>>> float('+1.23')
1.23
>>> float(' -12345\n')
-12345.0
>>> float('1e-003')
0.001
>>> float('+1E6')
1000000.0
>>> float('-Infinity')
-inf
```

如果引數是字串，則它必須是包含十進位制數字的字串，字串前面可以有符號，之前也可以有空格。選擇性的符號有 '+' 和 '-'；'+' 對建立的值的正負有影響。引數也可以是 NaN（非數字）或正負無窮大的字串。確切地說，除去首尾的空格後，輸入必須遵循以下語法中 *floatvalue* 的生成規則：

```
sign          ::= "+" | "-"
infinity      ::= "Infinity" | "inf"
nan           ::= "nan"
digit         ::= <a Unicode decimal digit, i.e. characters in Unicode general category Nd>
digitpart    ::= digit (["_"] digit)*
number       ::= [digitpart] "." digitpart | digitpart ["."]
exponent     ::= ("e" | "E") [sign] digitpart
floatnumber  ::= number [exponent]
absfloatvalue ::= floatnumber | infinity | nan
floatvalue   ::= [sign] absfloatvalue
```

字母大小寫不影響，例如，“inf”、“Inf”、“INFINITY”、“iNfINity”都可以表示正無窮大。

否則，如果引數是整數或浮點數，則回傳具有相同值（在 Python 浮點精度範圍內）的浮點數。如果引數在 Python 浮點精度範圍外，則會引發 `OverflowError`。

對於一般的 Python 物件 *x*，`float(x)` 會委派給 `x.__float__()`。如果未定義 `__float__()` 則會回退到 `__index__()`。

如果沒有引數，則回傳 0.0。

數值型 --- *int*、*float*、*complex* 描述了浮點數型。

在 3.6 版的變更：可以使用底標將程式碼文字中的數字進行分組。

在 3.7 版的變更：現在僅限位置參數。

在 3.8 版的變更：如果 `__float__()` 未定義，則會回退到 `__index__()`。

**format** (*value, format\_spec="*)

將 *value* 轉為 *format\_spec* 控制的“格式化”表示。*format\_spec* 的解釋取於 *value* 引數的型，但是大多數型使用標準格式化語法：格式規格 (*Format Specification*) 迷你語言。

預設的 `format_spec` 是一個空字串，它通常和呼叫 `str(value)` 的效果相同。

呼叫 `format(value, format_spec)` 會轉成 `type(value).__format__(value, format_spec)`，當搜尋 `value` 的 `__format__()` method 時，會忽略實例中的字典。如果搜尋到 `object` 這個 method 但 `format_spec` 不空，或是 `format_spec` 或回傳值不是字串，則會引發 `TypeError`。

在 3.4 版的變更：當 `format_spec` 不是空字串時，`object().__format__(format_spec)` 會引發 `TypeError`。

**class frozenset** (*iterable=set()*)

回傳一個新的 `frozenset` 物件，它包含選擇性引數 `iterable` 中的元素。`frozenset` 是一個建立的 class。有關此 class 的文件，請參 `frozenset` 和 `Set Types --- set, frozenset`。

請參建立的 `set`、`list`、`tuple` 和 `dict` class，以及 `collections` module 來了解其它的容器。

**getattr** (*object, name*)

**getattr** (*object, name, default*)

回傳 `object` 之具名屬性的值。`name` 必須是字串。如果該字串是物件屬性之一的名稱，則回傳該屬性的值。例如，`getattr(x, 'foobar')` 等同於 `x.foobar`。如果指定的屬性不存在，且提供了 `default` 值，則回傳其值，否則引發 `AttributeError`。`name` 不必是個 Python 識符 (identifier) (請見 `setattr()`)。

#### 備

由於私有名稱改編 (private name mangling) 是發生在編譯期，因此你必須手動改編私有屬性 (有兩個前導底底 (的屬性) 的名稱，才能使用 `getattr()` 來取得它。

**globals** ()

回傳代表當前 module 命名空間的 dictionary。對於在函式中的程式碼來，這在定義函式時設定且不論該函式是在何處呼叫都會保持相同。

**hasattr** (*object, name*)

該引數是一個物件和一個字串。如果字串是物件屬性之一的名稱，則回傳 `True`，否則回傳 `False`。(此功能是透過呼叫 `getattr(object, name)` 檢查是否引發 `AttributeError` 來實作的。)

**hash** (*object*)

回傳該物件的雜值 (如果它有的話)。雜值是整數。它們在 dictionary 查詢元素時用來快速比較 dictionary 的鍵。相同大小的數字數值有相同的雜值 (即使它們型不同，如 1 和 1.0)。

#### 備

請注意，如果物件帶有自訂的 `__hash__()` 方法，`hash()` 將根據運行機器的位元長度來截斷回傳值。

**help** ()

**help** (*request*)

動的幫助系統 (此函式主要以互動式使用)。如果有引數，直譯器控制台會動互動式幫助系統。如果引數是一個字串，則會在 module、函式、class、method、關鍵字或明文件主題中搜索該字串，在控制台上列印幫助資訊。如果引數是其他任意物件，則會生成該物件的幫助頁。

請注意，呼叫 `help()` 時，如果斜 (/) 出現在函式的參數列表中，這表示斜前面的參數是僅限位置 (positional-only) 參數。有關更多資訊，請參常見問答集中的僅限位置參數條目。

此函式會被 `site` module 加入到命名空間。

在 3.4 版的變更：對於 `pydoc` 和 `inspect` 的變更，使得可呼叫物件回報的的簽名 (signature) 更加全面和一致。

**hex(x)**

將整數轉以“0x”前綴的小寫十六進位制字串。如果 *x* 不是 Python *int* 物件，則必須定義一個 `__index__()` method 且回傳一個整數。舉例來：

```
>>> hex(255)
'0xff'
>>> hex(-42)
'-0x2a'
```

如果要將整數轉大寫或小寫的十六進位制字串，可選擇有無“0x”前綴，則可以使用如下方法：

```
>>> '%#x' % 255, '%x' % 255, '%X' % 255
('0xff', 'ff', 'FF')
>>> format(255, '#x'), format(255, 'x'), format(255, 'X')
('0xff', 'ff', 'FF')
>>> f'{255:#x}', f'{255:x}', f'{255:X}'
('0xff', 'ff', 'FF')
```

可參考 `format()` 獲取更多資訊。

另請參 `int()` 將十六進位制字串轉以 16 基數的整數。

**備**

如果要獲取浮點數的十六進位制字串形式，請使用 `float.hex()` method。

**id(object)**

回傳物件的“識性”。該值是一個整數，在此物件的生命期中保證是唯一且固定的。兩個生命期不重疊的物件可能具有相同的 `id()` 值。

這是該物件在記憶體中的位址。

引發一個附帶引數 `id` 的稽核事件 `builtins.id`。

**input()****input(prompt)**

如果有提供 *prompt* 引數，則將其寫入標準輸出，末尾不帶行符。接下來，該函式從輸入中讀取一行，將其轉字串（去除末尾的行符）回傳。當讀取到 EOF 時，則引發 `EOFError`。例如：

```
>>> s = input('--> ')
--> Monty Python's Flying Circus
>>> s
"Monty Python's Flying Circus"
```

如果載入了 `readline module`，`input()` 將使用它來提供雜的行編輯和歷史記功能。

引發一個附帶讀取輸入前的引數 `prompt` 的稽核事件 `builtins.input`。

引發一個附帶成功讀取結果的稽核事件 `builtins.input/result`。

**class int(number=0, /)****class int(string, /, base=10)**

Return an integer object constructed from a number or a string, or return 0 if no arguments are given.

例如：

```
>>> int(123.45)
123
>>> int('123')
123
```

(繼續下一頁)

(繼續上一頁)

```

>>> int(' -12_345\n')
-12345
>>> int('FACE', 16)
64206
>>> int('0xface', 0)
64206
>>> int('01110011', base=2)
115

```

如果引數定義了 `__int__()`，則 `int(x)` 回傳 `x.__int__()`。如果引數定義了 `__index__()` 則回傳 `x.__index__()`。如果引數定義了 `__trunc__()` 則回傳 `x.__trunc__()`。對於浮點數，則會向零的方向無條件舍去。

如果引數不是數字或如果有給定 `base`，則它必須是個字串、`bytes` 或 `bytearray` 實例，表示基數 (radix) `base` 中的整數。可選地，字串之前可以有 `+` 或 `-` (中間有 `\` 有 )、可有個前導的零、也可被  包圍、或在數字間有單一底 `\`。

一個 `n` 進制的整數字串，包含各個代表 0 到 `n-1` 的數字，0-9 可以用任何 Unicode 十進制數字表示，10-35 可以用 `a` 到 `z` (或 `A` 到 `Z`) 表示。預設的 `base` 是 10。允許的進位制有 0、2-36。2、8、16 進位制的字串可以在程式碼中用 `0b/0B`、`0o/0O`、`0x/0X` 前綴來表示，如同程式碼中的整數文字。進位制 `0` 的字串將以和程式碼整數字面值 (integer literal in code) 類似的方式來直譯，最後由前綴 `\` 定的結果會是 2、8、10、16 進制中的一個，所以 `int('010', 0)` 是非法的，但 `int('010')` 和 `int('010', 8)` 是有效的。

整數型 `\` 定義請參 `\` 數值型 `\` --- `int`、`float`、`complex`。

在 3.4 版的變更: 如果 `base` 不是 `int` 的實例，但 `base` 物件有 `base.__index__ method`，則會呼叫該 `method` 來獲取此進位制所需的整數。以前的版本使用 `base.__int__` 而不是 `base.__index__`。

在 3.6 版的變更: 可以使用底 `\` 將程式碼文字中的數字進行分組。

在 3.7 版的變更: 第一個參數 `\` 僅限位置參數。

在 3.8 版的變更: 如果未定義 `__int__()` 則會回退到 `__index__()`。

在 3.11 版的變更: 對 `__trunc__()` 的委派已 `\` 用。

在 3.11 版的變更: `int` 的字串輸入和字串表示法可以被限制，以避免阻斷服務攻擊 (denial of service attack)。在字串 `x` 轉 `\` `int` 時已超出限制，或是在 `int` 轉 `\` 字串時將會超出限制時，會引發 `ValueError`。請參 `\` 整數字串轉 `\` 的長度限制 `\` 明文件。

### `isinstance(object, classinfo)`

如果 `object` 引數是 `classinfo` 引數的實例，或者是 (直接、間接或 `virtual`) subclass 的實例，則回傳 `True`。如果 `object` 不是給定型 `\` 的物件，函式始終回傳 `False`。如果 `classinfo` 是包含物件型 `\` 的 `tuple` (或多個遞 `\` `tuple`) 或一個包含多種型 `\` 的聯合型 `\` (`Union Type`)，若 `object` 是其中的任何一個物件的實例則回傳 `True`。如果 `classinfo` 既不是型 `\`，也不是型 `\` `tuple` 或型 `\` 的遞 `\` `tuple`，那 `\` 會引發 `TypeError` `\` 常。若是先前檢查已經成功，`TypeError` 可能不會再因 `\` 不合格的型 `\` 而被引發。

在 3.10 版的變更: `classinfo` 可以是一個聯合型 `\` (`Union Type`)。

### `issubclass(class, classinfo)`

如果 `class` 是 `classinfo` 的 subclass (直接、間接或 `virtual`)，則回傳 `True`。`classinfo` 可以是 `class` 物件的 `tuple` (或遞 `\` 地其他類似 `tuple`) 或是一個聯合型 `\` (`Union Type`)，此時若 `class` 是 `classinfo` 中任一元素的 subclass 時則回傳 `True`。其他情 `\`，會引發 `TypeError`。

在 3.10 版的變更: `classinfo` 可以是一個聯合型 `\` (`Union Type`)。

### `iter(object)`

#### `iter(object, sentinel)`

回傳一個 `iterator` 物件。根據是否存在第二個引數，第一個引數的意義是非常不同的。如果 `\` 有第二個引數，`object` 必須是支援 `iterable` 協定 (有 `__iter__()` `method`) 的集物件，或必須支援序列協定 (有 `__getitem__()` 方法，且數字引數從 0 開始)。如果它不支援這些協定，會引發 `TypeError`。如果有第二個引數 `sentinel`，那 `\` `object` 必須是可呼叫的物件，這種情 `\` 下生成的 `iterator`，每次 `\`

代呼叫 `__next__()` 時會不帶引數地呼叫 *object*；如果回傳的結果是 *sentinel* 則引發 `StopIteration`，否則回傳呼叫結果。

另請參 代器型。

`iter()` 的第二種形式有一個好用的應用，是能 建立一個區塊 讀器 (block-reader)。例如，從二進位資料庫檔案中讀取固定寬度的區塊，直到檔案的結尾：

```
from functools import partial
with open('mydata.db', 'rb') as f:
    for block in iter(partial(f.read, 64), b''):
        process_block(block)
```

### `len(s)`

回傳物件的長度 (元素個數)。引數可以是序列 (如 `string`、`bytes`、`tuple`、`list` 或 `range`) 或集合 (如 `dictionary`、`set` 或 `frozen set`)。

如果物件長度大於 `sys.maxsize`，像是 `range(2 ** 100)`，則 `len` 會引發 `OverflowError`。

### `class list`

#### `class list (iterable)`

除了是函式，`list` 也是可變序列型，詳情請參 `List (串列)` 和 `Sequence Types --- list, tuple, range`。

### `locals()`

Return a mapping object representing the current local symbol table, with variable names as the keys, and their currently bound references as the values.

At module scope, as well as when using `exec()` or `eval()` with a single namespace, this function returns the same namespace as `globals()`.

At class scope, it returns the namespace that will be passed to the metaclass constructor.

When using `exec()` or `eval()` with separate local and global arguments, it returns the local namespace passed in to the function call.

In all of the above cases, each call to `locals()` in a given frame of execution will return the *same* mapping object. Changes made through the mapping object returned from `locals()` will be visible as assigned, reassigned, or deleted local variables, and assigning, reassigned, or deleting local variables will immediately affect the contents of the returned mapping object.

In an *optimized scope* (including functions, generators, and coroutines), each call to `locals()` instead returns a fresh dictionary containing the current bindings of the function's local variables and any nonlocal cell references. In this case, name binding changes made via the returned dict are *not* written back to the corresponding local variables or nonlocal cell references, and assigning, reassigned, or deleting local variables and nonlocal cell references does *not* affect the contents of previously returned dictionaries.

Calling `locals()` as part of a comprehension in a function, generator, or coroutine is equivalent to calling it in the containing scope, except that the comprehension's initialised iteration variables will be included. In other scopes, it behaves as if the comprehension were running as a nested function.

Calling `locals()` as part of a generator expression is equivalent to calling it in a nested generator function.

在 3.12 版的變更: The behaviour of `locals()` in a comprehension has been updated as described in [PEP 709](#).

在 3.13 版的變更: As part of [PEP 667](#), the semantics of mutating the mapping objects returned from this function are now defined. The behavior in *optimized scopes* is now as described above. Aside from being defined, the behaviour in other scopes remains unchanged from previous versions.

### `map(function, iterable, *iterables)`

生一個將 *function* 應用於 *iterable* 中所有元素， 收集回傳結果的 iterator。如果傳遞了額外的 *iterables* 引數，則 *function* 必須接受相同個數的引數， 使用所有從 *iterables* 中同時獲取的元素。當

有多個 iterables 時，最短的 iterable 耗盡時 iterator 也會結束。如果函式的輸入已經被編排引數的 tuple，請參 `itertools.starmap()`。

**max** (*iterable*, \*, *key=None*)

**max** (*iterable*, \*, *default*, *key=None*)

**max** (*arg1*, *arg2*, \**args*, *key=None*)

回傳 iterable 中最大的元素，或者回傳兩個以上的引數中最大的。

如果只提供了一個位置引數，它必須是個 *iterable*，iterable 中最大的元素會被回傳。如果提供了兩個或以上的位置引數，則回傳最大的位置引數。

這個函式有兩個選擇性的僅限關鍵字引數。*key* 引數能指定單一引數所使用的排序函式，如同 `list.sort()` 的使用方式。*default* 引數是當 iterable 空時回傳的物件。如果 iterable 空，且有提供 *default*，則會引發 `ValueError`。

如果有多個最大元素，則此函式將回傳第一個找到的。這和其他穩定排序工具如 `sorted(iterable, key=keyfunc, reverse=True)[0]` 和 `heapq.nlargest(1, iterable, key=keyfunc)` 一致。

在 3.4 版的變更: 新增 *default* 僅限關鍵字參數。

在 3.8 版的變更: *key* 可以 `None`。

**class memoryview** (*object*)

回傳由給定的引數所建立之「memory view (記憶體檢視)」物件。有關詳細資訊，請參 [Memory Views](#)。

**min** (*iterable*, \*, *key=None*)

**min** (*iterable*, \*, *default*, *key=None*)

**min** (*arg1*, *arg2*, \**args*, *key=None*)

回傳 iterable 中最小的元素，或者回傳兩個以上的引數中最小的。

如果只提供了一個位置引數，它必須是個 *iterable*，iterable 中最小的元素會被回傳。如果提供了兩個或以上的位置引數，則回傳最小的位置引數。

這個函式有兩個選擇性的僅限關鍵字引數。*key* 引數能指定單一引數所使用的排序函式，如同 `list.sort()` 的使用方式。*default* 引數是當 iterable 空時回傳的物件。如果 iterable 空，且有提供 *default*，則會引發 `ValueError`。

如果有多個最小元素，則此函式將回傳第一個找到的。這和其他穩定排序工具如 `sorted(iterable, key=keyfunc)[0]` 和 `heapq.nsmallest(1, iterable, key=keyfunc)` 一致。

在 3.4 版的變更: 新增 *default* 僅限關鍵字參數。

在 3.8 版的變更: *key* 可以 `None`。

**next** (*iterator*)

**next** (*iterator*, *default*)

透過呼叫 *iterator* 的 `__next__()` method 獲取下一個元素。如果 *iterator* 耗盡，則回傳給定的預設值 *default*，如果 *iterator* 有預設值則引發 `StopIteration`。

**class object**

這是所有其他 class 的基礎，它具有所有 Python class 實例的通用 method。當建構函式被呼叫時，它會回傳一個新的有特徵 (featureless) 的物件。這個建構函式不接受任何引數。

#### 備註

由於 `object` 實例有 `__dict__` 屬性，因此無法將任意屬性賦給 `object` 的實例。

**oct** (*x*)

將一個整數轉變為一個前綴“0o”的八進位制字串。回傳結果是一個有效的 Python 運算式。如果 *x* 不是 Python 的 `int` 物件，那它需要定義 `__index__()` method 回傳一個整數。舉例來：

```
>>> oct(8)
'0o10'
>>> oct(-56)
'-0o70'
```

如果要將整數轉為八進位制字串，不論是否具備“0o”前綴，都可以使用下面的方法。

```
>>> '%#o' % 10, '%o' % 10
('0o12', '12')
>>> format(10, '#o'), format(10, 'o')
('0o12', '12')
>>> f'{10:#o}', f'{10:o}'
('0o12', '12')
```

可參考 `format()` 獲取更多資訊。

**open** (*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)

開 `file` 回傳對應的檔案物件。如果該檔案不能開，則引發 `OSError`。關於使用此函式的更多方法，請參 `tut-files`。

*file* 是一個類路徑物件，是將被開之檔案的路徑（對路徑或當前工作目的相對路徑），或是要被包裝 (wrap) 檔案的整數檔案描述器 (file descriptor)。（如果有給定檔案描述器，它會隨著回傳的 I/O 物件關閉而關閉，除非 `closefd` 被設 `False`。）

*mode* 是一個選擇性字串，用於指定開檔案的模式。預設值是 `'r'`，這意味著它以文字模式開讀。其他常見模式有：寫入 `'w'`（會舍去已經存在的檔案）、唯一性建立 `'x'`、追加寫入 `'a'`（在一些 Unix 系統上，無論當前的檔案指標在什麼位置，所有寫入都會追加到檔案末尾）。在文字模式，如果有指定 *encoding*，則根據電腦平臺來定使用的編碼：呼叫 `locale.getencoding()` 來獲取當前的本地編碼。（要讀取和寫入原始 bytes，請使用二進位制模式且不要指定 *encoding*。）可用的模式有：

字元	意義
'r'	讀取（預設）
'w'	寫入，會先清除檔案內容
'x'	唯一性建立，如果文件已存在則會失敗
'a'	寫入，如果檔案存在則在其末端附加內容
'b'	二進制模式
't'	文字模式（預設）
'+'	更新（讀取和寫入）

預設的模式是 `'r'`（開讀取文字，同 `'rt'`）。`'w+'` 和 `'w+b'` 模式會開清除檔案。`'r+'` 和 `'r+b'` 模式會開且保留檔案內容。

如總覽中所述，Python 能區分二進制和文字 I/O。在二進制模式下開的檔案（*mode* 引數中含有 `'b'`）會將其內容以 `bytes` 物件回傳，而不進行任何解碼。在文字模式（預設情況，或當 *mode* 引數中含有 `'t'`），檔案的內容會以 `str` 回傳，其位元組已經先被解碼，使用的是取於平台的編碼系統或是給定的 *encoding*。

**備**

Python 不會使用底層作業系統對於文字檔案的操作概念；所有的處理都是由 Python 獨自完成的，因此能獨立於不同平台。

*buffering* 是一個選擇性的整數，用於設定緩衝策略。傳入 0 表示關閉緩衝（僅在二進制模式下被允許），1 表示行緩衝 (line buffering, 僅在文字模式下可用)，而  $>1$  的整數是指示一個大小固定的區塊

緩衝區 (chunk buffer), 其位元組的數量。請注意, 此類指定緩衝區大小的方式適用於二進制緩衝 I/O, 但是 `TextIOWrapper` (以 `mode='r+'` 開的檔案) 會有另一種緩衝方式。若要在 `TextIOWrapper` 中停用緩衝, 可考慮使用 `io.TextIOWrapper.reconfigure()` 的 `write_through` 旗標。若未給定 `buffering` 引數, 則預設的緩衝策略會運作如下:

- 二進制檔案會以固定大小的區塊進行緩衝; 緩衝區的大小是使用發式嘗試 (heuristic trying) 來定底層設備的「區塊大小」, 會回退到 `io.DEFAULT_BUFFER_SIZE`。在許多系統上, 緩衝區的長度通常 4096 或 8192 個位元組。
- 「互動式」文字檔 (`isatty()` 回傳 `True` 的檔案) 會使用列緩衝。其他文字檔則使用上述的二進制檔案緩衝策略。

`encoding` 是用於解碼或編碼檔案的編碼系統之名稱。它只應該在文字模式下使用。預設的編碼系統會取於平台 (根據 `locale.getencoding()` 回傳的內容), 但 Python 支援的任何 `text encoding` (文字編碼) 都是可以使用的。關於支援的編碼系統清單, 請參 `codecs` module。

`errors` 是一個選擇性的字串, 用於指定要如何處理編碼和解碼的錯誤——它不能在二進制模式下使用。有許多不同的標準錯誤處理程式 (error handler, 在 `Error Handlers` 有列出清單), 不過任何已到 `codecs.register_error()` 的錯誤處理程式名稱也都是有效的。標準的名稱包括:

- 'strict' 如果發生編碼錯誤, 則引發 `ValueError` 例外。預設值 `None` 也有相同的效果。
- 'ignore' 忽略錯誤。請注意, 忽略編碼錯誤可能導致資料遺失。
- 'replace' 會在格式不正確的資料位置插入一個替標 (像是 '?')。
- 'surrogateescape' 會將任何不正確的位元組表示成低位代理碼元 (low surrogate code unit), 範圍從 `U+DC80` 到 `U+DCFF`。在寫入資料時, 這些代理碼元將會被還原回 `surrogateescape` 錯誤處理程式當時所處理的那些相同位元組。這對於處理未知編碼方式的檔案會很好用。
- 'xmlcharrefreplace' 僅在寫入檔案時可支援。編碼系統不支援的字元會被替成適當的 XML 字元參考 (character reference) `&#nnn;`。
- 'backslashreplace' 會用 Python 的反斜跳序列 (backslashed escape sequence) 替成格式不正確的資料。
- 'namereplace' (也僅在寫入時支援) 會將不支援的字元替成 `\N{...}` 跳序列。

`newline` 會定如何剖析資料串流 (stream) 中的行字元。它可以是 `None`、`''`、`'\n'`、`'\r'` 或 `'\r\n'`。它的運作規則如下:

- 從資料串流讀取輸入時, 如果 `newline` 是 `None`, 則會用通用行模式。輸入資料中的行結尾可以是 `'\n'`、`'\r'` 或 `'\r\n'`, 這些符號會被轉成 `'\n'` 之後再回傳給呼叫方。如果是 `''`, 也會用通用行模式, 但在回傳給呼叫方時, 行尾符號不會被轉。如果它是任何其他有效的值, 則輸入資料的行只會由給定的字串做結尾, 且在回傳給呼叫方時, 行尾符號不會被轉。
- 將輸出寫入資料串流時, 如果 `newline` 是 `None`, 則被寫入的任何 `'\n'` 字元都會轉成系統預設的行分隔符號 `os.linesep`。如果 `newline` 是 `''` 或 `'\n'`, 則不做任何轉。如果 `newline` 是任何其他有效的值, 則寫入的任何 `'\n'` 字元都將轉成給定的字串。

如果 `closefd` 是 `False`, 且給定的 `file` 引數是一個檔案描述器而不是檔名, 則當檔案關閉時, 底層的檔案描述器會保持開狀態。如果有給定一個檔名, 則 `closefd` 必須是 `True` (預設值); 否則將引發錯誤。

透過以 `opener` 傳遞一個可呼叫物件, 就可以自訂開函式。然後透過以引數 (`file, flags`) 呼叫 `opener`, 就能取得檔案物件的底層檔案描述器。`opener` 必須回傳一個開的檔案描述器 (將 `os.open` 作 `opener` 傳入, 在功能上的結果會相當於傳入 `None`)。

新建立的檔案是不可繼承的。

下面的範例使用 `os.open()` 函式回傳值當作 `dir_fd` 的參數, 從給定的目錄中用相對路徑開檔案:

```
>>> import os
>>> dir_fd = os.open('somedir', os.O_RDONLY)
>>> def opener(path, flags):
...     return os.open(path, flags, dir_fd=dir_fd)
```

(繼續下一頁)

(繼續上一頁)

```

...
>>> with open('spampam.txt', 'w', opener=opener) as f:
...     print('This will be written to somedir/spampam.txt', file=f)
...
>>> os.close(dir_fd) # don't leak a file descriptor

```

`open()` 函式回傳的 *file object* 型取於模式。當 `open()` 是在文字模式中開檔案時 ('w'、'r'、'wt'、'rt' 等)，它會回傳 `io.TextIOBase` 的一個 subclass (具體來，就是 `io.TextIOWrapper`)。使用有緩衝的二進制模式開檔案時，回傳的 class 則會是 `io.BufferedIOBase` 的 subclass。確切的 class 各不相同：在讀取的二進制模式，它會回傳 `io.BufferedReader`；在寫入和附加的二進制模式，它會回傳 `io.BufferedWriter`，而在讀 / 寫模式，它會回傳 `io.BufferedRandom`。當緩衝被停用時，會回傳原始資料串流 `io.FileIO`，它是 `io.RawIOBase` 的一個 subclass。

另請參檔案操作模組，例如 `fileinput`、`io` (定義了 `open()` 的 module)、`os`、`os.path`、`tempfile` 以及 `shutil`。

引發一個附帶引數 `path`、`mode`、`flags` 的稽核事件 `open`。

`mode` 和 `flags` 引數可能會被原始的呼叫所修改或推論 (infer)。

在 3.3 版的變更：

- 增加了 `opener` 參數。
- 增加了 'x' 模式。
- 過去引發的 `IOError`，現在是 `OSError` 的別名。
- 如果檔案已存在但使用了唯一性建立模式 ('x')，現在會引發 `FileExistsError`。

在 3.4 版的變更：

- 檔案在此版本開始是不可繼承的。

在 3.5 版的變更：

- 如果系統呼叫被中斷，但訊號處理程式有引發例外，此函式現在會重試系統呼叫，而不是引發 `InterruptedError` 例外 (原因詳見 [PEP 475](#))。
- 增加了 'namereplace' 錯誤處理程式。

在 3.6 版的變更：

- 增加對於實作 `os.PathLike` 物件的支援。
- 在 Windows 上，開一個控制臺緩衝區可能會回傳 `io.RawIOBase` 的 subclass，而不是 `io.FileIO`。

在 3.11 版的變更：'U' 模式被移除。

### `ord(c)`

對於代表單個 Unicode 字元的字串，回傳代表它 Unicode 編碼位置的整數。例如 `ord('a')` 回傳整數 97、`ord('€')` (歐元符號) 回傳 8364。這是 `chr()` 的逆函式。

### `pow(base, exp, mod=None)`

回傳 `base` 的 `exp` 次方；如果 `mod` 存在，則回傳 `base` 的 `exp` 次方對 `mod` 取余數 (比直接呼叫 `pow(base, exp) % mod` 計算更高效)。兩個引數形式的 `pow(exp, exp)` 等價於次方運算子：`base**exp`。

引數必須是數值型。對於混合型運算元，會套用二元算術運算子的制轉型 (coercion) 規則。對於 `int` 運算元，運算結果會 (在制轉型後) 與運算元的型相同，除非第二個引數是負數；在這種情況下，所有的引數都會被轉成浮點數得到浮點數的結果。例如，`pow(10, 2)` 會回傳 100，但 `pow(10, -2)` 會回傳 0.01。如果底數 (base) 是型 `int` 或 `float` 的負數且指數 (exponent) 不是整數，則會得到一個數的結果，例如 `pow(-9, 0.5)` 會回傳一個接近  $3j$  的值。如果底數 (base) 是型 `int` 或 `float` 的負數且指數整數，則會得到一個浮點數的結果，例如 `pow(-9, 2.0)` 會回傳 81.0。

對於 `int` 運算元 `base` 和 `exp`，如果有給定 `mod`，則 `mod` 也必須是整數型，且 `mod` 必須不零。如果有給定 `mod` 且 `exp` 負，則 `base` 必須與 `mod` 互質。在這種情況下，會回傳 `pow(inv_base, -exp, mod)`，其中 `inv_base` 是 `base` 對 `mod` 的模倒數 (inverse modulo)。

以下是一個計算 38 對 97 取模倒數的範例：

```
>>> pow(38, -1, mod=97)
23
>>> 23 * 38 % 97 == 1
True
```

在 3.8 版的變更：對於 `int` 運算元，現在 `pow` 的三引數形式允許第二個引數負數，也容許模倒數的計算。

在 3.8 版的變更：允許關鍵字引數。在此之前只支援位置引數。

`print(*objects, sep=',', end='\n', file=None, flush=False)`

將 `objects` 列印到文字資料串流 `file`，用 `sep` 分隔以 `end` 結尾。如果有給定 `sep`、`end`、`file` 和 `flush`，那它們必須是關鍵字引數的形式。

所有的非關鍵字引數都會像是 `str()` 操作一樣地被轉成字串，寫入資料串流，彼此以 `sep` 分隔，以 `end` 結尾。`sep` 和 `end` 都必須是字串；它們也可以是 `None`，這表示使用預設值。如果有給定 `objects`，`print()` 就只會寫入 `end`。

`file` 引數必須是一個有 `write(string)` method 的物件；如果有給定或被設 `None`，則將使用 `sys.stdout`。因要列印的引數會被轉成文字字串，所以 `print()` 不能用於二進位模式的檔案物件。對於此類物件，請改用 `file.write(...)`。

輸出緩衝通常會由 `file` 決定。但是如果 `flush` `True`，則資料串流會被制清除。

在 3.3 版的變更：增加了 `flush` 關鍵字引數。

`class property(fget=None, fset=None, fdel=None, doc=None)`

回傳 `property` 屬性。

`fget` 是一個用於取得屬性值的函式，`fset` 是一個用於設定屬性值的函式，`fdel` 是一個用於刪除屬性值的函式，而 `doc` 會為該屬性建立一個說明字串。

一個典型的用途是定義一個受管理的屬性 `x`：

```
class C:
    def __init__(self):
        self._x = None

    def getx(self):
        return self._x

    def setx(self, value):
        self._x = value

    def delx(self):
        del self._x

x = property(getx, setx, delx, "I'm the 'x' property.")
```

如果 `c` 是 `C` 的一個實例，則 `c.x` 將會呼叫取得器 (getter)，`c.x = value` 會呼叫設定器 (setter)，而 `del c.x` 會呼叫刪除器 (deleter)。

如果有給定 `doc`，它將會是 `property` 屬性的說明字串。否則，`property` 會為 `fget` 的說明字串（如果它存在的話）。這樣一來，就能輕鬆地使用 `property()` 作裝飾器來建立唯讀屬性：

```
class Parrot:
    def __init__(self):
        self._voltage = 100000
```

(繼續下一頁)

```
@property
def voltage(self):
    """Get the current voltage."""
    return self._voltage
```

The `@property` decorator turns the `voltage()` method into a “getter” for a read-only attribute with the same name, and it sets the docstring for `voltage` to “Get the current voltage.”

**@getter**

**@setter**

**@deleter**

A property object has `getter`, `setter`, and `deleter` methods usable as decorators that create a copy of the property with the corresponding accessor function set to the decorated function. This is best explained with an example:

```
class C:
    def __init__(self):
        self._x = None

    @property
    def x(self):
        """I'm the 'x' property."""
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x
```

This code is exactly equivalent to the first example. Be sure to give the additional functions the same name as the original property (`x` in this case.)

The returned property object also has the attributes `fget`, `fset`, and `fdel` corresponding to the constructor arguments.

在 3.5 版的變更: The docstrings of property objects are now writeable.

**\_\_name\_\_**

Attribute holding the name of the property. The name of the property can be changed at runtime.

在 3.13 版被加入.

**class range (stop)**

**class range (start, stop, step=1)**

Rather than being a function, `range` is actually an immutable sequence type, as documented in *Ranges and Sequence Types --- list, tuple, range*.

**repr (object)**

Return a string containing a printable representation of an object. For many types, this function makes an attempt to return a string that would yield an object with the same value when passed to `eval()`; otherwise, the representation is a string enclosed in angle brackets that contains the name of the type of the object together with additional information often including the name and address of the object. A class can control what this function returns for its instances by defining a `__repr__()` method. If `sys.displayhook()` is not accessible, this function will raise `RuntimeError`.

This class has a custom representation that can be evaluated:

```
class Person:
    def __init__(self, name, age):
        self.name = name
        self.age = age

    def __repr__(self):
        return f"Person('{self.name}', {self.age})"
```

**reversed** (*seq*)

Return a reverse *iterator*. *seq* must be an object which has a `__reversed__()` method or supports the sequence protocol (the `__len__()` method and the `__getitem__()` method with integer arguments starting at 0).

**round** (*number*, *ndigits=None*)

Return *number* rounded to *ndigits* precision after the decimal point. If *ndigits* is omitted or is `None`, it returns the nearest integer to its input.

For the built-in types supporting `round()`, values are rounded to the closest multiple of 10 to the power minus *ndigits*; if two multiples are equally close, rounding is done toward the even choice (so, for example, both `round(0.5)` and `round(-0.5)` are 0, and `round(1.5)` is 2). Any integer value is valid for *ndigits* (positive, zero, or negative). The return value is an integer if *ndigits* is omitted or `None`. Otherwise, the return value has the same type as *number*.

For a general Python object *number*, `round` delegates to `number.__round__`.

**i** 備 F

The behavior of `round()` for floats can be surprising: for example, `round(2.675, 2)` gives `2.67` instead of the expected `2.68`. This is not a bug: it's a result of the fact that most decimal fractions can't be represented exactly as a float. See `tut-fp-issues` for more information.

**class set****class set** (*iterable*)

Return a new *set* object, optionally with elements taken from *iterable*. *set* is a built-in class. See *set* and *Set Types --- set, frozenset* for documentation about this class.

For other containers see the built-in *frozenset*, *list*, *tuple*, and *dict* classes, as well as the *collections* module.

**setattr** (*object*, *name*, *value*)

This is the counterpart of `getattr()`. The arguments are an object, a string, and an arbitrary value. The string may name an existing attribute or a new attribute. The function assigns the value to the attribute, provided the object allows it. For example, `setattr(x, 'foobar', 123)` is equivalent to `x.foobar = 123`.

*name* need not be a Python identifier as defined in *identifiers* unless the object chooses to enforce that, for example in a custom `__getattribute__()` or via `__slots__`. An attribute whose name is not an identifier will not be accessible using the dot notation, but is accessible through `getattr()` etc..

**i** 備 F

Since private name mangling happens at compilation time, one must manually mangle a private attribute's (attributes with two leading underscores) name in order to set it with `setattr()`.

**class slice** (*stop*)**class slice** (*start*, *stop*, *step=None*)

Return a *slice* object representing the set of indices specified by `range(start, stop, step)`. The *start* and *step* arguments default to `None`.

**start****stop****step**

Slice objects have read-only data attributes `start`, `stop`, and `step` which merely return the argument values (or their default). They have no other explicit functionality; however, they are used by NumPy and other third-party packages.

Slice objects are also generated when extended indexing syntax is used. For example: `a[start:stop:step]` or `a[start:stop, i]`. See `itertools.islice()` for an alternate version that returns an *iterator*.

在 3.12 版的變更: Slice objects are now *hashable* (provided `start`, `stop`, and `step` are hashable).

**sorted** (*iterable*, /, \*, *key=None*, *reverse=False*)

Return a new sorted list from the items in *iterable*.

有兩個選擇性引數，只能使用關鍵字引數來指定。

*key* specifies a function of one argument that is used to extract a comparison key from each element in *iterable* (for example, `key=str.lower`). The default value is `None` (compare the elements directly).

*reverse* is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

Use `functools.cmp_to_key()` to convert an old-style *cmp* function to a *key* function.

The built-in `sorted()` function is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal --- this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

The sort algorithm uses only `<` comparisons between items. While defining an `__lt__()` method will suffice for sorting, **PEP 8** recommends that all six rich comparisons be implemented. This will help avoid bugs when using the same data with other ordering tools such as `max()` that rely on a different underlying method. Implementing all six comparisons also helps avoid confusion for mixed type comparisons which can call reflected the `__gt__()` method.

For sorting examples and a brief sorting tutorial, see `sortinghowto`.

**@staticmethod**

Transform a method into a static method.

A static method does not receive an implicit first argument. To declare a static method, use this idiom:

```
class C:
    @staticmethod
    def f(arg1, arg2, argN): ...
```

`@staticmethod` 語法是一個函式 *decorator* - 參見 `function` 中的詳細介紹。

A static method can be called either on the class (such as `C.f()`) or on an instance (such as `C().f()`). Moreover, the static method *descriptor* is also callable, so it can be used in the class definition (such as `f()`).

Static methods in Python are similar to those found in Java or C++. Also, see `classmethod()` for a variant that is useful for creating alternate class constructors.

Like all decorators, it is also possible to call `staticmethod` as a regular function and do something with its result. This is needed in some cases where you need a reference to a function from a class body and you want to avoid the automatic transformation to instance method. For these cases, use this idiom:

```
def regular_function():
    ...

class C:
    method = staticmethod(regular_function)
```

關於 `static method` 的更多資訊，請參考 `types`。

在 3.10 版的變更: `Static method` 現在繼承了 `method` 屬性 (`__module__`、`__name__`、`__qualname__`、`__doc__` 和 `__annotations__`)，☐擁有一個新的 `__wrapped__` 屬性，且☐如一般函式的可呼叫物件。

```
class str (object=)
```

```
class str (object=b", encoding='utf-8', errors='strict')
```

Return a `str` version of `object`. See `str()` for details.

`str` is the built-in string *class*. For general information about strings, see *Text Sequence Type --- str*.

```
sum (iterable, /, start=0)
```

Sums `start` and the items of an *iterable* from left to right and returns the total. The *iterable*'s items are normally numbers, and the start value is not allowed to be a string.

For some use cases, there are good alternatives to `sum()`. The preferred, fast way to concatenate a sequence of strings is by calling `''.join(sequence)`. To add floating-point values with extended precision, see `math.fsum()`. To concatenate a series of iterables, consider using `itertools.chain()`.

在 3.8 版的變更: `start` 參數可被指定☐關鍵字引數。

在 3.12 版的變更: Summation of floats switched to an algorithm that gives higher accuracy and better commutativity on most builds.

```
class super
```

```
class super (type, object_or_type=None)
```

Return a proxy object that delegates method calls to a parent or sibling class of `type`. This is useful for accessing inherited methods that have been overridden in a class.

The `object_or_type` determines the *method resolution order* to be searched. The search starts from the class right after the `type`.

For example, if `__mro__` of `object_or_type` is `D -> B -> C -> A -> object` and the value of `type` is `B`, then `super()` searches `C -> A -> object`.

The `__mro__` attribute of the class corresponding to `object_or_type` lists the method resolution search order used by both `getattr()` and `super()`. The attribute is dynamic and can change whenever the inheritance hierarchy is updated.

If the second argument is omitted, the `super` object returned is unbound. If the second argument is an object, `isinstance(obj, type)` must be true. If the second argument is a type, `issubclass(type2, type)` must be true (this is useful for classmethods).

When called directly within an ordinary method of a class, both arguments may be omitted ("zero-argument `super()`"). In this case, `type` will be the enclosing class, and `obj` will be the first argument of the immediately enclosing function (typically `self`). (This means that zero-argument `super()` will not work as expected within nested functions, including generator expressions, which implicitly create nested functions.)

There are two typical use cases for `super`. In a class hierarchy with single inheritance, `super` can be used to refer to parent classes without naming them explicitly, thus making the code more maintainable. This use closely parallels the use of `super` in other programming languages.

The second use case is to support cooperative multiple inheritance in a dynamic execution environment. This use case is unique to Python and is not found in statically compiled languages or languages that only support single inheritance. This makes it possible to implement "diamond diagrams" where multiple base classes implement the same method. Good design dictates that such implementations have the same calling signature in every case (because the order of calls is determined at runtime, because that order adapts to changes in the class hierarchy, and because that order can include sibling classes that are unknown prior to runtime).

For both use cases, a typical superclass call looks like this:

```
class C(B):
    def method(self, arg):
```

(繼續下一頁)

```
super().method(arg)    # This does the same thing as:
                       # super(C, self).method(arg)
```

In addition to method lookups, `super()` also works for attribute lookups. One possible use case for this is calling *descriptors* in a parent or sibling class.

Note that `super()` is implemented as part of the binding process for explicit dotted attribute lookups such as `super().__getitem__(name)`. It does so by implementing its own `__getattr__()` method for searching classes in a predictable order that supports cooperative multiple inheritance. Accordingly, `super()` is undefined for implicit lookups using statements or operators such as `super()[name]`.

Also note that, aside from the zero argument form, `super()` is not limited to use inside methods. The two argument form specifies the arguments exactly and makes the appropriate references. The zero argument form only works inside a class definition, as the compiler fills in the necessary details to correctly retrieve the class being defined, as well as accessing the current instance for ordinary methods.

For practical suggestions on how to design cooperative classes using `super()`, see [guide to using super\(\)](#).

**class tuple**

**class tuple** (*iterable*)

Rather than being a function, `tuple` is actually an immutable sequence type, as documented in *Tuples and Sequence Types --- list, tuple, range*.

**class type** (*object*)

**class type** (*name, bases, dict, \*\*kwds*)

With one argument, return the type of an *object*. The return value is a type object and generally the same object as returned by `object.__class__`.

The `isinstance()` built-in function is recommended for testing the type of an object, because it takes subclasses into account.

With three arguments, return a new type object. This is essentially a dynamic form of the `class` statement. The *name* string is the class name and becomes the `__name__` attribute. The *bases* tuple contains the base classes and becomes the `__bases__` attribute; if empty, *object*, the ultimate base of all classes, is added. The *dict* dictionary contains attribute and method definitions for the class body; it may be copied or wrapped before becoming the `__dict__` attribute. The following two statements create identical `type` objects:

```
>>> class X:
...     a = 1
...
>>> X = type('X', (), dict(a=1))
```

See also:

- Documentation on attributes and methods on classes.
- *Type Objects*

Keyword arguments provided to the three argument form are passed to the appropriate metaclass machinery (usually `__init_subclass__()`) in the same way that keywords in a class definition (besides *metaclass*) would.

另請參閱 [class-customization](#)。

在 3.6 版的變更: Subclasses of `type` which don't override `type.__new__` may no longer use the one-argument form to get the type of an object.

**vars()**

**vars** (*object*)

Return the `__dict__` attribute for a module, class, instance, or any other object with a `__dict__` attribute.

Objects such as modules and instances have an updateable `__dict__` attribute; however, other objects may have write restrictions on their `__dict__` attributes (for example, classes use a `types.MappingProxyType` to prevent direct dictionary updates).

Without an argument, `vars()` acts like `locals()`.

A `TypeError` exception is raised if an object is specified but it doesn't have a `__dict__` attribute (for example, if its class defines the `__slots__` attribute).

在 3.13 版的變更: The result of calling this function without an argument has been updated as described for the `locals()` builtin.

`zip(*iterables, strict=False)`

Iterate over several iterables in parallel, producing tuples with an item from each one.

例如:

```
>>> for item in zip([1, 2, 3], ['sugar', 'spice', 'everything nice']):
...     print(item)
...
(1, 'sugar')
(2, 'spice')
(3, 'everything nice')
```

More formally: `zip()` returns an iterator of tuples, where the  $i$ -th tuple contains the  $i$ -th element from each of the argument iterables.

Another way to think of `zip()` is that it turns rows into columns, and columns into rows. This is similar to transposing a matrix.

`zip()` is lazy: The elements won't be processed until the iterable is iterated on, e.g. by a `for` loop or by wrapping in a `list`.

One thing to consider is that the iterables passed to `zip()` could have different lengths; sometimes by design, and sometimes because of a bug in the code that prepared these iterables. Python offers three different approaches to dealing with this issue:

- By default, `zip()` stops when the shortest iterable is exhausted. It will ignore the remaining items in the longer iterables, cutting off the result to the length of the shortest iterable:

```
>>> list(zip(range(3), ['fee', 'fi', 'fo', 'fum']))
[(0, 'fee'), (1, 'fi'), (2, 'fo')]
```

- `zip()` is often used in cases where the iterables are assumed to be of equal length. In such cases, it's recommended to use the `strict=True` option. Its output is the same as regular `zip()`:

```
>>> list(zip(('a', 'b', 'c'), (1, 2, 3), strict=True))
[('a', 1), ('b', 2), ('c', 3)]
```

Unlike the default behavior, it raises a `ValueError` if one iterable is exhausted before the others:

```
>>> for item in zip(range(3), ['fee', 'fi', 'fo', 'fum'], strict=True):
...     print(item)
...
(0, 'fee')
(1, 'fi')
(2, 'fo')
Traceback (most recent call last):
...
ValueError: zip() argument 2 is longer than argument 1
```

Without the `strict=True` argument, any bug that results in iterables of different lengths will be silenced, possibly manifesting as a hard-to-find bug in another part of the program.

- Shorter iterables can be padded with a constant value to make all the iterables have the same length. This is done by `itertools.zip_longest()`.

Edge cases: With a single iterable argument, `zip()` returns an iterator of 1-tuples. With no arguments, it returns an empty iterator.

Tips and tricks:

- The left-to-right evaluation order of the iterables is guaranteed. This makes possible an idiom for clustering a data series into *n*-length groups using `zip(*[iter(s)]*n, strict=True)`. This repeats the *same* iterator *n* times so that each output tuple has the result of *n* calls to the iterator. This has the effect of dividing the input into *n*-length chunks.
- `zip()` in conjunction with the `*` operator can be used to unzip a list:

```
>>> x = [1, 2, 3]
>>> y = [4, 5, 6]
>>> list(zip(x, y))
[(1, 4), (2, 5), (3, 6)]
>>> x2, y2 = zip(*zip(x, y))
>>> x == list(x2) and y == list(y2)
True
```

在 3.10 版的變更: 增加了 `strict` 引數。

`__import__(name, globals=None, locals=None, fromlist=(), level=0)`

### 備 F

This is an advanced function that is not needed in everyday Python programming, unlike `importlib.import_module()`.

This function is invoked by the `import` statement. It can be replaced (by importing the `builtins` module and assigning to `builtins.__import__`) in order to change semantics of the `import` statement, but doing so is **strongly** discouraged as it is usually simpler to use import hooks (see [PEP 302](#)) to attain the same goals and does not cause issues with code which assumes the default import implementation is in use. Direct use of `__import__()` is also discouraged in favor of `importlib.import_module()`.

The function imports the module *name*, potentially using the given *globals* and *locals* to determine how to interpret the name in a package context. The *fromlist* gives the names of objects or submodules that should be imported from the module given by *name*. The standard implementation does not use its *locals* argument at all and uses its *globals* only to determine the package context of the `import` statement.

*level* specifies whether to use absolute or relative imports. 0 (the default) means only perform absolute imports. Positive values for *level* indicate the number of parent directories to search relative to the directory of the module calling `__import__()` (see [PEP 328](#) for the details).

When the *name* variable is of the form `package.module`, normally, the top-level package (the name up till the first dot) is returned, *not* the module named by *name*. However, when a non-empty *fromlist* argument is given, the module named by *name* is returned.

For example, the statement `import spam` results in bytecode resembling the following code:

```
spam = __import__('spam', globals(), locals(), [], 0)
```

The statement `import spam.ham` results in this call:

```
spam = __import__('spam.ham', globals(), locals(), [], 0)
```

Note how `__import__()` returns the toplevel module here because this is the object that is bound to a name by the `import` statement.

On the other hand, the statement `from spam.ham import eggs, sausage as saus` results in

```
_temp = __import__('spam.ham', globals(), locals(), ['eggs', 'sausage'], 0)
eggs = _temp.eggs
saus = _temp.sausage
```

Here, the `spam.ham` module is returned from `__import__()`. From this object, the names to import are retrieved and assigned to their respective names.

If you simply want to import a module (potentially within a package) by name, use `importlib.import_module()`.

在 3.3 版的變更: Negative values for *level* are no longer supported (which also changes the default value to 0).

在 3.9 版的變更: When the command line options `-E` or `-I` are being used, the environment variable `PYTHONCASEOK` is now ignored.

 解

---

## ☐ 建常數

---

有一小部分的常數存在於☐建命名空間中。他們是：

### False

在`bool`型☐中的 `false` 值。對於 `False` 的賦值是不合法的，☐且會☐出 `SyntaxError`。

### True

在`bool`型☐中的 `true` 值。對於 `True` 的賦值是不合法的，☐且會☐出 `SyntaxError`。

### None

型☐ `NoneType` 的唯一值。`None` 經常被使用來表達缺少值，例如未傳送預設的引數至函式時，相對應參數即會被賦予 `None`。對於 `None` 的賦值是不合法的，☐且會☐出 `SyntaxError`。`None` 是型☐ `NoneType` 的唯一實例。

### NotImplemented

會被二元特殊方法 (binary special methods) (如: `__eq__()`、`__lt__()`、`__add__()`、`__rsub__()` 等) 所回傳的特殊值，代表著該運算☐有針對其他型☐的實作。同理也可以被原地二元特殊方法 (in-place binary special methods) (如: `__imul__()`、`__iand__()` 等) 回傳。它不應該被作☐ `boolean` (布林) 來解讀。`NotImplemented` 是型☐ `types.NotImplementedType` 的唯一實例。

#### 備☐

當一個二元 (binary) 或原地 (in-place) 方法回傳 `NotImplemented`，直譯器會嘗試反映該操作到其他型☐ (或是其他後援 (fallback)，取☐於是哪種運算子)。如果所有的常識都回傳 `NotImplemented`，直譯器會☐出適當的例外。不正確的回傳 `NotImplemented` 會造成誤導的錯誤訊息或是 `NotImplemented` 值被傳回到 Python 程式碼中。

請參見實作算術操作 以找到更多範例。

#### 警示

`NotImplemented` and `NotImplementedError` are not interchangeable. This constant should only be used as described above; see `NotImplementedError` for details on correct usage of the exception.

在 3.9 版的變更: 在 `boolean` (布林) 上下文中解讀 `NotImplemented` 已經被☐用。雖然目前會被解讀成 `true`，但會發出一個 `DeprecationWarning`。在未來版本的 Python 將會☐出 `TypeError`。

**Ellipsis**

與“節號”...”字面相同。一特殊值，大多用於結合使用者定義資料型的延伸切片語法 (extended slicing syntax)。Ellipsis 是型 `types.EllipsisType` 的唯一實例。

**\_\_debug\_\_**

如果 Python 有被以 `-O` 選項動，則此常數 `true`。請參見 `assert` 陳述式。

**i 備**

`None`, `False`, `True`, 以及 `__debug__` 都是不能被重新賦值的（任何對它們的賦值，即使是屬性的名稱，也會出 `SyntaxError`）。因此，它們可以被視“真正的”常數。

## 3.1 由 site module (模組) 所添增的常數

`site` module (模組) (在動期間自動 `import`，除非有給予 `-s` 指令行選項) 會添增一些常數到建命名空間 (built-in namespace) 中。它們在互動式直譯器中是很有幫助的，但不應該在程式 (programs) 中被使用。

**quit** (`code=None`)

**exit** (`code=None`)

當印出物件時，會印出一個訊息：“Use quit() or Ctrl-D (i.e. EOF) to exit”。當被呼叫時，則會出 `SystemExit` 帶有指定的返回碼 (exit code)。

**help**

當印出此物件時，會印出訊息“Type help() for interactive help, or help(object) for help about object.”，在呼叫時按所述的方式操作 *elsewhere*。

**copyright**

**credits**

當印出或是呼叫此物件時，分會印出版權與致謝的文字。

**license**

當印出此物件時，會印出訊息“Type license() to see the full license text”，在呼叫時以分頁形式印出完整的許可證文字（一次一整個畫面）。

---

## 建置型

---

以下章節描述了直譯器中內建的標準型。

主要建置型是數字、序列、對映、class (類)、實例和例外。

有些集合類是 `mutable` (可變的)。那些用於原地 (`in-place`) 加入、移除或重新排列其成員且不回傳特定項的 `method` (方法)，也只會回傳 `None` 而非集合實例自己。

某些操作已被多種物件型支援；特別是實務上所有物件都已經可以做相等性比較、真值檢測及被轉成字串 (使用 `repr()` 函式或稍有差別的 `str()` 函式)，後者當物件傳入 `print()` 函式印出時在背後被呼叫的函式。

### 4.1 真值檢測

任何物件都可以進行檢測以判斷是否真值，以便在 `if` 或 `while` 條件中使用，或是作如下所述 `boolean` (布林) 運算之運算元所用。

預設情況下，一個物件會被視真值，除非它的 `class` 定義了會回傳 `False` 的 `__bool__()` `method` 或是定義了會回傳零的 `__len__()` `method`。<sup>1</sup> 以下列出了大部分會被視 `false` 的建置物件：

- 定義 `false` 之常數： `None` 與 `False`
- 任何數值型的零： `0`、`0.0`、`0j`、`Decimal(0)`、`Fraction(0, 1)`
- 空的序列和集合： `''`、`()`、`[]`、`{}`、`set()`、`range(0)`

除非另有特別說明，生成 `boolean` 結果的操作或建置函式都會回傳 `0` 或 `False` 作假值、`1` 或 `True` 作真值。(重要例外：`boolean` 運算 `or` 和 `and` 回傳的是其中一個運算元。)

### 4.2 Boolean (布林) 運算 --- `and`, `or`, `not`

下方 Boolean 運算，按優先順序排序：

運算	結果	解
<code>x or y</code>	假如 <code>x</code> 真，則 <code>x</code> ，否則 <code>y</code>	(1)
<code>x and y</code>	假如 <code>x</code> 假，則 <code>x</code> ，否則 <code>y</code>	(2)
<code>not x</code>	假如 <code>x</code> 假，則 <code>True</code> ，否則 <code>False</code>	(3)

<sup>1</sup> Additional information on these special methods may be found in the Python Reference Manual (customization).

解：

- (1) 這是一個短路運算子，所以他只有在第一個引數假時，才會對第二個引數求值。
- (2) 這是一個短路運算子，所以他只有在第一個引數真時，才會對第二個引數求值。
- (3) `not` 比非 `Boolean` 運算子有較低的優先權，因此 `not a == b` 可直譯 `not (a == b)`，而 `a == not b` 會導致語法錯誤。

## 4.3 比較運算

在 Python 共有 8 種比較運算。他們的優先順序都相同（皆優先於 `Boolean` 運算）。比較運算可以任意的串連；例如，`x < y <= z` 等同於 `x < y and y <= z`，差只在於前者的 `y` 只有被求值一次（但在這兩個例子中，當 `x < y` 假時，`z` 皆不會被求值）。

這個表格統整所有比較運算：

運算	含義
<code>&lt;</code>	小於
<code>&lt;=</code>	小於等於
<code>&gt;</code>	大於
<code>&gt;=</code>	大於等於
<code>==</code>	等於
<code>!=</code>	不等於
<code>is</code>	物件識別性
<code>is not</code>	否定的物件識別性

除了不同的數值型外，不同型的物件不能進行相等比較。運算子 `==` 總有定義，但在某些物件型（例如，`class` 物件）時，運算子會等同於 `is`。其他運算子 `<`、`<=`、`>` 及 `>=` 皆僅在有意義的部分有所定義；例如，當其中一個引數假數時，將引發一個 `TypeError` 的例外。

一個 `class` 的非相同實例通常會比較不相等，除非 `class` 有定義 `__eq__()` method。

一個 `class` 的實例不可以與其他相同 `class` 的實例或其他物件型進行排序，除非 `class` 定義足 `__lt__()` 的 method，包含 `__lt__()`、`__le__()`、`__gt__()` 及 `__ge__()`（一般來，使用 `__lt__()` 及 `__eq__()` 就可以滿足常規意義上的比較運算子）。

無法自定義 `is` 與 `is not` 運算子的行；這兩個運算子也可以運用在任意兩個物件且不會引發例外。

此外，擁有相同的語法優先序的 `in` 及 `not in` 兩種運算皆被可代物件或者有實作 `__contains__()` method 的型所支援。

## 4.4 數值型 --- `int`、`float`、`complex`

數值型共有三種：整數、浮點數及 `Complex` 數。此外，`Boolean` 整數中的一個子型。整數有無限的精度。浮點數通常使用 C 面的 `double` 實作。關於在你程式所運作的機器上之浮點數的精度及部表示法可以在 `sys.float_info` 進行查找。`Complex` 數包含實數及 `Complex` 數的部分，這兩部分各自是一個浮點數。若要從一個 `Complex` 數 `z` 提取這兩部分，需使用 `z.real` 及 `z.imag`。（標準函式庫包含額外的數值型，像是 `fractions.Fraction` 表示有理數，而 `decimal.Decimal` 表示可由使用者制定精度的浮點數。）

數字是由字面數值或建公式及運算子的結果所生的。未經修飾的字面數值（含十六進位、八進位及二進位數值）會 `yield` 整數。包含小數點或指數符號的字面數值會 `yield` 浮點數。在數值後面加上 `'j'` 或是 `'J'` 會 `yield` 一個 `Complex` 數（意即一個實數 `0` 的 `Complex` 數）。你也可以將整數與浮點數相加以得到一個有實部與 `Complex` 部的 `Complex` 數。

Python 完全支援混和運算：當一個二元運算子的運算元有不同數值型時，「較窄」型的運算元會被拓寬到另一個型的運算元；在此處，整數窄於浮點數，浮點數又窄於 `Complex` 數。不同型的數字間的比較等同於這些數字的精確值進行比較。<sup>2</sup>

<sup>2</sup> As a consequence, the list `[1, 2]` is considered equal to `[1.0, 2.0]`, and similarly for tuples.

建構函式：`int()`、`float()` 及 `complex()` 可以用來生特定型的數字。

所有數值型 (除數外) 皆支援以下的運算 (有關運算的先後順序, 詳見 `operator-summary`):

運算	結果	解	完整文件
<code>x + y</code>	<code>x</code> 及 <code>y</code> 的加總		
<code>x - y</code>	<code>x</code> 及 <code>y</code> 的相		
<code>x * y</code>	<code>x</code> 及 <code>y</code> 的相乘		
<code>x / y</code>	<code>x</code> 及 <code>y</code> 相除之商		
<code>x // y</code>	<code>x</code> 及 <code>y</code> 的整數除法	(1)(2)	
<code>x % y</code>	<code>x / y</code> 的余數	(2)	
<code>-x</code>	<code>x</code> 的負數		
<code>+x</code>	<code>x</code> 不變		
<code>abs(x)</code>	<code>x</code> 的對值或量 (magnitude)		<code>abs()</code>
<code>int(x)</code>	將 <code>x</code> 轉整數	(3)(6)	<code>int()</code>
<code>float(x)</code>	將 <code>x</code> 轉浮點數	(4)(6)	<code>float()</code>
<code>complex(re, im)</code>	一個數, 其實部 <code>re</code> , 部 <code>im</code> 。 <code>im</code> 預設零。	(6)	<code>complex()</code>
<code>c.conjugate()</code>	數 <code>c</code> 的共數		
<code>divmod(x, y)</code>	一對 ( <code>x // y</code> , <code>x % y</code> )	(2)	<code>divmod()</code>
<code>pow(x, y)</code>	<code>x</code> 的 <code>y</code> 次方	(5)	<code>pow()</code>
<code>x ** y</code>	<code>x</code> 的 <code>y</code> 次方	(5)	

解:

- 也被稱整數除法。對於型 `int` 的運算元來, 結果之型會是 `int`。對於型 `float` 的運算元來, 結果之型會是 `float`。一般來, 結果會是一個整數, 但其型不一定會是 `int`。結果總是會往負無窮大的方向取整數值: `1//2` 0、`(-1)//2` -1、`1//(-2)` -1 及 `(-1)//(-2)` 0。
- 不可用於數。在適當情形下, 可使用 `abs()` 轉浮點數。
- 從 `float` 轉 `int` 會導致截斷排除小數部分。詳見 `math.floor()` 及 `math.ceil()` 以了解更多轉方式。
- 浮點數也接受帶有可選的前綴 "+" 及 "-" 的 "nan" 及 "inf" 字串, 其分代表非數字 (NaN) 及正負無窮。
- Python 將 `pow(0, 0)` 及 `0 ** 0` 定義 1 這是程式語言的普遍做法。
- 字面數值接受包含數字 0 到 9 或任何等效的 Unicode 字元 (具有 `Nd` 屬性的 `code points` (碼位))。請參 Unicode 標準以了解具有 `Nd` 屬性的 `code points` 完整列表。

所有 `numbers.Real` 型 (`int` 及 `float`) 也適用下列運算:

運算	結果
<code>math.trunc(x)</code>	<code>x</code> 截斷 <code>Integral</code>
<code>round(x[, n])</code>	<code>x</code> 進位至小數點後第 <code>n</code> 位, 使用偶數舍入法。若省略 <code>n</code> , 則預設 0。
<code>math.floor(x)</code>	小於等於 <code>x</code> 的最大 <code>Integral</code>
<code>math.ceil(x)</code>	大於等於 <code>x</code> 的最小 <code>Integral</code>

關於其他數值運算請詳見 `math` 及 `cmath` modules (模組)。

#### 4.4.1 整數型的位元運算

位元運算只對整數有意義。位元運算的計算結果就如同對二的補數執行無窮多個符號位元。

二元位元運算的優先順序皆低於數字運算, 但高於比較運算; 一元運算 ~ 與其他一元數值運算有一致的優先順序 (+ 及 -)。

這個表格列出所有位元運算以優先順序由先至後排序。

運算	結果	解
$x   y$	$x$ 及 $y$ 的位元 或	(4)
$x ^ y$	$x$ 及 $y$ 的位元 邏輯互斥或	(4)
$x \& y$	$x$ 及 $y$ 的位元 與	(4)
$x \ll n$	$x$ 往左移動 $n$ 個位元	(1)(2)
$x \gg n$	$x$ 往右移動 $n$ 個位元	(1)(3)
$\sim x$	反轉 $x$ 的位元	

解:

- (1) 負數位移是不被允許會引發 `ValueError` 的錯誤。
- (2) 向左移動  $n$  個位元等同於乘以 `pow(2, n)`。
- (3) 向右移動  $n$  個位元等同於向下除法除以 `pow(2, n)`。
- (4) 在有限的二的補數表示法中執行這些計算（一個有效位元寬度  $1 + \max(x.bit\_length(), y.bit\_length())$  或以上）至少有一個額外的符號擴展位元，便足以得到與無窮多個符號位元相同的結果。

#### 4.4.2 整數型的附加 methods

整數型實作了 `numbers.Integral` 抽象基底類。此外，它提供了一些 methods:

`int.bit_length()`

回傳以二進位表示一個整數所需要的位元數，不包括符號及首位的零:

```
>>> n = -37
>>> bin(n)
'-0b100101'
>>> n.bit_length()
6
```

更準確來，若  $x$  非零，則 `x.bit_length()` 會得出滿足  $2^{k-1} \leq \text{abs}(x) < 2^k$  的單一正整數  $k$ 。同樣地，當 `abs(x)` 足小到能正確地取得舍入的對數，則  $k = 1 + \text{int}(\log(\text{abs}(x), 2))$ 。若  $x$  零，則 `x.bit_length()` 會回傳 0。

等同於:

```
def bit_length(self):
    s = bin(self)          # binary representation: bin(-37) --> '-0b100101'
    s = s.lstrip('-0b')   # remove leading zeros and minus sign
    return len(s)         # len('100101') --> 6
```

在 3.1 版被加入。

`int.bit_count()`

回傳在對值表示的二進位中 1 的個數。這也被稱作母體計數。舉例來:

```
>>> n = 19
>>> bin(n)
'0b10011'
>>> n.bit_count()
3
>>> (-n).bit_count()
3
```

等同於:

```
def bit_count(self):
    return bin(self).count("1")
```

在 3.10 版被加入。

`int.to_bytes` (*length=1, byteorder='big', \*, signed=False*)

回傳表示一個整數的一列位元組。

```
>>> (1024).to_bytes(2, byteorder='big')
b'\x04\x00'
>>> (1024).to_bytes(10, byteorder='big')
b'\x00\x00\x00\x00\x00\x00\x00\x00\x04\x00'
>>> (-1024).to_bytes(10, byteorder='big', signed=True)
b'\xff\xff\xff\xff\xff\xff\xff\xff\xfc\x00'
>>> x = 1000
>>> x.to_bytes((x.bit_length() + 7) // 8, byteorder='little')
b'\xe8\x03'
```

此整數會使用 *length* 位元組表示，且預設 1。如果該整數無法用給定的位元組數來表示，則會引發 `OverflowError`。

*byteorder* 引數定了用來表示整數的位元組順序且預設 "big"。如果 *byteorder* 是 "big"，最重要的位元組位於位元組陣列的開頭。如果 *byteorder* 是 "little"，最重要的位元組位於位元組陣列的結尾。

*signed* 引數定是否使用二的補數來表示整數。如果 *signed* 是 `False` 且給定了一個負整數，則會引發 `OverflowError`。*signed* 的預設值是 `False`。

預設值可以方便地將一個整數轉單位元組物件：

```
>>> (65).to_bytes()
b'A'
```

然而，使用預設引數時，不要嘗試轉大於 255 的值，否則你將會得到一個 `OverflowError`。

等同於：

```
def to_bytes(n, length=1, byteorder='big', signed=False):
    if byteorder == 'little':
        order = range(length)
    elif byteorder == 'big':
        order = reversed(range(length))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    return bytes((n >> i*8) & 0xff for i in order)
```

在 3.2 版被加入。

在 3.11 版的變更：`length` 和 *byteorder* 添加了預設引數值。

`classmethod int.from_bytes` (*bytes, byteorder='big', \*, signed=False*)

回傳由給定的位元組陣列表示的整數。

```
>>> int.from_bytes(b'\x00\x10', byteorder='big')
16
>>> int.from_bytes(b'\x00\x10', byteorder='little')
4096
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=True)
-1024
>>> int.from_bytes(b'\xfc\x00', byteorder='big', signed=False)
64512
>>> int.from_bytes([255, 0, 0], byteorder='big')
16711680
```

引數 *bytes* 必須是一個類位元組物件或是一個生位元組的可代物件。

`byteorder` 引數定义了用來表示整數的位元組順序且預設 "big"。如果 `byteorder` 是 "big", 最重要的位元組位於位元組陣列的開頭。如果 `byteorder` 是 "little", 最重要的位元組位於位元組陣列的結尾。若要請求主機系統的本機位元組順序, 請使用 `sys.byteorder` 作位元組順序值。

`signed` 引數指示是否使用二的補數來表示整數。

等同於:

```
def from_bytes(bytes, byteorder='big', signed=False):
    if byteorder == 'little':
        little_ordered = list(bytes)
    elif byteorder == 'big':
        little_ordered = list(reversed(bytes))
    else:
        raise ValueError("byteorder must be either 'little' or 'big'")

    n = sum(b << i*8 for i, b in enumerate(little_ordered))
    if signed and little_ordered and (little_ordered[-1] & 0x80):
        n -= 1 << 8*len(little_ordered)

    return n
```

在 3.2 版被加入。

在 3.11 版的變更: `byteorder` 添加了預設引數值。

`int.as_integer_ratio()`

回傳一對整數, 其比率等於原始整數且有一個正分母。整數 (整個數值) 的整數比率總是整數作分子, 且 1 作分母。

在 3.8 版被加入。

`int.is_integer()`

回傳 True。了與 `float.is_integer()` 的鴨子型相容而存在。

在 3.12 版被加入。

#### 4.4.3 浮點數的附加 methods

浮點數型實作了 `numbers.Real` 抽象基底類。浮點數也有下列附加 methods。

`float.as_integer_ratio()`

回傳一對整數, 其比率完全等於原始浮點數。比率是在最低條件下且有一個正分母。在無窮大時引發 `OverflowError`, 在 NaN 時引發 `ValueError`。

`float.is_integer()`

如果浮點數實例是有限的且具有整數值, 則回傳 True, 否則回傳 False:

```
>>> (-2.0).is_integer()
True
>>> (3.2).is_integer()
False
```

兩個 methods 皆支援十六進位字串之間的轉。由於 Python 的浮點數部以二進位數值儲存, 將浮點數轉或從十進位字串通常涉及一個小的四舍五入誤差。相反地, 十六進位字串允許精確表示和指定浮點數。這在除錯和數值工作中可能會有用。

`float.hex()`

回傳浮點數的十六進位字串表示。對於有限浮點數, 此表示方式總是包含一個前導 0x 及一個尾部 p 和指數。

`classmethod float.fromhex(s)`

Class method 回傳由十六進位字串 s 表示的浮點數。字串 s 可能有前導及尾部的空白。

請注意 `float.hex()` 是一個實例 method，而 `float.fromhex()` 是一個 class method。

一個十六進位字串的形式如下：

```
[sign] ['0x'] integer ['.' fraction] ['p' exponent]
```

其中可選的 `sign` 可以是 + 或 -，`integer` 和 `fraction` 是十六進位數字的字串，而 `exponent` 是一個十進位整數且有一個可選的前導符號。大小寫不重要，且整數或小數部分至少有一個十六進位數字。這個語法與 C99 標準的第 6.4.4.2 節指定的語法相似，也與 Java 1.5 以後的語法相似。特別是 `float.hex()` 的輸出可用作 C 或 Java 程式碼中的十六進位浮點數文字，且 C 的 `%a` 格式字元或 Java 的 `Double.toHexString()` 生的十六進位字串可被 `float.fromhex()` 接受。

請注意指數是以十進位而非十六進位寫入，且它給出了乘以數的 2 的次方。例如，十六進位字串 `0x3.a7p10` 表示浮點數  $(3 + 10./16 + 7./16**2) * 2.0**10$ ，或 3740.0：

```
>>> float.fromhex('0x3.a7p10')
3740.0
```

對 3740.0 應用反向轉會給出一個不同的十六進位字串，它表示相同的數字：

```
>>> float.hex(3740.0)
'0x1.d380000000000p+11'
```

#### 4.4.4 數值型的雜

對於數字  $x$  和  $y$ ，可能是不同型，當  $x == y$  時，`hash(x) == hash(y)` 是一個要求（詳見 `__hash__()` method 的文件以獲得更多細節）。了實作的便利性和效率跨越各種數值型（包括 `int`、`float`、`decimal.Decimal` 和 `fractions.Fraction`）Python 的數值型的雜是基於一個數學函式，它對於任何有理數都是定義的，因此適用於所有 `int` 和 `fractions.Fraction` 的實例，以及所有有限的 `float` 和 `decimal.Decimal` 的實例。基本上，這個函式是由簡化的 modulo（模數） $P$  給出一個固定的質數  $P$ 。  $P$  的值作 `sys.hash_info` 的 `modulus` 屬性提供給 Python。

目前在具有 32 位元 C longs 的機器上所使用的質數是  $P = 2^{31} - 1$ ，而在具有 64 位元 C longs 的機器上  $P = 2^{61} - 1$ 。

以下是詳細的規則：

- 如果  $x = m / n$  是一個非負的有理數，且  $n$  不可被  $P$  整除，則將 `hash(x)` 定義  $m * \text{invmod}(n, P) \% P$ 。其中 `invmod(n, P)` 對模數  $P$  的倒數。
- 如果  $x = m / n$  是一個非負的有理數，且  $n$  可被  $P$  整除（但  $m$  不行），則  $n$  有 inverse modulo（模倒數） $P$ ，且不適用於上述規則；在這種情況下，將 `hash(x)` 定義常數值 `sys.hash_info.inf`。
- 如果  $x = m / n$  是一個負的有理數，則將 `hash(x)` 定義 `-hash(-x)`。如果結果的雜是 `-1`，則將其替 `-2`。
- 特定值 `sys.hash_info.inf` 和 `-sys.hash_info.inf`（分）被用作正無窮大或負無窮大的雜值。
- 對於一個 `complex` 值  $z$ ，實部和部的雜值藉由 `hash(z.real) + sys.hash_info.imag * hash(z.imag)` 的計算進行組合，對  $2^{**} \text{sys.hash_info.width}$  取模數使其介於 `range(-2^{**}(\text{sys.hash_info.width} - 1), 2^{**}(\text{sys.hash_info.width} - 1))`。同樣地，如果結果是 `-1`，則將其替 `-2`。

了闡明上述規則，這有一些 Python 程式碼範例，等同於建的雜，用於計算有理數、`float` 或 `complex` 的雜：

```
import sys, math

def hash_fraction(m, n):
    """Compute the hash of a rational number m / n.

    Assumes m and n are integers, with n positive.
```

(繼續下一頁)

```

Equivalent to hash(fractions.Fraction(m, n)).

"""
P = sys.hash_info.modulus
# Remove common factors of P. (Unnecessary if m and n already coprime.)
while m % P == n % P == 0:
    m, n = m // P, n // P

if n % P == 0:
    hash_value = sys.hash_info.inf
else:
    # Fermat's Little Theorem: pow(n, P-1, P) is 1, so
    # pow(n, P-2, P) gives the inverse of n modulo P.
    hash_value = (abs(m) % P) * pow(n, P - 2, P) % P
if m < 0:
    hash_value = -hash_value
if hash_value == -1:
    hash_value = -2
return hash_value

def hash_float(x):
    """Compute the hash of a float x."""

    if math.isnan(x):
        return object.__hash__(x)
    elif math.isinf(x):
        return sys.hash_info.inf if x > 0 else -sys.hash_info.inf
    else:
        return hash_fraction(*x.as_integer_ratio())

def hash_complex(z):
    """Compute the hash of a complex number z."""

    hash_value = hash_float(z.real) + sys.hash_info.imag * hash_float(z.imag)
    # do a signed reduction modulo 2**sys.hash_info.width
    M = 2**(sys.hash_info.width - 1)
    hash_value = (hash_value & (M - 1)) - (hash_value & M)
    if hash_value == -1:
        hash_value = -2
    return hash_value

```

## 4.5 Boolean 型 `bool`

Boolean 值代表 truth values (真值)。`bool` 型有兩個常數實例：True 和 False。

建函式 `bool()` 將任何值轉 `bool` 值，如果該值可以被直譯一個 truth value (真值) (見上面的真值檢測章節)。

對於邏輯運算，使用 *boolean 運算子* `and`、`or` 和 `not`。當將位元運算子 `&`、`|`、`^` 應用於兩個 `bool` 值時，它們會回傳一個等同於邏輯運算“and”、“or”、“xor”的 `bool` 值。然而，應該優先使用邏輯運算子 `and`、`or` 和 `!=` 而不是 `&`、`|` 和 `^`。

在 3.12 版之後被用：位元反轉運算子 `~` 的使用已被用且將在 Python 3.16 中引發錯誤。

`bool` 是 `int` 的子類 (見數值型 `int`、`float`、`complex`)。在許多數值情境中，False 和 True 分像整數 0 和 1 一樣。然而，不鼓勵依賴這一點；請使用 `int()` 進行顯式轉。

## 4.6 代器型

Python 支援對容器的代概念。這是實作兩種不同的 methods；這些方法被用於允許使用者自定義的 classes 以支援代。序列則總是支援這些代 methods，在下方有更詳細的描述。

需要容器物件定義一個 method 來提供可代物件支援：

```
container.__iter__()
```

回傳一個代器物件。該物件需要支援下述的代器協定。如果一個容器支援不同型的代，則可以提供額外的 methods 來專門請求這些代型的代器。（支援多種形式代的物件的一個例子是支援廣度優先和深度優先遍歷的樹結構。）此 method 對應 Python/C API 中 Python 物件的型結構的 `tp_iter` 插槽。

代器物件本身需要支援下列兩個 methods，他們一起形成了代器協定：

```
iterator.__iter__()
```

回傳代器物件本身。這是為了允許容器和代器都可以與 `for` 和 `in` 在陳述式中使用。此 method 對應於 Python/C API 中 Python 物件的型結構的 `tp_iter` 插槽。

```
iterator.__next__()
```

從代器回傳下一個項目。如果還有更多項目，則引發 `StopIteration` 例外。此 method 對應於 Python/C API 中 Python 物件的型結構的 `tp_iternext` 插槽。

Python 定義了幾個代器物件來支援對一般和特定序列型、字典和其他更專門的形式的代。這些特定型除了實作代器協定外不重要。

一旦代器的 `__next__()` method 引發 `StopIteration`，則它必須在後續呼叫中繼續這樣做。不遵守此屬性的實作被認為是有問題的。

### 4.6.1 Generator Types

Python's *generators* provide a convenient way to implement the iterator protocol. If a container object's `__iter__()` method is implemented as a generator, it will automatically return an iterator object (technically, a generator object) supplying the `__iter__()` and `__next__()` methods. More information about generators can be found in the documentation for the `yield` expression.

## 4.7 Sequence Types --- list, tuple, range

There are three basic sequence types: lists, tuples, and range objects. Additional sequence types tailored for processing of *binary data* and *text strings* are described in dedicated sections.

### 4.7.1 Common Sequence Operations

The operations in the following table are supported by most sequence types, both mutable and immutable. The `collections.abc.Sequence` ABC is provided to make it easier to correctly implement these operations on custom sequence types.

This table lists the sequence operations sorted in ascending priority. In the table, *s* and *t* are sequences of the same type, *n*, *i*, *j* and *k* are integers and *x* is an arbitrary object that meets any type and value restrictions imposed by *s*.

The `in` and `not in` operations have the same priorities as the comparison operations. The `+` (concatenation) and `*` (repetition) operations have the same priority as the corresponding numeric operations.<sup>3</sup>

<sup>3</sup> They must have since the parser can't tell the type of the operands.

運算	結果	F解
<code>x in s</code>	True if an item of <i>s</i> is equal to <i>x</i> , else False	(1)
<code>x not in s</code>	False if an item of <i>s</i> is equal to <i>x</i> , else True	(1)
<code>s + t</code>	the concatenation of <i>s</i> and <i>t</i>	(6)(7)
<code>s * n</code> 或 <code>n * s</code>	equivalent to adding <i>s</i> to itself <i>n</i> times	(2)(7)
<code>s[i]</code>	<i>i</i> th item of <i>s</i> , origin 0	(3)
<code>s[i:j]</code>	slice of <i>s</i> from <i>i</i> to <i>j</i>	(3)(4)
<code>s[i:j:k]</code>	slice of <i>s</i> from <i>i</i> to <i>j</i> with step <i>k</i>	(3)(5)
<code>len(s)</code>	<i>s</i> 的長度	
<code>min(s)</code>	<i>s</i> 中最小的項目	
<code>max(s)</code>	<i>s</i> 中最大的項目	
<code>s.index(x[, i[, j]])</code>	index of the first occurrence of <i>x</i> in <i>s</i> (at or after index <i>i</i> and before index <i>j</i> )	(8)
<code>s.count(x)</code>	total number of occurrences of <i>x</i> in <i>s</i>	

Sequences of the same type also support comparisons. In particular, tuples and lists are compared lexicographically by comparing corresponding elements. This means that to compare equal, every element must compare equal and the two sequences must be of the same type and have the same length. (For full details see comparisons in the language reference.)

Forward and reversed iterators over mutable sequences access values using an index. That index will continue to march forward (or backward) even if the underlying sequence is mutated. The iterator terminates only when an `IndexError` or a `StopIteration` is encountered (or when the index drops below zero).

F解:

- (1) While the `in` and `not in` operations are used only for simple containment testing in the general case, some specialised sequences (such as `str`, `bytes` and `bytearray`) also use them for subsequence testing:

```
>>> "gg" in "eggs"
True
```

- (2) Values of *n* less than 0 are treated as 0 (which yields an empty sequence of the same type as *s*). Note that items in the sequence *s* are not copied; they are referenced multiple times. This often haunts new Python programmers; consider:

```
>>> lists = [[]] * 3
>>> lists
[[], [], []]
>>> lists[0].append(3)
>>> lists
[[3], [3], [3]]
```

What has happened is that `[[]]` is a one-element list containing an empty list, so all three elements of `[[]] * 3` are references to this single empty list. Modifying any of the elements of `lists` modifies this single list. You can create a list of different lists this way:

```
>>> lists = [[] for i in range(3)]
>>> lists[0].append(3)
>>> lists[1].append(5)
>>> lists[2].append(7)
>>> lists
[[3], [5], [7]]
```

Further explanation is available in the FAQ entry [faq-multidimensional-list](#).

- (3) If *i* or *j* is negative, the index is relative to the end of sequence *s*: `len(s) + i` or `len(s) + j` is substituted. But note that `-0` is still 0.
- (4) The slice of *s* from *i* to *j* is defined as the sequence of items with index *k* such that `i <= k < j`. If *i* or *j* is

greater than `len(s)`, use `len(s)`. If `i` is omitted or `None`, use 0. If `j` is omitted or `None`, use `len(s)`. If `i` is greater than or equal to `j`, the slice is empty.

- (5) The slice of `s` from `i` to `j` with step `k` is defined as the sequence of items with index  $x = i + n*k$  such that  $0 \leq n < (j-i)/k$ . In other words, the indices are `i`, `i+k`, `i+2*k`, `i+3*k` and so on, stopping when `j` is reached (but never including `j`). When `k` is positive, `i` and `j` are reduced to `len(s)` if they are greater. When `k` is negative, `i` and `j` are reduced to `len(s) - 1` if they are greater. If `i` or `j` are omitted or `None`, they become "end" values (which end depends on the sign of `k`). Note, `k` cannot be zero. If `k` is `None`, it is treated like 1.
- (6) Concatenating immutable sequences always results in a new object. This means that building up a sequence by repeated concatenation will have a quadratic runtime cost in the total sequence length. To get a linear runtime cost, you must switch to one of the alternatives below:
  - if concatenating `str` objects, you can build a list and use `str.join()` at the end or else write to an `io.StringIO` instance and retrieve its value when complete
  - if concatenating `bytes` objects, you can similarly use `bytes.join()` or `io.BytesIO`, or you can do in-place concatenation with a `bytearray` object. `bytearray` objects are mutable and have an efficient overall allocation mechanism
  - if concatenating `tuple` objects, extend a `list` instead
  - for other types, investigate the relevant class documentation
- (7) Some sequence types (such as `range`) only support item sequences that follow specific patterns, and hence don't support sequence concatenation or repetition.
- (8) `index` raises `ValueError` when `x` is not found in `s`. Not all implementations support passing the additional arguments `i` and `j`. These arguments allow efficient searching of subsections of the sequence. Passing the extra arguments is roughly equivalent to using `s[i:j].index(x)`, only without copying any data and with the returned index being relative to the start of the sequence rather than the start of the slice.

## 4.7.2 Immutable Sequence Types

The only operation that immutable sequence types generally implement that is not also implemented by mutable sequence types is support for the `hash()` built-in.

This support allows immutable sequences, such as `tuple` instances, to be used as `dict` keys and stored in `set` and `frozenset` instances.

Attempting to hash an immutable sequence that contains unhashable values will result in `TypeError`.

## 4.7.3 Mutable Sequence Types

The operations in the following table are defined on mutable sequence types. The `collections.abc.MutableSequence` ABC is provided to make it easier to correctly implement these operations on custom sequence types.

In the table `s` is an instance of a mutable sequence type, `t` is any iterable object and `x` is an arbitrary object that meets any type and value restrictions imposed by `s` (for example, `bytearray` only accepts integers that meet the value restriction  $0 \leq x \leq 255$ ).

運算	結果	<b>F</b> 解
<code>s[i] = x</code>	item <i>i</i> of <i>s</i> is replaced by <i>x</i>	
<code>s[i:j] = t</code>	slice of <i>s</i> from <i>i</i> to <i>j</i> is replaced by the contents of the iterable <i>t</i>	
<code>del s[i:j]</code>	same as <code>s[i:j] = []</code>	
<code>s[i:j:k] = t</code>	the elements of <code>s[i:j:k]</code> are replaced by those of <i>t</i>	(1)
<code>del s[i:j:k]</code>	removes the elements of <code>s[i:j:k]</code> from the list	
<code>s.append(x)</code>	appends <i>x</i> to the end of the sequence (same as <code>s[len(s):len(s)] = [x]</code> )	
<code>s.clear()</code>	removes all items from <i>s</i> (same as <code>del s[:]</code> )	(5)
<code>s.copy()</code>	creates a shallow copy of <i>s</i> (same as <code>s[:]</code> )	(5)
<code>s.extend(t)</code> 或 <code>s += t</code>	extends <i>s</i> with the contents of <i>t</i> (for the most part the same as <code>s[len(s):len(s)] = t</code> )	
<code>s *= n</code>	updates <i>s</i> with its contents repeated <i>n</i> times	(6)
<code>s.insert(i, x)</code>	inserts <i>x</i> into <i>s</i> at the index given by <i>i</i> (same as <code>s[i:i] = [x]</code> )	
<code>s.pop()</code> 或 <code>s.pop(i)</code>	retrieves the item at <i>i</i> and also removes it from <i>s</i>	(2)
<code>s.remove(x)</code>	removes the first item from <i>s</i> where <code>s[i]</code> is equal to <i>x</i>	(3)
<code>s.reverse()</code>	reverses the items of <i>s</i> in place	(4)

**F**解:

- (1) If *k* is not equal to 1, *t* must have the same length as the slice it is replacing.
- (2) The optional argument *i* defaults to -1, so that by default the last item is removed and returned.
- (3) `remove()` raises `ValueError` when *x* is not found in *s*.
- (4) The `reverse()` method modifies the sequence in place for economy of space when reversing a large sequence. To remind users that it operates by side effect, it does not return the reversed sequence.
- (5) `clear()` and `copy()` are included for consistency with the interfaces of mutable containers that don't support slicing operations (such as `dict` and `set`). `copy()` is not part of the `collections.abc.MutableSequence` ABC, but most concrete mutable sequence classes provide it.  
在 3.3 版被加入: `clear()` and `copy()` methods.
- (6) The value *n* is an integer, or an object implementing `__index__()`. Zero and negative values of *n* clear the sequence. Items in the sequence are not copied; they are referenced multiple times, as explained for `s * n` under *Common Sequence Operations*.

#### 4.7.4 List (串列)

Lists are mutable sequences, typically used to store collections of homogeneous items (where the precise degree of similarity will vary by application).

```
class list ([iterable])
```

Lists may be constructed in several ways:

- Using a pair of square brackets to denote the empty list: `[]`
- Using square brackets, separating items with commas: `[a], [a, b, c]`
- Using a list comprehension: `[x for x in iterable]`
- Using the type constructor: `list()` or `list(iterable)`

The constructor builds a list whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a list, a copy is made and returned, similar to `iterable[:]`. For example, `list('abc')` returns `['a', 'b', 'c']` and `list((1, 2, 3))` returns `[1, 2, 3]`. If no argument is given, the constructor creates a new empty list, `[]`.

Many other operations also produce lists, including the `sorted()` built-in.

Lists implement all of the *common* and *mutable* sequence operations. Lists also provide the following additional method:

**sort** (\*, *key=None*, *reverse=False*)

This method sorts the list in place, using only < comparisons between items. Exceptions are not suppressed - if any comparison operations fail, the entire sort operation will fail (and the list will likely be left in a partially modified state).

*sort()* accepts two arguments that can only be passed by keyword (*keyword-only arguments*):

*key* specifies a function of one argument that is used to extract a comparison key from each list element (for example, *key=str.lower*). The key corresponding to each item in the list is calculated once and then used for the entire sorting process. The default value of `None` means that list items are sorted directly without calculating a separate key value.

The *functools.cmp\_to\_key()* utility is available to convert a 2.x style *cmp* function to a *key* function.

*reverse* is a boolean value. If set to `True`, then the list elements are sorted as if each comparison were reversed.

This method modifies the sequence in place for economy of space when sorting a large sequence. To remind users that it operates by side effect, it does not return the sorted sequence (use *sorted()* to explicitly request a new sorted list instance).

The *sort()* method is guaranteed to be stable. A sort is stable if it guarantees not to change the relative order of elements that compare equal --- this is helpful for sorting in multiple passes (for example, sort by department, then by salary grade).

For sorting examples and a brief sorting tutorial, see [sortinghowto](#).

**CPython 實作細節：** While a list is being sorted, the effect of attempting to mutate, or even inspect, the list is undefined. The C implementation of Python makes the list appear empty for the duration, and raises *ValueError* if it can detect that the list has been mutated during a sort.

## 4.7.5 Tuples

Tuples are immutable sequences, typically used to store collections of heterogeneous data (such as the 2-tuples produced by the *enumerate()* built-in). Tuples are also used for cases where an immutable sequence of homogeneous data is needed (such as allowing storage in a *set* or *dict* instance).

**class tuple** (*[iterable]*)

Tuples may be constructed in a number of ways:

- Using a pair of parentheses to denote the empty tuple: `()`
- Using a trailing comma for a singleton tuple: `a,` or `(a,)`
- Separating items with commas: `a, b, c` or `(a, b, c)`
- Using the *tuple()* built-in: `tuple()` or `tuple(iterable)`

The constructor builds a tuple whose items are the same and in the same order as *iterable*'s items. *iterable* may be either a sequence, a container that supports iteration, or an iterator object. If *iterable* is already a tuple, it is returned unchanged. For example, `tuple('abc')` returns `('a', 'b', 'c')` and `tuple([1, 2, 3])` returns `(1, 2, 3)`. If no argument is given, the constructor creates a new empty tuple, `()`.

Note that it is actually the comma which makes a tuple, not the parentheses. The parentheses are optional, except in the empty tuple case, or when they are needed to avoid syntactic ambiguity. For example, `f(a, b, c)` is a function call with three arguments, while `f((a, b, c))` is a function call with a 3-tuple as the sole argument.

Tuples implement all of the *common* sequence operations.

For heterogeneous collections of data where access by name is clearer than access by index, *collections.namedtuple()* may be a more appropriate choice than a simple tuple object.

## 4.7.6 Ranges

The `range` type represents an immutable sequence of numbers and is commonly used for looping a specific number of times in `for` loops.

**class** `range` (*stop*)

**class** `range` (*start*, *stop* [, *step* ])

The arguments to the range constructor must be integers (either built-in `int` or any object that implements the `__index__()` special method). If the `step` argument is omitted, it defaults to 1. If the `start` argument is omitted, it defaults to 0. If `step` is zero, `ValueError` is raised.

For a positive `step`, the contents of a range `r` are determined by the formula  $r[i] = \text{start} + \text{step} * i$  where  $i \geq 0$  and  $r[i] < \text{stop}$ .

For a negative `step`, the contents of the range are still determined by the formula  $r[i] = \text{start} + \text{step} * i$ , but the constraints are  $i \geq 0$  and  $r[i] > \text{stop}$ .

A range object will be empty if `r[0]` does not meet the value constraint. Ranges do support negative indices, but these are interpreted as indexing from the end of the sequence determined by the positive indices.

Ranges containing absolute values larger than `sys.maxsize` are permitted but some features (such as `len()`) may raise `OverflowError`.

Range examples:

```
>>> list(range(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> list(range(0, 30, 5))
[0, 5, 10, 15, 20, 25]
>>> list(range(0, 10, 3))
[0, 3, 6, 9]
>>> list(range(0, -10, -1))
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
>>> list(range(0))
[]
>>> list(range(1, 0))
[]
```

Ranges implement all of the *common* sequence operations except concatenation and repetition (due to the fact that range objects can only represent sequences that follow a strict pattern and repetition and concatenation will usually violate that pattern).

**start**

The value of the `start` parameter (or 0 if the parameter was not supplied)

**stop**

The value of the `stop` parameter

**step**

The value of the `step` parameter (or 1 if the parameter was not supplied)

The advantage of the `range` type over a regular `list` or `tuple` is that a `range` object will always take the same (small) amount of memory, no matter the size of the range it represents (as it only stores the `start`, `stop` and `step` values, calculating individual items and subranges as needed).

Range objects implement the `collections.abc.Sequence` ABC, and provide features such as containment tests, element index lookup, slicing and support for negative indices (see *Sequence Types --- list, tuple, range*):

```
>>> r = range(0, 20, 2)
>>> r
range(0, 20, 2)
>>> 11 in r
```

(繼續下一頁)

(繼續上一頁)

```

False
>>> 10 in r
True
>>> r.index(10)
5
>>> r[5]
10
>>> r[:5]
range(0, 10, 2)
>>> r[-1]
18

```

Testing range objects for equality with `==` and `!=` compares them as sequences. That is, two range objects are considered equal if they represent the same sequence of values. (Note that two range objects that compare equal might have different *start*, *stop* and *step* attributes, for example `range(0) == range(2, 1, 3)` or `range(0, 3, 2) == range(0, 4, 2)`.)

在 3.2 版的變更: Implement the Sequence ABC. Support slicing and negative indices. Test *int* objects for membership in constant time instead of iterating through all items.

在 3.3 版的變更: Define `'=='` and `'!='` to compare range objects based on the sequence of values they define (instead of comparing based on object identity).

Added the *start*, *stop* and *step* attributes.

#### ➔ 也參考

- The [linspace recipe](#) shows how to implement a lazy version of range suitable for floating-point applications.

## 4.8 Text Sequence Type --- `str`

Textual data in Python is handled with *str* objects, or *strings*. Strings are immutable *sequences* of Unicode code points. String literals are written in a variety of ways:

- Single quotes: `'allows embedded "double" quotes'`
- Double quotes: `"allows embedded 'single' quotes"`
- Triple quoted: `'''Three single quotes''', """Three double quotes"""`

Triple quoted strings may span multiple lines - all associated whitespace will be included in the string literal.

String literals that are part of a single expression and have only whitespace between them will be implicitly converted to a single string literal. That is, `("spam " "eggs") == "spam eggs"`.

See strings for more about the various forms of string literal, including supported escape sequences, and the `r` ("raw") prefix that disables most escape sequence processing.

Strings may also be created from other objects using the *str* constructor.

Since there is no separate "character" type, indexing a string produces strings of length 1. That is, for a non-empty string *s*, `s[0] == s[0:1]`.

There is also no mutable string type, but `str.join()` or `io.StringIO` can be used to efficiently construct strings from multiple fragments.

在 3.3 版的變更: For backwards compatibility with the Python 2 series, the `u` prefix is once again permitted on string literals. It has no effect on the meaning of string literals and cannot be combined with the `r` prefix.

```
class str(object="")
```

**class** `str` (*object*=`b`", *encoding*='utf-8', *errors*='strict')

Return a *string* version of *object*. If *object* is not provided, returns the empty string. Otherwise, the behavior of `str()` depends on whether *encoding* or *errors* is given, as follows.

If neither *encoding* nor *errors* is given, `str(object)` returns `type(object).__str__(object)`, which is the "informal" or nicely printable string representation of *object*. For string objects, this is the string itself. If *object* does not have a `__str__()` method, then `str()` falls back to returning `repr(object)`.

If at least one of *encoding* or *errors* is given, *object* should be a *bytes-like object* (e.g. `bytes` or `bytearray`). In this case, if *object* is a `bytes` (or `bytearray`) object, then `str(bytes, encoding, errors)` is equivalent to `bytes.decode(encoding, errors)`. Otherwise, the bytes object underlying the buffer object is obtained before calling `bytes.decode()`. See *Binary Sequence Types --- bytes, bytearray, memoryview and bufferobjects* for information on buffer objects.

Passing a `bytes` object to `str()` without the *encoding* or *errors* arguments falls under the first case of returning the informal string representation (see also the `-b` command-line option to Python). For example:

```
>>> str(b'Zoot!')
"b'Zoot!'"
```

For more information on the `str` class and its methods, see *Text Sequence Type --- str* and the *String Methods* section below. To output formatted strings, see the *f-strings* and *格式化文字語法* sections. In addition, see the *文本處理 (Text Processing) 服務* section.

## 4.8.1 String Methods

Strings implement all of the *common* sequence operations, along with the additional methods described below.

Strings also support two styles of string formatting, one providing a large degree of flexibility and customization (see `str.format()`, *格式化文字語法* and *自訂字串格式*) and the other based on C `printf` style formatting that handles a narrower range of types and is slightly harder to use correctly, but is often faster for the cases it can handle (*printf-style String Formatting*).

The *文本處理 (Text Processing) 服務* section of the standard library covers a number of other modules that provide various text related utilities (including regular expression support in the `re` module).

`str.capitalize()`

Return a copy of the string with its first character capitalized and the rest lowercased.

在 3.8 版的變更: The first character is now put into titlecase rather than uppercase. This means that characters like digraphs will only have their first letter capitalized, instead of the full character.

`str.casefold()`

Return a casefolded copy of the string. Casefolded strings may be used for caseless matching.

Casefolding is similar to lowercasing but more aggressive because it is intended to remove all case distinctions in a string. For example, the German lowercase letter 'ß' is equivalent to "ss". Since it is already lowercase, `lower()` would do nothing to 'ß'; `casefold()` converts it to "ss".

The casefolding algorithm is described in section 3.13 'Default Case Folding' of the Unicode Standard.

在 3.3 版被加入.

`str.center(width[, fillchar])`

Return centered in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.count(sub[, start[, end]])`

Return the number of non-overlapping occurrences of substring *sub* in the range `[start, end]`. Optional arguments *start* and *end* are interpreted as in slice notation.

If *sub* is empty, returns the number of empty strings between characters which is the length of the string plus one.

`str.encode(encoding='utf-8', errors='strict')`

Return the string encoded to *bytes*.

*encoding* defaults to 'utf-8'; see *Standard Encodings* for possible values.

*errors* controls how encoding errors are handled. If 'strict' (the default), a *UnicodeError* exception is raised. Other possible values are 'ignore', 'replace', 'xmlcharrefreplace', 'backslashreplace' and any other name registered via *codecs.register\_error()*. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless an encoding error actually occurs, *Python 開發模式* is enabled or a debug build is used.

在 3.1 版的變更: 新增關鍵字引數的支援。

在 3.9 版的變更: The value of the *errors* argument is now checked in *Python 開發模式* and in debug mode.

`str.endswith(suffix[, start[, end]])`

Return `True` if the string ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

`str.expandtabs(tabsize=8)`

Return a copy of the string where all tab characters are replaced by one or more spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* characters (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the string, the current column is set to zero and the string is examined character by character. If the character is a tab (`\t`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the character is a newline (`\n`) or return (`\r`), it is copied and the current column is reset to zero. Any other character is copied unchanged and the current column is incremented by one regardless of how the character is represented when printed.

```
>>> '01\t012\t0123\t01234'.expandtabs()
'01      012      0123      01234'
>>> '01\t012\t0123\t01234'.expandtabs(4)
'01  012 0123  01234'
```

`str.find(sub[, start[, end]])`

Return the lowest index in the string where substring *sub* is found within the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

**備 F**

The `find()` method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> 'Py' in 'Python'
True
```

`str.format(*args, **kwargs)`

Perform a string formatting operation. The string on which this method is called can contain literal text or replacement fields delimited by braces `{}`. Each replacement field contains either the numeric index of a positional argument, or the name of a keyword argument. Returns a copy of the string where each replacement field is replaced with the string value of the corresponding argument.

```
>>> "The sum of 1 + 2 is {0}".format(1+2)
'The sum of 1 + 2 is 3'
```

See *格式化文字語法* for a description of the various formatting options that can be specified in format strings.

## 備 F

When formatting a number (*int*, *float*, *complex*, *decimal.Decimal* and subclasses) with the *n* type (ex: `{:n}'.format(1234)`), the function temporarily sets the `LC_CTYPE` locale to the `LC_NUMERIC` locale to decode `decimal_point` and `thousands_sep` fields of `localeconv()` if they are non-ASCII or longer than 1 byte, and the `LC_NUMERIC` locale is different than the `LC_CTYPE` locale. This temporary change affects other threads.

在 3.7 版的變更: When formatting a number with the *n* type, the function sets temporarily the `LC_CTYPE` locale to the `LC_NUMERIC` locale in some cases.

`str.format_map(mapping, /)`

Similar to `str.format(**mapping)`, except that `mapping` is used directly and not copied to a *dict*. This is useful if for example `mapping` is a *dict* subclass:

```
>>> class Default(dict):
...     def __missing__(self, key):
...         return key
...
>>> '{name} was born in {country}'.format_map(Default(name='Guido'))
'Guido was born in country'
```

在 3.2 版被加入。

`str.index(sub[, start[, end]])`

Like `find()`, but raise `ValueError` when the substring is not found.

`str.isalnum()`

Return `True` if all characters in the string are alphanumeric and there is at least one character, `False` otherwise. A character *c* is alphanumeric if one of the following returns `True`: `c.isalpha()`, `c.isdecimal()`, `c.isdigit()`, or `c.isnumeric()`.

`str.isalpha()`

Return `True` if all characters in the string are alphabetic and there is at least one character, `False` otherwise. Alphabetic characters are those characters defined in the Unicode character database as "Letter", i.e., those with general category property being one of "Lm", "Lt", "Lu", "Ll", or "Lo". Note that this is different from the Alphabetic property defined in the section 4.10 'Letters, Alphabetic, and Ideographic' of the Unicode Standard.

`str.isascii()`

Return `True` if the string is empty or all characters in the string are ASCII, `False` otherwise. ASCII characters have code points in the range U+0000-U+007F.

在 3.7 版被加入。

`str.isdecimal()`

Return `True` if all characters in the string are decimal characters and there is at least one character, `False` otherwise. Decimal characters are those that can be used to form numbers in base 10, e.g. U+0660, ARABIC-INDIC DIGIT ZERO. Formally a decimal character is a character in the Unicode General Category "Nd".

`str.isdigit()`

Return `True` if all characters in the string are digits and there is at least one character, `False` otherwise. Digits include decimal characters and digits that need special handling, such as the compatibility superscript digits. This covers digits which cannot be used to form numbers in base 10, like the Kharosthi numbers. Formally, a digit is a character that has the property value `Numeric_Type=Digit` or `Numeric_Type=Decimal`.

`str.isidentifier()`

Return `True` if the string is a valid identifier according to the language definition, section identifiers.

`keyword.iskeyword()` can be used to test whether string *s* is a reserved identifier, such as `def` and `class`.

範例:

```
>>> from keyword import iskeyword

>>> 'hello'.isidentifier(), iskeyword('hello')
(True, False)
>>> 'def'.isidentifier(), iskeyword('def')
(True, True)
```

`str.islower()`

Return `True` if all cased characters<sup>4</sup> in the string are lowercase and there is at least one cased character, `False` otherwise.

`str.isnumeric()`

Return `True` if all characters in the string are numeric characters, and there is at least one character, `False` otherwise. Numeric characters include digit characters, and all characters that have the Unicode numeric value property, e.g. U+2155, VULGAR FRACTION ONE FIFTH. Formally, numeric characters are those with the property value `Numeric_Type=Digit`, `Numeric_Type=Decimal` or `Numeric_Type=Numeric`.

`str.isprintable()`

Return `true` if all characters in the string are printable, `false` if it contains at least one non-printable character.

Here “printable” means the character is suitable for `repr()` to use in its output; “non-printable” means that `repr()` on built-in types will hex-escape the character. It has no bearing on the handling of strings written to `sys.stdout` or `sys.stderr`.

The printable characters are those which in the Unicode character database (see *unicodedata*) have a general category in group Letter, Mark, Number, Punctuation, or Symbol (L, M, N, P, or S); plus the ASCII space 0x20. Nonprintable characters are those in group Separator or Other (Z or C), except the ASCII space.

`str.isspace()`

Return `True` if there are only whitespace characters in the string and there is at least one character, `False` otherwise.

A character is *whitespace* if in the Unicode character database (see *unicodedata*), either its general category is `Zs` (“Separator, space”), or its bidirectional class is one of `WS`, `B`, or `S`.

`str.istitle()`

Return `True` if the string is a titlecased string and there is at least one character, for example uppercase characters may only follow uncased characters and lowercase characters only cased ones. Return `False` otherwise.

`str.isupper()`

Return `True` if all cased characters<sup>4</sup> in the string are uppercase and there is at least one cased character, `False` otherwise.

```
>>> 'BANANA'.isupper()
True
>>> 'banana'.isupper()
False
>>> 'baNana'.isupper()
False
>>> ''.isupper()
False
```

`str.join(iterable)`

Return a string which is the concatenation of the strings in *iterable*. A `TypeError` will be raised if there are any non-string values in *iterable*, including *bytes* objects. The separator between elements is the string providing this method.

`str.ljust(width[, fillchar])`

Return the string left justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

<sup>4</sup> Cased characters are those with general category property being one of “Lu” (Letter, uppercase), “Ll” (Letter, lowercase), or “Lt” (Letter, titlecase).

`str.lower()`

Return a copy of the string with all the cased characters<sup>Page 55, 4</sup> converted to lowercase.

The lowercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

`str.lstrip([chars])`

Return a copy of the string with leading characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> '   spacious   '.lstrip()
'spacious   '
>>> 'www.example.com'.lstrip('cmowz.')
'example.com'
```

See `str.removeprefix()` for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> 'Arthur: three!'.lstrip('Arthur: ')
'ee!'
>>> 'Arthur: three!'.removeprefix('Arthur: ')
'three!'
```

**static** `str.maketrans(x[, y[, z]])`

This static method returns a translation table usable for `str.translate()`.

If there is only one argument, it must be a dictionary mapping Unicode ordinals (integers) or characters (strings of length 1) to Unicode ordinals, strings (of arbitrary lengths) or `None`. Character keys will then be converted to ordinals.

If there are two arguments, they must be strings of equal length, and in the resulting dictionary, each character in *x* will be mapped to the character at the same position in *y*. If there is a third argument, it must be a string, whose characters will be mapped to `None` in the result.

`str.partition(sep)`

Split the string at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing the string itself, followed by two empty strings.

`str.removeprefix(prefix, /)`

If the string starts with the *prefix* string, return `string[len(prefix):]`. Otherwise, return a copy of the original string:

```
>>> 'TestHook'.removeprefix('Test')
'Hook'
>>> 'BaseTestCase'.removeprefix('Test')
'BaseTestCase'
```

在 3.9 版被加入.

`str.removesuffix(suffix, /)`

If the string ends with the *suffix* string and that *suffix* is not empty, return `string[:-len(suffix)]`. Otherwise, return a copy of the original string:

```
>>> 'MiscTests'.removesuffix('Tests')
'Misc'
>>> 'TmpDirMixin'.removesuffix('Tests')
'TmpDirMixin'
```

在 3.9 版被加入.

`str.replace(`*old*`,` *new*`,` *count=-1*`)`

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If *count* is given, only the first *count* occurrences are replaced. If *count* is not specified or `-1`, then all occurrences are replaced.

在 3.13 版的變更: *count* 現在作 關鍵字引數被支援。

`str.rfind(`*sub*`[,` *start*`[,` *end*`]])`

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

`str.rindex(`*sub*`[,` *start*`[,` *end*`]])`

Like `rfind()` but raises `ValueError` when the substring *sub* is not found.

`str.rjust(`*width*`[,` *fillchar*`])`

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to `len(s)`.

`str.rpartition(`*sep*`)`

Split the string at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty strings, followed by the string itself.

`str.rsplit(`*sep=None*`,` *maxsplit=-1*`)`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any whitespace string is a separator. Except for splitting from the right, `rsplit()` behaves like `split()` which is described in detail below.

`str.rstrip(`*chars*`)`

Return a copy of the string with trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> '  spacious  '.rstrip()
'  spacious'
>>> 'mississippi'.rstrip('ipz')
'mississ'
```

See `str.removesuffix()` for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> 'Monty Python'.rstrip(' Python')
'M'
>>> 'Monty Python'.removesuffix(' Python')
'Monty'
```

`str.split(`*sep=None*`,` *maxsplit=-1*`)`

Return a list of the words in the string, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done (thus, the list will have at most `maxsplit+1` elements). If *maxsplit* is not specified or `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty strings (for example, `'1,,2'.split(',')` returns `['1', '', '2']`). The *sep* argument may consist of multiple characters as a single delimiter (to split with multiple delimiters, use `re.split()`). Splitting an empty string with a specified separator returns `['']`.

舉例來:

```
>>> '1,2,3'.split(',')
['1', '2', '3']
>>> '1,2,3'.split(',', maxsplit=1)
```

(繼續下一頁)

(繼續上一頁)

```

['1', '2,3']
>>> '1,2,,3,'.split(',')
['1', '2', '', '3', '']
>>> '1<>2<>3<4'.split('<>')
['1', '2', '3<4']

```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the string has leading or trailing whitespace. Consequently, splitting an empty string or a string consisting of just whitespace with a `None` separator returns `[]`.

舉例來 F:

```

>>> '1 2 3'.split()
['1', '2', '3']
>>> '1 2 3'.split(maxsplit=1)
['1', '2 3']
>>> ' 1 2 3 '.split()
['1', '2', '3']

```

`str.splitlines` (*keepends=False*)

Return a list of the lines in the string, breaking at line boundaries. Line breaks are not included in the resulting list unless *keepends* is given and true.

This method splits on the following line boundaries. In particular, the boundaries are a superset of *universal newlines*.

Representation	描述
<code>\n</code>	Line Feed
<code>\r</code>	Carriage Return
<code>\r\n</code>	Carriage Return + Line Feed
<code>\v</code> 或 <code>\x0b</code>	Line Tabulation
<code>\f</code> 或 <code>\x0c</code>	Form Feed
<code>\x1c</code>	File Separator
<code>\x1d</code>	Group Separator
<code>\x1e</code>	Record Separator
<code>\x85</code>	Next Line (C1 Control Code)
<code>\u2028</code>	Line Separator
<code>\u2029</code>	Paragraph Separator

在 3.2 版的變更: `\v` and `\f` added to list of line boundaries.

舉例來 F:

```

>>> 'ab c\n\nde fg\rkl\r\n'.splitlines()
['ab c', '', 'de fg', 'kl']
>>> 'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
['ab c\n', '\n', 'de fg\r', 'kl\r\n']

```

Unlike `split()` when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```

>>> "".splitlines()
[]
>>> "One line\n".splitlines()
['One line']

```

For comparison, `split('\n')` gives:

```
>>> ''.split('\n')
['']
>>> 'Two lines\n'.split('\n')
['Two lines', '']
```

`str.startswith(prefix[, start[, end]])`

Return `True` if string starts with the *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test string beginning at that position. With optional *end*, stop comparing string at that position.

`str.strip([chars])`

Return a copy of the string with the leading and trailing characters removed. The *chars* argument is a string specifying the set of characters to be removed. If omitted or `None`, the *chars* argument defaults to removing whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> '  spacious  '.strip()
'spacious'
>>> 'www.example.com'.strip('cmowz.')
'example'
```

The outermost leading and trailing *chars* argument values are stripped from the string. Characters are removed from the leading end until reaching a string character that is not contained in the set of characters in *chars*. A similar action takes place on the trailing end. For example:

```
>>> comment_string = '#..... Section 3.2.1 Issue #32 .....'
>>> comment_string.strip('#! ')
'Section 3.2.1 Issue #32'
```

`str.swapcase()`

Return a copy of the string with uppercase characters converted to lowercase and vice versa. Note that it is not necessarily true that `s.swapcase().swapcase() == s`.

`str.title()`

Return a titlecased version of the string where words start with an uppercase character and the remaining characters are lowercase.

舉例來:

```
>>> 'Hello world'.title()
'Hello World'
```

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> "they're bill's friends from the UK".title()
'They'Re Bill'S Friends From The Uk'
```

The `string.capwords()` function does not have this problem, as it splits words on spaces only.

Alternatively, a workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(r"[A-Za-z]+(' [A-Za-z]+)?",
...                   lambda mo: mo.group(0).capitalize(),
...                   s)
...
>>> titlecase("they're bill's friends.")
'They're Bill's Friends.'
```

`str.translate(table)`

Return a copy of the string in which each character has been mapped through the given translation table. The table must be an object that implements indexing via `__getitem__()`, typically a *mapping* or *sequence*. When indexed by a Unicode ordinal (an integer), the table object can do any of the following: return a Unicode ordinal or a string, to map the character to one or more other characters; return `None`, to delete the character from the return string; or raise a `LookupError` exception, to map the character to itself.

You can use `str.maketrans()` to create a translation map from character-to-character mappings in different formats.

See also the `codecs` module for a more flexible approach to custom character mappings.

`str.upper()`

Return a copy of the string with all the cased characters<sup>Page 55, 4</sup> converted to uppercase. Note that `s.upper().isupper()` might be `False` if `s` contains uncased characters or if the Unicode category of the resulting character(s) is not "Lu" (Letter, uppercase), but e.g. "Lt" (Letter, titlecase).

The uppercasing algorithm used is described in section 3.13 'Default Case Folding' of the Unicode Standard.

`str.zfill(width)`

Return a copy of the string left filled with ASCII '0' digits to make a string of length `width`. A leading sign prefix ('+'/'-') is handled by inserting the padding *after* the sign character rather than before. The original string is returned if `width` is less than or equal to `len(s)`.

舉例來 F:

```
>>> "42".zfill(5)
'00042'
>>> "-42".zfill(5)
'-0042'
```

## 4.8.2 printf-style String Formatting

### 備 F

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). Using the newer formatted string literals, the `str.format()` interface, or *template strings* may help avoid these errors. Each of these alternatives provides their own trade-offs and benefits of simplicity, flexibility, and/or extensibility.

String objects have one unique built-in operation: the `%` operator (modulo). This is also known as the string *formatting* or *interpolation* operator. Given `format % values` (where `format` is a string), `%` conversion specifications in `format` are replaced with zero or more elements of `values`. The effect is similar to using the `sprintf()` function in the C language. For example:

```
>>> print('%s has %d quote types.' % ('Python', 2))
Python has 2 quote types.
```

If `format` requires a single argument, `values` may be a single non-tuple object.<sup>5</sup> Otherwise, `values` must be a tuple with exactly the number of items specified by the format string, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.

<sup>5</sup> To format only a tuple you should therefore provide a singleton tuple whose only element is the tuple to be formatted.

4. Minimum field width (optional). If specified as an '\*' (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a '.' (dot) followed by the precision. If specified as '\*' (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).
7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the string *must* include a parenthesised mapping key into that dictionary inserted immediately after the '%' character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print('%(language)s has %(number)03d quote types.' %
...       {'language': "Python", "number": 2})
Python has 002 quote types.
```

In this case no \* specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

Flag	含義
'#'	The value conversion will use the "alternate form" (where defined below).
'0'	The conversion will be zero padded for numeric values.
'-'	The converted value is left adjusted (overrides the '0' conversion if both are given).
' '	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
'+'	A sign character ('+' or '-') will precede the conversion (overrides a "space" flag).

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python -- so e.g. %ld is identical to %d.

The conversion types are:

Con- version	含義	<span style="border: 1px solid black; padding: 0 2px;">F</span> 解
'd'	Signed integer decimal.	
'i'	Signed integer decimal.	
'o'	Signed octal value.	(1)
'u'	Obsolete type -- it is identical to 'd'.	(6)
'x'	Signed hexadecimal (lowercase).	(2)
'X'	Signed hexadecimal (uppercase).	(2)
'e'	Floating-point exponential format (lowercase).	(3)
'E'	Floating-point exponential format (uppercase).	(3)
'f'	Floating-point decimal format.	(3)
'F'	Floating-point decimal format.	(3)
'g'	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'G'	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'c'	Single character (accepts integer or single character string).	
'r'	String (converts any Python object using <i>repr()</i> ).	(5)
's'	String (converts any Python object using <i>str()</i> ).	(5)
'a'	String (converts any Python object using <i>ascii()</i> ).	(5)
'%'	No argument is converted, results in a '%' character in the result.	

F解:

- (1) The alternate form causes a leading octal specifier ('0o') to be inserted before the first digit.
- (2) The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.
- (3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.  
The precision determines the number of digits after the decimal point and defaults to 6.
- (4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.  
The precision determines the number of significant digits before and after the decimal point and defaults to 6.
- (5) If precision is *N*, the output is truncated to *N* characters.
- (6) 參 F PEP 237。

Since Python strings have an explicit length, %s conversions do not assume that '\0' is the end of the string.

在 3.1 版的變更: %f conversions for numbers whose absolute value is over 1e50 are no longer replaced by %g conversions.

## 4.9 Binary Sequence Types --- bytes, bytearray, memoryview

The core built-in types for manipulating binary data are *bytes* and *bytearray*. They are supported by *memoryview* which uses the buffer protocol to access the memory of other binary objects without needing to make a copy.

The *array* module supports efficient storage of basic data types like 32-bit integers and IEEE754 double-precision floating values.

### 4.9.1 Bytes Objects

Bytes objects are immutable sequences of single bytes. Since many major binary protocols are based on the ASCII text encoding, bytes objects offer several methods that are only valid when working with ASCII compatible data and are closely related to string objects in a variety of other ways.

```
class bytes ([source[, encoding[, errors]]])
```

Firstly, the syntax for bytes literals is largely the same as that for string literals, except that a *b* prefix is added:

- Single quotes: `b'still allows embedded "double" quotes'`
- Double quotes: `b"still allows embedded 'single' quotes"`
- Triple quoted: `b'''3 single quotes''',b"""3 double quotes"""`

Only ASCII characters are permitted in bytes literals (regardless of the declared source code encoding). Any binary values over 127 must be entered into bytes literals using the appropriate escape sequence.

As with string literals, bytes literals may also use a *r* prefix to disable processing of escape sequences. See strings for more about the various forms of bytes literal, including supported escape sequences.

While bytes literals and representations are based on ASCII text, bytes objects actually behave like immutable sequences of integers, with each value in the sequence restricted such that  $0 \leq x < 256$  (attempts to violate this restriction will trigger *ValueError*). This is done deliberately to emphasise that while many binary formats include ASCII based elements and can be usefully manipulated with some text-oriented algorithms, this is not generally the case for arbitrary binary data (blindly applying text processing algorithms to binary data formats that are not ASCII compatible will usually lead to data corruption).

In addition to the literal forms, bytes objects can be created in a number of other ways:

- A zero-filled bytes object of a specified length: `bytes(10)`
- From an iterable of integers: `bytes(range(20))`
- Copying existing binary data via the buffer protocol: `bytes(obj)`

Also see the *bytes* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytes type has an additional class method to read data in that format:

**classmethod** `fromhex(string)`

This *bytes* class method returns a bytes object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytes.fromhex('2Ef0 F1f2 ')
b'\xf0\xf1\xf2'
```

在 3.7 版的變更: `bytes.fromhex()` now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytes object into its hexadecimal representation.

**hex**(`[sep[, bytes_per_sep]]`)

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> b'\xf0\xf1\xf2'.hex()
'f0f1f2'
```

If you want to make the hex string easier to read, you can specify a single character separator *sep* parameter to include in the output. By default, this separator will be included between each byte. A second optional *bytes\_per\_sep* parameter controls the spacing. Positive values calculate the separator position from the right, negative values from the left.

```
>>> value = b'\xf0\xf1\xf2'
>>> value.hex('-')
'f0-f1-f2'
>>> value.hex('_', 2)
'f0_f1f2'
>>> b'UUDDLRLRAB'.hex(' ', -4)
'55554444 4c524c52 4142'
```

在 3.5 版被加入。

在 3.8 版的變更: `bytes.hex()` now supports optional *sep* and *bytes\_per\_sep* parameters to insert separators between bytes in the hex output.

Since bytes objects are sequences of integers (akin to a tuple), for a bytes object *b*, `b[0]` will be an integer, while `b[0:1]` will be a bytes object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytes objects uses the literal format (`b'...'`) since it is often more useful than e.g. `bytes([46, 46, 46])`. You can always convert a bytes object into a list of integers using `list(b)`.

## 4.9.2 bytearray Objects

*bytearray* objects are a mutable counterpart to *bytes* objects.

**class** `bytearray([source[, encoding[, errors]])`

There is no dedicated literal syntax for bytearray objects, instead they are always created by calling the constructor:

- Creating an empty instance: `bytearray()`
- Creating a zero-filled instance with a given length: `bytearray(10)`
- From an iterable of integers: `bytearray(range(20))`
- Copying existing binary data via the buffer protocol: `bytearray(b'Hi!')`

As bytearray objects are mutable, they support the *mutable* sequence operations in addition to the common bytes and bytearray operations described in *Bytes and Bytearray Operations*.

Also see the *bytearray* built-in.

Since 2 hexadecimal digits correspond precisely to a single byte, hexadecimal numbers are a commonly used format for describing binary data. Accordingly, the bytearray type has an additional class method to read data in that format:

**classmethod** `fromhex(string)`

This *bytearray* class method returns bytearray object, decoding the given string object. The string must contain two hexadecimal digits per byte, with ASCII whitespace being ignored.

```
>>> bytearray.fromhex('2Ef0 F1f2 ')
bytearray(b'\xf0\xf1\xf2')
```

在 3.7 版的變更: *bytearray.fromhex()* now skips all ASCII whitespace in the string, not just spaces.

A reverse conversion function exists to transform a bytearray object into its hexadecimal representation.

**hex** (`[sep[, bytes_per_sep]]`)

Return a string object containing two hexadecimal digits for each byte in the instance.

```
>>> bytearray(b'\xf0\xf1\xf2').hex()
'f0f1f2'
```

在 3.5 版被加入.

在 3.8 版的變更: Similar to *bytes.hex()*, *bytearray.hex()* now supports optional *sep* and *bytes\_per\_sep* parameters to insert separators between bytes in the hex output.

Since bytearray objects are sequences of integers (akin to a list), for a bytearray object *b*, *b*[0] will be an integer, while *b*[0:1] will be a bytearray object of length 1. (This contrasts with text strings, where both indexing and slicing will produce a string of length 1)

The representation of bytearray objects uses the bytes literal format (`bytearray(b'...')`) since it is often more useful than e.g. `bytearray([46, 46, 46])`. You can always convert a bytearray object into a list of integers using `list(b)`.

### 4.9.3 Bytes and Bytearray Operations

Both bytes and bytearray objects support the *common* sequence operations. They interoperate not just with operands of the same type, but with any *bytes-like object*. Due to this flexibility, they can be freely mixed in operations without causing errors. However, the return type of the result may depend on the order of operands.

#### 備 F

The methods on bytes and bytearray objects don't accept strings as their arguments, just as the methods on strings don't accept bytes as their arguments. For example, you have to write:

```
a = "abc"
b = a.replace("a", "f")
```

和:

```
a = b"abc"
b = a.replace(b"a", b"f")
```

Some bytes and bytearray operations assume the use of ASCII compatible binary formats, and hence should be avoided when working with arbitrary binary data. These restrictions are covered below.

**i** 備

Using these ASCII based operations to manipulate binary data that is not stored in an ASCII based format may lead to data corruption.

The following methods on bytes and bytearray objects can be used with arbitrary binary data.

`bytes.count(sub[, start[, end]])`

`bytearray.count(sub[, start[, end]])`

Return the number of non-overlapping occurrences of subsequence *sub* in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

If *sub* is empty, returns the number of empty slices between characters which is the length of the bytes object plus one.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.removeprefix(prefix, /)`

`bytearray.removeprefix(prefix, /)`

If the binary data starts with the *prefix* string, return `bytes[len(prefix):]`. Otherwise, return a copy of the original binary data:

```
>>> b'TestHook'.removeprefix(b'Test')
b'Hook'
>>> b'BaseTestCase'.removeprefix(b'Test')
b'BaseTestCase'
```

The *prefix* may be any *bytes-like object*.

**i** 備

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

在 3.9 版被加入.

`bytes.removesuffix(suffix, /)`

`bytearray.removesuffix(suffix, /)`

If the binary data ends with the *suffix* string and that *suffix* is not empty, return `bytes[:-len(suffix)]`. Otherwise, return a copy of the original binary data:

```
>>> b'MiscTests'.removesuffix(b'Tests')
b'Misc'
>>> b'TmpDirMixin'.removesuffix(b'Tests')
b'TmpDirMixin'
```

The *suffix* may be any *bytes-like object*.

**i** 備

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

在 3.9 版被加入.

`bytes.decode(encoding='utf-8', errors='strict')`

`bytearray.decode(encoding='utf-8', errors='strict')`

Return the bytes decoded to a *str*.

*encoding* defaults to 'utf-8'; see *Standard Encodings* for possible values.

*errors* controls how decoding errors are handled. If 'strict' (the default), a *UnicodeError* exception is raised. Other possible values are 'ignore', 'replace', and any other name registered via *codecs.register\_error()*. See *Error Handlers* for details.

For performance reasons, the value of *errors* is not checked for validity unless a decoding error actually occurs, *Python* 開發模式 is enabled or a debug build is used.

**i 備 F**

Passing the *encoding* argument to *str* allows decoding any *bytes-like object* directly, without needing to make a temporary *bytes* or *bytearray* object.

在 3.1 版的變更: 新增關鍵字引數的支援。

在 3.9 版的變更: The value of the *errors* argument is now checked in *Python* 開發模式 and in debug mode.

`bytes.endswith(suffix[, start[, end]])`

`bytearray.endswith(suffix[, start[, end]])`

Return `True` if the binary data ends with the specified *suffix*, otherwise return `False`. *suffix* can also be a tuple of suffixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The suffix(es) to search for may be any *bytes-like object*.

`bytes.find(sub[, start[, end]])`

`bytearray.find(sub[, start[, end]])`

Return the lowest index in the data where the subsequence *sub* is found, such that *sub* is contained in the slice `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` if *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

**i 備 F**

The *find()* method should be used only if you need to know the position of *sub*. To check if *sub* is a substring or not, use the `in` operator:

```
>>> b'Py' in b'Python'
True
```

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.index(sub[, start[, end]])`

`bytearray.index(sub[, start[, end]])`

Like *find()*, but raise *ValueError* when the subsequence is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.join(iterable)`

`bytearray.join(iterable)`

Return a bytes or bytearray object which is the concatenation of the binary data sequences in *iterable*. A *TypeError* will be raised if there are any values in *iterable* that are not *bytes-like objects*, including *str* objects. The separator between elements is the contents of the bytes or bytearray object providing this method.

**static** `bytes.maketrans` (*from*, *to*)

**static** `bytearray.maketrans` (*from*, *to*)

This static method returns a translation table usable for `bytes.translate()` that will map each character in *from* into the character at the same position in *to*; *from* and *to* must both be *bytes-like objects* and have the same length.

在 3.1 版被加入。

`bytes.partition` (*sep*)

`bytearray.partition` (*sep*)

Split the sequence at the first occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing a copy of the original sequence, followed by two empty bytes or bytearray objects.

The separator to search for may be any *bytes-like object*.

`bytes.replace` (*old*, *new* [, *count* ])

`bytearray.replace` (*old*, *new* [, *count* ])

Return a copy of the sequence with all occurrences of subsequence *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

The subsequence to search for and its replacement may be any *bytes-like object*.

**i 備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.rfind` (*sub* [, *start* [, *end* ] ])

`bytearray.rfind` (*sub* [, *start* [, *end* ] ])

Return the highest index in the sequence where the subsequence *sub* is found, such that *sub* is contained within `s[start:end]`. Optional arguments *start* and *end* are interpreted as in slice notation. Return `-1` on failure.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.rindex` (*sub* [, *start* [, *end* ] ])

`bytearray.rindex` (*sub* [, *start* [, *end* ] ])

Like `rfind()` but raises `ValueError` when the subsequence *sub* is not found.

The subsequence to search for may be any *bytes-like object* or an integer in the range 0 to 255.

在 3.3 版的變更: Also accept an integer in the range 0 to 255 as the subsequence.

`bytes.rpartition` (*sep*)

`bytearray.rpartition` (*sep*)

Split the sequence at the last occurrence of *sep*, and return a 3-tuple containing the part before the separator, the separator itself or its bytearray copy, and the part after the separator. If the separator is not found, return a 3-tuple containing two empty bytes or bytearray objects, followed by a copy of the original sequence.

The separator to search for may be any *bytes-like object*.

`bytes.startswith` (*prefix* [, *start* [, *end* ] ])

`bytearray.startswith` (*prefix* [, *start* [, *end* ] ])

Return `True` if the binary data starts with the specified *prefix*, otherwise return `False`. *prefix* can also be a tuple of prefixes to look for. With optional *start*, test beginning at that position. With optional *end*, stop comparing at that position.

The prefix(es) to search for may be any *bytes-like object*.

`bytes.translate(table, /, delete=b"")`

`bytearray.translate(table, /, delete=b"")`

Return a copy of the bytes or bytearray object where all bytes occurring in the optional argument *delete* are removed, and the remaining bytes have been mapped through the given translation table, which must be a bytes object of length 256.

You can use the `bytes.maketrans()` method to create a translation table.

Set the *table* argument to `None` for translations that only delete characters:

```
>>> b'read this short text'.translate(None, b'aeiou')
b'rd ths shrt txt'
```

在 3.6 版的變更: *delete* is now supported as a keyword argument.

The following methods on bytes and bytearray objects have default behaviours that assume the use of ASCII compatible binary formats, but can still be used with arbitrary binary data by passing appropriate arguments. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

`bytes.center(width[, fillbyte])`

`bytearray.center(width[, fillbyte])`

Return a copy of the object centered in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

**備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.ljust(width[, fillbyte])`

`bytearray.ljust(width[, fillbyte])`

Return a copy of the object left justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

**備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.lstrip([chars])`

`bytearray.lstrip([chars])`

Return a copy of the sequence with specified leading bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.lstrip()
b'spacious   '
>>> b'www.example.com'.lstrip(b'cmowz.')
b'example.com'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See `removeprefix()` for a method that will remove a single prefix string rather than all of a set of characters. For example:

```
>>> b'Arthur: three!'.rstrip(b'Arthur: ')
b'ee!'
>>> b'Arthur: three!'.removeprefix(b'Arthur: ')
b'three!'
```

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.rjust` (*width* [, *fillbyte* ])

`bytearray.rjust` (*width* [, *fillbyte* ])

Return a copy of the object right justified in a sequence of length *width*. Padding is done using the specified *fillbyte* (default is an ASCII space). For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(s)`.

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.rspl`*it* (*sep=None, maxsplit=-1*)

`bytearray.rspl`*it* (*sep=None, maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given, at most *maxsplit* splits are done, the *rightmost* ones. If *sep* is not specified or `None`, any subsequence consisting solely of ASCII whitespace is a separator. Except for splitting from the right, *rsplit()* behaves like *split()* which is described in detail below.

`bytes.rstrip` (*chars* )

`bytearray.rstrip` (*chars* )

Return a copy of the sequence with specified trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a suffix; rather, all combinations of its values are stripped:

```
>>> b'   spacious   '.rstrip()
b'   spacious'
>>> b'mississippi'.rstrip(b'ipz')
b'mississ'
```

The binary sequence of byte values to remove may be any *bytes-like object*. See *removesuffix()* for a method that will remove a single suffix string rather than all of a set of characters. For example:

```
>>> b'Monty Python'.rstrip(b' Python')
b'M'
>>> b'Monty Python'.removesuffix(b' Python')
b'Monty'
```

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.spl`*it* (*sep=None, maxsplit=-1*)

`bytearray.split` (*sep=None, maxsplit=-1*)

Split the binary sequence into subsequences of the same type, using *sep* as the delimiter string. If *maxsplit* is given and non-negative, at most *maxsplit* splits are done (thus, the list will have at most *maxsplit*+1 elements). If *maxsplit* is not specified or is `-1`, then there is no limit on the number of splits (all possible splits are made).

If *sep* is given, consecutive delimiters are not grouped together and are deemed to delimit empty subsequences (for example, `b'1,,2'.split(b',')` returns `[b'1', b'', b'2']`). The *sep* argument may consist of a multibyte sequence as a single delimiter. Splitting an empty sequence with a specified separator returns `[b'']` or `[bytearray(b'')]` depending on the type of object being split. The *sep* argument may be any *bytes-like object*.

舉例來 F:

```
>>> b'1,2,3'.split(b',')
[b'1', b'2', b'3']
>>> b'1,2,3'.split(b',', maxsplit=1)
[b'1', b'2,3']
>>> b'1,2,,3'.split(b',')
[b'1', b'2', b'', b'3', b'']
>>> b'1<>2<>3<4'.split(b'<>')
[b'1', b'2', b'3<4']
```

If *sep* is not specified or is `None`, a different splitting algorithm is applied: runs of consecutive ASCII whitespace are regarded as a single separator, and the result will contain no empty strings at the start or end if the sequence has leading or trailing whitespace. Consequently, splitting an empty sequence or a sequence consisting solely of ASCII whitespace without a specified separator returns `[]`.

舉例來 F:

```
>>> b'1 2 3'.split()
[b'1', b'2', b'3']
>>> b'1 2 3'.split(maxsplit=1)
[b'1', b'2 3']
>>> b' 1 2 3 '.split()
[b'1', b'2', b'3']
```

`bytes.strip` (*[chars]*)

`bytearray.strip` (*[chars]*)

Return a copy of the sequence with specified leading and trailing bytes removed. The *chars* argument is a binary sequence specifying the set of byte values to be removed - the name refers to the fact this method is usually used with ASCII characters. If omitted or `None`, the *chars* argument defaults to removing ASCII whitespace. The *chars* argument is not a prefix or suffix; rather, all combinations of its values are stripped:

```
>>> b'  spacious '.strip()
b'spacious'
>>> b'www.example.com'.strip(b'cmowz.')
b'example'
```

The binary sequence of byte values to remove may be any *bytes-like object*.

#### **i** 備 F

The `bytearray` version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

The following methods on bytes and bytearray objects assume the use of ASCII compatible binary formats and should not be applied to arbitrary binary data. Note that all of the bytearray methods in this section do *not* operate in place, and instead produce new objects.

`bytes.capitalize` ()

`bytearray.capitalize()`

Return a copy of the sequence with each byte interpreted as an ASCII character, and the first byte capitalized and the rest lowercased. Non-ASCII byte values are passed through unchanged.

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.expandtabs(tabsize=8)`

`bytearray.expandtabs(tabsize=8)`

Return a copy of the sequence where all ASCII tab characters are replaced by one or more ASCII spaces, depending on the current column and the given tab size. Tab positions occur every *tabsize* bytes (default is 8, giving tab positions at columns 0, 8, 16 and so on). To expand the sequence, the current column is set to zero and the sequence is examined byte by byte. If the byte is an ASCII tab character (`b'\t'`), one or more space characters are inserted in the result until the current column is equal to the next tab position. (The tab character itself is not copied.) If the current byte is an ASCII newline (`b'\n'`) or carriage return (`b'\r'`), it is copied and the current column is reset to zero. Any other byte value is copied unchanged and the current column is incremented by one regardless of how the byte value is represented when printed:

```
>>> b'01\t012\t0123\t01234'.expandtabs()
b'01      012      0123      01234'
>>> b'01\t012\t0123\t01234'.expandtabs(4)
b'01  012 0123  01234'
```

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.isalnum()`

`bytearray.isalnum()`

Return `True` if all bytes in the sequence are alphabetical ASCII characters or ASCII decimal digits and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

舉例來:

```
>>> b'ABCabc1'.isalnum()
True
>>> b'ABC abc1'.isalnum()
False
```

`bytes.isalpha()`

`bytearray.isalpha()`

Return `True` if all bytes in the sequence are alphabetic ASCII characters and the sequence is not empty, `False` otherwise. Alphabetic ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

舉例來:

```
>>> b'ABCabc'.isalpha()
True
>>> b'ABCabc1'.isalpha()
False
```

`bytes.isascii()`

`bytearray.isascii()`

Return `True` if the sequence is empty or all bytes in the sequence are ASCII, `False` otherwise. ASCII bytes are in the range 0-0x7F.

在 3.7 版被加入。

`bytes.isdigit()`

`bytearray.isdigit()`

Return `True` if all bytes in the sequence are ASCII decimal digits and the sequence is not empty, `False` otherwise. ASCII decimal digits are those byte values in the sequence `b'0123456789'`.

舉例來:

```
>>> b'1234'.isdigit()
True
>>> b'1.23'.isdigit()
False
```

`bytes.islower()`

`bytearray.islower()`

Return `True` if there is at least one lowercase ASCII character in the sequence and no uppercase ASCII characters, `False` otherwise.

舉例來:

```
>>> b'hello world'.islower()
True
>>> b'Hello world'.islower()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.isspace()`

`bytearray.isspace()`

Return `True` if all bytes in the sequence are ASCII whitespace and the sequence is not empty, `False` otherwise. ASCII whitespace characters are those byte values in the sequence `b' \t\n\r\x0b\x0c'` (space, tab, newline, carriage return, vertical tab, form feed).

`bytes.istitle()`

`bytearray.istitle()`

Return `True` if the sequence is ASCII titlecase and the sequence is not empty, `False` otherwise. See `bytes.title()` for more details on the definition of "titlecase".

舉例來:

```
>>> b'Hello World'.istitle()
True
>>> b'Hello world'.istitle()
False
```

`bytes.isupper()`

`bytearray.isupper()`

Return `True` if there is at least one uppercase alphabetic ASCII character in the sequence and no lowercase ASCII characters, `False` otherwise.

舉例來:

```
>>> b'HELLO WORLD'.isupper()
True
>>> b'Hello world'.isupper()
False
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`.  
Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

`bytes.lower()`

`bytearray.lower()`

Return a copy of the sequence with all the uppercase ASCII characters converted to their corresponding lowercase counterpart.

舉例來:

```
>>> b'Hello World'.lower()
b'hello world'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`.  
Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

#### 備

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.splitlines(keepends=False)`

`bytearray.splitlines(keepends=False)`

Return a list of the lines in the binary sequence, breaking at ASCII line boundaries. This method uses the *universal newlines* approach to splitting lines. Line breaks are not included in the resulting list unless *keepends* is given and true.

舉例來:

```
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines()
[b'ab c', b'', b'de fg', b'kl']
>>> b'ab c\n\nde fg\rkl\r\n'.splitlines(keepends=True)
[b'ab c\n', b'\n', b'de fg\r', b'kl\r\n']
```

Unlike `split()` when a delimiter string *sep* is given, this method returns an empty list for the empty string, and a terminal line break does not result in an extra line:

```
>>> b"".split(b'\n'), b"Two lines\n".split(b'\n')
([], [b'Two lines', b''])
>>> b"".splitlines(), b"One line\n".splitlines()
([], [b'One line'])
```

`bytes.swapcase()`

`bytearray.swapcase()`

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart and vice-versa.

舉例來:

```
>>> b'Hello World'.swapcase()
b'hELLO wORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`.  
Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

Unlike `str.swapcase()`, it is always the case that `bin.swapcase().swapcase() == bin` for the binary versions. Case conversions are symmetrical in ASCII, even though that is not generally true for arbitrary Unicode code points.

**備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.title()`

`bytearray.title()`

Return a titlecased version of the binary sequence where words start with an uppercase ASCII character and the remaining characters are lowercase. Uncased byte values are left unmodified.

舉例來 F:

```
>>> b'Hello world'.title()
b'Hello World'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`. All other byte values are uncased.

The algorithm uses a simple language-independent definition of a word as groups of consecutive letters. The definition works in many contexts but it means that apostrophes in contractions and possessives form word boundaries, which may not be the desired result:

```
>>> b"they're bill's friends from the UK".title()
b'They'Re Bill'S Friends From The Uk"
```

A workaround for apostrophes can be constructed using regular expressions:

```
>>> import re
>>> def titlecase(s):
...     return re.sub(rb"[A-Za-z]+(' [A-Za-z]+)?",
...                   lambda mo: mo.group(0)[0:1].upper() +
...                               mo.group(0)[1:].lower(),
...                   s)
...
>>> titlecase(b"they're bill's friends.")
b'They're Bill's Friends.'
```

**備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.upper()`

`bytearray.upper()`

Return a copy of the sequence with all the lowercase ASCII characters converted to their corresponding uppercase counterpart.

舉例來 F:

```
>>> b'Hello World'.upper()
b'HELLO WORLD'
```

Lowercase ASCII characters are those byte values in the sequence `b'abcdefghijklmnopqrstuvwxyz'`. Uppercase ASCII characters are those byte values in the sequence `b'ABCDEFGHIJKLMNOPQRSTUVWXYZ'`.

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

`bytes.zfill(width)`

`bytearray.zfill(width)`

Return a copy of the sequence left filled with ASCII `b'0'` digits to make a sequence of length *width*. A leading sign prefix (`b'+' / b'-'`) is handled by inserting the padding *after* the sign character rather than before. For *bytes* objects, the original sequence is returned if *width* is less than or equal to `len(seq)`.

舉例來:

```
>>> b"42".zfill(5)
b'00042'
>>> b"-42".zfill(5)
b'-0042'
```

**備**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

## 4.9.4 printf-style Bytes Formatting

**備**

The formatting operations described here exhibit a variety of quirks that lead to a number of common errors (such as failing to display tuples and dictionaries correctly). If the value being printed may be a tuple or dictionary, wrap it in a tuple.

Bytes objects (*bytes*/*bytearray*) have one unique built-in operation: the `%` operator (modulo). This is also known as the bytes *formatting* or *interpolation* operator. Given *format % values* (where *format* is a bytes object), `%` conversion specifications in *format* are replaced with zero or more elements of *values*. The effect is similar to using the `sprintf()` in the C language.

If *format* requires a single argument, *values* may be a single non-tuple object.<sup>Page 60, 5</sup> Otherwise, *values* must be a tuple with exactly the number of items specified by the format bytes object, or a single mapping object (for example, a dictionary).

A conversion specifier contains two or more characters and has the following components, which must occur in this order:

1. The `'%'` character, which marks the start of the specifier.
2. Mapping key (optional), consisting of a parenthesised sequence of characters (for example, `(somename)`).
3. Conversion flags (optional), which affect the result of some conversion types.
4. Minimum field width (optional). If specified as an `'*'` (asterisk), the actual width is read from the next element of the tuple in *values*, and the object to convert comes after the minimum field width and optional precision.
5. Precision (optional), given as a `'.'` (dot) followed by the precision. If specified as `'*'` (an asterisk), the actual precision is read from the next element of the tuple in *values*, and the value to convert comes after the precision.
6. Length modifier (optional).

7. Conversion type.

When the right argument is a dictionary (or other mapping type), then the formats in the bytes object *must* include a parenthesised mapping key into that dictionary inserted immediately after the '%' character. The mapping key selects the value to be formatted from the mapping. For example:

```
>>> print(b'%(language)s has %(number)03d quote types.' %
...       {b'language': b'Python', b'number': 2})
b'Python has 002 quote types.'
```

In this case no \* specifiers may occur in a format (since they require a sequential parameter list).

The conversion flag characters are:

Flag	含義
'#'	The value conversion will use the "alternate form" (where defined below).
'0'	The conversion will be zero padded for numeric values.
'-'	The converted value is left adjusted (overrides the '0' conversion if both are given).
' '	(a space) A blank should be left before a positive number (or empty string) produced by a signed conversion.
'+'	A sign character ('+' or '-') will precede the conversion (overrides a "space" flag).

A length modifier (h, l, or L) may be present, but is ignored as it is not necessary for Python -- so e.g. %ld is identical to %d.

The conversion types are:

Con- version	含義	F 解
'd'	Signed integer decimal.	
'i'	Signed integer decimal.	
'o'	Signed octal value.	(1)
'u'	Obsolete type -- it is identical to 'd'.	(8)
'x'	Signed hexadecimal (lowercase).	(2)
'X'	Signed hexadecimal (uppercase).	(2)
'e'	Floating-point exponential format (lowercase).	(3)
'E'	Floating-point exponential format (uppercase).	(3)
'f'	Floating-point decimal format.	(3)
'F'	Floating-point decimal format.	(3)
'g'	Floating-point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'G'	Floating-point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.	(4)
'c'	Single byte (accepts integer or single byte objects).	
'b'	Bytes (any object that follows the buffer protocol or has <code>__bytes__()</code> ).	(5)
's'	's' is an alias for 'b' and should only be used for Python2/3 code bases.	(6)
'a'	Bytes (converts any Python object using <code>repr(obj).encode('ascii', 'backslashreplace')</code> ).	(5)
'r'	'r' is an alias for 'a' and should only be used for Python2/3 code bases.	(7)
'%'	No argument is converted, results in a '%' character in the result.	

F解:

- (1) The alternate form causes a leading octal specifier ('0o') to be inserted before the first digit.
- (2) The alternate form causes a leading '0x' or '0X' (depending on whether the 'x' or 'X' format was used) to be inserted before the first digit.

- (3) The alternate form causes the result to always contain a decimal point, even if no digits follow it.  
The precision determines the number of digits after the decimal point and defaults to 6.
- (4) The alternate form causes the result to always contain a decimal point, and trailing zeroes are not removed as they would otherwise be.  
The precision determines the number of significant digits before and after the decimal point and defaults to 6.
- (5) If precision is *N*, the output is truncated to *N* characters.
- (6) `b'%s'` is deprecated, but will not be removed during the 3.x series.
- (7) `b'%r'` is deprecated, but will not be removed during the 3.x series.
- (8) 參 F [PEP 237](#).

**備 F**

The bytearray version of this method does *not* operate in place - it always produces a new object, even if no changes were made.

[PEP 461](#) - Adding % formatting to bytes and bytearray

在 3.5 版被加入。

## 4.9.5 Memory Views

`memoryview` objects allow Python code to access the internal data of an object that supports the buffer protocol without copying.

**class** `memoryview`(*object*)

Create a `memoryview` that references *object*. *object* must support the buffer protocol. Built-in objects that support the buffer protocol include `bytes` and `bytearray`.

A `memoryview` has the notion of an *element*, which is the atomic memory unit handled by the originating *object*. For many simple types such as `bytes` and `bytearray`, an element is a single byte, but other types such as `array.array` may have bigger elements.

`len(view)` is equal to the length of `tolist`, which is the nested list representation of the view. If `view.ndim = 1`, this is equal to the number of elements in the view.

在 3.12 版的變更: If `view.ndim == 0`, `len(view)` now raises `TypeError` instead of returning 1.

The `itemsize` attribute will give you the number of bytes in a single element.

A `memoryview` supports slicing and indexing to expose its data. One-dimensional slicing will result in a subview:

```
>>> v = memoryview(b'abcefg')
>>> v[1]
98
>>> v[-1]
103
>>> v[1:4]
<memory at 0x7f3ddc9f4350>
>>> bytes(v[1:4])
b'bce'
```

If *format* is one of the native format specifiers from the `struct` module, indexing with an integer or a tuple of integers is also supported and returns a single *element* with the correct type. One-dimensional memoryviews

can be indexed with an integer or a one-integer tuple. Multi-dimensional memoryviews can be indexed with tuples of exactly *ndim* integers where *ndim* is the number of dimensions. Zero-dimensional memoryviews can be indexed with the empty tuple.

Here is an example with a non-byte format:

```
>>> import array
>>> a = array.array('l', [-11111111, 22222222, -33333333, 44444444])
>>> m = memoryview(a)
>>> m[0]
-11111111
>>> m[-1]
44444444
>>> m[::2].tolist()
[-11111111, -33333333]
```

If the underlying object is writable, the memoryview supports one-dimensional slice assignment. Resizing is not allowed:

```
>>> data = bytearray(b'abcefg')
>>> v = memoryview(data)
>>> v.readonly
False
>>> v[0] = ord(b'z')
>>> data
bytearray(b'zbcefg')
>>> v[1:4] = b'123'
>>> data
bytearray(b'z123fg')
>>> v[2:3] = b'spam'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: memoryview assignment: lvalue and rvalue have different structures
>>> v[2:6] = b'spam'
>>> data
bytearray(b'z1spam')
```

One-dimensional memoryviews of *hashable* (read-only) types with formats 'B', 'b' or 'c' are also hashable. The hash is defined as `hash(m) == hash(m.tobytes())`:

```
>>> v = memoryview(b'abcefg')
>>> hash(v) == hash(b'abcefg')
True
>>> hash(v[2:4]) == hash(b'ce')
True
>>> hash(v[::2]) == hash(b'abcefg'[::2])
True
```

在 3.3 版的變更: One-dimensional memoryviews can now be sliced. One-dimensional memoryviews with formats 'B', 'b' or 'c' are now *hashable*.

在 3.4 版的變更: memoryview is now registered automatically with `collections.abc.Sequence`

在 3.5 版的變更: memoryviews can now be indexed with tuple of integers.

`memoryview` has several methods:

`__eq__` (*exporter*)

A memoryview and a **PEP 3118** exporter are equal if their shapes are equivalent and if all corresponding values are equal when the operands' respective format codes are interpreted using `struct` syntax.

For the subset of `struct` format strings currently supported by `tolist()`, `v` and `w` are equal if `v.tolist() == w.tolist()`:

```

>>> import array
>>> a = array.array('I', [1, 2, 3, 4, 5])
>>> b = array.array('d', [1.0, 2.0, 3.0, 4.0, 5.0])
>>> c = array.array('b', [5, 3, 1])
>>> x = memoryview(a)
>>> y = memoryview(b)
>>> x == a == y == b
True
>>> x.tolist() == a.tolist() == y.tolist() == b.tolist()
True
>>> z = y[::-2]
>>> z == c
True
>>> z.tolist() == c.tolist()
True

```

If either format string is not supported by the `struct` module, then the objects will always compare as unequal (even if the format strings and buffer contents are identical):

```

>>> from ctypes import BigEndianStructure, c_long
>>> class BEPoint(BigEndianStructure):
...     _fields_ = [("x", c_long), ("y", c_long)]
...
>>> point = BEPoint(100, 200)
>>> a = memoryview(point)
>>> b = memoryview(point)
>>> a == point
False
>>> a == b
False

```

Note that, as with floating-point numbers, `v is w` does *not* imply `v == w` for memoryview objects.

在 3.3 版的變更: Previous versions compared the raw memory disregarding the item format and the logical array structure.

#### `tobytes` (`order='C'`)

Return the data in the buffer as a bytestring. This is equivalent to calling the `bytes` constructor on the memoryview.

```

>>> m = memoryview(b"abc")
>>> m.tobytes()
b'abc'
>>> bytes(m)
b'abc'

```

For non-contiguous arrays the result is equal to the flattened list representation with all elements converted to bytes. `tobytes()` supports all format strings, including those that are not in `struct` module syntax.

在 3.8 版被加入: `order` can be `{'C', 'F', 'A'}`. When `order` is `'C'` or `'F'`, the data of the original array is converted to C or Fortran order. For contiguous views, `'A'` returns an exact copy of the physical memory. In particular, in-memory Fortran order is preserved. For non-contiguous views, the data is converted to C first. `order=None` is the same as `order='C'`.

#### `hex` (`[sep[, bytes_per_sep]]`)

Return a string object containing two hexadecimal digits for each byte in the buffer.

```

>>> m = memoryview(b"abc")
>>> m.hex()
'616263'

```

在 3.5 版被加入.

在 3.8 版的變更: Similar to `bytes.hex()`, `memoryview.hex()` now supports optional `sep` and `bytes_per_sep` parameters to insert separators between bytes in the hex output.

#### `tolist()`

Return the data in the buffer as a list of elements.

```
>>> memoryview(b'abc').tolist()
[97, 98, 99]
>>> import array
>>> a = array.array('d', [1.1, 2.2, 3.3])
>>> m = memoryview(a)
>>> m.tolist()
[1.1, 2.2, 3.3]
```

在 3.3 版的變更: `tolist()` now supports all single character native formats in `struct` module syntax as well as multi-dimensional representations.

#### `toreadonly()`

Return a readonly version of the memoryview object. The original memoryview object is unchanged.

```
>>> m = memoryview(bytearray(b'abc'))
>>> mm = m.toreadonly()
>>> mm.tolist()
[97, 98, 99]
>>> mm[0] = 42
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
>>> m[0] = 43
>>> mm.tolist()
[43, 98, 99]
```

在 3.8 版被加入.

#### `release()`

Release the underlying buffer exposed by the memoryview object. Many objects take special actions when a view is held on them (for example, a `bytearray` would temporarily forbid resizing); therefore, calling `release()` is handy to remove these restrictions (and free any dangling resources) as soon as possible.

After this method has been called, any further operation on the view raises a `ValueError` (except `release()` itself which can be called multiple times):

```
>>> m = memoryview(b'abc')
>>> m.release()
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

The context management protocol can be used for a similar effect, using the `with` statement:

```
>>> with memoryview(b'abc') as m:
...     m[0]
...
97
>>> m[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: operation forbidden on released memoryview object
```

在 3.2 版被加入.

**cast** (*format*[, *shape*])

Cast a memoryview to a new format or shape. *shape* defaults to `[byte_length//new_itemsize]`, which means that the result view will be one-dimensional. The return value is a new memoryview, but the buffer itself is not copied. Supported casts are 1D -> C-contiguous and C-contiguous -> 1D.

The destination format is restricted to a single element native format in *struct* syntax. One of the formats must be a byte format ('B', 'b' or 'c'). The byte length of the result must be the same as the original length. Note that all byte lengths may depend on the operating system.

Cast 1D/long to 1D/unsigned bytes:

```
>>> import array
>>> a = array.array('l', [1,2,3])
>>> x = memoryview(a)
>>> x.format
'l'
>>> x.itemsize
8
>>> len(x)
3
>>> x.nbytes
24
>>> y = x.cast('B')
>>> y.format
'B'
>>> y.itemsize
1
>>> len(y)
24
>>> y.nbytes
24
```

Cast 1D/unsigned bytes to 1D/char:

```
>>> b = bytearray(b'xyz')
>>> x = memoryview(b)
>>> x[0] = b'a'
Traceback (most recent call last):
...
TypeError: memoryview: invalid type for format 'B'
>>> y = x.cast('c')
>>> y[0] = b'a'
>>> b
bytearray(b'ayz')
```

Cast 1D/bytes to 3D/int to 1D/signed char:

```
>>> import struct
>>> buf = struct.pack("i"*12, *list(range(12)))
>>> x = memoryview(buf)
>>> y = x.cast('i', shape=[2,2,3])
>>> y.tolist()
[[[0, 1, 2], [3, 4, 5]], [[6, 7, 8], [9, 10, 11]]]
>>> y.format
'i'
>>> y.itemsize
4
>>> len(y)
2
>>> y.nbytes
48
>>> z = y.cast('b')
>>> z.format
```

(繼續下一頁)

(繼續上一頁)

```
'b'
>>> z.itemsize
1
>>> len(z)
48
>>> z.nbytes
48
```

Cast 1D/unsigned long to 2D/unsigned long:

```
>>> buf = struct.pack("L"*6, *list(range(6)))
>>> x = memoryview(buf)
>>> y = x.cast('L', shape=[2,3])
>>> len(y)
2
>>> y.nbytes
48
>>> y.tolist()
[[0, 1, 2], [3, 4, 5]]
```

在 3.3 版被加入.

在 3.5 版的變更: The source format is no longer restricted when casting to a byte view.

There are also several readonly attributes available:

**obj**

The underlying object of the memoryview:

```
>>> b = bytearray(b'xyz')
>>> m = memoryview(b)
>>> m.obj is b
True
```

在 3.3 版被加入.

**nbytes**

`nbytes == product(shape) * itemsize == len(m.tobytes())`. This is the amount of space in bytes that the array would use in a contiguous representation. It is not necessarily equal to `len(m)`:

```
>>> import array
>>> a = array.array('i', [1,2,3,4,5])
>>> m = memoryview(a)
>>> len(m)
5
>>> m.nbytes
20
>>> y = m[:2]
>>> len(y)
3
>>> y.nbytes
12
>>> len(y.tobytes())
12
```

Multi-dimensional arrays:

```
>>> import struct
>>> buf = struct.pack("d"*12, *[1.5*x for x in range(12)])
>>> x = memoryview(buf)
>>> y = x.cast('d', shape=[3,4])
```

(繼續下一頁)

(繼續上一頁)

```

>>> y.tolist()
[[0.0, 1.5, 3.0, 4.5], [6.0, 7.5, 9.0, 10.5], [12.0, 13.5, 15.0, 16.5]]
>>> len(y)
3
>>> y.nbytes
96

```

在 3.3 版被加入.

**readonly**

A bool indicating whether the memory is read only.

**format**

A string containing the format (in *struct* module style) for each element in the view. A memoryview can be created from exporters with arbitrary format strings, but some methods (e.g. *tolist()*) are restricted to native single element formats.

在 3.3 版的變更: format 'B' is now handled according to the struct module syntax. This means that `memoryview(b'abc')[0] == b'abc'[0] == 97`.

**itemsize**

The size in bytes of each element of the memoryview:

```

>>> import array, struct
>>> m = memoryview(array.array('H', [32000, 32001, 32002]))
>>> m.itemsize
2
>>> m[0]
32000
>>> struct.calcsize('H') == m.itemsize
True

```

**ndim**

An integer indicating how many dimensions of a multi-dimensional array the memory represents.

**shape**

A tuple of integers the length of *ndim* giving the shape of the memory as an N-dimensional array.

在 3.3 版的變更: An empty tuple instead of `None` when *ndim* = 0.

**strides**

A tuple of integers the length of *ndim* giving the size in bytes to access each element for each dimension of the array.

在 3.3 版的變更: An empty tuple instead of `None` when *ndim* = 0.

**suboffsets**

Used internally for PIL-style arrays. The value is informational only.

**c\_contiguous**

A bool indicating whether the memory is C-*contiguous*.

在 3.3 版被加入.

**f\_contiguous**

A bool indicating whether the memory is Fortran *contiguous*.

在 3.3 版被加入.

**contiguous**

A bool indicating whether the memory is *contiguous*.

在 3.3 版被加入.

## 4.10 Set Types --- `set`, `frozenset`

A `set` object is an unordered collection of distinct *hashable* objects. Common uses include membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference. (For other containers see the built-in `dict`, `list`, and `tuple` classes, and the `collections` module.)

Like other collections, sets support `x in set`, `len(set)`, and `for x in set`. Being an unordered collection, sets do not record element position or order of insertion. Accordingly, sets do not support indexing, slicing, or other sequence-like behavior.

There are currently two built-in set types, `set` and `frozenset`. The `set` type is mutable --- the contents can be changed using methods like `add()` and `remove()`. Since it is mutable, it has no hash value and cannot be used as either a dictionary key or as an element of another set. The `frozenset` type is immutable and *hashable* --- its contents cannot be altered after it is created; it can therefore be used as a dictionary key or as an element of another set.

Non-empty sets (not `frozensets`) can be created by placing a comma-separated list of elements within braces, for example: `{'jack', 'sjoerd'}`, in addition to the `set` constructor.

The constructors for both classes work the same:

```
class set ([iterable])
class frozenset ([iterable])
```

Return a new set or `frozenset` object whose elements are taken from *iterable*. The elements of a set must be *hashable*. To represent sets of sets, the inner sets must be `frozenset` objects. If *iterable* is not specified, a new empty set is returned.

Sets can be created by several means:

- Use a comma-separated list of elements within braces: `{'jack', 'sjoerd'}`
- Use a set comprehension: `{c for c in 'abracadabra' if c not in 'abc'}`
- Use the type constructor: `set()`, `set('foobar')`, `set(['a', 'b', 'foo'])`

Instances of `set` and `frozenset` provide the following operations:

**len(s)**

Return the number of elements in set *s* (cardinality of *s*).

**x in s**

Test *x* for membership in *s*.

**x not in s**

Test *x* for non-membership in *s*.

**isdisjoint(*other*)**

Return `True` if the set has no elements in common with *other*. Sets are disjoint if and only if their intersection is the empty set.

**issubset(*other*)**

**set <= other**

Test whether every element in the set is in *other*.

**set < other**

Test whether the set is a proper subset of *other*, that is, `set <= other` and `set != other`.

**issuperset(*other*)**

**set >= other**

Test whether every element in *other* is in the set.

**set > other**

Test whether the set is a proper superset of *other*, that is, `set >= other` and `set != other`.

**union(\*others)**

**set | other | ...**

Return a new set with elements from the set and all others.

**intersection(\*others)**

**set & other & ...**

Return a new set with elements common to the set and all others.

**difference(\*others)**

**set - other - ...**

Return a new set with elements in the set that are not in the others.

**symmetric\_difference(other)**

**set ^ other**

Return a new set with elements in either the set or *other* but not both.

**copy()**

Return a shallow copy of the set.

Note, the non-operator versions of `union()`, `intersection()`, `difference()`, `symmetric_difference()`, `issubset()`, and `issuperset()` methods will accept any iterable as an argument. In contrast, their operator based counterparts require their arguments to be sets. This precludes error-prone constructions like `set('abc') & 'cbs'` in favor of the more readable `set('abc').intersection('cbs')`.

Both `set` and `frozenset` support set to set comparisons. Two sets are equal if and only if every element of each set is contained in the other (each is a subset of the other). A set is less than another set if and only if the first set is a proper subset of the second set (is a subset, but is not equal). A set is greater than another set if and only if the first set is a proper superset of the second set (is a superset, but is not equal).

Instances of `set` are compared to instances of `frozenset` based on their members. For example, `set('abc') == frozenset('abc')` returns `True` and so does `set('abc') in set([frozenset('abc')])`.

The subset and equality comparisons do not generalize to a total ordering function. For example, any two nonempty disjoint sets are not equal and are not subsets of each other, so *all* of the following return `False`: `a < b`, `a == b`, or `a > b`.

Since sets only define partial ordering (subset relationships), the output of the `list.sort()` method is undefined for lists of sets.

Set elements, like dictionary keys, must be *hashable*.

Binary operations that mix `set` instances with `frozenset` return the type of the first operand. For example: `frozenset('ab') | set('bc')` returns an instance of `frozenset`.

The following table lists operations available for `set` that do not apply to immutable instances of `frozenset`:

**update(\*others)**

**set |= other | ...**

Update the set, adding elements from all others.

**intersection\_update(\*others)**

**set &= other & ...**

Update the set, keeping only elements found in it and all others.

**difference\_update(\*others)**

```
set -= other | ...
```

Update the set, removing elements found in others.

```
symmetric_difference_update(other)
```

```
set ^= other
```

Update the set, keeping only elements found in either set, but not in both.

```
add(elem)
```

Add element *elem* to the set.

```
remove(elem)
```

Remove element *elem* from the set. Raises *KeyError* if *elem* is not contained in the set.

```
discard(elem)
```

Remove element *elem* from the set if it is present.

```
pop()
```

Remove and return an arbitrary element from the set. Raises *KeyError* if the set is empty.

```
clear()
```

Remove all elements from the set.

Note, the non-operator versions of the *update()*, *intersection\_update()*, *difference\_update()*, and *symmetric\_difference\_update()* methods will accept any iterable as an argument.

Note, the *elem* argument to the *\_\_contains\_\_()*, *remove()*, and *discard()* methods may be a set. To support searching for an equivalent frozenset, a temporary one is created from *elem*.

## 4.11 Mapping Types --- dict

A *mapping* object maps *hashable* values to arbitrary objects. Mappings are mutable objects. There is currently only one standard mapping type, the *dictionary*. (For other containers see the built-in *list*, *set*, and *tuple* classes, and the *collections* module.)

A dictionary's keys are *almost* arbitrary values. Values that are not *hashable*, that is, values containing lists, dictionaries or other mutable types (that are compared by value rather than by object identity) may not be used as keys. Values that compare equal (such as 1, 1.0, and True) can be used interchangeably to index the same dictionary entry.

```
class dict (**kwargs)
```

```
class dict (mapping, **kwargs)
```

```
class dict (iterable, **kwargs)
```

Return a new dictionary initialized from an optional positional argument and a possibly empty set of keyword arguments.

Dictionaries can be created by several means:

- Use a comma-separated list of key: value pairs within braces: {'jack': 4098, 'sjoerd': 4127} or {4098: 'jack', 4127: 'sjoerd'}
- Use a dict comprehension: {}, {x: x \*\* 2 for x in range(10)}
- Use the type constructor: dict(), dict([('foo', 100), ('bar', 200)]), dict(foo=100, bar=200)

If no positional argument is given, an empty dictionary is created. If a positional argument is given and it defines a *keys()* method, a dictionary is created by calling *\_\_getitem\_\_()* on the argument with each returned key from the method. Otherwise, the positional argument must be an *iterable* object. Each item in the iterable must itself be an iterable with exactly two elements. The first element of each item becomes a key in the new dictionary, and the second element the corresponding value. If a key occurs more than once, the last value for that key becomes the corresponding value in the new dictionary.

If keyword arguments are given, the keyword arguments and their values are added to the dictionary created from the positional argument. If a key being added is already present, the value from the keyword argument replaces the value from the positional argument.

To illustrate, the following examples all return a dictionary equal to {"one": 1, "two": 2, "three": 3}:

```
>>> a = dict(one=1, two=2, three=3)
>>> b = {'one': 1, 'two': 2, 'three': 3}
>>> c = dict(zip(['one', 'two', 'three'], [1, 2, 3]))
>>> d = dict([('two', 2), ('one', 1), ('three', 3)])
>>> e = dict({'three': 3, 'one': 1, 'two': 2})
>>> f = dict({'one': 1, 'three': 3}, two=2)
>>> a == b == c == d == e == f
True
```

Providing keyword arguments as in the first example only works for keys that are valid Python identifiers. Otherwise, any valid keys can be used.

These are the operations that dictionaries support (and therefore, custom mapping types should support too):

#### **list(d)**

Return a list of all the keys used in the dictionary *d*.

#### **len(d)**

Return the number of items in the dictionary *d*.

#### **d[key]**

Return the item of *d* with key *key*. Raises a *KeyError* if *key* is not in the map.

If a subclass of `dict` defines a method `__missing__()` and *key* is not present, the `d[key]` operation calls that method with the key *key* as argument. The `d[key]` operation then returns or raises whatever is returned or raised by the `__missing__(key)` call. No other operations or methods invoke `__missing__()`. If `__missing__()` is not defined, *KeyError* is raised. `__missing__()` must be a method; it cannot be an instance variable:

```
>>> class Counter(dict):
...     def __missing__(self, key):
...         return 0
...
>>> c = Counter()
>>> c['red']
0
>>> c['red'] += 1
>>> c['red']
1
```

The example above shows part of the implementation of `collections.Counter`. A different `__missing__` method is used by `collections.defaultdict`.

#### **d[key] = value**

Set `d[key]` to *value*.

#### **del d[key]**

Remove `d[key]` from *d*. Raises a *KeyError* if *key* is not in the map.

#### **key in d**

Return `True` if *d* has a key *key*, else `False`.

#### **key not in d**

Equivalent to `not key in d`.

**iter(d)**

Return an iterator over the keys of the dictionary. This is a shortcut for `iter(d.keys())`.

**clear()**

Remove all items from the dictionary.

**copy()**

Return a shallow copy of the dictionary.

**classmethod fromkeys(iterable, value=None, /)**

Create a new dictionary with keys from *iterable* and values set to *value*.

*fromkeys()* is a class method that returns a new dictionary. *value* defaults to `None`. All of the values refer to just a single instance, so it generally doesn't make sense for *value* to be a mutable object such as an empty list. To get distinct values, use a dict comprehension instead.

**get(key, default=None)**

Return the value for *key* if *key* is in the dictionary, else *default*. If *default* is not given, it defaults to `None`, so that this method never raises a `KeyError`.

**items()**

Return a new view of the dictionary's items ((*key*, *value*) pairs). See the *documentation of view objects*.

**keys()**

Return a new view of the dictionary's keys. See the *documentation of view objects*.

**pop(key[, default])**

If *key* is in the dictionary, remove it and return its value, else return *default*. If *default* is not given and *key* is not in the dictionary, a `KeyError` is raised.

**popitem()**

Remove and return a (*key*, *value*) pair from the dictionary. Pairs are returned in LIFO (last-in, first-out) order.

*popitem()* is useful to destructively iterate over a dictionary, as often used in set algorithms. If the dictionary is empty, calling *popitem()* raises a `KeyError`.

在 3.7 版的變更: LIFO order is now guaranteed. In prior versions, *popitem()* would return an arbitrary key/value pair.

**reversed(d)**

Return a reverse iterator over the keys of the dictionary. This is a shortcut for `reversed(d.keys())`.

在 3.8 版被加入。

**setdefault(key, default=None)**

If *key* is in the dictionary, return its value. If not, insert *key* with a value of *default* and return *default*. *default* defaults to `None`.

**update([other])**

Update the dictionary with the key/value pairs from *other*, overwriting existing keys. Return `None`.

*update()* accepts either another object with a `keys()` method (in which case `__getitem__()` is called with every key returned from the method) or an iterable of key/value pairs (as tuples or other iterables of length two). If keyword arguments are specified, the dictionary is then updated with those key/value pairs: `d.update(red=1, blue=2)`.

**values()**

Return a new view of the dictionary's values. See the *documentation of view objects*.

An equality comparison between one `dict.values()` view and another will always return `False`. This also applies when comparing `dict.values()` to itself:

```
>>> d = {'a': 1}
>>> d.values() == d.values()
False
```

**d | other**

Create a new dictionary with the merged keys and values of *d* and *other*, which must both be dictionaries. The values of *other* take priority when *d* and *other* share keys.

在 3.9 版被加入.

**d |= other**

Update the dictionary *d* with keys and values from *other*, which may be either a *mapping* or an *iterable* of key/value pairs. The values of *other* take priority when *d* and *other* share keys.

在 3.9 版被加入.

Dictionaries compare equal if and only if they have the same (key, value) pairs (regardless of ordering). Order comparisons ('<', '<=', '>=', '>') raise *TypeError*.

Dictionaries preserve insertion order. Note that updating a key does not affect the order. Keys added after deletion are inserted at the end.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(d)
['one', 'two', 'three', 'four']
>>> list(d.values())
[1, 2, 3, 4]
>>> d["one"] = 42
>>> d
{'one': 42, 'two': 2, 'three': 3, 'four': 4}
>>> del d["two"]
>>> d["two"] = None
>>> d
{'one': 42, 'three': 3, 'four': 4, 'two': None}
```

在 3.7 版的變更: Dictionary order is guaranteed to be insertion order. This behavior was an implementation detail of CPython from 3.6.

Dictionaries and dictionary views are reversible.

```
>>> d = {"one": 1, "two": 2, "three": 3, "four": 4}
>>> d
{'one': 1, 'two': 2, 'three': 3, 'four': 4}
>>> list(reversed(d))
['four', 'three', 'two', 'one']
>>> list(reversed(d.values()))
[4, 3, 2, 1]
>>> list(reversed(d.items()))
[('four', 4), ('three', 3), ('two', 2), ('one', 1)]
```

在 3.8 版的變更: Dictionaries are now reversible.

**也參考**

*types.MappingProxyType* can be used to create a read-only view of a *dict*.

### 4.11.1 字典視圖物件

The objects returned by `dict.keys()`, `dict.values()` and `dict.items()` are *view objects*. They provide a dynamic view on the dictionary's entries, which means that when the dictionary changes, the view reflects these changes.

Dictionary views can be iterated over to yield their respective data, and support membership tests:

#### `len(dictview)`

Return the number of entries in the dictionary.

#### `iter(dictview)`

Return an iterator over the keys, values or items (represented as tuples of `(key, value)`) in the dictionary.

Keys and values are iterated over in insertion order. This allows the creation of `(value, key)` pairs using `zip(): pairs = zip(d.values(), d.keys())`. Another way to create the same list is `pairs = [(v, k) for (k, v) in d.items()]`.

Iterating views while adding or deleting entries in the dictionary may raise a `RuntimeError` or fail to iterate over all entries.

在 3.7 版的變更: Dictionary order is guaranteed to be insertion order.

#### `x in dictview`

Return `True` if `x` is in the underlying dictionary's keys, values or items (in the latter case, `x` should be a `(key, value)` tuple).

#### `reversed(dictview)`

Return a reverse iterator over the keys, values or items of the dictionary. The view will be iterated in reverse order of the insertion.

在 3.8 版的變更: Dictionary views are now reversible.

#### `dictview.mapping`

Return a `types.MappingProxyType` that wraps the original dictionary to which the view refers.

在 3.10 版被加入.

Keys views are set-like since their entries are unique and *hashable*. Items views also have set-like operations since the `(key, value)` pairs are unique and the keys are hashable. If all values in an items view are hashable as well, then the items view can interoperate with other sets. (Values views are not treated as set-like since the entries are generally not unique.) For set-like views, all of the operations defined for the abstract base class `collections.abc.Set` are available (for example, `==`, `<`, or `^`). While using set operators, set-like views accept any iterable as the other operand, unlike sets which only accept sets as the input.

An example of dictionary view usage:

```
>>> dishes = {'eggs': 2, 'sausage': 1, 'bacon': 1, 'spam': 500}
>>> keys = dishes.keys()
>>> values = dishes.values()

>>> # iteration
>>> n = 0
>>> for val in values:
...     n += val
...
>>> print(n)
504

>>> # keys and values are iterated over in the same order (insertion order)
>>> list(keys)
['eggs', 'sausage', 'bacon', 'spam']
>>> list(values)
[2, 1, 1, 500]
```

(繼續下一頁)

(繼續上一頁)

```

>>> # view objects are dynamic and reflect dict changes
>>> del dishes['eggs']
>>> del dishes['sausage']
>>> list(keys)
['bacon', 'spam']

>>> # set operations
>>> keys & {'eggs', 'bacon', 'salad'}
{'bacon'}
>>> keys ^ {'sausage', 'juice'} == {'juice', 'sausage', 'bacon', 'spam'}
True
>>> keys | ['juice', 'juice', 'juice'] == {'bacon', 'spam', 'juice'}
True

>>> # get back a read-only proxy for the original dictionary
>>> values.mapping
mappingproxy({'bacon': 1, 'spam': 500})
>>> values.mapping['spam']
500

```

## 4.12 情境管理器型 F

Python 的 `with` 陳述式支援了由情境管理器定義之 `runtime` 情境的概念，要使用兩個方法來實作，該方法讓使用者定義類 F 能 F 去定義 `runtime` 情境，且該情境在執行陳述式主體 (statement body) 之前進入、在陳述式結束時退出：

`contextmanager.__enter__()`

輸入 `runtime` 情境 F 回傳此物件或者與 `runtime` 情境相關的另一個物件。此方法回傳的值有被綁定到使用此情境管理器的 `with` 陳述式的 `as` 子句中的識 F 字。

一個會回傳自己的情境管理器範例是 `file object`。檔案物件從 `__enter__()` 回傳自己，以允許將 `open()` 用作 `with` 陳述式中的情境運算式。

一個會回傳相關物件的情境管理器範例是由 `decimal.localcontext()` 回傳的管理器。這些管理器將有效的十進位情境設定 F 原始十進位情境的副本，然後回傳該副本。這允許對 `with` 陳述式主體中的當前十進位情境進行更改，而不會影響 `with` 陳述式外部的程式碼。

`contextmanager.__exit__(exc_type, exc_val, exc_tb)`

退出 `runtime` 情境 F 回傳布林旗標以表示是否應抑制曾發生的任何例外。如果在執行 `with` 陳述式主體時發生例外，則引數包含例外型 F、值和回溯 (traceback) 資訊。否則，所有三個引數都是 `None`。

從此方法回傳 `true` 值將導致 `with` 陳述式抑制例外 F 繼續執行緊接著 `with` 陳述式之後的陳述式。否則，該例外將在該方法執行完畢後繼續傳播 (propagate)。執行此方法期間發生的例外會取代 `with` 陳述式主體中發生的任何例外。

傳入的例外不應明確重新引發 - 取而代之的是，此方法應回傳 `false` 值以指示該方法已成功完成且不希望抑制引發的例外。這讓情境管理程式碼能輕鬆檢測 `__exit__()` 方法是否曾實際失敗過。

Python 定義了多個情境管理器來支援簡單的執行緒同步、檔案或其他物件的提示關閉以及對有效十進位算術情境的更簡單操作。除了情境管理協定的實作之外，不會對特定型 F 進行特殊處理。更多範例請參 F `contextlib` 模組。

Python 的 `generator` 和 `contextlib.contextmanager` 裝飾器提供了一種便捷的方法來實作這些協定。如果 F 生器函式以 `contextlib.contextmanager` 裝飾器裝飾，它將回傳一個有實作出需要的 `__enter__()` 和 `__exit__()` 方法的情境管理器，而不是由未裝飾 F 生器函式 F 生的 F 代器。

請注意，Python/C API 中 Python 物件的型 F 結構中的任何方法都 F 有特定的槽。想要定義這些方法的擴充型 F 必須將它們作 F 普通的 Python 可存取方法提供。與設定 `runtime` 情境的開銷相比，單一類 F 字典查找的開銷可以忽略不計。

## 4.13 型釋的型 --- 泛型名 (Generic Alias)、聯合 (Union)

型釋的核心建型是泛型和聯合。

### 4.13.1 泛型名

`GenericAlias` 物件通常是透過下標 (subscripting) 一個類來建立的。它們最常與容器類一起使用，像是 `list` 或 `dict`。例如 `list[int]` 是一個 `GenericAlias` 物件，它是透過使用引數 `int` 來下標 `list` 類而建立的。`GenericAlias` 物件主要會與型釋一起使用。

#### 備

通常只有當類有實作特殊方法 `__class_getitem__()` 時才可以去下標該類。

將一個 `GenericAlias` 物件用作 *generic type* 的代理，實作參數化泛型 (*parameterized generics*)。

對於一個容器類，提供給該類的下標引數可以代表物件所包含元素的型。例如 `set[bytes]` 可以用於型釋來表示一個 `set`，其中所有元素的型都是 `bytes`。

對於定義 `__class_getitem__()` 但不是容器的類，提供給該類的下標引數通常會指示物件上有定義的一個或多個方法的回傳型。例如正規表示式可以用於 `str` 和 `bytes` 資料型：

- 如果 `x = re.search('foo', 'foo')`，`x` 將會是一個 `re.Match` 物件，其中 `x.group(0)` 和 `x[0]` 的回傳值都是 `str` 型。我們就可以用 `GenericAlias re.Match[str]` 在型釋中表示這種物件。
- 如果 `y = re.search(b'bar', b'bar')` (注意 `bytes` 的 `b`)，`y` 也會是 `re.Match` 的實例，但 `y.group(0)` 和 `y[0]` 的回傳值的型都是 `bytes`。在型釋中，我們將用 `re.Match[bytes]` 來表示各種 `re.Match` 物件。

`GenericAlias` 物件是 `types.GenericAlias` 類的實例，也可以用來直接建立 `GenericAlias` 物件。

#### T[X, Y, ...]

建立一個 `GenericAlias` 來表示一個型 `T`，其以型 `X`、`Y` 等 (取於所使用的 `T`) 來參數化。例如，一個函式需要一個包含 `float` 元素的 `list`：

```
def average(values: list[float]) -> float:
    return sum(values) / len(values)
```

對映物件的另一個範例，使用 `dict`，它是一個泛型型，需要兩個型參數，分表示鍵型和值型。在此範例中，函式需要一個 `dict`，其帶有 `str` 型的鍵和 `int` 型的值：

```
def send_post_request(url: str, body: dict[str, int]) -> None:
    ...
```

建函式 `isinstance()` 和 `issubclass()` 不接受 `GenericAlias` 型作第二個引數：

```
>>> isinstance([1, 2], list[str])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

Python runtime 不制執行型釋。這也擴展到泛型及其型參數。當從 `GenericAlias` 建立容器物件時，不會檢查容器中元素的型。例如，不鼓勵使用以下程式碼，但 runtime 不會出現錯誤：

```
>>> t = list[str]
>>> t([1, 2, 3])
[1, 2, 3]
```

此外，參數化泛型在物件建立期間會擦除 (erase) 型參數：

```
>>> t = list[str]
>>> type(t)
<class 'types.GenericAlias'>

>>> l = t()
>>> type(l)
<class 'list'>
```

在泛型上呼叫 `repr()` 或 `str()` 會顯示參數化型：

```
>>> repr(list[int])
'list[int]'

>>> str(list[int])
'list[int]'
```

防止像是 `dict[str][str]` 的錯誤出現，泛型容器的 `__getitem__()` 方法會在這種情況下引發例外：

```
>>> dict[str][str]
Traceback (most recent call last):
...
TypeError: dict[str] is not a generic class
```

然而當使用型變數 (*type variable*) 時，此類運算式是有效的。索引的元素數量必須與 `GenericAlias` 物件的 `__args__` 中的型變數項目一樣多：

```
>>> from typing import TypeVar
>>> Y = TypeVar('Y')
>>> dict[str, Y][int]
dict[str, int]
```

### 標準泛型類

以下標準函式庫類有支援參數化泛型。此列表非詳盡無遺。

- `tuple`
- `list`
- `dict`
- `set`
- `frozenset`
- `type`
- `collections.deque`
- `collections.defaultdict`
- `collections.OrderedDict`
- `collections.Counter`
- `collections.ChainMap`
- `collections.abc.Awaitable`
- `collections.abc.Coroutine`
- `collections.abc.AsyncIterable`
- `collections.abc.AsyncIterator`
- `collections.abc.AsyncGenerator`
- `collections.abc.Iterable`

- `collections.abc.Iterator`
- `collections.abc.Generator`
- `collections.abc.Reversible`
- `collections.abc.Container`
- `collections.abc.Collection`
- `collections.abc.Callable`
- `collections.abc.Set`
- `collections.abc.MutableSet`
- `collections.abc.Mapping`
- `collections.abc.MutableMapping`
- `collections.abc.Sequence`
- `collections.abc.MutableSequence`
- `collections.abc.ByteString`
- `collections.abc.MappingView`
- `collections.abc.KeysView`
- `collections.abc.ItemsView`
- `collections.abc.ValuesView`
- `contextlib.AbstractContextManager`
- `contextlib.AbstractAsyncContextManager`
- `dataclasses.Field`
- `functools.cached_property`
- `functools.partialmethod`
- `os.PathLike`
- `queue.LifoQueue`
- `queue.Queue`
- `queue.PriorityQueue`
- `queue.SimpleQueue`
- `re.Pattern`
- `re.Match`
- `shelve.BsdDbShelf`
- `shelve.DbfilenameShelf`
- `shelve.Shelf`
- `types.MappingProxyType`
- `weakref.WeakKeyDictionary`
- `weakref.WeakMethod`
- `weakref.WeakSet`
- `weakref.WeakValueDictionary`

### GenericAlias 物件的特殊屬性

所有參數化泛型都有實作特殊的唯讀屬性。

`genericalias.__origin__`

此屬性指向非參數化泛型類：

```
>>> list[int].__origin__
<class 'list'>
```

`genericalias.__args__`

此屬性是傳遞給泛型類之原始 `__class_getitem__()` 的泛型型 `tuple` (長度可以 1)：

```
>>> dict[str, list[int]].__args__
(<class 'str'>, list[int])
```

`genericalias.__parameters__`

此屬性是個會被延遲計算 (lazily computed) 的元組 (可能空)，包含了在 `__args__` 中找得到的不重型變數：

```
>>> from typing import TypeVar

>>> T = TypeVar('T')
>>> list[T].__parameters__
(~T,)
```

#### 備

具有 `typing.ParamSpec` 參數的一個 `GenericAlias` 物件在替後可能 有正確的 `__parameters__`，因 `typing.ParamSpec` 主要用於態型檢查。

`genericalias.__unpacked__`

如果名已使用 `*` 運算子解包 (unpack) 則 `true` 的布林值 (請參 `TypeVarTuple`)。

在 3.11 版被加入。

#### 也參考

##### PEP 484 - 型提示

引入 Python 的型釋框架。

##### PEP 585 - 標準集合 (Standard Collections) 中的型提示泛型

引入原生參數化標準函式庫類的的能力，前提是它們有實作特殊的類方法 `__class_getitem__()`。

##### 泛型、使用者定義泛型和 `typing.Generic`

有關如何實作可以在 `runtime` 參數化能被態型檢查器理解的泛型類的文件。

在 3.9 版被加入。

## 4.13.2 聯合型 (Union Type)

一個聯合物件可以保存多個型物件 (`type object`) 之 (位元 or) 運算的值。這些型主要用於型釋 (`type annotation`)。與 `typing.Union` 相比，聯合型運算式可以讓型提示語法更清晰簡潔。

`X | Y | ...`

定義一個包含 `X`、`Y` 等型的聯合物件。`X | Y` 表示 `X` 或 `Y`。它相當於 `typing.Union[X, Y]`。舉例來，下列函式需要一個型 `int` 或 `float` 的引數：

```
def square(number: int | float) -> int | float:
    return number ** 2
```

### 備

不能在 runtime 使用 | 運算元 (operand) 來定義有一個以上的成員向前參照 (forward reference) 的聯合。例如 `int | "Foo"`，其中 "Foo" 是對未定義類型的參照，將在 runtime 失敗。對於包含向前參照的聯合，請將整個運算式以字串呈現，例如 `"int | Foo"`。

### union\_object == other

聯合物件可以與其他聯合物件一起進行相等性測試。細節如下：

- 聯合的聯合會被扁平化：

```
(int | str) | float == int | str | float
```

- 冗餘型會被刪除：

```
int | str | int == int | str
```

- 比較聯合時，順序會被忽略：

```
int | str == str | int
```

- 它與 `typing.Union` 相容：

```
int | str == typing.Union[int, str]
```

- 可選型可以表示與 `None` 的聯合：

```
str | None == typing.Optional[str]
```

### isinstance(obj, union\_object)

### issubclass(obj, union\_object)

聯合物件也支援 `isinstance()` 和 `issubclass()` 的呼叫：

```
>>> isinstance("", int | str)
True
```

然而聯合物件中的參數化泛型則無法被檢查：

```
>>> isinstance(1, int | list[int]) # short-circuit evaluation
True
>>> isinstance([1], int | list[int])
Traceback (most recent call last):
...
TypeError: isinstance() argument 2 cannot be a parameterized generic
```

構成聯合物件的對使用者公開型 (user-exposed type) 可以透過 `types.UnionType` 存取用於 `isinstance()` 檢查。物件不能以型來實例化：

```
>>> import types
>>> isinstance(int | str, types.UnionType)
True
>>> types.UnionType()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot create 'types.UnionType' instances
```

**備**

新增了型物件的 `__or__()` 方法來支援 `x | y` 語法。如果元類有實作 `__or__()`，則 `Union` 可以覆寫 (override) 它：

```
>>> class M(type):
...     def __or__(self, other):
...         return "Hello"
...
>>> class C(metaclass=M):
...     pass
...
>>> C | int
'Hello'
>>> int | C
int | C
```

**也參考**

**PEP 604** -- PEP 提出 `x | y` 語法和聯合型。

在 3.10 版被加入。

## 4.14 Other Built-in Types

The interpreter supports several other kinds of objects. Most of these support only one or two operations.

### 4.14.1 模組

The only special operation on a module is attribute access: `m.name`, where `m` is a module and `name` accesses a name defined in `m`'s symbol table. Module attributes can be assigned to. (Note that the `import` statement is not, strictly speaking, an operation on a module object; `import foo` does not require a module object named `foo` to exist, rather it requires an (external) *definition* for a module named `foo` somewhere.)

A special attribute of every module is `__dict__`. This is the dictionary containing the module's symbol table. Modifying this dictionary will actually change the module's symbol table, but direct assignment to the `__dict__` attribute is not possible (you can write `m.__dict__['a'] = 1`, which defines `m.a` to be 1, but you can't write `m.__dict__ = {}`). Modifying `__dict__` directly is not recommended.

Modules built into the interpreter are written like this: `<module 'sys' (built-in)>`. If loaded from a file, they are written as `<module 'os' from '/usr/local/lib/pythonX.Y/os.pyc'>`.

### 4.14.2 Classes and Class Instances

See objects and class for these.

### 4.14.3 函式

Function objects are created by function definitions. The only operation on a function object is to call it: `func(argument-list)`.

There are really two flavors of function objects: built-in functions and user-defined functions. Both support the same operation (to call the function), but the implementation is different, hence the different object types.

更多資訊請見 `function`。

#### 4.14.4 Methods

Methods are functions that are called using the attribute notation. There are two flavors: built-in methods (such as `append()` on lists) and class instance method. Built-in methods are described with the types that support them.

If you access a method (a function defined in a class namespace) through an instance, you get a special object: a *bound method* (also called instance method) object. When called, it will add the `self` argument to the argument list. Bound methods have two special read-only attributes: `m.__self__` is the object on which the method operates, and `m.__func__` is the function implementing the method. Calling `m(arg-1, arg-2, ..., arg-n)` is completely equivalent to calling `m.__func__(m.__self__, arg-1, arg-2, ..., arg-n)`.

Like function objects, bound method objects support getting arbitrary attributes. However, since method attributes are actually stored on the underlying function object (`method.__func__`), setting method attributes on bound methods is disallowed. Attempting to set an attribute on a method results in an `AttributeError` being raised. In order to set a method attribute, you need to explicitly set it on the underlying function object:

```
>>> class C:
...     def method(self):
...         pass
...
>>> c = C()
>>> c.method.whoami = 'my name is method' # 不得設定於方法
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
AttributeError: 'method' object has no attribute 'whoami'
>>> c.method.__func__.whoami = 'my name is method'
>>> c.method.whoami
'my name is method'
```

更多資訊請見 `instance-methods`。

#### 4.14.5 程式碼物件

Code objects are used by the implementation to represent "pseudo-compiled" executable Python code such as a function body. They differ from function objects because they don't contain a reference to their global execution environment. Code objects are returned by the built-in `compile()` function and can be extracted from function objects through their `__code__` attribute. See also the `code` module.

存取 `__code__` 會引發一個附帶引數 `obj` 與 `"__code__"` 的稽核事件 `object.__getattr__`。

A code object can be executed or evaluated by passing it (instead of a source string) to the `exec()` or `eval()` built-in functions.

更多資訊請見 `types`。

#### 4.14.6 Type Objects

Type objects represent the various object types. An object's type is accessed by the built-in function `type()`. There are no special operations on types. The standard module `types` defines names for all standard built-in types.

Types are written like this: `<class 'int'>`.

#### 4.14.7 Null 物件

This object is returned by functions that don't explicitly return a value. It supports no special operations. There is exactly one null object, named `None` (a built-in name). `type(None)()` produces the same singleton.

它被寫成 `None`。

### 4.14.8 The Ellipsis Object

This object is commonly used by slicing (see slicings). It supports no special operations. There is exactly one ellipsis object, named `Ellipsis` (a built-in name). `type(Ellipsis)()` produces the `Ellipsis` singleton.

它被寫 `Ellipsis` 或 `...`。

### 4.14.9 NotImplemented 物件

This object is returned from comparisons and binary operations when they are asked to operate on types they don't support. See comparisons for more information. There is exactly one `NotImplemented` object. `type(NotImplemented)()` produces the singleton instance.

It is written as `NotImplemented`.

### 4.14.10 Internal Objects

See types for this information. It describes stack frame objects, traceback objects, and slice objects.

## 4.15 特殊屬性

The implementation adds a few special read-only attributes to several object types, where they are relevant. Some of these are not reported by the `dir()` built-in function.

definition. `__name__`

The name of the class, function, method, descriptor, or generator instance.

definition. `__qualname__`

The *qualified name* of the class, function, method, descriptor, or generator instance.

在 3.3 版被加入。

definition. `__module__`

The name of the module in which a class or function was defined.

definition. `__doc__`

The documentation string of a class or function, or `None` if undefined.

definition. `__type_params__`

The type parameters of generic classes, functions, and *type aliases*. For classes and functions that are not generic, this will be an empty tuple.

在 3.12 版被加入。

## 4.16 Integer string conversion length limitation

CPython has a global limit for converting between `int` and `str` to mitigate denial of service attacks. This limit *only* applies to decimal or other non-power-of-two number bases. Hexadecimal, octal, and binary conversions are unlimited. The limit can be configured.

The `int` type in CPython is an arbitrary length number stored in binary form (commonly known as a "bignum"). There exists no algorithm that can convert a string to a binary integer or a binary integer to a string in linear time, *unless* the base is a power of 2. Even the best known algorithms for base 10 have sub-quadratic complexity. Converting a large value such as `int('1' * 500_000)` can take over a second on a fast CPU.

Limiting conversion size offers a practical way to avoid [CVE 2020-10735](#).

The limit is applied to the number of digit characters in the input or output string when a non-linear conversion algorithm would be involved. Underscores and the sign are not counted towards the limit.

When an operation would exceed the limit, a `ValueError` is raised:

```

>>> import sys
>>> sys.set_int_max_str_digits(4300) # Illustrative, this is the default.
>>> _ = int('2' * 5432)
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion: value has 5432_
↳digits; use sys.set_int_max_str_digits() to increase the limit
>>> i = int('2' * 4300)
>>> len(str(i))
4300
>>> i_squared = i*i
>>> len(str(i_squared))
Traceback (most recent call last):
...
ValueError: Exceeds the limit (4300 digits) for integer string conversion; use sys.set_int_
↳max_str_digits() to increase the limit
>>> len(hex(i_squared))
7144
>>> assert int(hex(i_squared), base=16) == i*i # Hexadecimal is unlimited.

```

The default limit is 4300 digits as provided in `sys.int_info.default_max_str_digits`. The lowest limit that can be configured is 640 digits as provided in `sys.int_info.str_digits_check_threshold`.

Verification:

```

>>> import sys
>>> assert sys.int_info.default_max_str_digits == 4300, sys.int_info
>>> assert sys.int_info.str_digits_check_threshold == 640, sys.int_info
>>> msg = int('578966293710682886880994035146873798396722250538762761564'
...         '9252925514383915483333812743580549779436104706260696366600'
...         '571186405732').to_bytes(53, 'big')
...

```

在 3.11 版被加入。

#### 4.16.1 受影響的 API

The limitation only applies to potentially slow conversions between `int` and `str` or `bytes`:

- `int(string)` 以預設的 10 為底。
- `int(string, base)` for all bases that are not a power of 2.
- `str(integer)`。
- `repr(integer)`。
- any other string conversion to base 10, for example `f"{integer}", "{}".format(integer)`, or `b"%d" % integer`.

The limitations do not apply to functions with a linear algorithm:

- `int(string, base)` with base 2, 4, 8, 16, or 32.
- `int.from_bytes()` 和 `int.to_bytes()`。
- `hex()`、`oct()`、`bin()`。
- 格式規格 (*Format Specification*) 迷你語言 for hex, octal, and binary numbers.
- `str` to `float`.
- `str` to `decimal.Decimal`.

## 4.16.2 設定限制

Before Python starts up you can use an environment variable or an interpreter command line flag to configure the limit:

- `PYTHONINTMAXSTRDIGITS`, e.g. `PYTHONINTMAXSTRDIGITS=640 python3` to set the limit to 640 or `PYTHONINTMAXSTRDIGITS=0 python3` to disable the limitation.
- `-X int_max_str_digits`, 例如 `python3 -X int_max_str_digits=640`
- `sys.flags.int_max_str_digits` contains the value of `PYTHONINTMAXSTRDIGITS` or `-X int_max_str_digits`. If both the env var and the `-X` option are set, the `-X` option takes precedence. A value of `-1` indicates that both were unset, thus a value of `sys.int_info.default_max_str_digits` was used during initialization.

From code, you can inspect the current limit and set a new one using these `sys` APIs:

- `sys.get_int_max_str_digits()` and `sys.set_int_max_str_digits()` are a getter and setter for the interpreter-wide limit. Subinterpreters have their own limit.

Information about the default and minimum can be found in `sys.int_info`:

- `sys.int_info.default_max_str_digits` is the compiled-in default limit.
- `sys.int_info.str_digits_check_threshold` is the lowest accepted value for the limit (other than 0 which disables it).

在 3.11 版被加入。

### ⚠ 警示

Setting a low limit *can* lead to problems. While rare, code exists that contains integer constants in decimal in their source that exceed the minimum threshold. A consequence of setting the limit is that Python source code containing decimal integer literals longer than the limit will encounter an error during parsing, usually at startup time or import time or even at installation time - anytime an up to date `.pyc` does not already exist for the code. A workaround for source that contains such large constants is to convert them to `0x` hexadecimal form as it has no limit.

Test your application thoroughly if you use a low limit. Ensure your tests run with the limit set early via the environment or flag so that it applies during startup and even during any installation step that may invoke Python to precompile `.py` sources to `.pyc` files.

## 4.16.3 建議的配置

The default `sys.int_info.default_max_str_digits` is expected to be reasonable for most applications. If your application requires a different limit, set it from your main entry point using Python version agnostic code as these APIs were added in security patch releases in versions before 3.12.

範例：

```
>>> import sys
>>> if hasattr(sys, "set_int_max_str_digits"):
...     upper_bound = 68000
...     lower_bound = 4004
...     current_limit = sys.get_int_max_str_digits()
...     if current_limit == 0 or current_limit > upper_bound:
...         sys.set_int_max_str_digits(upper_bound)
...     elif current_limit < lower_bound:
...         sys.set_int_max_str_digits(lower_bound)
```

If you need to disable it entirely, set it to 0.

---

## ☐ 建的例外

---

在 Python 中，所有例外必須是從 `BaseException` 衍生的類☐的實例。在陳述式 `try` 搭配 `except` 子句☐提到一個特定的類☐時，那個子句也會處理任何從該類☐衍生的例外類☐（但不會處理該類☐衍生自的例外類☐）。兩個不是由子類☐關☐關聯起來的例外類☐永遠不相等，就算它們有相同的名稱也是如此。

此章節☐列出的☐建例外可以從直譯器或☐建函式☐生。除了特☐提到的地方之外，它們會有一個關聯值表示錯誤發生的詳細原因。這可能是一個字串，或者是一些資訊項目組成的元組（例如一個錯誤代碼及一個解釋該代碼的字串）。這個關聯值通常當作引數傳遞給例外類☐的建構函式。

使用者的程式碼可以引發☐建例外。這可以用來測試例外處理器或者用來回報一個錯誤條件，就像直譯器會引發相同例外的情☐；但需要注意的是☐有任何方式可以避免使用者的程式碼引發不適當的錯誤。

可以從☐建的例外類☐定義新的例外子類☐；程式設計師被鼓勵從 `Exception` 類☐或其子類☐衍生新的例外，而不是從 `BaseException` 來衍生。更多關於定義例外的資訊可以在 Python 教學中的 `tut-userexceptions` ☐取得。

### 5.1 例外的情境

三個例外物件上的屬性提供關於引發此例外的情境的資訊：

`BaseException.__context__`

`BaseException.__cause__`

`BaseException.__suppress_context__`

當引發一個新的例外而同時有另一個例外已經正在被處理時，這個新例外的 `__context__` 屬性會自動被設成那個已處理的例外。當使用 `except` 或 `finally` 子句或 `with` 陳述式的時候例外會被處理。

這個隱含的例外情境可以透過使用 `from` 搭配 `raise` 來補充明確的原因：

```
raise new_exc from original_exc
```

在 `from` 後面的運算式必須是一個例外或 `None`。它將會被設定成所引發例外的 `__cause__`。設定 `__cause__` 也隱含地設定 `__suppress_context__` 屬性☐ `True`，因此使用 `raise new_exc from None` 實際上會以新的例外取代舊的例外以利於顯示（例如轉☐ `KeyError` ☐ `AttributeError`），同時保持舊的例外可以透過 `__context__` 取得以方便 `debug` 的時候檢查。

預設的回溯 (`traceback`) 顯示程式碼會顯示這些連鎖的例外 (`chained exception`) 加上例外本身的回溯。當存在的時候，在 `__cause__` 中明確地連鎖的例外總是會被顯示。而在 `__context__` 中隱含地連鎖的例外只有當 `__cause__` 是 `None` 且 `__suppress_context__` 是 `false` 時才會顯示。

在任一情況下，例外本身總是會顯示在任何連鎖例外的後面，因此回溯的最後一列總是顯示最後一個被引發的例外。

## 5.2 繼承自建的例外

使用者的程式碼可以建立繼承自例外型的子類。建議一次只繼承一種例外型以避免在基底類之間如何處理 `args` 屬性的任何可能衝突，以及可能的記憶體局 (memory layout) 不相容。

為了效率，大部分的自建例外使用 C 來實作，參考 `Objects/exceptions.c`。一些例外有客體化的記憶體局，使其不可能建立一個繼承多種例外型的子類。型的記憶體局是實作細節且可能會在不同 Python 版本間改變，造成未來新的衝突。因此，總之建議避免繼承多種例外型。

## 5.3 基底類 (base classes)

以下的例外大部分被用在當作其他例外的基底類。

### exception BaseException

所有建例外的基底類。這不是了讓使用者定義的類直接繼承 (可以使用 `Exception`)。如果在這個類的實例上呼叫 `str()`，會回傳實例的引數的表示，或者有引數的時候會回傳空字串。

#### args

提供給該例外建構函式的引數元組。一些建的例外 (像是 `OSError`) 預期接受特定數量的引數賦予該元組的每一個元素一個特的意義，其他例外則通常用一個提供錯誤訊息的單一字串來呼叫。

#### with\_traceback (tb)

此方法設定 `tb` 該例外的新的回溯回傳該例外物件。在 `PEP 3134` 的例外連鎖功能變得可用之前，此方法曾被更普遍使用。下面的範例顯示我們如何將 `SomeException` 的實例轉 `OtherException` 的實例同時保留回溯。一旦被引發，目前的 `frame` 會被加進 `OtherException` 的回溯，就像原來 `SomeException` 的回溯會發生的一樣，我們允許它被傳遞給呼叫者：

```
try:
    ...
except SomeException:
    tb = sys.exception().__traceback__
    raise OtherException(...).with_traceback(tb)
```

#### \_\_traceback\_\_

可寫入的欄位，儲存關聯到該例外的回溯物件。也可以參考 `raise`。

#### add\_note (note)

新增字串 `note` 到例外的備，在標準的回溯，備出現在例外字串的後面。如果 `note` 不是字串則引發 `TypeError`。

在 3.11 版被加入。

#### \_\_notes\_\_

該例外的備串列，使用 `add_note()` 來新增。此屬性在 `add_note()` 被呼叫的時候建立。

在 3.11 版被加入。

### exception Exception

所有建、非系統退出 (non-system-exiting) 的例外都衍生自此類。所有使用者定義的例外應該也要衍生自此類。

### exception ArithmeticError

各種運算錯誤所引發的那些建例外：`OverflowError`、`ZeroDivisionError`、`FloatingPointError` 的基底類。

**exception `BufferError`**

當緩衝 (buffer) 相關的操作無法被執行時會引發此例外。

**exception `LookupError`**

當使用在對映或序列上的鍵或索引是無效的時候所引發的例外：`IndexError`、`KeyError` 的基底類 [F](#)。這可以被 `codecs.lookup()` 直接引發。

## 5.4 實體例外

以下的例外是通常會被引發的例外。

**exception `AssertionError`**

當 `assert` 陳述式失敗的時候被引發。

**exception `AttributeError`**

當屬性參照 (參考 [attribute-references](#)) 或賦值失敗的時候被引發。(當物件根本不支援屬性參照或屬性賦值的時候, `TypeError` 會被引發。)

`name` 和 `obj` 屬性可以使用建構函式的僅限關鍵字 (keyword-only) 引數來設定。當被設定的時候, 它們分 [F](#) 代表被嘗試存取的屬性名稱以及被以該屬性存取的物件。

在 3.10 版的變更: 新增 `name` 與 `obj` 屬性。

**exception `EOFError`**

當 `input()` 函式在 [F](#) 有讀到任何資料而到達檔案結尾 (end-of-file, EOF) 條件的時候被引發。(注意: `io.IOBase.read()` 和 `io.IOBase.readline()` 方法當達到 EOF 時會回傳空字串。)

**exception `FloatingPointError`**

目前 [F](#) 有被使用。

**exception `GeneratorExit`**

當 `generator` 或 `coroutine` 被關閉的時候被引發; 參考 `generator.close()` 和 `coroutine.close()`。此例外直接繼承自 `BaseException` 而不是 `Exception`, 因 [F](#) 技術上來 [F](#) 這不是一個錯誤。

**exception `ImportError`**

當 `import` 陳述式嘗試載入模組遇到問題的時候會被引發。當 `from ... import F` 的 "from list" 包含找不到的名稱時也會被引發。

可選的僅限關鍵字引數 `name` 和 `path` 設定對應的屬性:

**name**

嘗試引入 (import) 的模組名稱。

**path**

觸發此例外的任何檔案的路徑。

在 3.3 版的變更: 新增 `name` 與 `path` 屬性。

**exception `ModuleNotFoundError`**

`ImportError` 的子類 [F](#), 當模組不能被定位的時候會被 `import` 所引發。當在 `sys.modules` [F](#) 找到 `None` 時也會被引發。

在 3.6 版被加入。

**exception `IndexError`**

當序列的索引超出範圍的時候會被引發。(切片索引 (slice indices) 會默默地被截短使其能落在允許的範圍 [F](#); 如果索引不是整數, `TypeError` 會被引發。)

**exception `KeyError`**

當對映 (字典) 的鍵無法在已存在的鍵的集合中被找到時會被引發。

**exception KeyboardInterrupt**

當使用者輸入中斷鍵 (interrupt key) (一般來是 Control-C 或 Delete) 時會被引發。在執行過程中，會定期檢查是否發生中斷。此例外繼承自 `BaseException` 以防止意外地被捕捉 `Exception` 的程式碼所捕捉，而因此讓直譯器無法結束。

**備**

捕捉 `KeyboardInterrupt` 需要特殊的考量。因它可以在無法預期的時間點被引發，可能在某些情況下讓正在跑的程式處在一個不一致的狀態。一般來最好讓 `KeyboardInterrupt` 越快結束程式越好，或者完全避免引發它。(參考訊號處理程式與例外的說明。)

**exception MemoryError**

當一個操作用光了記憶體但還可能被修復 (rescued) (透過除一些物件) 的時候被引發。關聯值是一個字串，表示什麼類型的 (部) 操作用光了記憶體。需注意的是因底層的記憶體管理架構 (C 的 `malloc()` 函式)，直譯器可能無法總是完整地從該情中修復；儘管如此，它還是引發例外以讓堆回溯可以被印出，以防原因出在失控的程式。

**exception NameError**

當找不到本地或全域的名稱時會被引發。這只應用在不合格的名稱 (unqualified name) 上。關聯值是一個錯誤訊息，包含那個無法被找到的名稱。

`name` 屬性可以使用僅限關鍵字引數來設定到建構函式。當被設定的時候它代表被嘗試存取的變數名稱。

在 3.10 版的變更: 新增 `name` 屬性。

**exception NotImplementedError**

此例外衍生自 `RuntimeError`。在使用者定義的基礎類，當抽象方法要求衍生類覆寫該方法時應該要引發此例外，或者當類正在開發中，可用此例外表示還需要加入真正的實作。

**備**

此例外不應該用來表示根本有要支援的運算子或方法 —— 在這個情下可以讓該運算子或方法保持未定義，或者如果是子類的話將其設成 `None`。

**警告**

`NotImplementedError` and `NotImplemented` are not interchangeable. This exception should only be used as described above; see `NotImplemented` for details on correct usage of the built-in constant.

**exception OSError ([arg])****exception OSError (errno, strerror[, filename[, winerror[, filename2]]])**

當系統函式回傳系統相關錯誤，包含像“找不到檔案”或“硬碟已滿”的 I/O 失敗會引發此例外 (而非不合法的引數或其他次要的錯誤)。

建構函式的第二種形式會設定以下描述的相對應屬性。如果有給定則屬性預設 `None`。了向後相容，如果傳入三個引數，`args` 屬性只會是包含建構函式前兩個引數的雙元素元組。

如同下面的作業系統例外所描述，實際上建構函式通常回傳 `OSError` 的子類。會依據最後 `errno` 的值定特定子類。這個行只發生在直接建構 `OSError` 或透過名，且生子類的時候不會被繼承。

**errno**

從 C 變數 `errno` 而來的數值錯誤代碼。

**winerror**

在 Windows 下，這會提供你原生的 Windows 錯誤代碼。而 `errno` 屬性是一個該原生錯誤代碼對於 POSIX 來<sup>[1]</sup>的近似翻譯。

在 Windows 下，如果建構函式引數 `winerror` 是整數，則 `errno` 屬性會根據該 Windows 錯誤代碼來<sup>[1]</sup>定，且 `errno` 引數會被忽略。在其他平台上，`winerror` 引數會被忽略，而 `winerror` 屬性會不存在。

**strerror**

作業系統提供的對應錯誤訊息。在 POSIX 下會使用 C 函式 `perror()` 做格式化，而在 Windows 下會使用 `FormatMessage()`。

**filename****filename2**

對於包含檔案系統路徑的例外（像是 `open()` 或 `os.unlink()`），`filename` 是傳入函式的檔案名稱。對於包含兩個檔案系統路徑的函式（像是 `os.rename()`），`filename2` 對應到傳入函式的第二個檔案名稱。

在 3.3 版的變更: `EnvironmentError`、`IOError`、`WindowsError`、`socket.error`、`select.error` 及 `mmap.error` 已合<sup>[1]</sup>進 `OSError`，而建構函式可能會回傳子類<sup>[1]</sup>。

在 3.4 版的變更: `filename` 屬性現在是傳入函式的原始檔名，而不是從檔案系統編碼和錯誤處理函式編碼或解碼過的名稱。<sup>[1]</sup>且新增 `filename2` 建構函式引數與屬性。

**exception OverflowError**

當運算操作的結果太大而無法表示的時候會引發此例外。這不會發生在整數上（會改成引發 `MemoryError` 而不是放<sup>[1]</sup>）。然而，因<sup>[1]</sup>一些歷史因素，`OverflowError` 有時候會因<sup>[1]</sup>整數在要求範圍之外而引發。因<sup>[1]</sup>在 C <sup>[1]</sup>面缺乏浮點數例外處理的標準化，大部分的浮點數運算都<sup>[1]</sup>有被檢查。

**exception PythonFinalizationError**

此例外衍生自 `RuntimeError`。當一個操作在直譯器關閉（也稱作 *Python 最終化 (Python finalization)*）期間被阻塞會引發此例外。

在 Python 最終化期間，能<sup>[1]</sup>以 `PythonFinalizationError` 被阻塞的操作範例：

- 建立新的 Python 執行緒。
- `os.fork()`。

也可以參<sup>[1]</sup> `sys.is_finalizing()` 函式。

在 3.13 版被加入: 在之前，會引發一般的 `RuntimeError`。

**exception RecursionError**

此例外衍生自 `RuntimeError`。當直譯器偵測到超過最大的遞<sup>[1]</sup>深度（參考 `sys.getrecursionlimit()`）時會引發此例外。

在 3.5 版被加入: 在之前，會引發一般的 `RuntimeError`。

**exception ReferenceError**

當一個被 `weakref.proxy()` 函式建立的弱參照代理 (weak reference proxy) 被用來存取已經被垃圾回收 (garbage collected) 的參照物屬性時會引發此例外。更多關於弱參照的資訊參考 `weakref` 模組。

**exception RuntimeError**

當偵測到一個不屬於任何其他種類的錯誤時會引發此例外。關聯值是一個表示確切什<sup>[1]</sup>地方出錯的字串。

**exception StopIteration**

會被<sup>[1]</sup>建構函式 `next()` 及 `iterator` 的 `__next__()` 方法引發，用來表示<sup>[1]</sup>代器<sup>[1]</sup>有更多項目可以<sup>[1]</sup>生。

**value**

此例外物件有單一屬性 `value`，當建構此例外時會以引數給定，預設<sup>[1]</sup> `None`。

當 *generator* 或 *coroutine* 函式回傳時，新的 *StopIteration* 實例會被引發，而該函式的回傳值會被用來當作此例外建構函式的 *value* 參數。

如果 生成器程式直接或間接引發 *StopIteration*，則其會被轉成 *RuntimeError* (保留 *StopIteration* 作新例外的成因)。

在 3.3 版的變更: 新增 *value* 屬性且 生成器函式可以用它來回傳值。

在 3.5 版的變更: 透過 `from __future__ import generator_stop` 引入 *RuntimeError* 的轉，參考 [PEP 479](#)。

在 3.7 版的變更: 預設對所有程式用 [PEP 479](#): 在 生成器引發的 *StopIteration* 錯誤會轉成 *RuntimeError*。

#### exception *StopAsyncIteration*

此例外必須被 *asynchronous iterator* 物件的 `__anext__()` 方法引發來停止 代。

在 3.5 版被加入。

#### exception *SyntaxError* (*message, details*)

當剖析器遇到語法錯誤時會引發此例外。這可能發生在 `import` 陳述式、在呼叫 建函式 `compile()`、`exec()` 或 `eval()` 的時候，或者在讀取初始 本或標準輸入 (也包含互動式) 的時候。

例外實例的 `str()` 只回傳錯誤訊息。Details 是個元組，其成員也能以分開的屬性取得。

##### filename

發生語法錯誤所在的檔案名稱。

##### lineno

發生錯誤所在檔案的列號。這是以 1 開始的索引: 檔案第一列的 `lineno` 是 1。

##### offset

發生錯誤所在該列的欄號 (column)。這是以 1 開始的索引: 該列第一個字元的 `offset` 是 1。

##### text

涉及該錯誤的原始程式碼文字。

##### end\_lineno

發生錯誤所在檔案的結束列號。這是以 1 開始的索引: 檔案第一列的 `lineno` 是 1。

##### end\_offset

發生錯誤所在該結束列的欄號。這是以 1 開始的索引: 該列第一個字元的 `offset` 是 1。

對於發生在 f-string 欄位的錯誤，訊息會以 "f-string: " 前綴，而偏移量 (offset) 是從替代表達式建構的文字的偏移量。例如編譯 `f'Bad {a b} field'` 會得到這個 `args` 屬性: `('f-string: ...', ('', 1, 2, '(a b)n', 1, 5))`。

在 3.10 版的變更: 新增 `end_lineno` 與 `end_offset` 屬性。

#### exception *IndentationError*

與不正確的縮排有關的語法錯誤的基礎類。這是 *SyntaxError* 的子類。

#### exception *TabError*

當縮排包含 表符號 (tab) 和空白的不一致用法時會引發此例外。這是 *IndentationError* 的子類。

#### exception *SystemError*

當直譯器找到一個 部錯誤，但該情 看起來 有嚴重到要讓它放 所有的希望時會引發此例外。關聯值是一個表示什 地方出錯的字串 (以低階的方式表達)。在 *CPython* 中，這可能是因 錯誤地使用 Python 的 C API，例如回傳一個 `NULL` 值而 有設定例外。

如果你確定這個例外不是你的或者所用套件的錯，你應該向你的 Python 直譯器作者或維護者回報此錯誤。務必要回報該 Python 直譯器的版本 (`sys.version`; 這也會在互動式 Python 會話的開頭被印出)、確切的錯誤訊息 (該例外的關聯值) 及如果可能的話，觸發此錯誤的程式來源。

**exception SystemExit**

此例外會被 `sys.exit()` 函式引發。它繼承自 `BaseException` 而不是 `Exception` 因此不會被捕捉 `Exception` 的程式意外地捕捉。這允許例外可以正確地向上傳遞導致直譯器結束。當它未被處理時，Python 直譯器會結束；不會印出堆回溯。建構函式接受跟傳入 `sys.exit()` 一樣的可選引數。如果該值是整數，它會指定系統的結束狀態（傳入 C 的 `exit()` 函式）；如果它是 `None`，結束狀態會是 0；如果它是其他型（例如字串），則物件的值會被印出而結束狀態是 1。

對 `sys.exit()` 的呼叫會轉譯成例外讓負責清理的處理函式（try 陳述式的 `finally` 子句）可以被執行，且讓除錯器可以在不冒著失去控制的風險下執行。如果在對有有必要立即結束的情況（例如在子行程呼叫完 `os.fork()` 之後）可以使用 `os._exit()` 函式。

**code**

傳入建構函式的結束狀態或錯誤訊息。（預設是 `None`。）

**exception TypeError**

當一個操作或函式被用在不適合的型的物件時會引發此例外。關聯值是一個字串，提供關於不相符型的細節。

此例外可能被使用者程式碼引發，以表示不支援物件上所嘗試的操作，且本來就無意這樣做。如果一個物件有意要支援某個給定的操作但尚未提供實作，該引發的正確例外是 `NotImplementedError`。

傳入錯誤型的引數（例如當預期傳入 `int` 傳入 `list`）應該要導致 `TypeError`，但傳入帶有錯誤值的引數（例如超出預期範圍的數值）應該要導致 `ValueError`。

**exception UnboundLocalError**

當在函式或方法引用某個區域變數，但該變數尚未被結到任何值的時候會引發此例外。這是 `NameError` 的子類。

**exception UnicodeError**

當 Unicode 相關的編碼或解碼錯誤發生時會引發此例外。這是 `ValueError` 的子類。

`UnicodeError` 有屬性描述編碼或解碼錯誤。例如 `err.object[err.start:err.end]` 會提供讓編解碼器失敗的具體無效輸入。

**encoding**

引發錯誤的編碼名稱。

**reason**

描述特定編解碼器錯誤的字串。

**object**

編解碼器嘗試編碼或解碼的物件。

**start**

在 `object` 中無效資料的開始索引。

**end**

在 `object` 中最後的無效資料後的索引。

**exception UnicodeEncodeError**

在編碼當中發生 Unicode 相關錯誤時會引發此例外。這是 `UnicodeError` 的子類。

**exception UnicodeDecodeError**

在解碼當中發生 Unicode 相關錯誤時會引發此例外。這是 `UnicodeError` 的子類。

**exception UnicodeTranslateError**

在轉譯當中發生 Unicode 相關錯誤時會引發此例外。這是 `UnicodeError` 的子類。

**exception ValueError**

當一個操作或函式收到引數是正確型但是不適合的值，且該情況無法被更精確的例外例如 `IndexError` 所描述時會引發此例外。

**exception ZeroDivisionError**

當除法或模數運算 (modulo operation) 的第二個引數是 0 的時候會引發此例外。關聯值是一個字串，表示運算元及運算的類型。

以下例外是 了相容於之前版本而保留；從 Python 3.3 開始，它們是 *OSError* 的 名。

**exception EnvironmentError****exception IOError****exception WindowsError**

僅限於在 Windows 中使用。

**5.4.1 作業系統例外**

以下的例外是 *OSError* 的子類，它們根據系統錯誤代碼來引發。

**exception BlockingIOError**

當設置 非阻塞操作的物件 (例如 socket) 上的操作將要阻塞時會引發此例外。對應到 *errno* *EAGAIN*、*EALREADY*、*EWOULDBLOCK* 及 *EINPROGRESS*。

除了 *OSError* 的那些屬性之外，*BlockingIOError* 有多一個屬性：

**characters\_written**

一個整數， 容 在其阻塞之前，已寫進串流的字元數。當使用 *io* 模組 的緩衝 I/O 類 時這個屬性是可用的。

**exception ChildProcessError**

當子行程上的操作失敗時會引發此例外。對應到 *errno* *ECHILD*。

**exception ConnectionError**

連 相關問題的基礎類。

子 類 有 *BrokenPipeError*、*ConnectionAbortedError*、*ConnectionRefusedError* 及 *ConnectionResetError*。

**exception BrokenPipeError**

*ConnectionError* 的子類，當嘗試寫入管道 (pipe) 同時另一端已經被關閉時會引發此例外，或者當嘗試寫入已關閉寫入的 socket 時也會引發。對應到 *errno* *EPIPE* 及 *ESHUTDOWN*。

**exception ConnectionAbortedError**

*ConnectionError* 的子類。當一個連 的嘗試被對等端點 (peer) 中斷時會引發此例外。對應到 *errno* *ECONNABORTED*。

**exception ConnectionRefusedError**

*ConnectionError* 的子類。當一個連 的嘗試被對等端點拒 時會引發此例外。對應到 *errno* *ECONNREFUSED*。

**exception ConnectionResetError**

*ConnectionError* 的子類。當一個連 被對等端點重置時會引發此例外。對應到 *errno* *ECONNRESET*。

**exception FileExistsError**

當嘗試建立已存在的檔案或目 時會引發此例外。對應到 *errno* *EEXIST*。

**exception FileNotFoundError**

當請求不存在的檔案或目 時會引發此例外。對應到 *errno* *ENOENT*。

**exception InterruptedError**

當系統呼叫被傳入的信號中斷時會引發此例外。對應到 *errno* *EINTR*。

在 3.5 版的變更：現在當 *syscall* 被信號中斷時 Python 會重試系統呼叫而不會引發 *InterruptedError*，除非信號處理器引發例外 (理由可參考 [PEP 475](#))。

**exception IsADirectoryError**

當在目錄上請求檔案操作（例如 `os.remove()`）時會引發此例外。對應到 `errno EISDIR`。

**exception NotADirectoryError**

當在某個不是目錄的東西上請求目錄操作（例如 `os.listdir()`）時會引發此例外。在大多數的 POSIX 平台上，如果嘗試操作開檔或遍歷一個當作目錄的非目錄檔案也會引發此例外。對應到 `errno ENOTDIR`。

**exception PermissionError**

當嘗試執行一個有合乎存取權限的操作時會引發此例外—例如檔案系統權限。對應到 `errno EACCES`、`EPERM` 及 `ENOTCAPABLE`。

在 3.11.1 版的變更: WASI 的 `ENOTCAPABLE` 現在對應到 `PermissionError`。

**exception ProcessLookupError**

當給定的行程不存在時會引發此例外。對應到 `errno ESRCH`。

**exception TimeoutError**

當系統函式在系統層級超時時會引發此例外。對應到 `errno ETIMEDOUT`。

在 3.3 版被加入: 加入以上所有的 `OSError` 子類。

 **也參考**

**PEP 3151** — 改寫作業系統與 IO 例外階層

## 5.5 警告

以下的例外是當作警告的種類使用；更多細節參考 *Warning Categories* 文件。

**exception Warning**

警告種類的基礎類。

**exception UserWarning**

使用者程式碼生的警告的基礎類。

**exception DeprecationWarning**

關於已用功能的警告的基礎類，且當那些警告是針對其他 Python 開發者。

會被預設的警告過濾器忽略，在 `__main__` 模組除外 (**PEP 565**)。用 Python 開發模式會顯示此警告。

用原則描述在 **PEP 387**。

**exception PendingDeprecationWarning**

關於過時且預期未來要被用，但目前尚未被用的功能的警告的基礎類。

因發出關於可能即將被用的警告是不尋常的，此類很少被使用，而對已經被用的情況會優先使用 `DeprecationWarning`。

會被預設的警告過濾器忽略。用 Python 開發模式會顯示此警告。

用原則描述在 **PEP 387**。

**exception SyntaxWarning**

關於可疑語法的警告的基礎類。

**exception RuntimeWarning**

關於可疑執行環境行的警告的基礎類。

**exception FutureWarning**

關於已用功能的警告的基礎類，且當那些警告是針對以 Python 寫的應用程式的終端使用者。

**exception ImportError**

關於在模組引入的可能錯誤的警告的基礎類。

會被預設的警告過濾器忽略。用 `Python` 開發模式會顯示此警告。

**exception UnicodeWarning**

Unicode 相關警告的基礎類。

**exception EncodingWarning**

編碼相關警告的基礎類。

細節參考選擇性加入的編碼警告。

在 3.10 版被加入。

**exception BytesWarning**

`bytes` 及 `bytearray` 相關警告的基礎類。

**exception ResourceWarning**

資源用法相關警告的基礎類。

會被預設的警告過濾器忽略。用 `Python` 開發模式會顯示此警告。

在 3.2 版被加入。

## 5.6 例外群組

當需要引發多個不相關例外時會使用下列的類。它們是例外階層的一部分所以可以像所有其他例外一樣使用 `except` 來處理。此外，它們會以包含的例外型基礎來比對其子群組而被 `except*` 辨認出來。

**exception ExceptionGroup(msg, excs)****exception BaseExceptionGroup(msg, excs)**

這兩個例外型都將例外包裝在序列 `excs` 中。`msg` 參數必須是字串。這兩個類的差別是 `BaseExceptionGroup` 擴充了 `BaseException` 且可以包裝任何例外，而 `ExceptionGroup` 擴充了 `Exception` 且只能包裝 `Exception` 的子類。這個設計使得 `except Exception` 可以捕捉 `ExceptionGroup` 但不能捕捉 `BaseExceptionGroup`。

如果所有包含的例外都是 `Exception` 實例，`BaseExceptionGroup` 建構函式會回傳 `ExceptionGroup` 而不是 `BaseExceptionGroup`，因此可以被使用來讓這樣的選擇自動化。另一方面來，如果任何包含的例外不是 `Exception` 的子類，`ExceptionGroup` 建構函式會引發 `TypeError`。

**message**

建構函式的 `msg` 引數。這是一個唯讀的屬性。

**exceptions**

指定給建構函式 `excs` 序列中的例外組成的元組。這是一個唯讀的屬性。

**subgroup(condition)**

回傳只包含從現有群組比對到 `condition` 的例外的例外群組，或者當結果空時回傳 `None`。

條件式可以是一個例外型或是例外型的元組，在此情況下，每個例外都會使用與 `except` 子句中使用的相同檢查方法來檢查是否有匹配。條件式也可以是一個可呼叫物件（除了型物件之外），其接受一個例外作單一引數，而如果該例外應該在子群組中就回傳 `true`。

現有例外的巢狀結構會保留在結果，其 `message`、`__traceback__`、`__cause__`、`__context__` 及 `__notes__` 欄位的值也一樣。空的巢狀群組會從結果排除。

條件會對巢狀例外群組的所有例外做檢查，包括頂層及任何巢狀的例外群組。如果條件對這樣的例外群組 `true`，它會被完整包含在結果。

在 3.13 版被加入：`condition` 可以是任何不是型物件的可呼叫物件。

**split**(condition)

像 `subgroup()` 一樣，但回傳一對 (match, rest)，其中 match 是 `subgroup(condition)` 而 rest 是剩下沒有比對到的部分。

**derive**(excs)

回傳有相同 `message` 但將例外包裝在 `excs` 的例外群組。

此方法被 `subgroup()` 及 `split()` 使用，被用來在各種情境下拆分例外群組。子類需要覆寫它來讓 `subgroup()` 及 `split()` 回傳子類而不是 `ExceptionGroup` 的實例。

`subgroup()` 及 `split()` 會從原始的例外群組的 `__traceback__`、`__cause__`、`__context__` 和 `__notes__` 欄位到 `derive()` 所回傳的例外群組上，因此這些欄位不需要被 `derive()` 更新。

```
>>> class MyGroup(ExceptionGroup):
...     def derive(self, excs):
...         return MyGroup(self.message, excs)
...
>>> e = MyGroup("eg", [ValueError(1), TypeError(2)])
>>> e.add_note("a note")
>>> e.__context__ = Exception("context")
>>> e.__cause__ = Exception("cause")
>>> try:
...     raise e
... except Exception as e:
...     exc = e
...
>>> match, rest = exc.split(ValueError)
>>> exc, exc.__context__, exc.__cause__, exc.__notes__
(MyGroup('eg', [ValueError(1), TypeError(2)]), Exception('context'), Exception(
↪ 'cause'), ['a note'])
>>> match, match.__context__, match.__cause__, match.__notes__
(MyGroup('eg', [ValueError(1)]), Exception('context'), Exception('cause'), ['a note
↪'])
>>> rest, rest.__context__, rest.__cause__, rest.__notes__
(MyGroup('eg', [TypeError(2)]), Exception('context'), Exception('cause'), ['a note
↪'])
>>> exc.__traceback__ is match.__traceback__ is rest.__traceback__
True
```

需注意 `BaseExceptionGroup` 定義了 `__new__()`，因此需要不同建構函式簽名的子類需要覆寫它而不是 `__init__()`。例如下面定義了一個例外群組子類接受 `exit_code` 從中建構群組的訊息：

```
class Errors(ExceptionGroup):
    def __new__(cls, errors, exit_code):
        self = super().__new__(Errors, f"exit code: {exit_code}", errors)
        self.exit_code = exit_code
        return self

    def derive(self, excs):
        return Errors(excs, self.exit_code)
```

像 `ExceptionGroup` 一樣，任何 `BaseExceptionGroup` 的子類且也是 `Exception` 的子類只能包裝 `Exception` 的實例。

在 3.11 版被加入。

## 5.7 例外階層

建例外的類階層如下：

```

BaseException
├── BaseExceptionGroup

## 文本處理 (Text Processing) 服務

---

本章節介紹的模組 (module) 提供了廣泛的字串操作與其他文本處理服務。

在二進位資料服務下所描述的 `codecs` 模組也與文本處理高度相關。另外也請參閱在 *Text Sequence Type --- str* 中所描述的 Python 建置字串型。

### 6.1 string --- 常見的字串操作

原始碼: `Lib/string.py`

---

#### 也參考

*Text Sequence Type --- str*

*String Methods*

#### 6.1.1 字串常數

此模組中定義的常數：

`string.ascii_letters`

下文描述的 `ascii_lowercase` 和 `ascii_uppercase` 常數的串接，該值不依賴於區域設定。

`string.ascii_lowercase`

小寫字母 'abcdefghijklmnopqrstuvwxyz'。該值與地區設定無關且不會改變。

`string.ascii_uppercase`

大寫字母 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'。此值與地區設定無關且不會改變。

`string.digits`

字串 '0123456789'。

`string.hexdigits`

字串 '0123456789abcdefABCDEF'。

`string.octdigits`

字串 `'01234567'`。

`string.punctuation`

在 C 語言中被視標點符號的 ASCII 字元的字串：`!"#$%&'()*+,-./:;<=>?@[\\]^_`{|}~`。

`string.printable`

ASCII 字元的字串被 Python 是可被列印輸出的。這是 `digits`、`ascii_letters`、`punctuation` 和 `whitespace` 的組合。

### 備

By design, `string.printable.isprintable()` returns `False`. In particular, `string.printable` is not printable in the POSIX sense (see `LC_CTYPE`).

`string.whitespace`

包含所有 ASCII 字元的字串都視空白字元 (whitespace)。包含空格 (space)、表符號 (tab)、行符號 (linefeed)、return、頁符號 (formfeed) 和垂直表符號 (vertical tab) 這些字元。

## 6.1.2 自訂字串格式

透過 [PEP 3101](#) 中描述的 `format()` 方法，建字串類提供了進行雜變數替換和數值格式化的能力。`string` 模組中的 `Formatter` 類模組可讓你使用與建 `format()` 方法相同的實作來建立和自訂你自己的字串格式化行。

`class string.Formatter`

`Formatter` 類有以下的公開方法：

**format** (*format\_string*, *l*, \*args, \*\*kwargs)

主要的 API 方法。它接收一個格式字串及一組任意的位引數與關鍵字引數，是呼叫 `vformat()` 的包裝器 (wrapper)。

在 3.7 版的變更：現在格式字串引數是僅限位引數。

**vformat** (*format\_string*, args, kwargs)

This function does the actual work of formatting. It is exposed as a separate function for cases where you want to pass in a predefined dictionary of arguments, rather than unpacking and repacking the dictionary as individual arguments using the `*args` and `**kwargs` syntax. `vformat()` does the work of breaking up the format string into character data and replacement fields. It calls the various methods described below.

In addition, the `Formatter` defines a number of methods that are intended to be replaced by subclasses:

**parse** (*format\_string*)

將 `format_string` 放入圈，回傳一個可代物件，其元素 (`literal_text`, `field_name`, `format_spec`, `conversion`)。這會被 `vformat()` 用於將字串裁切字面文本或替欄位。

The values in the tuple conceptually represent a span of literal text followed by a single replacement field. If there is no literal text (which can happen if two replacement fields occur consecutively), then `literal_text` will be a zero-length string. If there is no replacement field, then the values of `field_name`, `format_spec` and `conversion` will be `None`.

**get\_field** (*field\_name*, args, kwargs)

Given `field_name` as returned by `parse()` (see above), convert it to an object to be formatted. Returns a tuple (obj, used\_key). The default version takes strings of the form defined in [PEP 3101](#), such as `"0[name]"` or `"label.title"`. `args` and `kwargs` are as passed in to `vformat()`. The return value `used_key` has the same meaning as the `key` parameter to `get_value()`.

**get\_value** (*key*, *args*, *kwargs*)

Retrieve a given field value. The *key* argument will be either an integer or a string. If it is an integer, it represents the index of the positional argument in *args*; if it is a string, then it represents a named argument in *kwargs*.

The *args* parameter is set to the list of positional arguments to `vformat()`, and the *kwargs* parameter is set to the dictionary of keyword arguments.

For compound field names, these functions are only called for the first component of the field name; subsequent components are handled through normal attribute and indexing operations.

So for example, the field expression '0.name' would cause `get_value()` to be called with a *key* argument of 0. The `name` attribute will be looked up after `get_value()` returns by calling the built-in `getattr()` function.

If the index or keyword refers to an item that does not exist, then an `IndexError` or `KeyError` should be raised.

**check\_unused\_args** (*used\_args*, *args*, *kwargs*)

Implement checking for unused arguments if desired. The arguments to this function is the set of all argument keys that were actually referred to in the format string (integers for positional arguments, and strings for named arguments), and a reference to the *args* and *kwargs* that was passed to `vformat`. The set of unused args can be calculated from these parameters. `check_unused_args()` is assumed to raise an exception if the check fails.

**format\_field** (*value*, *format\_spec*)

`format_field()` simply calls the global `format()` built-in. The method is provided so that subclasses can override it.

**convert\_field** (*value*, *conversion*)

Converts the value (returned by `get_field()`) given a conversion type (as in the tuple returned by the `parse()` method). The default version understands 's' (str), 'r' (repr) and 'a' (ascii) conversion types.

### 6.1.3 格式化文字語法

The `str.format()` method and the `Formatter` class share the same syntax for format strings (although in the case of `Formatter`, subclasses can define their own format string syntax). The syntax is related to that of formatted string literals, but it is less sophisticated and, in particular, does not support arbitrary expressions.

Format strings contain "replacement fields" surrounded by curly braces `{}`. Anything that is not contained in braces is considered literal text, which is copied unchanged to the output. If you need to include a brace character in the literal text, it can be escaped by doubling: `{{` and `}}`.

The grammar for a replacement field is as follows:

```
replacement_field ::= "{" [field_name] ["!" conversion] [":" format_spec] "}"
field_name        ::= arg_name ("." attribute_name | "[" element_index "]")*
arg_name          ::= [identifier | digit+]
attribute_name    ::= identifier
element_index     ::= digit+ | index_string
index_string      ::= <any source character except "]"> +
conversion        ::= "r" | "s" | "a"
format_spec       ::= format-spec:format_spec
```

In less formal terms, the replacement field can start with a *field\_name* that specifies the object whose value is to be formatted and inserted into the output instead of the replacement field. The *field\_name* is optionally followed by a *conversion* field, which is preceded by an exclamation point '!', and a *format\_spec*, which is preceded by a colon ':'. These specify a non-default format for the replacement value.

另請參閱格式規格 (*Format Specification*) 迷你語言 部份。

The *field\_name* itself begins with an *arg\_name* that is either a number or a keyword. If it's a number, it refers to a positional argument, and if it's a keyword, it refers to a named keyword argument. An *arg\_name* is treated as a

number if a call to `str.isdecimal()` on the string would return true. If the numerical `arg_names` in a format string are 0, 1, 2, ... in sequence, they can all be omitted (not just some) and the numbers 0, 1, 2, ... will be automatically inserted in that order. Because `arg_name` is not quote-delimited, it is not possible to specify arbitrary dictionary keys (e.g., the strings `'10'` or `':-1'`) within a format string. The `arg_name` can be followed by any number of index or attribute expressions. An expression of the form `'.name'` selects the named attribute using `getattr()`, while an expression of the form `'[index]'` does an index lookup using `__getitem__()`.

在 3.1 版的變更: The positional argument specifiers can be omitted for `str.format()`, so `'{} {}'.format(a, b)` is equivalent to `'{0} {1}'.format(a, b)`.

在 3.4 版的變更: The positional argument specifiers can be omitted for `Formatter`.

Some simple format string examples:

```
"First, thou shalt count to {0}" # References first positional argument
"Bring me a {}"                # Implicitly references the first positional argument
"From {} to {}".format(1, 2)   # Same as "From {0} to {1}"
"My quest is {name}"           # References keyword argument 'name'
"Weight in tons {0.weight}"    # 'weight' attribute of first positional arg
"Units destroyed: {players[0]}" # First element of keyword argument 'players'.
```

The `conversion` field causes a type coercion before formatting. Normally, the job of formatting a value is done by the `__format__()` method of the value itself. However, in some cases it is desirable to force a type to be formatted as a string, overriding its own definition of formatting. By converting the value to a string before calling `__format__()`, the normal formatting logic is bypassed.

目前支援三種轉旗標: `!s` 會對該值呼叫 `str()`, `!r` 會對該值呼叫 `repr()`, 而 `!a` 則會對該值呼叫 `ascii()`。

一些範例:

```
"Harold's a clever {0!s}"       # Calls str() on the argument first
"Bring out the holy {name!r}"   # Calls repr() on the argument first
"More {!a}"                     # Calls ascii() on the argument first
```

`format_spec` 欄位描述了值的呈現規格, 例如欄位寬度、對齊、填充 (padding)、小數精度等細節資訊。每種值類型都可以定義自己的「格式化迷你語言 (formatting mini-language)」或對 `format_spec` 的解釋。

大多數 Python 都支援常見的格式化迷你語言, 下一節將會詳細說明。

`format_spec` 欄位還可以在其內部包含巢狀的替換欄位。這些巢狀的替換欄位可能包含欄位名稱、轉旗標、格式規格描述, 但是不允許再更深層的巢狀結構。`format_spec` 內部的替換欄位會在 `format_spec` 字串被直譯前被替換。這讓數值的格式能被動態地指定。

範例請見格式範例。

## 格式規格 (Format Specification) 迷你語言

「格式規格」在格式字串 (format string) 中包含的替換欄位中使用, 以定義各個值如何被呈現 (請參考格式化文字語法和 f-strings)。它們也能直接傳遞給 Python 的 `format()` 函式。每個可格式化型 (formattable type) 可以定義格式規格如何被直譯。

大部分 Python 了格式規格實作了下列選項, 不過有些選項只被數值型 Python 支援。

一般來, 輸入空格式規格會產生和對值呼叫 `str()` 函式相同的結果, 非空的格式規格才會修改結果。

標準格式符號 (standard format specifier) 的一般型式如下:

```
format_spec ::= [[fill]align][sign]["z"]["#"]["0"][width][grouping_option][ "." precision ] [ty
fill ::= <any character>
align ::= "<" | ">" | "=" | "^"
sign ::= "+" | "-" | " "
width ::= digit+
grouping_option ::= "_" | ",",
precision ::= digit+
```

```
type ::= "b" | "c" | "d" | "e" | "E" | "f" | "F" | "g" | "G" | "n" | "o" | "s" | "x"
```

如果給定了一個有效的 *align* 值，則可以在它之前加一個 *fill* 字元，且該字元可任意字元，若不加的話預設空格。使用格式字串或 `str.format()` 時是無法在其中使用大括號 (“{” 或 “}”) 作 *fill* 字元的，但仍可透過巢狀替欄位的方式插入大括號。此限制不影響 `format()` 函式。

The meaning of the various alignment options is as follows:

選項	含義
'<'	制欄位在可用空間靠左對齊（這是大多數物件的預設值）。
'>'	制欄位在可用空間靠右對齊（這是數字的預設值）。
'='	Forces the padding to be placed after the sign (if any) but before the digits. This is used for printing fields in the form '+000000120'. This alignment option is only valid for numeric types, excluding <i>complex</i> . It becomes the default for numbers when '0' immediately precedes the field width.
'^'	制欄位在可用空間置中。

請注意，除非有定義了最小欄位寬度，否則欄位寬度將始終與填充它的資料大小相同，故在該情下的對齊選項是有意義的。

*sign* 選項只適用於數字型，可以下之一：

選項	含義
'+'	表示正數與負數均需使用符號。
'-'	indicates that a sign should be used only for negative numbers (this is the default behavior).
空格	表示正數應使用前導空格，負數應使用號。

The 'z' option coerces negative zero floating-point values to positive zero after rounding to the format precision. This option is only valid for floating-point presentation types.

在 3.11 版的變更: 新增 'z' 選項 (請見 [PEP 682](#))。

The '#' option causes the "alternate form" to be used for the conversion. The alternate form is defined differently for different types. This option is only valid for integer, float and complex types. For integers, when binary, octal, or hexadecimal output is used, this option adds the respective prefix '0b', '0o', '0x', or '0X' to the output value. For float and complex the alternate form causes the result of the conversion to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for 'g' and 'G' conversions, trailing zeros are not removed from the result.

The ',' option signals the use of a comma for a thousands separator for floating-point presentation types and for integer presentation type 'd'. For other presentation types, this option is an error. For a locale aware separator, use the 'n' integer presentation type instead.

在 3.1 版的變更: 新增 ',' 選項 (請見 [PEP 378](#))。

'\_' 選項表示對於浮點表示型和整數表示型 'd' 使用底作千位分隔符號。對於整數表示型 'b', 'o', 'x' 和 'X', 每 4 位數字會插入底。對於其他表示型，指定此選項會出錯。

在 3.6 版的變更: 新增 '\_' 選項 (請見 [PEP 515](#))。

*width* 是一個十進位整數，定義了最小總欄位寬度，包括任何前綴、分隔符號和其他格式字元。如果未指定，則欄位寬度將由容定。

當未給予明確的對齊指示，在 *width* 欄位前面填入零 ('0') 字元將會 *complex* 以外的數值型用有符號察覺的零填充 (sign-aware zero-padding)。這相當於使用 '0' *fill* 字元且對齊類型 '='。

在 3.10 版的變更: 在 *width* 欄位前面加上 '0' 不再影響字串的預設對齊方式。

*precision* 是一個十進位整數，指定表示類型 'f' 和 'F' 的小數點後應顯示多少位，或表示類型 'g' 或 'G' 的小數點前後應顯示多少位。對於字串表示類型，該欄位指定最大欄位大小 - 言之，將使用欄位中的多少字元。整數表示類型不允許使用 *precision*。

最終，型 定义了資料將會如何呈現

可用的字串表示型 有：

型	含義
's'	String format. This is the default type for strings and may be omitted.
None	與 's' 相同。

The available integer presentation types are:

型	含義
'b'	Binary format. Outputs the number in base 2.
'c'	Character. Converts the integer to the corresponding unicode character before printing.
'd'	Decimal Integer. Outputs the number in base 10.
'o'	Octal format. Outputs the number in base 8.
'x'	十六進位格式。輸出以 16 基數的數字，9 以上的數字使用小寫字母。
'X'	十六進位格式。輸出以 16 基數的數字，9 以上的數字使用大寫字母。如果指定了 '#'，則前綴 '0x' 也會被轉成大寫的 '0X'。
'n'	Number. This is the same as 'd', except that it uses the current locale setting to insert the appropriate number separator characters.
None	與 'd' 相同。

In addition to the above presentation types, integers can be formatted with the floating-point presentation types listed below (except 'n' and None). When doing so, `float()` is used to convert the integer to a floating-point number before formatting.

The available presentation types for `float` and `Decimal` values are:

型 F	含義
'e'	Scientific notation. For a given precision $p$ , formats the number in scientific notation with the letter 'e' separating the coefficient from the exponent. The coefficient has one digit before and $p$ digits after the decimal point, for a total of $p + 1$ significant digits. With no precision given, uses a precision of 6 digits after the decimal point for <i>float</i> , and shows all coefficient digits for <i>Decimal</i> . If $p=0$ , the decimal point is omitted unless the # option is used.
'E'	Scientific notation. Same as 'e' except it uses an upper case 'E' as the separator character.
'f'	Fixed-point notation. For a given precision $p$ , formats the number as a decimal number with exactly $p$ digits following the decimal point. With no precision given, uses a precision of 6 digits after the decimal point for <i>float</i> , and uses a precision large enough to show all coefficient digits for <i>Decimal</i> . If $p=0$ , the decimal point is omitted unless the # option is used.
'F'	Fixed-point notation. Same as 'f', but converts <i>nan</i> to NAN and <i>inf</i> to INF.
'g'	General format. For a given precision $p \geq 1$ , this rounds the number to $p$ significant digits and then formats the result in either fixed-point format or in scientific notation, depending on its magnitude. A precision of 0 is treated as equivalent to a precision of 1. The precise rules are as follows: suppose that the result formatted with presentation type 'e' and precision $p-1$ would have exponent $exp$ . Then, if $m \leq exp < p$ , where $m$ is -4 for floats and -6 for <i>Decimals</i> , the number is formatted with presentation type 'f' and precision $p-1-exp$ . Otherwise, the number is formatted with presentation type 'e' and precision $p-1$ . In both cases insignificant trailing zeros are removed from the significand, and the decimal point is also removed if there are no remaining digits following it, unless the '#' option is used. With no precision given, uses a precision of 6 significant digits for <i>float</i> . For <i>Decimal</i> , the coefficient of the result is formed from the coefficient digits of the value; scientific notation is used for values smaller than $1e-6$ in absolute value and values where the place value of the least significant digit is larger than 1, and fixed-point notation is used otherwise. Positive and negative infinity, positive and negative zero, and nans, are formatted as <i>inf</i> , <i>-inf</i> , 0, <i>-0</i> and <i>nan</i> respectively, regardless of the precision.
'G'	General format. Same as 'g' except switches to 'E' if the number gets too large. The representations of infinity and NaN are uppercased, too.
'n'	Number. This is the same as 'g', except that it uses the current locale setting to insert the appropriate number separator characters.
'%'	Percentage. Multiplies the number by 100 and displays in fixed ('f') format, followed by a percent sign.
None	For <i>float</i> this is like the 'g' type, except that when fixed-point notation is used to format the result, it always includes at least one digit past the decimal point, and switches to the scientific notation when $exp \geq p - 1$ . When the precision is not specified, the latter will be as large as needed to represent the given value faithfully. For <i>Decimal</i> , this is the same as either 'g' or 'G' depending on the value of <i>context.capitals</i> for the current decimal context. The overall effect is to match the output of <i>str()</i> as altered by the other format modifiers.

The result should be correctly rounded to a given precision  $p$  of digits after the decimal point. The rounding mode for *float* matches that of the *round()* builtin. For *Decimal*, the rounding mode of the current *context* will be used.

The available presentation types for *complex* are the same as those for *float* ('%' is not allowed). Both the real and imaginary components of a complex number are formatted as floating-point numbers, according to the specified presentation type. They are separated by the mandatory sign of the imaginary part, the latter being terminated by a *j* suffix. If the presentation type is missing, the result will match the output of *str()* (complex numbers with a non-zero real part are also surrounded by parentheses), possibly altered by other format modifiers.

**格式范例**

本節包含 `str.format()` 語法以及與舊式 `%` 格式的比較。

此語法在大多情況下與舊式的 `%` 格式類似，只是增加了 `{}` 和 `:` 來取代 `%`。例如，`'%03.2f'` 可以改寫為 `'{:03.2f}'`。

新的語法還支援新的選項，將在以下的範例中說明。

按位置存取引數：

```
>>> '{0}, {1}, {2}'.format('a', 'b', 'c')
'a, b, c'
>>> '{}, {}, {}'.format('a', 'b', 'c') # 3.1+ only
'a, b, c'
>>> '{2}, {1}, {0}'.format('a', 'b', 'c')
'c, b, a'
>>> '{2}, {1}, {0}'.format(*'abc') # 解包引數序列
'c, b, a'
>>> '{0}{1}{0}'.format('abra', 'cad') # 引數索引可以重覆
'abracadabra'
```

按名稱存取引數：

```
>>> 'Coordinates: {latitude}, {longitude}'.format(latitude='37.24N', longitude='-115.81W')
'Coordinates: 37.24N, -115.81W'
>>> coord = {'latitude': '37.24N', 'longitude': '-115.81W'}
>>> 'Coordinates: {latitude}, {longitude}'.format(**coord)
'Coordinates: 37.24N, -115.81W'
```

存取引數的屬性：

```
>>> c = 3-5j
>>> ('The complex number {0} is formed from the real part {0.real} '
... 'and the imaginary part {0.imag}.').format(c)
'The complex number (3-5j) is formed from the real part 3.0 and the imaginary part -5.0.'
>>> class Point:
...     def __init__(self, x, y):
...         self.x, self.y = x, y
...     def __str__(self):
...         return 'Point({self.x}, {self.y})'.format(self=self)
...
>>> str(Point(4, 2))
'Point(4, 2)'
```

存取引數的區容：

```
>>> coord = (3, 5)
>>> 'X: {0[0]}; Y: {0[1]}'.format(coord)
'X: 3; Y: 5'
```

替換 `%s` 和 `%r`：

```
>>> "repr() shows quotes: {!r}; str() doesn't: {!s}".format('test1', 'test2')
'repr() shows quotes: 'test1'; str() doesn't: test2'
```

對齊文字以及指定寬度：

```
>>> '{:<30}'.format('left aligned')
'left aligned'
>>> '{:>30}'.format('right aligned')
'right aligned'
>>> '{:^30}'.format('centered')
'centered'
```

10	A	12	1010
11	B	13	1011

### 6.1.4 模板字串

模板字串提供如 [PEP 292](#) 所述更簡單的字串替換。模板字串的主要用例是國際化 (i18n)，因在這種情況下，更簡單的語法和功能使得它比其他 Python 建置字串格式化工具更容易翻譯。基於模板字串建構的 i18n 函式庫範例，請參閱 [fluff.i18n](#) 套件。

Template strings support  $\$$ -based substitutions, using the following rules:

- $\$\$$  is an escape; it is replaced with a single  $\$$ .
- $\$identifier$  names a substitution placeholder matching a mapping key of "identifier". By default, "identifier" is restricted to any case-insensitive ASCII alphanumeric string (including underscores) that starts with an underscore or ASCII letter. The first non-identifier character after the  $\$$  character terminates this placeholder specification.
- $\${identifier}$  is equivalent to  $\$identifier$ . It is required when valid identifier characters follow the placeholder but are not part of the placeholder, such as  $\${noun}ification$ .

Any other appearance of  $\$$  in the string will result in a `ValueError` being raised.

The `string` module provides a `Template` class that implements these rules. The methods of `Template` are:

```
class string.Template(template)
```

The constructor takes a single argument which is the template string.

```
substitute(mapping={}, /, **kwds)
```

進行模板替換，回傳一個新的字串。`mapping` 是任何有金鑰符合模板位符號的字典型物件。或者如果關鍵字就是位符號時，你也可以改提供關鍵字引數。當 `mapping` 跟 `kwds` 同時給定存在重疊時，`kwds` 的位符號會被優先使用。

```
safe_substitute(mapping={}, /, **kwds)
```

類似於 `substitute()`，但如果 `mapping` 與 `kwds` 中缺少位符號的話，原始的位符號會完整地出現在結果字串中，而不會引發 `KeyError` 例外。此外，與 `substitute()` 不同的是，任何包含  $\$$  的字句會直接回傳  $\$$  而非引發 `ValueError`。

雖然仍可能發生其他例外，但這個方法被認爲是「安全」的，因它總是試圖回傳一個有用的字串而不是引發例外。從另一個角度來看，`safe_substitute()` 可能非完全安全，因它會默默忽略格式錯誤的模板，這些模板包含了多余的左右定界符、不匹配的括號，或者不是有效的 Python 識字的位符號。

```
is_valid()
```

如果模板有將導致 `substitute()` 引發 `ValueError` 的無效位符號，就會回傳 `false`。

在 3.11 版被加入。

```
get_identifiers()
```

回傳模板中有效識字的串列，按照它們首次出現的順序，忽略任何無效的識字。

在 3.11 版被加入。

`Template` 實例也提供一個公開的資料屬性：

```
template
```

這是傳遞給建構函式 `template` 引數的物件。一般來，你不應該改變它，但它有制設定成唯讀。

以下是如何使用 `Template` 的一個範例：

```
>>> from string import Template
>>> s = Template('$who likes $what')
>>> s.substitute(who='tim', what='kung pao')
'tim likes kung pao'
>>> d = dict(who='tim')
>>> Template('Give $who $100').substitute(d)
Traceback (most recent call last):
...
ValueError: Invalid placeholder in string: line 1, col 11
>>> Template('$who likes $what').substitute(d)
Traceback (most recent call last):
...
KeyError: 'what'
>>> Template('$who likes $what').safe_substitute(d)
'tim likes $what'
```

進階用法：你可以衍生 `Template` 類來自定義位符號語法、左右定界符字元，或者用於剖析模板字串的正規表示式。你可以透過覆寫這些類屬性來達成：

- *delimiter* -- 這是描述引入左右定界符的文字字串。預設值是 `$`。請注意這不是正規表示式，因實作會在需要時對這個字串呼叫 `re.escape()`。也請注意你不能在建立類後修改左右定界符。（意即在子類的命名空間中必須設置不同的左右定界符）
- *idpattern* -- This is the regular expression describing the pattern for non-braced placeholders. The default value is the regular expression `(?a:[_a-z][_a-z0-9]*)`. If this is given and *braceidpattern* is `None` this pattern will also apply to braced placeholders.

#### 備

Since default *flags* is `re.IGNORECASE`, pattern `[a-z]` can match with some non-ASCII characters. That's why we use the local `a` flag here.

在 3.7 版的變更: *braceidpattern* can be used to define separate patterns used inside and outside the braces.

- *braceidpattern* -- This is like *idpattern* but describes the pattern for braced placeholders. Defaults to `None` which means to fall back to *idpattern* (i.e. the same pattern is used both inside and outside braces). If given, this allows you to define different patterns for braced and unbraced placeholders.

在 3.7 版被加入。

- *flags* -- The regular expression flags that will be applied when compiling the regular expression used for recognizing substitutions. The default value is `re.IGNORECASE`. Note that `re.VERBOSE` will always be added to the flags, so custom *idpatterns* must follow conventions for verbose regular expressions.

在 3.2 版被加入。

Alternatively, you can provide the entire regular expression pattern by overriding the class attribute *pattern*. If you do this, the value must be a regular expression object with four named capturing groups. The capturing groups correspond to the rules given above, along with the invalid placeholder rule:

- *escaped* -- 此群組與跳序列匹配，例如在預設模式下 `$$`。
- *named* -- 此群組與不帶大括號的位符號名稱匹配；它不應包含取群組中的左右定界符號。
- *braced* -- 此群組與大括號括起來的位符號名稱匹配；它不應在取群組中包含左右定界符或大括號。
- *invalid* -- 此群組與任何其他左右定界符模式（通常是單一左右定界符）匹配，且它應該出現在正規表示式的最後。

當此模式有匹配於模板但這些命名組中有任何一個不匹配，此類的方法將引發 `ValueError`。

## 6.1.5 輔助函式

`string.capwords(s, sep=None)`

使用 `str.split()` 將引數分割成字詞，使用 `str.capitalize()` 將每個單字大寫，使用 `str.join()` 將大寫字詞連接起來。如果可選的第二引數 `sep` 不存在或 `None`，則連續的空白字元將替換成單一空格，且除前導和尾隨空白；在其他情況下則使用 `sep` 來分割和連接單字。

## 6.2 re --- 正規表示式 (regular expression) 操作

原始碼：[Lib/re/](#)

此模組提供類似於 Perl 中正規表示式的配對操作。

被搜尋的模式 (pattern) 與字串可以是 Unicode 字串 (`str`)，也可以是 8-bit 字串 (`bytes`)。然而，Unicode 字串和 8-bit 字串不能混用：也就是，你不能用 `byte` 模式配對 Unicode 字串，反之亦然；同樣地，替換時，用來替換的字串必須與模式和搜尋字串是相同的型別 (type)。

正規表示式使用反斜線字元 (`'\'`) 表示特殊的形式，或是使用特殊字元而不調用它們的特殊意義。這與 Python 在字串文本 (literal) 中，為了一樣的目的使用同一個字元的目的相衝突；舉例來說，為了配對一個反斜線文字，一個人可能需要寫 `'\\'` 當作模式字串，因為正規表示式必須是 `\\`，而且每個反斜線在一個普通的 Python 字串文本中必須表示 `\\`。另外，請注意在 Python 的字串文本中使用反斜線的任何無效跳序列目前會產生一個 `SyntaxWarning`，而在未來這會變成一個 `SyntaxError`。儘管它對正規表示式是一個有效的跳序列，這種行也會發生。

解法方法是對正規表示式模式使用 Python 的原始字串符號；反斜線在一個以 `'r'` 前綴的字串文本中不會被用任何特殊的方式處理。所以 `r"\n"` 是一個兩個字元的字串，包含 `'\'` 和 `'n'`，同時 `"\n"` 是一個單個字元的字串，包含一個換行符號。通常模式在 Python 程式中會使用這個原始字串符號表示。

請務必注意到大部分的正規表示式操作是在模組層級的函式和 *compiled regular expressions* 中的方法使用的。這些函式是個捷徑且讓你不需要先編譯一個正規表示式物件，但是會缺少一些微調參數。

### 也參考

第三方的 `regex` 模組，有著和標準函式庫 `re` 模組相容的 API，但是提供額外的功能以及更完整的 Unicode 支援。

### 6.2.1 正規表示式語法

A regular expression (or RE) specifies a set of strings that matches it; the functions in this module let you check if a particular string matches a given regular expression (or if a given regular expression matches a particular string, which comes down to the same thing).

Regular expressions can be concatenated to form new regular expressions; if *A* and *B* are both regular expressions, then *AB* is also a regular expression. In general, if a string *p* matches *A* and another string *q* matches *B*, the string *pq* will match *AB*. This holds unless *A* or *B* contain low precedence operations; boundary conditions between *A* and *B*; or have numbered group references. Thus, complex expressions can easily be constructed from simpler primitive expressions like the ones described here. For details of the theory and implementation of regular expressions, consult the Friedl book [Frie09], or almost any textbook about compiler construction.

A brief explanation of the format of regular expressions follows. For further information and a gentler presentation, consult the `regex-howto`.

Regular expressions can contain both special and ordinary characters. Most ordinary characters, like `'A'`, `'a'`, or `'0'`, are the simplest regular expressions; they simply match themselves. You can concatenate ordinary characters, so `last` matches the string `'last'`. (In the rest of this section, we'll write RE's in this special style, usually without quotes, and strings to be matched 'in single quotes'.)

Some characters, like `'|'` or `'('`, are special. Special characters either stand for classes of ordinary characters, or affect how the regular expressions around them are interpreted.

Repetition operators or quantifiers (`*`, `+`, `?`, `{m, n}`, etc) cannot be directly nested. This avoids ambiguity with the non-greedy modifier suffix `?`, and with other modifiers in other implementations. To apply a second repetition to an inner repetition, parentheses may be used. For example, the expression `(?:a{6})*` matches any multiple of six 'a' characters.

The special characters are:

- `.`  
(Dot.) In the default mode, this matches any character except a newline. If the `DOTALL` flag has been specified, this matches any character including a newline. `(?:s:.)` matches any character regardless of flags.
  - `^`  
(Caret.) Matches the start of the string, and in `MULTILINE` mode also matches immediately after each newline.
  - `$`  
Matches the end of the string or just before the newline at the end of the string, and in `MULTILINE` mode also matches before a newline. `foo` matches both 'foo' and 'foobar', while the regular expression `foo$` matches only 'foo'. More interestingly, searching for `foo.$` in 'foo1\nfoo2\n' matches 'foo2' normally, but 'foo1' in `MULTILINE` mode; searching for a single `$` in 'foo\n' will find two (empty) matches: one just before the newline, and one at the end of the string.
  - `*`  
Causes the resulting RE to match 0 or more repetitions of the preceding RE, as many repetitions as are possible. `ab*` will match 'a', 'ab', or 'a' followed by any number of 'b's.
  - `+`  
Causes the resulting RE to match 1 or more repetitions of the preceding RE. `ab+` will match 'a' followed by any non-zero number of 'b's; it will not match just 'a'.
  - `?`  
Causes the resulting RE to match 0 or 1 repetitions of the preceding RE. `ab?` will match either 'a' or 'ab'.
  - `*?, +?, ??`  
The `'*'`, `'+'`, and `'?'` quantifiers are all *greedy*; they match as much text as possible. Sometimes this behaviour isn't desired; if the RE `<.*>` is matched against `<a> b <c>`, it will match the entire string, and not just `<a>`. Adding `?` after the quantifier makes it perform the match in *non-greedy* or *minimal* fashion; as few characters as possible will be matched. Using the RE `<.*?>` will match only `<a>`.
  - `*+, ++, ?+`  
Like the `'*'`, `'+'`, and `'?'` quantifiers, those where `'+'` is appended also match as many times as possible. However, unlike the true greedy quantifiers, these do not allow back-tracking when the expression following it fails to match. These are known as *possessive* quantifiers. For example, `a*a` will match 'aaaa' because the `a*` will match all 4 'a's, but, when the final 'a' is encountered, the expression is backtracked so that in the end the `a*` ends up matching 3 'a's total, and the fourth 'a' is matched by the final 'a'. However, when `a*+a` is used to match 'aaaa', the `a*+` will match all 4 'a', but when the final 'a' fails to find any more characters to match, the expression cannot be backtracked and will thus fail to match. `x*+, x++` and `x?+` are equivalent to `(?>x*)`, `(?>x+)` and `(?>x?)` correspondingly.
- 在 3.11 版被加入。
- `{m}`  
Specifies that exactly `m` copies of the previous RE should be matched; fewer matches cause the entire RE not to match. For example, `a{6}` will match exactly six 'a' characters, but not five.
  - `{m, n}`  
Causes the resulting RE to match from `m` to `n` repetitions of the preceding RE, attempting to match as many repetitions as possible. For example, `a{3, 5}` will match from 3 to 5 'a' characters. Omitting `m` specifies a lower bound of zero, and omitting `n` specifies an infinite upper bound. As an example, `a{4, }b` will match 'aaaab' or a thousand 'a' characters followed by a 'b', but not 'aaab'. The comma may not be omitted or the modifier would be confused with the previously described form.
  - `{m, n}?`  
Causes the resulting RE to match from `m` to `n` repetitions of the preceding RE, attempting to match as few repetitions as possible. This is the non-greedy version of the previous quantifier. For example, on the 6-character string 'aaaaaa', `a{3, 5}` will match 5 'a' characters, while `a{3, 5}?` will only match 3 characters.

`{m,n}+`

Causes the resulting RE to match from  $m$  to  $n$  repetitions of the preceding RE, attempting to match as many repetitions as possible *without* establishing any backtracking points. This is the possessive version of the quantifier above. For example, on the 6-character string 'aaaaaa', `a{3,5}+aa` attempt to match 5 'a' characters, then, requiring 2 more 'a's, will need more characters than available and thus fail, while `a{3,5}aa` will match with `a{3,5}` capturing 5, then 4 'a's by backtracking and then the final 2 'a's are matched by the final `aa` in the pattern. `x{m,n}+` is equivalent to `(?>x{m,n})`.

在 3.11 版被加入。

\

Either escapes special characters (permitting you to match characters like '\*', '?', and so forth), or signals a special sequence; special sequences are discussed below.

If you're not using a raw string to express the pattern, remember that Python also uses the backslash as an escape sequence in string literals; if the escape sequence isn't recognized by Python's parser, the backslash and subsequent character are included in the resulting string. However, if Python would recognize the resulting sequence, the backslash should be repeated twice. This is complicated and hard to understand, so it's highly recommended that you use raw strings for all but the simplest expressions.

[]

Used to indicate a set of characters. In a set:

- Characters can be listed individually, e.g. `[amk]` will match 'a', 'm', or 'k'.
- Ranges of characters can be indicated by giving two characters and separating them by a '-', for example `[a-z]` will match any lowercase ASCII letter, `[0-5][0-9]` will match all the two-digits numbers from 00 to 59, and `[0-9A-Fa-f]` will match any hexadecimal digit. If - is escaped (e.g. `[a\ -z]`) or if it's placed as the first or last character (e.g. `[-a]` or `[a-]`), it will match a literal '-'.  
 Note: `[a-z]` will not match the hyphen character itself.
- Special characters lose their special meaning inside sets. For example, `[(+*)]` will match any of the literal characters '(', '+', '\*', or ')'.  
 Note: `[+]` will not match the plus character itself.
- Character classes such as `\w` or `\S` (defined below) are also accepted inside a set, although the characters they match depend on the *flags* used.
- Characters that are not within a range can be matched by *complementing* the set. If the first character of the set is '^', all the characters that are *not* in the set will be matched. For example, `[^5]` will match any character except '5', and `[^^]` will match any character except '^'. ^ has no special meaning if it's not the first character in the set.
- To match a literal ']' inside a set, precede it with a backslash, or place it at the beginning of the set. For example, both `[() \ ] {}]` and `[ ] () [{}]` will match a right bracket, as well as left bracket, braces, and parentheses.
- Support of nested sets and set operations as in [Unicode Technical Standard #18](#) might be added in the future. This would change the syntax, so to facilitate this change a *FutureWarning* will be raised in ambiguous cases for the time being. That includes sets starting with a literal '[' or containing literal character sequences '--', '&&', '~', and '|'. To avoid a warning escape them with a backslash.

在 3.7 版的變更: *FutureWarning* is raised if a character set contains constructs that will change semantically in the future.

|

`A|B`, where  $A$  and  $B$  can be arbitrary REs, creates a regular expression that will match either  $A$  or  $B$ . An arbitrary number of REs can be separated by the '|' in this way. This can be used inside groups (see below) as well. As the target string is scanned, REs separated by '|' are tried from left to right. When one pattern completely matches, that branch is accepted. This means that once  $A$  matches,  $B$  will not be tested further, even if it would produce a longer overall match. In other words, the '|' operator is never greedy. To match a literal '|', use `\|`, or enclose it inside a character class, as in `[|]`.

(...)

Matches whatever regular expression is inside the parentheses, and indicates the start and end of a group; the contents of a group can be retrieved after a match has been performed, and can be matched later in the string

with the `\number` special sequence, described below. To match the literals `' ( ' or ' ) '`, use `\ ( or \ )`, or enclose them inside a character class: `[ (, ) ]`.

**(?...)**

This is an extension notation (a `' ? '` following a `' ( '` is not meaningful otherwise). The first character after the `' ? '` determines what the meaning and further syntax of the construct is. Extensions usually do not create a new group; `(?P<name>...)` is the only exception to this rule. Following are the currently supported extensions.

**(?aiLmsux)**

(One or more letters from the set `' a ', ' i ', ' L ', ' m ', ' s ', ' u ', ' x '`.) The group matches the empty string; the letters set the corresponding flags for the entire regular expression:

- `re.A` (ASCII-only matching)
- `re.I` (ignore case)
- `re.L` (locale dependent)
- `re.M` (multi-line)
- `re.S` (dot matches all)
- `re.U` (Unicode matching)
- `re.X` (verbose)

(The flags are described in [模組內容](#).) This is useful if you wish to include the flags as part of the regular expression, instead of passing a *flag* argument to the `re.compile()` function. Flags should be used first in the expression string.

在 3.11 版的變更: This construction can only be used at the start of the expression.

**(?:...)**

A non-capturing version of regular parentheses. Matches whatever regular expression is inside the parentheses, but the substring matched by the group *cannot* be retrieved after performing a match or referenced later in the pattern.

**(?aiLmsux-imsx:...)**

(Zero or more letters from the set `' a ', ' i ', ' L ', ' m ', ' s ', ' u ', ' x '`, optionally followed by `' - '` followed by one or more letters from the `' i ', ' m ', ' s ', ' x '`.) The letters set or remove the corresponding flags for the part of the expression:

- `re.A` (ASCII-only matching)
- `re.I` (ignore case)
- `re.L` (locale dependent)
- `re.M` (multi-line)
- `re.S` (dot matches all)
- `re.U` (Unicode matching)
- `re.X` (verbose)

(The flags are described in [模組內容](#).)

The letters `' a ', ' L '` and `' u '` are mutually exclusive when used as inline flags, so they can't be combined or follow `' - '`. Instead, when one of them appears in an inline group, it overrides the matching mode in the enclosing group. In Unicode patterns `(?a:...)` switches to ASCII-only matching, and `(?u:...)` switches to Unicode matching (default). In bytes patterns `(?L:...)` switches to locale dependent matching, and `(?a:...)` switches to ASCII-only matching (default). This override is only in effect for the narrow inline group, and the original matching mode is restored outside of the group.

在 3.6 版被加入.

在 3.7 版的變更: The letters `' a ', ' L '` and `' u '` also can be used in a group.

**(?>...)**

Attempts to match ... as if it was a separate regular expression, and if successful, continues to match the rest of the pattern following it. If the subsequent pattern fails to match, the stack can only be unwound to a point *before* the (?>...) because once exited, the expression, known as an *atomic group*, has thrown away all stack points within itself. Thus, (?>.\*). would never match anything because first the .\* would match all characters possible, then, having nothing left to match, the final . would fail to match. Since there are no stack points saved in the Atomic Group, and there is no stack point before it, the entire expression would thus fail to match.

在 3.11 版被加入。

**(?P<name>...)**

Similar to regular parentheses, but the substring matched by the group is accessible via the symbolic group name *name*. Group names must be valid Python identifiers, and in *bytes* patterns they can only contain bytes in the ASCII range. Each group name must be defined only once within a regular expression. A symbolic group is also a numbered group, just as if the group were not named.

Named groups can be referenced in three contexts. If the pattern is (?P<quote>["']).\*?(?P=quote) (i.e. matching a string quoted with either single or double quotes):

Context of reference to group "quote"	Ways to reference it
in the same pattern itself	<ul style="list-style-type: none"> <li>• (?P=quote) (as shown)</li> <li>• \1</li> </ul>
when processing match object <i>m</i>	<ul style="list-style-type: none"> <li>• m.group('quote')</li> <li>• m.end('quote') (etc.)</li> </ul>
in a string passed to the <i>repl</i> argument of <code>re.sub()</code>	<ul style="list-style-type: none"> <li>• \g&lt;quote&gt;</li> <li>• \g&lt;1&gt;</li> <li>• \1</li> </ul>

在 3.12 版的變更: In *bytes* patterns, group *name* can only contain bytes in the ASCII range (b'\x00'-b'\x7f').

**(?P=name)**

A backreference to a named group; it matches whatever text was matched by the earlier group named *name*.

**(?#...)**

A comment; the contents of the parentheses are simply ignored.

**(?=...)**

Matches if ... matches next, but doesn't consume any of the string. This is called a *lookahead assertion*. For example, `Isaac (?=Asimov)` will match 'Isaac ' only if it's followed by 'Asimov'.

**(?!...)**

Matches if ... doesn't match next. This is a *negative lookahead assertion*. For example, `Isaac (?!Asimov)` will match 'Isaac ' only if it's *not* followed by 'Asimov'.

**(?<=...)**

Matches if the current position in the string is preceded by a match for ... that ends at the current position. This is called a *positive lookbehind assertion*. `(?<=abc)def` will find a match in 'abcdef', since the lookbehind will back up 3 characters and check if the contained pattern matches. The contained pattern must only match strings of some fixed length, meaning that `abc` or `a|b` are allowed, but `a*` and `a{3,4}` are not. Note that patterns which start with positive lookbehind assertions will not match at the beginning of the string being searched; you will most likely want to use the `search()` function rather than the `match()` function:

```
>>> import re
>>> m = re.search('(?!<=abc)def', 'abcdef')
```

(繼續下一頁)

(繼續上一頁)

```
>>> m.group(0)
'def'
```

This example looks for a word following a hyphen:

```
>>> m = re.search(r'(?<=-)\w+', 'spam-egg')
>>> m.group(0)
'egg'
```

在 3.5 版的變更: Added support for group references of fixed length.

**(?<!. . .)**

Matches if the current position in the string is not preceded by a match for . . . . This is called a *negative lookbehind assertion*. Similar to positive lookbehind assertions, the contained pattern must only match strings of some fixed length. Patterns which start with negative lookbehind assertions may match at the beginning of the string being searched.

**(?(id/name)yes-pattern|no-pattern)**

Will try to match with `yes-pattern` if the group with given *id* or *name* exists, and with `no-pattern` if it doesn't. `no-pattern` is optional and can be omitted. For example, `(<)?(\w+@\w+(?:\.\w+)+)(?(1)>|$)` is a poor email matching pattern, which will match with `<user@host.com>` as well as `'user@host.com'`, but not with `'<user@host.com'` nor `'user@host.com>'`.

在 3.12 版的變更: Group *id* can only contain ASCII digits. In *bytes* patterns, group *name* can only contain bytes in the ASCII range (`b'\x00'-b'\x7f'`).

The special sequences consist of `'\'` and a character from the list below. If the ordinary character is not an ASCII digit or an ASCII letter, then the resulting RE will match the second character. For example, `\$` matches the character `'$'`.

**\number**

Matches the contents of the group of the same number. Groups are numbered starting from 1. For example, `(.+)\1` matches `'the the'` or `'55 55'`, but not `'thethe'` (note the space after the group). This special sequence can only be used to match one of the first 99 groups. If the first digit of *number* is 0, or *number* is 3 octal digits long, it will not be interpreted as a group match, but as the character with octal value *number*. Inside the `'['` and `']'` of a character class, all numeric escapes are treated as characters.

**\A**

Matches only at the start of the string.

**\b**

Matches the empty string, but only at the beginning or end of a word. A word is defined as a sequence of word characters. Note that formally, `\b` is defined as the boundary between a `\w` and a `\W` character (or vice versa), or between `\w` and the beginning or end of the string. This means that `r'\bat\b'` matches `'at'`, `'at.'`, `'(at)'`, and `'as at ay'` but not `'attempt'` or `'atlas'`.

The default word characters in Unicode (str) patterns are Unicode alphanumerics and the underscore, but this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

 備 F

Inside a character range, `\b` represents the backspace character, for compatibility with Python's string literals.

**\B**

Matches the empty string, but only when it is *not* at the beginning or end of a word. This means that `r'at\B'` matches `'athens'`, `'atom'`, `'attorney'`, but not `'at'`, `'at.'`, or `'at!'`. `\B` is the opposite of `\b`, so word characters in Unicode (str) patterns are Unicode alphanumerics or the underscore, although this can be changed by using the *ASCII* flag. Word boundaries are determined by the current locale if the *LOCALE* flag is used.

 備 F

Note that `\B` does not match an empty string, which differs from RE implementations in other programming languages such as Perl. This behavior is kept for compatibility reasons.

`\d`**For Unicode (str) patterns:**

Matches any Unicode decimal digit (that is, any character in Unicode character category `[Nd]`). This includes `[0-9]`, and also many other digit characters.

Matches `[0-9]` if the `ASCII` flag is used.

**For 8-bit (bytes) patterns:**

Matches any decimal digit in the ASCII character set; this is equivalent to `[0-9]`.

`\D`

Matches any character which is not a decimal digit. This is the opposite of `\d`.

Matches `[^0-9]` if the `ASCII` flag is used.

`\s`**For Unicode (str) patterns:**

Matches Unicode whitespace characters (as defined by `str.isspace()`). This includes `[\t\n\r\f\v]`, and also many other characters, for example the non-breaking spaces mandated by typography rules in many languages.

Matches `[\t\n\r\f\v]` if the `ASCII` flag is used.

**For 8-bit (bytes) patterns:**

Matches characters considered whitespace in the ASCII character set; this is equivalent to `[\t\n\r\f\v]`.

`\S`

Matches any character which is not a whitespace character. This is the opposite of `\s`.

Matches `[^\t\n\r\f\v]` if the `ASCII` flag is used.

`\w`**For Unicode (str) patterns:**

Matches Unicode word characters; this includes all Unicode alphanumeric characters (as defined by `str.isalnum()`), as well as the underscore (`_`).

Matches `[a-zA-Z0-9_]` if the `ASCII` flag is used.

**For 8-bit (bytes) patterns:**

Matches characters considered alphanumeric in the ASCII character set; this is equivalent to `[a-zA-Z0-9_]`. If the `LOCALE` flag is used, matches characters considered alphanumeric in the current locale and the underscore.

`\W`

Matches any character which is not a word character. This is the opposite of `\w`. By default, matches non-underscore (`_`) characters for which `str.isalnum()` returns `False`.

Matches `[^a-zA-Z0-9_]` if the `ASCII` flag is used.

If the `LOCALE` flag is used, matches characters which are neither alphanumeric in the current locale nor the underscore.

`\Z`

Matches only at the end of the string.

Most of the escape sequences supported by Python string literals are also accepted by the regular expression parser:

<code>\a</code>	<code>\b</code>	<code>\f</code>	<code>\n</code>
<code>\N</code>	<code>\r</code>	<code>\t</code>	<code>\u</code>
<code>\U</code>	<code>\v</code>	<code>\x</code>	<code>\\</code>

(Note that `\b` is used to represent word boundaries, and means "backspace" only inside character classes.)

'`\u`', '`\U`', and '`\N`' escape sequences are only recognized in Unicode (str) patterns. In bytes patterns they are errors. Unknown escapes of ASCII letters are reserved for future use and treated as errors.

Octal escapes are included in a limited form. If the first digit is a 0, or if there are three octal digits, it is considered an octal escape. Otherwise, it is a group reference. As for string literals, octal escapes are always at most three digits in length.

在 3.3 版的變更: The '`\u`' and '`\U`' escape sequences have been added.

在 3.6 版的變更: Unknown escapes consisting of '`\`' and an ASCII letter now are errors.

在 3.8 版的變更: The '`\N{name}`' escape sequence has been added. As in string literals, it expands to the named Unicode character (e.g. '`\N{EM DASH}`').

## 6.2.2 模組 F 容

The module defines several functions, constants, and an exception. Some of the functions are simplified versions of the full featured methods for compiled regular expressions. Most non-trivial applications always use the compiled form.

### 旗標

在 3.6 版的變更: Flag constants are now instances of `RegexFlag`, which is a subclass of `enum.IntFlag`.

**class** `re.RegexFlag`

An `enum.IntFlag` class containing the regex options listed below.

在 3.11 版被加入: - added to `__all__`

**re.A**

**re.ASCII**

Make `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` perform ASCII-only matching instead of full Unicode matching. This is only meaningful for Unicode (str) patterns, and is ignored for bytes patterns.

Corresponds to the inline flag `(?a)`.

### **i** 備 F

The `U` flag still exists for backward compatibility, but is redundant in Python 3 since matches are Unicode by default for `str` patterns, and Unicode matching isn't allowed for bytes patterns. `UNICODE` and the inline flag `(?u)` are similarly redundant.

**re.DEBUG**

Display debug information about compiled expression.

No corresponding inline flag.

**re.I**

**re.IGNORECASE**

Perform case-insensitive matching; expressions like `[A-Z]` will also match lowercase letters. Full Unicode matching (such as `Ü` matching `ü`) also works unless the `ASCII` flag is used to disable non-ASCII matches. The current locale does not change the effect of this flag unless the `LOCALE` flag is also used.

Corresponds to the inline flag `(?i)`.

Note that when the Unicode patterns `[a-z]` or `[A-Z]` are used in combination with the `IGNORECASE` flag, they will match the 52 ASCII letters and 4 additional non-ASCII letters: `İ` (U+0130, Latin capital letter I with dot above), `ı` (U+0131, Latin small letter dotless i), `ſ` (U+017F, Latin small letter long s) and `Ɔ` (U+212A, Kelvin sign). If the `ASCII` flag is used, only letters `'a'` to `'z'` and `'A'` to `'Z'` are matched.

re.L

re.LOCALE

Make `\w`, `\W`, `\b`, `\B` and case-insensitive matching dependent on the current locale. This flag can be used only with bytes patterns.

Corresponds to the inline flag `(?L)`.

This flag is discouraged; consider Unicode matching instead. The locale mechanism is very unreliable as it only handles one "culture" at a time and only works with 8-bit locales. Unicode matching is enabled by default for Unicode (str) patterns and it is able to handle different locales and languages.

在 3.6 版的變更: `LOCALE` can be used only with bytes patterns and is not compatible with `ASCII`.

在 3.7 版的變更: Compiled regular expression objects with the `LOCALE` flag no longer depend on the locale at compile time. Only the locale at matching time affects the result of matching.

re.M

re.MULTILINE

When specified, the pattern character `'^'` matches at the beginning of the string and at the beginning of each line (immediately following each newline); and the pattern character `'$'` matches at the end of the string and at the end of each line (immediately preceding each newline). By default, `'^'` matches only at the beginning of the string, and `'$'` only at the end of the string and immediately before the newline (if any) at the end of the string.

Corresponds to the inline flag `(?m)`.

re.NOFLAG

Indicates no flag being applied, the value is 0. This flag may be used as a default value for a function keyword argument or as a base value that will be conditionally ORed with other flags. Example of use as a default value:

```
def myfunc(text, flag=re.NOFLAG):
    return re.match(text, flag)
```

在 3.11 版被加入。

re.S

re.DOTALL

Make the `'.'` special character match any character at all, including a newline; without this flag, `'.'` will match anything *except* a newline.

Corresponds to the inline flag `(?s)`.

re.U

re.UNICODE

In Python 3, Unicode characters are matched by default for `str` patterns. This flag is therefore redundant with **no effect** and is only kept for backward compatibility.

See `ASCII` to restrict matching to ASCII characters instead.

re.X

re.VERBOSE

This flag allows you to write regular expressions that look nicer and are more readable by allowing you to visually separate logical sections of the pattern and add comments. Whitespace within the pattern is ignored,

except when in a character class, or when preceded by an unescaped backslash, or within tokens like `*?`, `(?:` or `(?P<...>`. For example, `(? :` and `* ?` are not allowed. When a line contains a `#` that is not in a character class and is not preceded by an unescaped backslash, all characters from the leftmost such `#` through the end of the line are ignored.

This means that the two following regular expression objects that match a decimal number are functionally equal:

```
a = re.compile(r"""\d + # the integral part
               \.  # the decimal point
               \d * # some fractional digits""", re.X)
b = re.compile(r"\d+\.\d*")
```

Corresponds to the inline flag `(?x)`.

## 函式

**re.compile** (*pattern*, *flags=0*)

將正規表示式模式編譯成正規表示式物件，可以使用它的 `match()`、`search()` 等方法來匹配，如下所述。

可以透過指定 *flags* 值來修改運算式的行<sup>[1]</sup>，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、`|` 運算子) 組合。

順序<sup>[2]</sup>:

```
prog = re.compile(pattern)
result = prog.match(string)
```

等價於:

```
result = re.match(pattern, string)
```

但是當表示式在單一程式中多次使用時，使用 `re.compile()` <sup>[3]</sup> 保存<sup>[4]</sup> 生的正規表示式物件以供重<sup>[5]</sup> 使用會更有效率。

### 備<sup>[6]</sup>

傳遞給 `re.compile()` 之最新模式的編譯版本和模組層級匹配函式都會被快取，因此一次僅使用幾個正規表示式的程式不必去擔心編譯正規表示式。

**re.search** (*pattern*, *string*, *flags=0*)

掃描 *string* 以尋找正規表示式 *pattern* <sup>[7]</sup> 生匹配的第一個位置，<sup>[8]</sup> 回傳對應的 `Match`。如果字串中<sup>[9]</sup> 有與模式匹配的位置則回傳 `None`；請注意，這與在字串中的某個點查找零長度匹配不同。

可以透過指定 *flags* 值來修改運算式的行<sup>[10]</sup>，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、`|` 運算子) 組合。

**re.match** (*pattern*, *string*, *flags=0*)

如果 *string* 開頭的零個或多個字元與正規表示式 *pattern* 匹配，則回傳對應的 `Match`。如果字串與模式不匹配，則回傳 `None`；請注意，這與零長度匹配不同。

請注意，即使在 `MULTILINE` 模式 (mode) 下，`re.match()` 只會於字串的开頭匹配，而非每行的開頭。

如果你想在 *string* 中的任何位置找到匹配項，請使用 `search()` (另請參<sup>[11]</sup> `search()` vs. `match()`)。

可以透過指定 *flags* 值來修改運算式的行<sup>[12]</sup>，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、`|` 運算子) 組合。

`re.fullmatch(pattern, string, flags=0)`

如果整個 *string* 與正規表示式 *pattern* 匹配，則回傳對應的 *Match*。如果字串與模式不匹配，則回傳 `None`；請注意，這與零長度匹配不同。

可以透過指定 *flags* 值來修改運算式的行，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、`|` 運算子) 組合。

在 3.4 版被加入。

`re.split(pattern, string, maxsplit=0, flags=0)`

依 *pattern* 的出現次數拆分 *string*。如果在 *pattern* 中使用捕獲括號，則模式中所有群組的文字也會作結果串列的一部分回傳。如果 *maxsplit* 非零，則最多發生 *maxsplit* 次拆分，且字串的其余部分會作串列的最終元素回傳。

```
>>> re.split(r'\W+', 'Words, words, words.')
['Words', 'words', 'words', '']
>>> re.split(r'(\W+)', 'Words, words, words.')
['Words', ', ', 'words', ', ', ', ', 'words', '.', '']
>>> re.split(r'\W+', 'Words, words, words.', maxsplit=1)
['Words', 'words, words.']
>>> re.split('[a-f]+', '0a3B9', flags=re.IGNORECASE)
['0', '3', '9']
```

如果分隔符號中有捕獲群組且它在字串的開頭匹配，則結果將以空字串開頭。這同樣適用於字串的結尾：

```
>>> re.split(r'(\W+)', '...words, words...')
['', '...', 'words', ', ', ', ', 'words', '...', '']
```

如此一來，分隔符號元件始終可以在結果串列中的相同相對索引處找到。

只有當與先前的空匹配不相鄰時，模式的空匹配才會拆分字串。

```
>>> re.split(r'\b', 'Words, words, words.')
['', 'Words', ', ', ', ', 'words', ', ', ', ', 'words', '.', '']
>>> re.split(r'\W*', '...words...')
['', '', 'w', 'o', 'r', 'd', 's', '', '']
>>> re.split(r'(\W*)', '...words...')
['', '...', '', '', 'w', '', 'o', '', 'r', '', 'd', '', 's', '...', '', '', '']
```

可以透過指定 *flags* 值來修改運算式的行，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、`|` 運算子) 組合。

在 3.1 版的變更：新增可選的旗標引數。

在 3.7 版的變更：新增了對可以匹配空字串之模式進行拆分的支援。

在 3.13 版之後被用：將 *maxsplit* 和 *flags* 作位置引數傳遞的用法已被用。在未來的 Python 版本中，它們將會是僅限關鍵字參數。

`re.findall(pattern, string, flags=0)`

以字串或元組串列的形式回傳 *string* 中 *pattern* 的所有非重匹配項。從左到右掃描 *string*，按找到的順序回傳符合項目。結果中會包含空匹配項。

結果取於模式中捕獲群組的數量。如果有群組，則回傳與整個模式匹配的字串串列。如果恰好存在一個群組，則回傳與該群組匹配的字串串列。如果存在多個群組，則回傳與群組匹配的字串元組串列。非捕獲群組則不影響結果的形式。

```
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.findall(r'(\w+)=(\d+)', 'set width=20 and height=10')
[('width', '20'), ('height', '10')]
```

可以透過指定 *flags* 值來修改運算式的行，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、| 運算子) 組合。

在 3.7 版的變更: 非空匹配現在可以剛好在前一個空匹配的後面開始。

`re.finditer(pattern, string, flags=0)`

回傳一個 *iterator*，在 *string* 中的 RE *pattern* 的所有非重匹配上 yield *Match* 物件。從左到右掃描 *string*，按找到的順序回傳匹配項目。結果中包含空匹配項。

可以透過指定 *flags* 值來修改運算式的行，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、| 運算子) 組合。

在 3.7 版的變更: 非空匹配現在可以剛好在前一個空匹配的後面開始。

`re.sub(pattern, repl, string, count=0, flags=0)`

回傳透過以替 *repl* 取代 *string* 中最左邊不重出現的 *pattern* 所獲得的字串。如果未找到該模式，則不改變 *string* 回傳。 *repl* 可以是字串或函式；如果它是字串，則處理其中的任何反斜轉義。也就是 `\n` 會被轉成單一符、`\r` 會被轉成回車符 (carriage return) 等等。ASCII 字母的未知轉義符會被保留以供將來使用被視錯誤。其他未知轉義符例如 `\&` 會被單獨保留。例如 `\6` 的反向參照將被替成模式中第 6 組匹配的子字串。例如：

```
>>> re.sub(r'def\s+([a-zA-Z_][a-zA-Z_0-9]*)\s*\s*:',
...        r'static PyObject*\numpy_\1(void)\n{',
...        'def myfunc():')
'static PyObject*\numpy_myfunc(void)\n{'
```

如果 *repl* 是一個函式，則 *pattern* 的每個不重出現之處都會呼叫它。此函式接收單一 *Match* 引數，回傳替字串。例如：

```
>>> def dashrepl(matchobj):
...     if matchobj.group(0) == '-': return ' '
...     else: return '-'
...
>>> re.sub('-{1,2}', dashrepl, 'pro---gram-files')
'pro--gram files'
>>> re.sub(r'\sAND\s', ' & ', 'Baked Beans And Spam', flags=re.IGNORECASE)
'Baked Beans & Spam'
```

此模式可以是字串或 *Pattern*。

可選引數 *count* 是要替的模式出現的最大次數；*count* 必須是非負整數。如果省略或零，則所有出現的容都將被替。只有當與先前的空匹配不相鄰時，模式的空匹配才會被替，因此 `sub('x*', '-', 'abxd')` 會回傳 `'-a-b--d -'`。

在字串型 *repl* 引數中，除了上述字元轉義和反向參照之外，`\g<name>` 將使用名 *name* 的群組所匹配到的子字串，如 `(?P<name>...)` 所定義的語法。`\g<number>` 使用對應的群組編號；因此 `\g<2>` 等價於 `\2`，但在諸如 `\g<2>0` 之類的替中非模糊不清 (isn't ambiguous)。`\20` 將被直譯對群組 20 的參照，而不是對後面跟著字面字元 '0' 的群組 2 的參照。反向參照 `\g<0>` 會取代以 RE 所匹配到的整個子字串。

可以透過指定 *flags* 值來修改運算式的行，值可以是任何 *flags* 變數，使用位元 OR (bitwise OR、| 運算子) 組合。

在 3.1 版的變更: 新增可選的旗標引數。

在 3.5 版的變更: 不匹配的群組將被替成空字串。

在 3.6 版的變更: 在由 `'\'` 和一個 ASCII 字母組成之 *pattern* 中的未知轉義符現在錯誤。

在 3.7 版的變更: 由 `'\'` 和一個 ASCII 字母組成之 *repl* 中的未知轉義符現在錯誤。當與先前的非空匹配相鄰時，模式的空匹配將被替。

在 3.12 版的變更: 群組 *id* 只能包含 ASCII 數字。在 *bytes* 替字串中，群組 *name* 只能包含 ASCII 範圍的位元組 (`b'\x00'-b'\x7f'`)。

在 3.13 版之後被用: 將 *count* 和 *flags* 作位置引數傳遞的用法已被用。在未來的 Python 版本中, 它們將會是僅限關鍵字參數。

`re.subn(pattern, repl, string, count=0, flags=0)`

執行與 `sub()` 相同的操作, 但回傳一個元組 (`new_string, number_of_subs_made`)。

可以透過指定 *flags* 值來修改運算式的行, 值可以是任何 *flags* 變數, 使用位元 OR (bitwise OR、`|` 運算子) 組合。

`re.escape(pattern)`

對 *pattern* 中的特殊字元進行轉義。如果你想要匹配其中可能包含正規表示式元字元 (metacharacter) 的任意文本字串, 這會非常有用。例如:

```
>>> print(re.escape('https://www.python.org'))
https://www\.python\.org

>>> legal_chars = string.ascii_lowercase + string.digits + "!#$%&'*+-.^_`|~:"
>>> print('[%s]+' % re.escape(legal_chars))
[abcdefghijklmnopqrstuvwxyz0123456789!\#$%&'*\+\-\.\^_\`|\~:]+

>>> operators = ['+', '-', '*', '/', '**']
>>> print('|'.join(map(re.escape, sorted(operators, reverse=True))))
/|-|\+|\*\|\/\*\|*
```

此函式不得用於 `sub()` 和 `subn()` 中的替字串, 僅應轉義反斜。例如:

```
>>> digits_re = r'\d+'
>>> sample = '/usr/sbin/sendmail - 0 errors, 12 warnings'
>>> print(re.sub(digits_re, digits_re.replace('\d', r'\d'), sample))
/usr/sbin/sendmail - \d+ errors, \d+ warnings
```

在 3.3 版的變更: `'_'` 字元不再被轉義。

在 3.7 版的變更: Only characters that can have special meaning in a regular expression are escaped. As a result, `'!'`, `'\"'`, `'%'`, `'\"'`, `'.'`, `'/'`, `':'`, `','`, `'<'`, `'='`, `'>'`, `'@'`, and `\"` are no longer escaped.

`re.purge()`

清除正規表示式快取。

## 例外

**exception** `re.PatternError(msg, pattern=None, pos=None)`

當傳遞給此處函式之一的字串不是有效的正規表示式 (例如它可能包含不匹配的括號) 或在編譯或匹配期間發生某些其他錯誤時, 將引發例外。如果字串不包含模式匹配項, 則不是錯誤。`PatternError` 實例具有以下附加屬性:

**msg**

未格式化的錯誤訊息。

**pattern**

正規表示式模式。

**pos**

*pattern* 中編譯失敗的索引 (可能是 `None`)。

**lineno**

對應 *pos* 的列 (可能是 `None`)。

**colno**

對應 *pos* 的欄 (可能是 `None`)。

在 3.5 版的變更: 新增額外屬性。

在 3.13 版的變更: `PatternError` 最初被命名 `error`; 後者了向後相容性而被保留名。

## 6.2.3 Regular Expression Objects

**class** `re.Pattern`

Compiled regular expression object returned by `re.compile()`.

在 3.9 版的變更: `re.Pattern` supports `[]` to indicate a Unicode (str) or bytes pattern. See 泛型 名型.

`Pattern.search(string[, pos[, endpos]])`

Scan through `string` looking for the first location where this regular expression produces a match, and return a corresponding `Match`. Return `None` if no position in the string matches the pattern; note that this is different from finding a zero-length match at some point in the string.

The optional second parameter `pos` gives an index in the string where the search is to start; it defaults to 0. This is not completely equivalent to slicing the string; the `^` pattern character matches at the real beginning of the string and at positions just after a newline, but not necessarily at the index where the search is to start.

The optional parameter `endpos` limits how far the string will be searched; it will be as if the string is `endpos` characters long, so only the characters from `pos` to `endpos - 1` will be searched for a match. If `endpos` is less than `pos`, no match will be found; otherwise, if `rx` is a compiled regular expression object, `rx.search(string, 0, 50)` is equivalent to `rx.search(string[:50], 0)`.

```
>>> pattern = re.compile("d")
>>> pattern.search("dog")      # Match at index 0
<re.Match object; span=(0, 1), match='d'>
>>> pattern.search("dog", 1)  # No match; search doesn't include the "d"
```

`Pattern.match(string[, pos[, endpos]])`

If zero or more characters at the *beginning* of `string` match this regular expression, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional `pos` and `endpos` parameters have the same meaning as for the `search()` method.

```
>>> pattern = re.compile("o")
>>> pattern.match("dog")      # No match as "o" is not at the start of "dog".
>>> pattern.match("dog", 1)   # Match as "o" is the 2nd character of "dog".
<re.Match object; span=(1, 2), match='o'>
```

If you want to locate a match anywhere in `string`, use `search()` instead (see also `search()` vs. `match()`).

`Pattern.fullmatch(string[, pos[, endpos]])`

If the whole `string` matches this regular expression, return a corresponding `Match`. Return `None` if the string does not match the pattern; note that this is different from a zero-length match.

The optional `pos` and `endpos` parameters have the same meaning as for the `search()` method.

```
>>> pattern = re.compile("o[gh]")
>>> pattern.fullmatch("dog")  # No match as "o" is not at the start of "dog".
>>> pattern.fullmatch("ogre") # No match as not the full string matches.
>>> pattern.fullmatch("doggie", 1, 3) # Matches within given limits.
<re.Match object; span=(1, 3), match='og'>
```

在 3.4 版被加入.

`Pattern.split(string, maxsplit=0)`

Identical to the `split()` function, using the compiled pattern.

`Pattern.findall(string[, pos[, endpos]])`

Similar to the `findall()` function, using the compiled pattern, but also accepts optional `pos` and `endpos` parameters that limit the search region like for `search()`.

`Pattern.finditer(string[, pos[, endpos]])`

Similar to the `finditer()` function, using the compiled pattern, but also accepts optional `pos` and `endpos` parameters that limit the search region like for `search()`.

`Pattern.sub(repl, string, count=0)`

Identical to the `sub()` function, using the compiled pattern.

`Pattern.subn(repl, string, count=0)`

Identical to the `subn()` function, using the compiled pattern.

`Pattern.flags`

The regex matching flags. This is a combination of the flags given to `compile()`, any `(?...)` inline flags in the pattern, and implicit flags such as `UNICODE` if the pattern is a Unicode string.

`Pattern.groups`

The number of capturing groups in the pattern.

`Pattern.groupindex`

A dictionary mapping any symbolic group names defined by `(?P<id>)` to group numbers. The dictionary is empty if no symbolic groups were used in the pattern.

`Pattern.pattern`

The pattern string from which the pattern object was compiled.

在 3.7 版的變更: Added support of `copy.copy()` and `copy.deepcopy()`. Compiled regular expression objects are considered atomic.

## 6.2.4 Match Objects

Match objects always have a boolean value of `True`. Since `match()` and `search()` return `None` when there is no match, you can test whether there was a match with a simple `if` statement:

```
match = re.search(pattern, string)
if match:
    process(match)
```

**class** `re.Match`

Match object returned by successful matches and searches.

在 3.9 版的變更: `re.Match` supports `[]` to indicate a Unicode (str) or bytes match. See 泛型 名.

`Match.expand(template)`

Return the string obtained by doing backslash substitution on the template string `template`, as done by the `sub()` method. Escapes such as `\n` are converted to the appropriate characters, and numeric backreferences (`\1`, `\2`) and named backreferences (`\g<1>`, `\g<name>`) are replaced by the contents of the corresponding group. The backreference `\g<0>` will be replaced by the entire match.

在 3.5 版的變更: 不匹配的群組將被替 空字串。

`Match.group([group1, ...])`

Returns one or more subgroups of the match. If there is a single argument, the result is a single string; if there are multiple arguments, the result is a tuple with one item per argument. Without arguments, `group1` defaults to zero (the whole match is returned). If a `groupN` argument is zero, the corresponding return value is the entire matching string; if it is in the inclusive range `[1..99]`, it is the string matching the corresponding parenthesized group. If a group number is negative or larger than the number of groups defined in the pattern, an `IndexError` exception is raised. If a group is contained in a part of the pattern that did not match, the corresponding result is `None`. If a group is contained in a part of the pattern that matched multiple times, the last match is returned.

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m.group(0)          # The entire match
'Isaac Newton'
>>> m.group(1)          # The first parenthesized subgroup.
'Isaac'
>>> m.group(2)          # The second parenthesized subgroup.
```

(繼續下一頁)

(繼續上一頁)

```
'Newton'
>>> m.group(1, 2)    # Multiple arguments give us a tuple.
('Isaac', 'Newton')
```

If the regular expression uses the `(?P<name>...)` syntax, the `groupN` arguments may also be strings identifying groups by their group name. If a string argument is not used as a group name in the pattern, an `IndexError` exception is raised.

A moderately complicated example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.group('first_name')
'Malcolm'
>>> m.group('last_name')
'Reynolds'
```

Named groups can also be referred to by their index:

```
>>> m.group(1)
'Malcolm'
>>> m.group(2)
'Reynolds'
```

If a group matches multiple times, only the last match is accessible:

```
>>> m = re.match(r"(.)+", "a1b2c3")    # Matches 3 times.
>>> m.group(1)                          # Returns only the last match.
'c3'
```

Match.**\_\_getitem\_\_** (*g*)

This is identical to `m.group(g)`. This allows easier access to an individual group from a match:

```
>>> m = re.match(r"(\w+) (\w+)", "Isaac Newton, physicist")
>>> m[0]    # The entire match
'Isaac Newton'
>>> m[1]    # The first parenthesized subgroup.
'Isaac'
>>> m[2]    # The second parenthesized subgroup.
'Newton'
```

Named groups are supported as well:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Isaac Newton")
>>> m['first_name']
'Isaac'
>>> m['last_name']
'Newton'
```

在 3.6 版被加入.

Match.**groups** (*default=None*)

Return a tuple containing all the subgroups of the match, from 1 up to however many groups are in the pattern. The *default* argument is used for groups that did not participate in the match; it defaults to `None`.

舉例來 F:

```
>>> m = re.match(r"(\d+)\.(\d+)", "24.1632")
>>> m.groups()
('24', '1632')
```

If we make the decimal place and everything after it optional, not all groups might participate in the match. These groups will default to `None` unless the *default* argument is given:

```
>>> m = re.match(r"(\d+)\.?(?!\d+)?", "24")
>>> m.groups()          # Second group defaults to None.
('24', None)
>>> m.groups('0')     # Now, the second group defaults to '0'.
('24', '0')
```

Match.**groupdict** (*default=None*)

Return a dictionary containing all the *named* subgroups of the match, keyed by the subgroup name. The *default* argument is used for groups that did not participate in the match; it defaults to *None*. For example:

```
>>> m = re.match(r"(?P<first_name>\w+) (?P<last_name>\w+)", "Malcolm Reynolds")
>>> m.groupdict()
{'first_name': 'Malcolm', 'last_name': 'Reynolds'}
```

Match.**start** (*[group]*)

Match.**end** (*[group]*)

Return the indices of the start and end of the substring matched by *group*; *group* defaults to zero (meaning the whole matched substring). Return *-1* if *group* exists but did not contribute to the match. For a match object *m*, and a group *g* that did contribute to the match, the substring matched by group *g* (equivalent to `m.group(g)`) is

```
m.string[m.start(g):m.end(g)]
```

Note that `m.start(group)` will equal `m.end(group)` if *group* matched a null string. For example, after `m = re.search('b(c?)', 'cba')`, `m.start(0)` is 1, `m.end(0)` is 2, `m.start(1)` and `m.end(1)` are both 2, and `m.start(2)` raises an *IndexError* exception.

An example that will remove *remove\_this* from email addresses:

```
>>> email = "tony@tiremove_thisger.net"
>>> m = re.search("remove_this", email)
>>> email[:m.start()] + email[m.end():]
'tony@tiger.net'
```

Match.**span** (*[group]*)

For a match *m*, return the 2-tuple (`m.start(group)`, `m.end(group)`). Note that if *group* did not contribute to the match, this is `(-1, -1)`. *group* defaults to zero, the entire match.

Match.**pos**

The value of *pos* which was passed to the `search()` or `match()` method of a *regex object*. This is the index into the string at which the RE engine started looking for a match.

Match.**endpos**

The value of *endpos* which was passed to the `search()` or `match()` method of a *regex object*. This is the index into the string beyond which the RE engine will not go.

Match.**lastindex**

The integer index of the last matched capturing group, or *None* if no group was matched at all. For example, the expressions `(a)b`, `((a)(b))`, and `((ab))` will have `lastindex == 1` if applied to the string `'ab'`, while the expression `(a)(b)` will have `lastindex == 2`, if applied to the same string.

Match.**lastgroup**

The name of the last matched capturing group, or *None* if the group didn't have a name, or if no group was matched at all.

Match.**re**

The *regular expression object* whose `match()` or `search()` method produced this match instance.

Match.**string**

The string passed to `match()` or `search()`.

在 3.7 版的變更: Added support of `copy.copy()` and `copy.deepcopy()`. Match objects are considered atomic.

## 6.2.5 Regular Expression Examples

### Checking for a Pair

In this example, we'll use the following helper function to display match objects a little more gracefully:

```
def displaymatch(match):
    if match is None:
        return None
    return '<Match: %r, groups=%r>' % (match.group(), match.groups())
```

Suppose you are writing a poker program where a player's hand is represented as a 5-character string with each character representing a card, "a" for ace, "k" for king, "q" for queen, "j" for jack, "t" for 10, and "2" through "9" representing the card with that value.

To see if a given string is a valid hand, one could do the following:

```
>>> valid = re.compile(r"^[a2-9tjqk]{5}$")
>>> displaymatch(valid.match("akt5q")) # Valid.
"<Match: 'akt5q', groups=()>"
>>> displaymatch(valid.match("akt5e")) # Invalid.
>>> displaymatch(valid.match("akt")) # Invalid.
>>> displaymatch(valid.match("727ak")) # Valid.
"<Match: '727ak', groups=()>"
```

That last hand, "727ak", contained a pair, or two of the same valued cards. To match this with a regular expression, one could use backreferences as such:

```
>>> pair = re.compile(r"*(.*)*\1")
>>> displaymatch(pair.match("717ak")) # Pair of 7s.
"<Match: '717', groups=('7',)>"
>>> displaymatch(pair.match("718ak")) # No pairs.
>>> displaymatch(pair.match("354aa")) # Pair of aces.
"<Match: '354aa', groups=('a',)>"
```

To find out what card the pair consists of, one could use the `group()` method of the match object in the following manner:

```
>>> pair = re.compile(r"*(.*)*\1")
>>> pair.match("717ak").group(1)
'7'

# Error because re.match() returns None, which doesn't have a group() method:
>>> pair.match("718ak").group(1)
Traceback (most recent call last):
  File "<pysshell#23>", line 1, in <module>
    re.match(r"*(.*)*\1", "718ak").group(1)
AttributeError: 'NoneType' object has no attribute 'group'

>>> pair.match("354aa").group(1)
'a'
```

### 模擬 scanf()

Python does not currently have an equivalent to `scanf()`. Regular expressions are generally more powerful, though also more verbose, than `scanf()` format strings. The table below offers some more-or-less equivalent mappings between `scanf()` format tokens and regular expressions.

<code>scanf()</code> Token	Regular Expression
<code>%c</code>	<code>.</code>
<code>%5c</code>	<code>.{5}</code>
<code>%d</code>	<code>[+]? \d+</code>
<code>%e, %E, %f, %g</code>	<code>[+]? (\d+ (\.\d*)?  \.\d+) ([eE] [+]? \d+)?</code>
<code>%i</code>	<code>[+]? (0 [xX] [\dA-Fa-f]+   0 [0-7]*   \d+)</code>
<code>%o</code>	<code>[+]? [0-7]+</code>
<code>%s</code>	<code>\S+</code>
<code>%u</code>	<code>\d+</code>
<code>%x, %X</code>	<code>[+]? (0 [xX])? [\dA-Fa-f]+</code>

To extract the filename and numbers from a string like

```
/usr/sbin/sendmail - 0 errors, 4 warnings
```

you would use a `scanf()` format like

```
%s - %d errors, %d warnings
```

The equivalent regular expression would be

```
(\S+) - (\d+) errors, (\d+) warnings
```

### search() vs. match()

Python offers different primitive operations based on regular expressions:

- `re.match()` checks for a match only at the beginning of the string
- `re.search()` checks for a match anywhere in the string (this is what Perl does by default)
- `re.fullmatch()` checks for entire string to be a match

舉例來:

```
>>> re.match("c", "abcdef") # No match
>>> re.search("c", "abcdef") # Match
<re.Match object; span=(2, 3), match='c'>
>>> re.fullmatch("p.*n", "python") # Match
<re.Match object; span=(0, 6), match='python'>
>>> re.fullmatch("r.*n", "python") # No match
```

Regular expressions beginning with `'^'` can be used with `search()` to restrict the match at the beginning of the string:

```
>>> re.match("c", "abcdef") # No match
>>> re.search("^c", "abcdef") # No match
>>> re.search("^a", "abcdef") # Match
<re.Match object; span=(0, 1), match='a'>
```

Note however that in *MULTILINE* mode `match()` only matches at the beginning of the string, whereas using `search()` with a regular expression beginning with `'^'` will match at the beginning of each line.

```
>>> re.match("X", "A\nB\nX", re.MULTILINE) # No match
>>> re.search("^X", "A\nB\nX", re.MULTILINE) # Match
<re.Match object; span=(4, 5), match='X'>
```

## Making a Phonebook

`split()` splits a string into a list delimited by the passed pattern. The method is invaluable for converting textual data into data structures that can be easily read and modified by Python as demonstrated in the following example that creates a phonebook.

First, here is the input. Normally it may come from a file, here we are using triple-quoted string syntax

```
>>> text = """Ross McFluff: 834.345.1254 155 Elm Street
...
... Ronald Heathmore: 892.345.3428 436 Finley Avenue
... Frank Burger: 925.541.7625 662 South Dogwood Way
...
...
... Heather Albrecht: 548.326.4584 919 Park Place"""
```

The entries are separated by one or more newlines. Now we convert the string into a list with each nonempty line having its own entry:

```
>>> entries = re.split("\n+", text)
>>> entries
['Ross McFluff: 834.345.1254 155 Elm Street',
 'Ronald Heathmore: 892.345.3428 436 Finley Avenue',
 'Frank Burger: 925.541.7625 662 South Dogwood Way',
 'Heather Albrecht: 548.326.4584 919 Park Place']
```

Finally, split each entry into a list with first name, last name, telephone number, and address. We use the `maxsplit` parameter of `split()` because the address has spaces, our splitting pattern, in it:

```
>>> [re.split("?: ", entry, maxsplit=3) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155 Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436 Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662 South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919 Park Place']]
```

The `?:` pattern matches the colon after the last name, so that it does not occur in the result list. With a `maxsplit` of 4, we could separate the house number from the street name:

```
>>> [re.split("?: ", entry, maxsplit=4) for entry in entries]
[['Ross', 'McFluff', '834.345.1254', '155', 'Elm Street'],
 ['Ronald', 'Heathmore', '892.345.3428', '436', 'Finley Avenue'],
 ['Frank', 'Burger', '925.541.7625', '662', 'South Dogwood Way'],
 ['Heather', 'Albrecht', '548.326.4584', '919', 'Park Place']]
```

## Text Munging

`sub()` replaces every occurrence of a pattern with a string or the result of a function. This example demonstrates using `sub()` with a function to “munge” text, or randomize the order of all the characters in each word of a sentence except for the first and last characters:

```
>>> def repl(m):
...     inner_word = list(m.group(2))
...     random.shuffle(inner_word)
...     return m.group(1) + "".join(inner_word) + m.group(3)
...
>>> text = "Professor Abdolmalek, please report your absences promptly."
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Poefsrosr Aealmlbdk, pslaee reorpt your abnseces plmrptoy.'
>>> re.sub(r"(\w)(\w+)(\w)", repl, text)
'Pofsroser Aodlambelk, plasee reorpt yuor asnebcas potlmpy.'
```

## Finding all Adverbs

`findall()` matches *all* occurrences of a pattern, not just the first one as `search()` does. For example, if a writer wanted to find all of the adverbs in some text, they might use `findall()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> re.findall(r"\w+ly\b", text)
['carefully', 'quickly']
```

## Finding all Adverbs and their Positions

If one wants more information about all matches of a pattern than the matched text, `finditer()` is useful as it provides `Match` objects instead of strings. Continuing with the previous example, if a writer wanted to find all of the adverbs *and their positions* in some text, they would use `finditer()` in the following manner:

```
>>> text = "He was carefully disguised but captured quickly by police."
>>> for m in re.finditer(r"\w+ly\b", text):
...     print('%02d-%02d: %s' % (m.start(), m.end(), m.group(0)))
07-16: carefully
40-47: quickly
```

## Raw String Notation

Raw string notation (`r"text"`) keeps regular expressions sane. Without it, every backslash (`'\'`) in a regular expression would have to be prefixed with another one to escape it. For example, the two following lines of code are functionally identical:

```
>>> re.match(r"\W(.)\1\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
>>> re.match("\\W(.)\\1\\W", " ff ")
<re.Match object; span=(0, 4), match=' ff '>
```

When one wants to match a literal backslash, it must be escaped in the regular expression. With raw string notation, this means `r"\"`. Without raw string notation, one must use `"\\\"`, making the following lines of code functionally identical:

```
>>> re.match(r"\"", r"\"")
<re.Match object; span=(0, 1), match='\">
>>> re.match("\\\"", r"\"")
<re.Match object; span=(0, 1), match='\">
```

## Writing a Tokenizer

A *tokenizer* or *scanner* analyzes a string to categorize groups of characters. This is a useful first step in writing a compiler or interpreter.

The text categories are specified with regular expressions. The technique is to combine those into a single master regular expression and to loop over successive matches:

```
from typing import NamedTuple
import re

class Token(NamedTuple):
    type: str
    value: str
    line: int
    column: int

def tokenize(code):
    keywords = {'IF', 'THEN', 'ENDIF', 'FOR', 'NEXT', 'GOSUB', 'RETURN'}
    token_specification = [
```

(繼續下一頁)

(繼續上一頁)

```

('NUMBER', r'\d+(\.\d*)?'), # Integer or decimal number
('ASSIGN', r':='),         # Assignment operator
('END', r';'),             # Statement terminator
('ID', r'[A-Za-z]+'),     # Identifiers
('OP', r'[+\-*/]'),       # Arithmetic operators
('NEWLINE', r'\n'),       # Line endings
('SKIP', r'[\t]+'),       # Skip over spaces and tabs
('MISMATCH', r'.'),       # Any other character
]
tok_regex = '|'.join('(?P<%s>%s)' % pair for pair in token_specification)
line_num = 1
line_start = 0
for mo in re.finditer(tok_regex, code):
    kind = mo.lastgroup
    value = mo.group()
    column = mo.start() - line_start
    if kind == 'NUMBER':
        value = float(value) if '.' in value else int(value)
    elif kind == 'ID' and value in keywords:
        kind = value
    elif kind == 'NEWLINE':
        line_start = mo.end()
        line_num += 1
        continue
    elif kind == 'SKIP':
        continue
    elif kind == 'MISMATCH':
        raise RuntimeError(f'{value!r} unexpected on line {line_num}')
    yield Token(kind, value, line_num, column)

statements = '''
    IF quantity THEN
        total := total + price * quantity;
        tax := price * 0.05;
    ENDIF;
'''

for token in tokenize(statements):
    print(token)

```

The tokenizer produces the following output:

```

Token(type='IF', value='IF', line=2, column=4)
Token(type='ID', value='quantity', line=2, column=7)
Token(type='THEN', value='THEN', line=2, column=16)
Token(type='ID', value='total', line=3, column=8)
Token(type='ASSIGN', value=':=' , line=3, column=14)
Token(type='ID', value='total', line=3, column=17)
Token(type='OP', value='+', line=3, column=23)
Token(type='ID', value='price', line=3, column=25)
Token(type='OP', value='*', line=3, column=31)
Token(type='ID', value='quantity', line=3, column=33)
Token(type='END', value=';', line=3, column=41)
Token(type='ID', value='tax', line=4, column=8)
Token(type='ASSIGN', value=':=' , line=4, column=12)
Token(type='ID', value='price', line=4, column=15)
Token(type='OP', value='*', line=4, column=21)
Token(type='NUMBER', value=0.05, line=4, column=23)
Token(type='END', value=';', line=4, column=27)
Token(type='ENDIF', value='ENDIF', line=5, column=4)
Token(type='END', value=';', line=5, column=9)

```

## 6.3 difflib --- 計算差別的輔助工具

原始碼: `Lib/difflib.py`

This module provides classes and functions for comparing sequences. It can be used for example, for comparing files, and can produce information about file differences in various formats, including HTML and context and unified diffs. For comparing directories and files, see also, the `filecmp` module.

**class** `difflib.SequenceMatcher`

This is a flexible class for comparing pairs of sequences of any type, so long as the sequence elements are *hashable*. The basic algorithm predates, and is a little fancier than, an algorithm published in the late 1980's by Ratcliff and Obershelp under the hyperbolic name "gestalt pattern matching." The idea is to find the longest contiguous matching subsequence that contains no "junk" elements; these "junk" elements are ones that are uninteresting in some sense, such as blank lines or whitespace. (Handling junk is an extension to the Ratcliff and Obershelp algorithm.) The same idea is then applied recursively to the pieces of the sequences to the left and to the right of the matching subsequence. This does not yield minimal edit sequences, but does tend to yield matches that "look right" to people.

**Timing:** The basic Ratcliff-Obershelp algorithm is cubic time in the worst case and quadratic time in the expected case. `SequenceMatcher` is quadratic time for the worst case and has expected-case behavior dependent in a complicated way on how many elements the sequences have in common; best case time is linear.

**Automatic junk heuristic:** `SequenceMatcher` supports a heuristic that automatically treats certain sequence items as junk. The heuristic counts how many times each individual item appears in the sequence. If an item's duplicates (after the first one) account for more than 1% of the sequence and the sequence is at least 200 items long, this item is marked as "popular" and is treated as junk for the purpose of sequence matching. This heuristic can be turned off by setting the `autojunk` argument to `False` when creating the `SequenceMatcher`.

在 3.2 版的變更: 新增 `autojunk` 參數。

**class** `difflib.Differ`

This is a class for comparing sequences of lines of text, and producing human-readable differences or deltas. `Differ` uses `SequenceMatcher` both to compare sequences of lines, and to compare sequences of characters within similar (near-matching) lines.

Each line of a `Differ` delta begins with a two-letter code:

Code	含義
'- '	line unique to sequence 1
'+ '	line unique to sequence 2
' '	line common to both sequences
'? '	line not present in either input sequence

Lines beginning with '?' attempt to guide the eye to intraline differences, and were not present in either input sequence. These lines can be confusing if the sequences contain whitespace characters, such as spaces, tabs or line breaks.

**class** `difflib.HtmlDiff`

This class can be used to create an HTML table (or a complete HTML file containing the table) showing a side by side, line by line comparison of text with inter-line and intra-line change highlights. The table can be generated in either full or contextual difference mode.

The constructor for this class is:

```
__init__(tabsize=8, wrapcolumn=None, linejunk=None, charjunk=IS_CHARACTER_JUNK)
```

Initializes instance of `HtmlDiff`.

`tabsize` is an optional keyword argument to specify tab stop spacing and defaults to 8.

*wrapcolumn* is an optional keyword to specify column number where lines are broken and wrapped, defaults to `None` where lines are not wrapped.

*linejunk* and *charjunk* are optional keyword arguments passed into `ndiff()` (used by `HtmlDiff` to generate the side by side HTML differences). See `ndiff()` documentation for argument default values and descriptions.

The following methods are public:

**make\_file** (*fromlines*, *tolines*, *fromdesc*=", *todesc*=", *context*=False, *numlines*=5, \*, *charset*='utf-8')

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML file containing a table showing line by line differences with inter-line and intra-line changes highlighted.

*fromdesc* and *todesc* are optional keyword arguments to specify from/to file column header strings (both default to an empty string).

*context* and *numlines* are both optional keyword arguments. Set *context* to `True` when contextual differences are to be shown, else the default is `False` to show the full files. *numlines* defaults to 5. When *context* is `True` *numlines* controls the number of context lines which surround the difference highlights. When *context* is `False` *numlines* controls the number of lines which are shown before a difference highlight when using the "next" hyperlinks (setting to zero would cause the "next" hyperlinks to place the next difference highlight at the top of the browser without any leading context).

*fromdesc* and *todesc* are interpreted as unescaped HTML and should be properly escaped while receiving input from untrusted sources.

在 3.5 版的變更: *charset* keyword-only argument was added. The default charset of HTML document changed from 'ISO-8859-1' to 'utf-8'.

**make\_table** (*fromlines*, *tolines*, *fromdesc*=", *todesc*=", *context*=False, *numlines*=5)

Compares *fromlines* and *tolines* (lists of strings) and returns a string which is a complete HTML table showing line by line differences with inter-line and intra-line changes highlighted.

The arguments for this method are the same as those for the `make_file()` method.

`difflib.context_diff(a, b, fromfile=", tofile=", fromfiledate=", tofiledate=", n=3, lineterm='\n')`

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in context diff format.

Context diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in a before/after style. The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with `***` or `---`) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to `" "` so that the output will be uniformly newline free.

The context diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> import sys
>>> from difflib import *
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(context_diff(s1, s2, fromfile='before.py',
...                                 tofile='after.py'))
...
*** before.py
--- after.py
```

(繼續下一頁)

```

一個更詳盡的範例請見 *A command-line interface to difflib*。

`difflib.get_close_matches(word, possibilities, n=3, cutoff=0.6)`

Return a list of the best "good enough" matches. *word* is a sequence for which close matches are desired (typically a string), and *possibilities* is a list of sequences against which to match *word* (typically a list of strings).

Optional argument *n* (default 3) is the maximum number of close matches to return; *n* must be greater than 0.

Optional argument *cutoff* (default 0.6) is a float in the range [0, 1]. Possibilities that don't score at least that similar to *word* are ignored.

The best (no more than *n*) matches among the possibilities are returned in a list, sorted by similarity score, most similar first.

```

>>> get_close_matches('appel', ['ape', 'apple', 'peach', 'puppy'])
['apple', 'ape']
>>> import keyword
>>> get_close_matches('wheel', keyword.kwlist)
['while']
>>> get_close_matches('pineapple', keyword.kwlist)
[]
>>> get_close_matches('accept', keyword.kwlist)
['except']

```

`difflib.ndiff(a, b, linejunk=None, charjunk=IS_CHARACTER_JUNK)`

Compare *a* and *b* (lists of strings); return a *Differ*-style delta (a *generator* generating the delta lines).

Optional keyword parameters *linejunk* and *charjunk* are filtering functions (or None):

*linejunk*: A function that accepts a single string argument, and returns true if the string is junk, or false if not. The default is None. There is also a module-level function `IS_LINE_JUNK()`, which filters out lines without visible characters, except for at most one pound character ('#') -- however the underlying *SequenceMatcher* class does a dynamic analysis of which lines are so frequent as to constitute noise, and this usually works better than using this function.

*charjunk*: A function that accepts a character (a string of length 1), and returns if the character is junk, or false if not. The default is module-level function `IS_CHARACTER_JUNK()`, which filters out whitespace characters (a blank or tab; it's a bad idea to include newline in this!).

```

>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...             'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> print('\n'.join(diff), end="")
- one
? ^
+ ore
? ^
- two
- three
? -

```

(繼續下一頁)

(繼續上一頁)

```
+ tree
+ emu
```

`difflib.restore` (*sequence*, *which*)

Return one of the two sequences that generated a delta.

Given a *sequence* produced by `Differ.compare()` or `ndiff()`, extract lines originating from file 1 or 2 (parameter *which*), stripping off line prefixes.

範例：

```
>>> diff = ndiff('one\ntwo\nthree\n'.splitlines(keepends=True),
...             'ore\ntree\nemu\n'.splitlines(keepends=True))
>>> diff = list(diff) # materialize the generated delta into a list
>>> print(''.join(restore(diff, 1)), end="")
one
two
three
>>> print(''.join(restore(diff, 2)), end="")
ore
tree
emu
```

`difflib.unified_diff` (*a*, *b*, *fromfile*=", *tofile*=", *fromfiledate*=", *tofiledate*=", *n*=3, *lineterm*='\n')

Compare *a* and *b* (lists of strings); return a delta (a *generator* generating the delta lines) in unified diff format.

Unified diffs are a compact way of showing just the lines that have changed plus a few lines of context. The changes are shown in an inline style (instead of separate before/after blocks). The number of context lines is set by *n* which defaults to three.

By default, the diff control lines (those with ---, +++, or @@) are created with a trailing newline. This is helpful so that inputs created from `io.IOBase.readlines()` result in diffs that are suitable for use with `io.IOBase.writelines()` since both the inputs and outputs have trailing newlines.

For inputs that do not have trailing newlines, set the *lineterm* argument to "" so that the output will be uniformly newline free.

The unified diff format normally has a header for filenames and modification times. Any or all of these may be specified using strings for *fromfile*, *tofile*, *fromfiledate*, and *tofiledate*. The modification times are normally expressed in the ISO 8601 format. If not specified, the strings default to blanks.

```
>>> s1 = ['bacon\n', 'eggs\n', 'ham\n', 'guido\n']
>>> s2 = ['python\n', 'eggy\n', 'hamster\n', 'guido\n']
>>> sys.stdout.writelines(unified_diff(s1, s2, fromfile='before.py', tofile='after.py'))
--- before.py
+++ after.py
@@ -1,4 +1,4 @@
-bacon
-eggs
-ham
+python
+eggy
+hamster
guido
```

一個更詳盡的範例請見 [A command-line interface to difflib](#).

`difflib.diff_bytes` (*dfunc*, *a*, *b*, *fromfile*=*b*", *tofile*=*b*", *fromfiledate*=*b*", *tofiledate*=*b*", *n*=3, *lineterm*=*b*'\n')

Compare *a* and *b* (lists of bytes objects) using *dfunc*; yield a sequence of delta lines (also bytes) in the format returned by *dfunc*. *dfunc* must be a callable, typically either `unified_diff()` or `context_diff()`.

Allows you to compare data with unknown or inconsistent encoding. All inputs except *n* must be bytes objects, not str. Works by losslessly converting all inputs (except *n*) to str, and calling `dfunc(a, b, fromfile,`

`tofile`, `fromfiledate`, `tofiledate`, `n`, `lineterm`). The output of `dfunc` is then converted back to bytes, so the delta lines that you receive have the same unknown/inconsistent encodings as `a` and `b`.

在 3.5 版被加入。

`difflib.IS_LINE_JUNK` (*line*)

Return `True` for ignorable lines. The line *line* is ignorable if *line* is blank or contains a single '#', otherwise it is not ignorable. Used as a default for parameter *linejunk* in `ndiff()` in older versions.

`difflib.IS_CHARACTER_JUNK` (*ch*)

Return `True` for ignorable characters. The character *ch* is ignorable if *ch* is a space or tab, otherwise it is not ignorable. Used as a default for parameter *charjunk* in `ndiff()`.

#### Pattern Matching: The Gestalt Approach

Discussion of a similar algorithm by John W. Ratcliff and D. E. Metzener. This was published in *Dr. Dobb's Journal* in July, 1988.

## 6.3.1 SequenceMatcher 物件

The `SequenceMatcher` class has this constructor:

```
class difflib.SequenceMatcher (isjunk=None, a="", b="", autojunk=True)
```

Optional argument *isjunk* must be `None` (the default) or a one-argument function that takes a sequence element and returns true if and only if the element is "junk" and should be ignored. Passing `None` for *isjunk* is equivalent to passing `lambda x: False`; in other words, no elements are ignored. For example, pass:

```
lambda x: x in " \t"
```

if you're comparing lines as sequences of characters, and don't want to synch up on blanks or hard tabs.

The optional arguments *a* and *b* are sequences to be compared; both default to empty strings. The elements of both sequences must be *hashable*.

The optional argument *autojunk* can be used to disable the automatic junk heuristic.

在 3.2 版的變更: 新增 *autojunk* 參數。

`SequenceMatcher` objects get three data attributes: *bjunk* is the set of elements of *b* for which *isjunk* is `True`; *bpopular* is the set of non-junk elements considered popular by the heuristic (if it is not disabled); *b2j* is a dict mapping the remaining elements of *b* to a list of positions where they occur. All three are reset whenever *b* is reset with `set_seqs()` or `set_seq2()`.

在 3.2 版被加入: The *bjunk* and *bpopular* attributes.

`SequenceMatcher` objects have the following methods:

`set_seqs` (*a*, *b*)

Set the two sequences to be compared.

`SequenceMatcher` computes and caches detailed information about the second sequence, so if you want to compare one sequence against many sequences, use `set_seq2()` to set the commonly used sequence once and call `set_seq1()` repeatedly, once for each of the other sequences.

`set_seq1` (*a*)

Set the first sequence to be compared. The second sequence to be compared is not changed.

`set_seq2` (*b*)

Set the second sequence to be compared. The first sequence to be compared is not changed.

**find\_longest\_match** (*alo=0, ahi=None, blo=0, bhi=None*)

Find longest matching block in `a[alo:ahi]` and `b[blo:bhi]`.

If *isjunk* was omitted or `None`, `find_longest_match()` returns `(i, j, k)` such that `a[i:i+k]` is equal to `b[j:j+k]`, where `alo <= i <= i+k <= ahi` and `blo <= j <= j+k <= bhi`. For all `(i', j', k')` meeting those conditions, the additional conditions `k >= k'`, `i <= i'`, and if `i == i'`, `j <= j'` are also met. In other words, of all maximal matching blocks, return one that starts earliest in *a*, and of all those maximal matching blocks that start earliest in *a*, return the one that starts earliest in *b*.

```
>>> s = SequenceMatcher(None, "abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=0, b=4, size=5)
```

If *isjunk* was provided, first the longest matching block is determined as above, but with the additional restriction that no junk element appears in the block. Then that block is extended as far as possible by matching (only) junk elements on both sides. So the resulting block never matches on junk except as identical junk happens to be adjacent to an interesting match.

Here's the same example as before, but considering blanks to be junk. That prevents `'abcd'` from matching the `'abcd'` at the tail end of the second sequence directly. Instead only the `'abcd'` can match, and matches the leftmost `'abcd'` in the second sequence:

```
>>> s = SequenceMatcher(lambda x: x==" ", "abcd", "abcd abcd")
>>> s.find_longest_match(0, 5, 0, 9)
Match(a=1, b=0, size=4)
```

If no blocks match, this returns `(alo, blo, 0)`.

This method returns a *named tuple* `Match(a, b, size)`.

在 3.9 版的變更: 新增預設引數。

**get\_matching\_blocks** ()

Return list of triples describing non-overlapping matching subsequences. Each triple is of the form `(i, j, n)`, and means that `a[i:i+n] == b[j:j+n]`. The triples are monotonically increasing in *i* and *j*.

The last triple is a dummy, and has the value `(len(a), len(b), 0)`. It is the only triple with `n == 0`. If `(i, j, n)` and `(i', j', n')` are adjacent triples in the list, and the second is not the last triple in the list, then `i+n < i'` or `j+n < j'`; in other words, adjacent triples always describe non-adjacent equal blocks.

```
>>> s = SequenceMatcher(None, "abxcd", "abcd")
>>> s.get_matching_blocks()
[Match(a=0, b=0, size=2), Match(a=3, b=2, size=2), Match(a=5, b=4, size=0)]
```

**get\_opcodes** ()

Return list of 5-tuples describing how to turn *a* into *b*. Each tuple is of the form `(tag, i1, i2, j1, j2)`. The first tuple has `i1 == j1 == 0`, and remaining tuples have *i1* equal to the *i2* from the preceding tuple, and, likewise, *j1* equal to the previous *j2*.

The *tag* values are strings, with these meanings:

Value	含義
'replace'	<code>a[i1:i2]</code> should be replaced by <code>b[j1:j2]</code> .
'delete'	<code>a[i1:i2]</code> should be deleted. Note that <code>j1 == j2</code> in this case.
'insert'	<code>b[j1:j2]</code> should be inserted at <code>a[i1:i1]</code> . Note that <code>i1 == i2</code> in this case.
'equal'	<code>a[i1:i2] == b[j1:j2]</code> (the sub-sequences are equal).

舉例來:

```

>>> a = "qabxcd"
>>> b = "abycdf"
>>> s = SequenceMatcher(None, a, b)
>>> for tag, i1, i2, j1, j2 in s.get_opcodes():
...     print('{:7}  a[{:}:{:}] --> b[{:}:{:}]  {:r:>8} -->  {:r}'.format (
...         tag, i1, i2, j1, j2, a[i1:i2], b[j1:j2]))
delete   a[0:1] --> b[0:0]      'q' --> ''
equal    a[1:3] --> b[0:2]      'ab' --> 'ab'
replace  a[3:4] --> b[2:3]      'x' --> 'y'
equal    a[4:6] --> b[3:5]      'cd' --> 'cd'
insert   a[6:6] --> b[5:6]      '' --> 'f'

```

**get\_grouped\_opcodes** (*n=3*)

Return a *generator* of groups with up to *n* lines of context.

Starting with the groups returned by *get\_opcodes()*, this method splits out smaller change clusters and eliminates intervening ranges which have no changes.

The groups are returned in the same format as *get\_opcodes()*.

**ratio** ()

Return a measure of the sequences' similarity as a float in the range [0, 1].

Where T is the total number of elements in both sequences, and M is the number of matches, this is  $2.0 * M / T$ . Note that this is 1.0 if the sequences are identical, and 0.0 if they have nothing in common.

This is expensive to compute if *get\_matching\_blocks()* or *get\_opcodes()* hasn't already been called, in which case you may want to try *quick\_ratio()* or *real\_quick\_ratio()* first to get an upper bound.

**備**

Caution: The result of a *ratio()* call may depend on the order of the arguments. For instance:

```

>>> SequenceMatcher(None, 'tide', 'diet').ratio()
0.25
>>> SequenceMatcher(None, 'diet', 'tide').ratio()
0.5

```

**quick\_ratio** ()

Return an upper bound on *ratio()* relatively quickly.

**real\_quick\_ratio** ()

Return an upper bound on *ratio()* very quickly.

The three methods that return the ratio of matching to total characters can give different results due to differing levels of approximation, although *quick\_ratio()* and *real\_quick\_ratio()* are always at least as large as *ratio()*:

```

>>> s = SequenceMatcher(None, "abcd", "bcde")
>>> s.ratio()
0.75
>>> s.quick_ratio()
0.75
>>> s.real_quick_ratio()
1.0

```

### 6.3.2 SequenceMatcher 范例

This example compares two strings, considering blanks to be "junk":

```
>>> s = SequenceMatcher(lambda x: x == " ",
...                       "private Thread currentThread;",
...                       "private volatile Thread currentThread;")
```

`ratio()` returns a float in [0, 1], measuring the similarity of the sequences. As a rule of thumb, a `ratio()` value over 0.6 means the sequences are close matches:

```
>>> print(round(s.ratio(), 3))
0.866
```

If you're only interested in where the sequences match, `get_matching_blocks()` is handy:

```
>>> for block in s.get_matching_blocks():
...     print("a[%d] and b[%d] match for %d elements" % block)
a[0] and b[0] match for 8 elements
a[8] and b[17] match for 21 elements
a[29] and b[38] match for 0 elements
```

Note that the last tuple returned by `get_matching_blocks()` is always a dummy, `(len(a), len(b), 0)`, and this is the only case in which the last tuple element (number of elements matched) is 0.

If you want to know how to change the first sequence into the second, use `get_opcodes()`:

```
>>> for opcode in s.get_opcodes():
...     print("%6s a[%d:%d] b[%d:%d]" % opcode)
equal a[0:8] b[0:8]
insert a[8:8] b[8:17]
equal a[8:29] b[17:38]
```

- Simple version control recipe for a small application built with `SequenceMatcher`.

### 6.3.3 Differ Objects

Note that `Differ`-generated deltas make no claim to be **minimal** diffs. To the contrary, minimal diffs are often counter-intuitive, because they synch up anywhere possible, sometimes accidental matches 100 pages apart. Restricting synch points to contiguous matches preserves some notion of locality, at the occasional cost of producing a longer diff.

The `Differ` class has this constructor:

```
class difflib.Differ (linejunk=None, charjunk=None)
```

Optional keyword parameters `linejunk` and `charjunk` are for filter functions (or `None`):

`linejunk`: A function that accepts a single string argument, and returns true if the string is junk. The default is `None`, meaning that no line is considered junk.

`charjunk`: A function that accepts a single character argument (a string of length 1), and returns true if the character is junk. The default is `None`, meaning that no character is considered junk.

These junk-filtering functions speed up matching to find differences and do not cause any differing lines or characters to be ignored. Read the description of the `find_longest_match()` method's `isjunk` parameter for an explanation.

`Differ` objects are used (deltas generated) via a single method:

`compare(a, b)`

Compare two sequences of lines, and generate the delta (a sequence of lines).

Each sequence must contain individual single-line strings ending with newlines. Such sequences can be obtained from the `readlines()` method of file-like objects. The delta generated also consists of newline-terminated strings, ready to be printed as-is via the `writelines()` method of a file-like object.

### 6.3.4 Differ Example

This example compares two texts. First we set up the texts, sequences of individual single-line strings ending with newlines (such sequences can also be obtained from the `readlines()` method of file-like objects):

```
>>> text1 = ''' 1. Beautiful is better than ugly.
... 2. Explicit is better than implicit.
... 3. Simple is better than complex.
... 4. Complex is better than complicated.
... '''.splitlines(keepends=True)
>>> len(text1)
4
>>> text1[0][-1]
'\n'
>>> text2 = ''' 1. Beautiful is better than ugly.
... 3. Simple is better than complex.
... 4. Complicated is better than complex.
... 5. Flat is better than nested.
... '''.splitlines(keepends=True)
```

Next we instantiate a `Differ` object:

```
>>> d = Differ()
```

Note that when instantiating a `Differ` object we may pass functions to filter out line and character "junk." See the `Differ()` constructor for details.

Finally, we compare the two:

```
>>> result = list(d.compare(text1, text2))
```

`result` is a list of strings, so let's pretty-print it:

```
>>> from pprint import pprint
>>> pprint(result)
[' 1. Beautiful is better than ugly.\n',
 '- 2. Explicit is better than implicit.\n',
 '- 3. Simple is better than complex.\n',
 '+ 3. Simple is better than complex.\n',
 '? ++\n',
 '- 4. Complex is better than complicated.\n',
 '? ^ ---- ^\n',
 '+ 4. Complicated is better than complex.\n',
 '? ++++ ^ ^\n',
 '+ 5. Flat is better than nested.\n']
```

As a single multi-line string it looks like this:

```
>>> import sys
>>> sys.stdout.writelines(result)
1. Beautiful is better than ugly.
- 2. Explicit is better than implicit.
- 3. Simple is better than complex.
+ 3. Simple is better than complex.
? ++
```

(繼續下一頁)

(繼續上一頁)

```

- 4. Complex is better than complicated.
?      ^                ---- ^
+ 4. Complicated is better than complex.
?      ++++ ^                ^
+ 5. Flat is better than nested.

```

### 6.3.5 A command-line interface to difflib

This example shows how to use difflib to create a diff-like utility.

```

""" Command line interface to difflib.py providing diffs in four formats:

* ndiff: lists every line and highlights interline changes.
* context: highlights clusters of changes in a before/after format.
* unified: highlights clusters of changes in an inline format.
* html: generates side by side comparison with change highlights.

"""

import sys, os, difflib, argparse
from datetime import datetime, timezone

def file_mtime(path):
    t = datetime.fromtimestamp(os.stat(path).st_mtime,
                              timezone.utc)
    return t.astimezone().isoformat()

def main():
    parser = argparse.ArgumentParser()
    parser.add_argument('-c', action='store_true', default=False,
                        help='Produce a context format diff (default)')
    parser.add_argument('-u', action='store_true', default=False,
                        help='Produce a unified format diff')
    parser.add_argument('-m', action='store_true', default=False,
                        help='Produce HTML side by side diff '
                              '(can use -c and -l in conjunction)')
    parser.add_argument('-n', action='store_true', default=False,
                        help='Produce a ndiff format diff')
    parser.add_argument('-l', '--lines', type=int, default=3,
                        help='Set number of context lines (default 3)')

```

### 6.3.6 ndiff 范例:

This example shows how to use `difflib.ndiff()`.

```

"""ndiff [-q] file1 file2
   or
ndiff (-r1 | -r2) < ndiff_output > file1_or_file2

Print a human-friendly file difference report to stdout. Both inter-
and intra-line differences are noted. In the second form, recreate file1
(-r1) or file2 (-r2) on stdout, from an ndiff report on stdin.

In the first form, if -q ("quiet") is not specified, the first two lines
of output are

-: file1
+: file2

Each remaining line begins with a two-letter code:

"- "   line unique to file1
"+ "   line unique to file2
" "    line common to both files
"? "   line not present in either input file

Lines beginning with "? " attempt to guide the eye to intraline
differences, and were not present in either input file. These lines can be
confusing if the source files contain tab characters.

The first file can be recovered by retaining only lines that begin with
" " or "- ", and deleting those 2-character prefixes; use ndiff with -r1.

The second file can be recovered similarly, but by retaining only " " and
"+ " lines; use ndiff with -r2; or, on Unix, the second file can be
recovered by piping the output through

    sed -n '/^[+ ] /s/^././p'
"""

## 6.4 textwrap --- 文字包裝與填充

原始碼: Lib/textwrap.py

The `textwrap` module provides some convenience functions, as well as `TextWrapper`, the class that does all the work. If you're just wrapping or filling one or two text strings, the convenience functions should be good enough; otherwise, you should use an instance of `TextWrapper` for efficiency.

```
textwrap.wrap(text, width=70, *, initial_indent="", subsequent_indent="", expand_tabs=True,
              replace_whitespace=True, fix_sentence_endings=False, break_long_words=True,
              drop_whitespace=True, break_on_hyphens=True, tabsize=8, max_lines=None, placeholder='
[...]')
```

Wraps the single paragraph in `text` (a string) so every line is at most `width` characters long. Returns a list of output lines, without final newlines.

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below.

See the `TextWrapper.wrap()` method for additional details on how `wrap()` behaves.

```
textwrap.fill(text, width=70, *, initial_indent="", subsequent_indent="", expand_tabs=True,
             replace_whitespace=True, fix_sentence_endings=False, break_long_words=True,
             drop_whitespace=True, break_on_hyphens=True, tabsize=8, max_lines=None, placeholder='
[...]')
```

Wraps the single paragraph in `text`, and returns a single string containing the wrapped paragraph. `fill()` is shorthand for

```
"\n".join(wrap(text, ...))
```

In particular, `fill()` accepts exactly the same keyword arguments as `wrap()`.

```
textwrap.shorten(text, width, *, fix_sentence_endings=False, break_long_words=True,
                break_on_hyphens=True, placeholder='[...]')
```

Collapse and truncate the given `text` to fit in the given `width`.

First the whitespace in `text` is collapsed (all whitespace is replaced by single spaces). If the result fits in the `width`, it is returned. Otherwise, enough words are dropped from the end so that the remaining words plus the `placeholder` fit within `width`:

```
>>> textwrap.shorten("Hello world!", width=12)
'Hello world!'
>>> textwrap.shorten("Hello world!", width=11)
'Hello [...]'
>>> textwrap.shorten("Hello world", width=10, placeholder="...")
'Hello...'
```

Optional keyword arguments correspond to the instance attributes of `TextWrapper`, documented below. Note that the whitespace is collapsed before the text is passed to the `TextWrapper.fill()` function, so changing the value of `tabsize`, `expand_tabs`, `drop_whitespace`, and `replace_whitespace` will have no effect.

在 3.4 版被加入。

`textwrap.dedent(text)`

Remove any common leading whitespace from every line in *text*.

This can be used to make triple-quoted strings line up with the left edge of the display, while still presenting them in the source code in indented form.

Note that tabs and spaces are both treated as whitespace, but they are not equal: the lines " hello" and "\thello" are considered to have no common leading whitespace.

Lines containing only whitespace are ignored in the input and normalized to a single newline character in the output.

舉例來 F:

```
def test():
    # end first line with \ to avoid the empty line!
    s = '''\
hello
    world
'''
    print(repr(s))          # prints ' hello\n    world\n '
    print(repr(dedent(s))) # prints 'hello\n world\n'
```

`textwrap.indent(text, prefix, predicate=None)`

Add *prefix* to the beginning of selected lines in *text*.

Lines are separated by calling `text.splitlines(True)`.

By default, *prefix* is added to all lines that do not consist solely of whitespace (including any line endings).

舉例來 F:

```
>>> s = 'hello\n\n \nworld'
>>> indent(s, ' ')
' hello\n\n \n world'
```

The optional *predicate* argument can be used to control which lines are indented. For example, it is easy to add *prefix* to even empty and whitespace-only lines:

```
>>> print(indent(s, '+ ', lambda line: True))
+ hello
+
+
+ world
```

在 3.3 版被加入。

`wrap()`, `fill()` and `shorten()` work by creating a `TextWrapper` instance and calling a single method on it. That instance is not reused, so for applications that process many text strings using `wrap()` and/or `fill()`, it may be more efficient to create your own `TextWrapper` object.

Text is preferably wrapped on whitespaces and right after the hyphens in hyphenated words; only then will long words be broken if necessary, unless `TextWrapper.break_long_words` is set to false.

`class textwrap.TextWrapper(**kwargs)`

The `TextWrapper` constructor accepts a number of optional keyword arguments. Each keyword argument corresponds to an instance attribute, so for example

```
wrapper = TextWrapper(initial_indent="* ")
```

is the same as

```
wrapper = TextWrapper()
wrapper.initial_indent = "* "
```

You can reuse the same `TextWrapper` object many times, and you can change any of its options through direct assignment to instance attributes between uses.

The `TextWrapper` instance attributes (and keyword arguments to the constructor) are as follows:

#### **width**

(default: 70) The maximum length of wrapped lines. As long as there are no individual words in the input text longer than `width`, `TextWrapper` guarantees that no output line will be longer than `width` characters.

#### **expand\_tabs**

(default: `True`) If true, then all tab characters in `text` will be expanded to spaces using the `expandtabs()` method of `text`.

#### **tabsize**

(default: 8) If `expand_tabs` is true, then all tab characters in `text` will be expanded to zero or more spaces, depending on the current column and the given tab size.

在 3.3 版被加入.

#### **replace\_whitespace**

(default: `True`) If true, after tab expansion but before wrapping, the `wrap()` method will replace each whitespace character with a single space. The whitespace characters replaced are as follows: tab, newline, vertical tab, formfeed, and carriage return (`'\t\n\v\f\r'`).

#### **備F**

If `expand_tabs` is false and `replace_whitespace` is true, each tab character will be replaced by a single space, which is *not* the same as tab expansion.

#### **備F**

If `replace_whitespace` is false, newlines may appear in the middle of a line and cause strange output. For this reason, text should be split into paragraphs (using `str.splitlines()` or similar) which are wrapped separately.

#### **drop\_whitespace**

(default: `True`) If true, whitespace at the beginning and ending of every line (after wrapping but before indenting) is dropped. Whitespace at the beginning of the paragraph, however, is not dropped if non-whitespace follows it. If whitespace being dropped takes up an entire line, the whole line is dropped.

#### **initial\_indent**

(default: `' '`) String that will be prepended to the first line of wrapped output. Counts towards the length of the first line. The empty string is not indented.

#### **subsequent\_indent**

(default: `' '`) String that will be prepended to all lines of wrapped output except the first. Counts towards the length of each line except the first.

#### **fix\_sentence\_endings**

(default: `False`) If true, `TextWrapper` attempts to detect sentence endings and ensure that sentences are always separated by exactly two spaces. This is generally desired for text in a monospaced font. However, the sentence detection algorithm is imperfect: it assumes that a sentence ending consists of a lowercase letter followed by one of `'.'`, `'!'`, or `'?'`, possibly followed by one of `'\"'` or `'\"'`, followed by a space. One problem with this algorithm is that it is unable to detect the difference between "Dr." in

```
[...] Dr. Frankenstein's monster [...]
```

and "Spot." in

```
[...] See Spot. See Spot run [...]
```

`fix_sentence_endings` is false by default.

Since the sentence detection algorithm relies on `string.lowercase` for the definition of “lowercase letter”, and a convention of using two spaces after a period to separate sentences on the same line, it is specific to English-language texts.

#### **break\_long\_words**

(default: `True`) If true, then words longer than `width` will be broken in order to ensure that no lines are longer than `width`. If it is false, long words will not be broken, and some lines may be longer than `width`. (Long words will be put on a line by themselves, in order to minimize the amount by which `width` is exceeded.)

#### **break\_on\_hyphens**

(default: `True`) If true, wrapping will occur preferably on whitespaces and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set `break_long_words` to false if you want truly insecable words. Default behaviour in previous versions was to always allow breaking hyphenated words.

#### **max\_lines**

(default: `None`) If not `None`, then the output will contain at most `max_lines` lines, with `placeholder` appearing at the end of the output.

在 3.4 版被加入。

#### **placeholder**

(default: `' [...]'`) String that will appear at the end of the output text if it has been truncated.

在 3.4 版被加入。

`TextWrapper` also provides some public methods, analogous to the module-level convenience functions:

#### **wrap**(*text*)

Wraps the single paragraph in *text* (a string) so every line is at most `width` characters long. All wrapping options are taken from instance attributes of the `TextWrapper` instance. Returns a list of output lines, without final newlines. If the wrapped output has no content, the returned list is empty.

#### **fill**(*text*)

Wraps the single paragraph in *text*, and returns a single string containing the wrapped paragraph.

## 6.5 unicodedata --- Unicode 資料庫

This module provides access to the Unicode Character Database (UCD) which defines character properties for all Unicode characters. The data contained in this database is compiled from the [UCD version 15.1.0](https://www.unicode.org/Public/15.1.0/).

The module uses the same names and symbols as defined by Unicode Standard Annex #44, “Unicode Character Database”. It defines the following functions:

#### `unicodedata.lookup`(*name*)

Look up character by name. If a character with the given name is found, return the corresponding character. If not found, `KeyError` is raised.

在 3.3 版的變更: Support for name aliases<sup>1</sup> and named sequences<sup>2</sup> has been added.

#### `unicodedata.name`(*chr*[, *default* ])

Returns the name assigned to the character *chr* as a string. If no name is defined, *default* is returned, or, if not given, `ValueError` is raised.

<sup>1</sup> <https://www.unicode.org/Public/15.1.0/ucd/NameAliases.txt>

<sup>2</sup> <https://www.unicode.org/Public/15.1.0/ucd/NamedSequences.txt>

`unicodedata.decimal(chr[, default])`

Returns the decimal value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.digit(chr[, default])`

Returns the digit value assigned to the character *chr* as integer. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.numeric(chr[, default])`

Returns the numeric value assigned to the character *chr* as float. If no such value is defined, *default* is returned, or, if not given, `ValueError` is raised.

`unicodedata.category(chr)`

Returns the general category assigned to the character *chr* as string.

`unicodedata.bidirectional(chr)`

Returns the bidirectional class assigned to the character *chr* as string. If no such value is defined, an empty string is returned.

`unicodedata.combining(chr)`

Returns the canonical combining class assigned to the character *chr* as integer. Returns 0 if no combining class is defined.

`unicodedata.east_asian_width(chr)`

Returns the east asian width assigned to the character *chr* as string.

`unicodedata.mirrored(chr)`

Returns the mirrored property assigned to the character *chr* as integer. Returns 1 if the character has been identified as a "mirrored" character in bidirectional text, 0 otherwise.

`unicodedata.decomposition(chr)`

Returns the character decomposition mapping assigned to the character *chr* as string. An empty string is returned in case no such mapping is defined.

`unicodedata.normalize(form, unistr)`

Return the normal form *form* for the Unicode string *unistr*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

The Unicode standard defines various normalization forms of a Unicode string, based on the definition of canonical equivalence and compatibility equivalence. In Unicode, several characters can be expressed in various way. For example, the character U+00C7 (LATIN CAPITAL LETTER C WITH CEDILLA) can also be expressed as the sequence U+0043 (LATIN CAPITAL LETTER C) U+0327 (COMBINING CEDILLA).

For each character, there are two normal forms: normal form C and normal form D. Normal form D (NFD) is also known as canonical decomposition, and translates each character into its decomposed form. Normal form C (NFC) first applies a canonical decomposition, then composes pre-combined characters again.

In addition to these two forms, there are two additional normal forms based on compatibility equivalence. In Unicode, certain characters are supported which normally would be unified with other characters. For example, U+2160 (ROMAN NUMERAL ONE) is really the same thing as U+0049 (LATIN CAPITAL LETTER I). However, it is supported in Unicode for compatibility with existing character sets (e.g. gb2312).

The normal form KD (NFKD) will apply the compatibility decomposition, i.e. replace all compatibility characters with their equivalents. The normal form KC (NFKC) first applies the compatibility decomposition, followed by the canonical composition.

Even if two unicode strings are normalized and look the same to a human reader, if one has combining characters and the other doesn't, they may not compare equal.

`unicodedata.is_normalized(form, unistr)`

Return whether the Unicode string *unistr* is in the normal form *form*. Valid values for *form* are 'NFC', 'NFKC', 'NFD', and 'NFKD'.

在 3.8 版被加入。

In addition, the module exposes the following constant:

`unicodedata.unicdata_version`

The version of the Unicode database used in this module.

`unicodedata.ucd_3_2_0`

This is an object that has the same methods as the entire module, but uses the Unicode database version 3.2 instead, for applications that require this specific version of the Unicode database (such as IDNA).

範例：

```
>>> import unicodedata
>>> unicodedata.lookup('LEFT CURLY BRACKET')
'{'
>>> unicodedata.name('/')
'SOLIDUS'
>>> unicodedata.decimal('9')
9
>>> unicodedata.decimal('a')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: not a decimal
>>> unicodedata.category('A') # 'L'etter, 'u'ppercase
'Lu'
>>> unicodedata.bidirectional('\u0660') # 'A'rabic, 'N'umber
'AN'
```

解

## 6.6 stringprep --- 網際網路字串的準備

原始碼：Lib/stringprep.py

在網際網路上識事物（例如主機名稱）時，通常需要比較這些識器的「相等性 (equality)」。

比較的具體執行方式可能取於應用程式領域，例如是否應該不區分大小寫。也可能有必要限制可能的識器，只允許由「可列印 (printable)」字元組成的識器。

**RFC 3454** 定義了在網際網路通訊協定中「準備」Unicode 字串的程序。在傳送字串到網路之前，先使用準備程序處理字串，之後字串就具有特定的規範化 (normalized) 形式。RFC 定義了一系列的表，這些表可以組合成設定檔 (profile)。每個設定檔必須定義它使用哪些表以及 `stringprep` 程序的哪些其他可選部分是設定檔的一部分。`stringprep` 配置文件的一個例子是 `nameprep`，它被用於國際化網域名稱。

`stringprep` 模組只開放 **RFC 3454** 中的表。由於這些表如果以字典或串列的方式來表示的話會非常大，因此模組內部使用 Unicode 字元資料庫。模組原始碼本身是使用 `mkstringprep.py` 工具來生的。

因此，這些表是以函式而非資料結構的形式呈現。RFC 中有兩種表：集合 (sets) 和對映 (mappings)。對於集合，`stringprep` 提供了「特徵函式 (characteristic function)」，也就是如果參數是集合的一部分就回傳 True 的函式。對於對映，它提供了對映函式：給定鍵，它會回傳相關的值。以下是模組中所有可用函式的清單。

`stringprep.in_table_a1 (code)`

判斷 `code` 是否在 tableA.1 (Unicode 3.2 中未指定的碼位 (code point)) 中。

`stringprep.in_table_b1 (code)`

判斷 `code` 是否在 tableB.1 (通常有對映到任何東西) 中。

`stringprep.map_table_b2 (code)`

根據 tableB.2 (使用 NFKC 形式的大小寫折 (case-folding) 對映) 回傳 `code` 的對映值。

`stringprep.map_table_b3 (code)`

根據 tableB.3 (使用有規範化的大小寫折對映) 回傳 `code` 的對映值。

`stringprep.in_table_c11` (*code*)

判斷 *code* 是否在 tableC.1.1 (ASCII 空格字元) 中。

`stringprep.in_table_c12` (*code*)

判斷 *code* 是否在 tableC.1.2 (非 ASCII 空格字元) 中。

`stringprep.in_table_c11_c12` (*code*)

判斷 *code* 是否在 tableC.1 (空格字元, 發 C.1.1 和 C.1.2 的聯集) 中。

`stringprep.in_table_c21` (*code*)

判斷 *code* 是否在 tableC.2.1 (ASCII 控制字元) 中。

`stringprep.in_table_c22` (*code*)

判斷 *code* 是否在 tableC.2.2 (非 ASCII 控制字元) 中。

`stringprep.in_table_c21_c22` (*code*)

判斷 *code* 是否在 tableC.2 (控制字元, 發 C.2.1 和 C.2.2 的聯集) 中。

`stringprep.in_table_c3` (*code*)

判斷 *code* 是否在 tableC.3 (私有使用) 中。

`stringprep.in_table_c4` (*code*)

判斷 *code* 是否在 tableC.4 (非字元碼位) 中。

`stringprep.in_table_c5` (*code*)

判斷 *code* 是否在 tableC.5 (代理碼) 中。

`stringprep.in_table_c6` (*code*)

判斷 *code* 是否在 tableC.6 (不適用於純文字) 中。

`stringprep.in_table_c7` (*code*)

判斷 *code* 是否在 tableC.7 (不適用於規範表示法 (canonical representation)) 中。

`stringprep.in_table_c8` (*code*)

判斷 *code* 是否在 tableC.8 (變更顯示屬性或已發) 中。

`stringprep.in_table_c9` (*code*)

判斷 *code* 是否在 tableC.9 (標記字元 (tagging characters)) 中。

`stringprep.in_table_d1` (*code*)

判斷 *code* 是否在 tableD.1 (具有雙向屬性”R”或”AL”的字元) 中。

`stringprep.in_table_d2` (*code*)

判斷 *code* 是否在 tableD.2 (具有雙向屬性”L”的字元) 中。

## 6.7 readline --- GNU readline 介面

---

The `readline` module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly, or via the `rlcompleter` module, which supports completion of Python identifiers at the interactive prompt. Settings made using this module affect the behaviour of both the interpreter’s interactive prompt and the prompts offered by the built-in `input()` function.

Readline keybindings may be configured via an initialization file, typically `.inputrc` in your home directory. See [Readline Init File](#) in the GNU Readline manual for information about the format and allowable constructs of that file, and the capabilities of the Readline library in general.

適用: not Android, not iOS, not WASI.

此模組在行動平台或 `WebAssembly` 平台上不支援。

**i 備**

The underlying Readline library API may be implemented by the `editline` (`libedit`) library instead of GNU `readline`. On macOS the `readline` module detects which library is being used at run time.

The configuration file for `editline` is different from that of GNU `readline`. If you programmatically load configuration strings you can use `backend` to determine which library is being used.

If you use `editline/libedit` `readline` emulation on macOS, the initialization file located in your home directory is named `.editrc`. For example, the following content in `~/.editrc` will turn ON `vi` keybindings and TAB completion:

```
python:bind -v
python:bind ^I rl_complete
```

Also note that different libraries may use different history file formats. When switching the underlying library, existing history files may become unusable.

`readline.backend`

The name of the underlying Readline library being used, either "readline" or "editline".

在 3.13 版被加入。

### 6.7.1 Init file

The following functions relate to the init file and user configuration:

`readline.parse_and_bind` (*string*)

Execute the init line provided in the *string* argument. This calls `rl_parse_and_bind()` in the underlying library.

`readline.read_init_file` (*[filename]*)

Execute a `readline` initialization file. The default filename is the last filename used. This calls `rl_read_init_file()` in the underlying library.

### 6.7.2 Line buffer

The following functions operate on the line buffer:

`readline.get_line_buffer` ()

Return the current contents of the line buffer (`rl_line_buffer` in the underlying library).

`readline.insert_text` (*string*)

Insert text into the line buffer at the cursor position. This calls `rl_insert_text()` in the underlying library, but ignores the return value.

`readline.redisplay` ()

Change what's displayed on the screen to reflect the current contents of the line buffer. This calls `rl_redisplay()` in the underlying library.

### 6.7.3 History file

The following functions operate on a history file:

`readline.read_history_file` (*[filename]*)

Load a `readline` history file, and append it to the history list. The default filename is `~/.history`. This calls `read_history()` in the underlying library.

`readline.write_history_file` (*[filename]*)

Save the history list to a `readline` history file, overwriting any existing file. The default filename is `~/.history`. This calls `write_history()` in the underlying library.

`readline.append_history_file(nelements[, filename])`

Append the last *nelements* items of history to a file. The default filename is `~/.history`. The file must already exist. This calls `append_history()` in the underlying library. This function only exists if Python was compiled for a version of the library that supports it.

在 3.5 版被加入。

`readline.get_history_length()`

`readline.set_history_length(length)`

Set or return the desired number of lines to save in the history file. The `write_history_file()` function uses this value to truncate the history file, by calling `history_truncate_file()` in the underlying library. Negative values imply unlimited history file size.

## 6.7.4 History list

The following functions operate on a global history list:

`readline.clear_history()`

Clear the current history. This calls `clear_history()` in the underlying library. The Python function only exists if Python was compiled for a version of the library that supports it.

`readline.get_current_history_length()`

Return the number of items currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

`readline.get_history_item(index)`

Return the current contents of history item at *index*. The item index is one-based. This calls `history_get()` in the underlying library.

`readline.remove_history_item(pos)`

Remove history item specified by its position from the history. The position is zero-based. This calls `remove_history()` in the underlying library.

`readline.replace_history_item(pos, line)`

Replace history item specified by its position with *line*. The position is zero-based. This calls `replace_history_entry()` in the underlying library.

`readline.add_history(line)`

Append *line* to the history buffer, as if it was the last line typed. This calls `add_history()` in the underlying library.

`readline.set_auto_history(enabled)`

Enable or disable automatic calls to `add_history()` when reading input via `readline`. The *enabled* argument should be a Boolean value that when true, enables auto history, and that when false, disables auto history.

在 3.6 版被加入。

**CPython 實作細節：** Auto history is enabled by default, and changes to this do not persist across multiple sessions.

## 6.7.5 Startup hooks

`readline.set_startup_hook([function])`

Set or remove the function invoked by the `rl_startup_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments just before `readline` prints the first prompt.

`readline.set_pre_input_hook([function])`

Set or remove the function invoked by the `rl_pre_input_hook` callback of the underlying library. If *function* is specified, it will be used as the new hook function; if omitted or `None`, any function already installed is removed. The hook is called with no arguments after the first prompt has been printed and just before `readline`

starts reading input characters. This function only exists if Python was compiled for a version of the library that supports it.

## 6.7.6 Completion

The following functions relate to implementing a custom word completion function. This is typically operated by the Tab key, and can suggest and automatically complete a word being typed. By default, Readline is set up to be used by `rlcompleter` to complete Python identifiers for the interactive interpreter. If the `readline` module is to be used with a custom completer, a different set of word delimiters should be set.

`readline.set_completer([function])`

Set or remove the completer function. If *function* is specified, it will be used as the new completer function; if omitted or `None`, any completer function already installed is removed. The completer function is called as `function(text, state)`, for *state* in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with *text*.

The installed completer function is invoked by the `entry_func` callback passed to `rl_completion_matches()` in the underlying library. The *text* string comes from the first parameter to the `rl_attempted_completion_function` callback of the underlying library.

`readline.get_completer()`

Get the completer function, or `None` if no completer function has been set.

`readline.get_completion_type()`

Get the type of completion being attempted. This returns the `rl_completion_type` variable in the underlying library as an integer.

`readline.get_begidx()`

`readline.get_endidx()`

Get the beginning or ending index of the completion scope. These indexes are the *start* and *end* arguments passed to the `rl_attempted_completion_function` callback of the underlying library. The values may be different in the same input editing scenario based on the underlying C readline implementation. Ex: `libedit` is known to behave differently than `libreadline`.

`readline.set_completer_delims(string)`

`readline.get_completer_delims()`

Set or get the word delimiters for completion. These determine the start of the word to be considered for completion (the completion scope). These functions access the `rl_completer_word_break_characters` variable in the underlying library.

`readline.set_completion_display_matches_hook([function])`

Set or remove the completion display function. If *function* is specified, it will be used as the new completion display function; if omitted or `None`, any completion display function already installed is removed. This sets or clears the `rl_completion_display_matches_hook` callback in the underlying library. The completion display function is called as `function(substitution, [matches], longest_match_length)` once each time matches need to be displayed.

## 6.7.7 范例

The following example demonstrates how to use the `readline` module's history reading and writing functions to automatically load and save a history file named `.python_history` from the user's home directory. The code below would normally be executed automatically during interactive sessions from the user's `PYTHONSTARTUP` file.

```
import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")
try:
    readline.read_history_file(histfile)
```

(繼續下一頁)

(繼續上一頁)

```

# default history len is -1 (infinite), which may grow unruly
readline.set_history_length(1000)
except FileNotFoundError:
    pass

atexit.register(readline.write_history_file, histfile)

```

This code is actually automatically run when Python is run in interactive mode (see *Readline configuration*).

The following example achieves the same goal but supports concurrent interactive sessions, by only appending the new history.

```

import atexit
import os
import readline

histfile = os.path.join(os.path.expanduser("~"), ".python_history")

try:
    readline.read_history_file(histfile)
    h_len = readline.get_current_history_length()
except FileNotFoundError:
    open(histfile, 'wb').close()
    h_len = 0

def save(prev_h_len, histfile):
    new_h_len = readline.get_current_history_length()
    readline.set_history_length(1000)
    readline.append_history_file(new_h_len - prev_h_len, histfile)
atexit.register(save, h_len, histfile)

```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```

import atexit
import code
import os
import readline

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/console-history")):
        code.InteractiveConsole.__init__(self, locals, filename)
        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except FileNotFoundError:
                pass
            atexit.register(self.save_history, histfile)

    def save_history(self, histfile):
        readline.set_history_length(1000)
        readline.write_history_file(histfile)

```

## 6.8 rlcompleter --- GNU readline 的補全函式

原始碼: `Lib/rlcompleter.py`

The `rlcompleter` module defines a completion function suitable to be passed to `set_completer()` in the `readline` module.

When this module is imported on a Unix platform with the `readline` module available, an instance of the `Completer` class is automatically created and its `complete()` method is set as the `readline completer`. The method provides completion of valid Python identifiers and keywords.

範例:

```
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
>>> readline. <TAB PRESSED>
readline.__doc__          readline.get_line_buffer(  readline.read_init_file(
readline.__file__        readline.insert_text(      readline.set_completer(
readline.__name__        readline.parse_and_bind(
>>> readline.
```

The `rlcompleter` module is designed for use with Python's interactive mode. Unless Python is run with the `-S` option, the module is automatically imported and configured (see [Readline configuration](#)).

On platforms without `readline`, the `Completer` class defined by this module can still be used for custom purposes.

**class** `rlcompleter.Completer`

Completer objects have the following method:

**complete** (*text*, *state*)

Return the next possible completion for *text*.

When called by the `readline` module, this method is called successively with `state == 0, 1, 2, ...` until the method returns `None`.

If called for *text* that doesn't include a period character ('.'), it will complete from names currently defined in `__main__`, `builtins` and keywords (as defined by the `keyword` module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()`) up to the last part, and find matches for the rest via the `dir()` function. Any exception raised during the evaluation of the expression is caught, silenced and `None` is returned.

---

## 二進位資料服務

---

本章所描述的模組提供了一些基本的二進位資料操作服務。而針對二進位資料的其他操作——尤其是關於檔案格式和網路協定的部分——則會在相關章節中詳細描述。

一些在文本處理 (*Text Processing*) 服務中提及的函式庫也可處理 ASCII 相容的二進位格式 (例如, *re*) 及所有的二進位資料 (例如, *difflib*)。

此外, 請參閱 Python 內建的二進位資料類型的文件, 詳情請參考 *Binary Sequence Types --- bytes, bytearray, memoryview*。

### 7.1 struct --- 將位元組直譯內建打包起來的二進位資料

原始碼: [Lib/struct.py](#)

---

This module converts between Python values and C structs represented as Python *bytes* objects. Compact *format strings* describe the intended conversions to/from Python values. The module's functions and objects can be used for two largely distinct applications, data exchange with external sources (files or network connections), or data transfer between the Python application and the C layer.

#### 備註

When no prefix character is given, native mode is the default. It packs or unpacks data based on the platform and compiler on which the Python interpreter was built. The result of packing a given C struct includes pad bytes which maintain proper alignment for the C types involved; similarly, alignment is taken into account when unpacking. In contrast, when communicating data between external sources, the programmer is responsible for defining byte ordering and padding between elements. See *Byte Order, Size, and Alignment* for details.

Several *struct* functions (and methods of *Struct*) take a *buffer* argument. This refers to objects that implement the *buffer* protocol and provide either a readable or read-writable buffer. The most common types used for that purpose are *bytes* and *bytearray*, but many other types that can be viewed as an array of bytes implement the *buffer* protocol, so that they can be read/filled without additional copying from a *bytes* object.

## 7.1.1 函式與例外

The module defines the following exception and functions:

**exception** `struct.error`

Exception raised on various occasions; argument is a string describing what is wrong.

`struct.pack` (*format*, *v1*, *v2*, ...)

Return a bytes object containing the values *v1*, *v2*, ... packed according to the format string *format*. The arguments must match the values required by the format exactly.

`struct.pack_into` (*format*, *buffer*, *offset*, *v1*, *v2*, ...)

Pack the values *v1*, *v2*, ... according to the format string *format* and write the packed bytes into the writable buffer *buffer* starting at position *offset*. Note that *offset* is a required argument.

`struct.unpack` (*format*, *buffer*)

Unpack from the buffer *buffer* (presumably packed by `pack(format, ...)`) according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes must match the size required by the format, as reflected by `calcsize()`.

`struct.unpack_from` (*format*, *i*, *buffer*, *offset=0*)

Unpack from *buffer* starting at position *offset*, according to the format string *format*. The result is a tuple even if it contains exactly one item. The buffer's size in bytes, starting at position *offset*, must be at least the size required by the format, as reflected by `calcsize()`.

`struct.iter_unpack` (*format*, *buffer*)

Iteratively unpack from the buffer *buffer* according to the format string *format*. This function returns an iterator which will read equally sized chunks from the buffer until all its contents have been consumed. The buffer's size in bytes must be a multiple of the size required by the format, as reflected by `calcsize()`.

Each iteration yields a tuple as specified by the format string.

在 3.4 版被加入。

`struct.calcsize` (*format*)

Return the size of the struct (and hence of the bytes object produced by `pack(format, ...)`) corresponding to the format string *format*.

## 7.1.2 Format Strings

Format strings describe the data layout when packing and unpacking data. They are built up from *format characters*, which specify the type of data being packed/unpacked. In addition, special characters control the *byte order*, *size* and *alignment*. Each format string consists of an optional prefix character which describes the overall properties of the data and one or more format characters which describe the actual data values and padding.

### Byte Order, Size, and Alignment

By default, C types are represented in the machine's native format and byte order, and properly aligned by skipping pad bytes if necessary (according to the rules used by the C compiler). This behavior is chosen so that the bytes of a packed struct correspond exactly to the memory layout of the corresponding C struct. Whether to use native byte ordering and padding or standard formats depends on the application.

Alternatively, the first character of the format string can be used to indicate the byte order, size and alignment of the packed data, according to the following table:

Character	Byte order	Size	Alignment
@	native	native	native
=	native	standard	none
<	little-endian	standard	none
>	big-endian	standard	none
!	network (= big-endian)	standard	none

If the first character is not one of these, '@' is assumed.

### 備

The number 1023 (0x3ff in hexadecimal) has the following byte representations:

- 03 ff in big-endian (>)
- ff 03 in little-endian (<)

Python example:

```
>>> import struct
>>> struct.pack('>h', 1023)
b'\x03\xff'
>>> struct.pack('<h', 1023)
b'\xff\x03'
```

Native byte order is big-endian or little-endian, depending on the host system. For example, Intel x86, AMD64 (x86-64), and Apple M1 are little-endian; IBM z and many legacy architectures are big-endian. Use `sys.byteorder` to check the endianness of your system.

Native size and alignment are determined using the C compiler's `sizeof` expression. This is always combined with native byte order.

Standard size depends only on the format character; see the table in the *Format Characters* section.

Note the difference between '@' and '=': both use native byte order, but the size and alignment of the latter is standardized.

The form '!' represents the network byte order which is always big-endian as defined in IETF RFC 1700.

There is no way to indicate non-native byte order (force byte-swapping); use the appropriate choice of '<' or '>'.

解:

- (1) Padding is only automatically added between successive structure members. No padding is added at the beginning or the end of the encoded struct.
- (2) No padding is added when using non-native size and alignment, e.g. with '<', '>', '=', and '!'.  
 (3) To align the end of a structure to the alignment requirement of a particular type, end the format with the code for that type with a repeat count of zero. See 範例.

## Format Characters

Format characters have the following meaning; the conversion between C and Python values should be obvious given their types. The 'Standard size' column refers to the size of the packed value in bytes when using standard size; that is, when the format string starts with one of '<', '>', '!' or '='. When using native size, the size of the packed value is platform-dependent.

Format	C Type	Python type	Standard size	解
x	pad byte	no value		(7)
c	char	bytes of length 1	1	
b	signed char	integer	1	(1), (2)
B	unsigned char	integer	1	(2)
?	_Bool	bool	1	(1)
h	short	integer	2	(2)
H	unsigned short	integer	2	(2)
i	int	integer	4	(2)
I	unsigned int	integer	4	(2)
l	long	integer	4	(2)
L	unsigned long	integer	4	(2)
q	long long	integer	8	(2)
Q	unsigned long long	integer	8	(2)
n	ssize_t	integer		(3)
N	size_t	integer		(3)
e	(6)	float	2	(4)
f	float	float	4	(4)
d	double	float	8	(4)
s	char[]	bytes		(9)
p	char[]	bytes		(8)
P	void*	integer		(5)

在 3.3 版的變更: 新增 'n' 與 'N' 格式的支援。

在 3.6 版的變更: 新增 'e' 格式的支援。

解:

- (1) The '?' conversion code corresponds to the `_Bool` type defined by C standards since C99. In standard mode, it is represented by one byte.
- (2) When attempting to pack a non-integer using any of the integer conversion codes, if the non-integer has a `__index__()` method then that method is called to convert the argument to an integer before packing.

在 3.2 版的變更: Added use of the `__index__()` method for non-integers.

- (3) The 'n' and 'N' conversion codes are only available for the native size (selected as the default or with the '@' byte order character). For the standard size, you can use whichever of the other integer formats fits your application.
- (4) For the 'f', 'd' and 'e' conversion codes, the packed representation uses the IEEE 754 binary32, binary64 or binary16 format (for 'f', 'd' or 'e' respectively), regardless of the floating-point format used by the platform.
- (5) The 'P' format character is only available for the native byte ordering (selected as the default or with the '@' byte order character). The byte order character '=' chooses to use little- or big-endian ordering based on the host system. The struct module does not interpret this as native ordering, so the 'P' format is not available.
- (6) The IEEE 754 binary16 "half precision" type was introduced in the 2008 revision of the [IEEE 754 standard](#). It has a sign bit, a 5-bit exponent and 11-bit precision (with 10 bits explicitly stored), and can represent numbers between approximately  $6.1e-05$  and  $6.5e+04$  at full precision. This type is not widely supported by C compilers: on a typical machine, an unsigned short can be used for storage, but not for math operations. See the Wikipedia page on the [half-precision floating-point format](#) for more information.
- (7) When packing, 'x' inserts one NUL byte.
- (8) The 'p' format character encodes a "Pascal string", meaning a short variable-length string stored in a *fixed number of bytes*, given by the count. The first byte stored is the length of the string, or 255, whichever is smaller. The bytes of the string follow. If the string passed in to `pack()` is too long (longer than the count minus 1), only the leading `count-1` bytes of the string are stored. If the string is shorter than `count-1`, it

is padded with null bytes so that exactly count bytes in all are used. Note that for `unpack()`, the 'p' format character consumes count bytes, but that the string returned can never contain more than 255 bytes.

- (9) For the 's' format character, the count is interpreted as the length of the bytes, not a repeat count like for the other format characters; for example, '10s' means a single 10-byte string mapping to or from a single Python byte string, while '10c' means 10 separate one byte character elements (e.g., cccccccccc) mapping to or from ten different Python byte objects. (See 範例 for a concrete demonstration of the difference.) If a count is not given, it defaults to 1. For packing, the string is truncated or padded with null bytes as appropriate to make it fit. For unpacking, the resulting bytes object always has exactly the specified number of bytes. As a special case, '0s' means a single, empty string (while '0c' means 0 characters).

A format character may be preceded by an integral repeat count. For example, the format string '4h' means exactly the same as 'hhhh'.

Whitespace characters between formats are ignored; a count and its format must not contain whitespace though.

When packing a value `x` using one of the integer formats ('b', 'B', 'h', 'H', 'i', 'I', 'l', 'L', 'q', 'Q'), if `x` is outside the valid range for that format then `struct.error` is raised.

在 3.1 版的變更: Previously, some of the integer formats wrapped out-of-range values and raised `DeprecationWarning` instead of `struct.error`.

For the '?' format character, the return value is either `True` or `False`. When packing, the truth value of the argument object is used. Either 0 or 1 in the native or standard bool representation will be packed, and any non-zero value will be `True` when unpacking.

## 範例

### 備 F

Native byte order examples (designated by the '@' format prefix or lack of any prefix character) may not match what the reader's machine produces as that depends on the platform and compiler.

Pack and unpack integers of three different sizes, using big endian ordering:

```
>>> from struct import *
>>> pack(">bh1", 1, 2, 3)
b'\x01\x00\x02\x00\x00\x00\x03'
>>> unpack('>bh1', b'\x01\x00\x02\x00\x00\x00\x03')
(1, 2, 3)
>>> calcsize('>bh1')
7
```

Attempt to pack an integer which is too large for the defined field:

```
>>> pack(">h", 99999)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
struct.error: 'h' format requires -32768 <= number <= 32767
```

Demonstrate the difference between 's' and 'c' format characters:

```
>>> pack("@ccc", b'1', b'2', b'3')
b'123'
>>> pack("@3s", b'123')
b'123'
```

Unpacked fields can be named by assigning them to variables or by wrapping the result in a named tuple:

```
>>> record = b'raymond \x32\x12\x08\x01\x08'
>>> name, serialnum, school, gradelevel = unpack('<10sHHb', record)
```

(繼續下一頁)

(繼續上一頁)

```
>>> from collections import namedtuple
>>> Student = namedtuple('Student', 'name serialnum school gradelevel')
>>> Student._make(unpack('<10sHHb', record))
Student(name=b'raymond', serialnum=4658, school=264, gradelevel=8)
```

The ordering of format characters may have an impact on size in native mode since padding is implicit. In standard mode, the user is responsible for inserting any desired padding. Note in the first `pack` call below that three NUL bytes were added after the packed '#' to align the following integer on a four-byte boundary. In this example, the output was produced on a little endian machine:

```
>>> pack('@ci', b'#', 0x12131415)
b'\x00\x00\x00\x15\x14\x13\x12'
>>> pack('@ic', 0x12131415, b'#')
b'\x15\x14\x13\x12#'
>>> calcsize('@ci')
8
>>> calcsize('@ic')
5
```

The following format '`llh01`' results in two pad bytes being added at the end, assuming the platform's longs are aligned on 4-byte boundaries:

```
>>> pack('@llh01', 1, 2, 3)
b'\x00\x00\x00\x01\x00\x00\x00\x02\x00\x03\x00\x00'
```

## 7.1.3 Applications

Two main applications for the `struct` module exist, data interchange between Python and C code within an application or another application compiled using the same compiler (*native formats*), and data interchange between applications using agreed upon data layout (*standard formats*). Generally speaking, the format strings constructed for these two domains are distinct.

### Native Formats

When constructing format strings which mimic native layouts, the compiler and machine architecture determine byte ordering and padding. In such cases, the `@` format character should be used to specify native byte ordering and data sizes. Internal pad bytes are normally inserted automatically. It is possible that a zero-repeat format code will be needed at the end of a format string to round up to the correct byte boundary for proper alignment of consecutive chunks of data.

Consider these two simple examples (on a 64-bit, little-endian machine):

```
>>> calcsize('@lh1')
24
>>> calcsize('@llh')
18
```

Data is not padded to an 8-byte boundary at the end of the second format string without the use of extra padding. A zero-repeat format code solves that problem:

```
>>> calcsize('@11h01')
24
```

The 'x' format code can be used to specify the repeat, but for native formats it is better to use a zero-repeat format like '01'.

By default, native byte ordering and alignment is used, but it is better to be explicit and use the '@' prefix character.

## Standard Formats

When exchanging data beyond your process such as networking or storage, be precise. Specify the exact byte order, size, and alignment. Do not assume they match the native order of a particular machine. For example, network byte order is big-endian, while many popular CPUs are little-endian. By defining this explicitly, the user need not care about the specifics of the platform their code is running on. The first character should typically be < or > (or !). Padding is the responsibility of the programmer. The zero-repeat format character won't work. Instead, the user must explicitly add 'x' pad bytes where needed. Revisiting the examples from the previous section, we have:

```
>>> calcsize('<qh6xq')
24
>>> pack('<qh6xq', 1, 2, 3) == pack('@hl', 1, 2, 3)
True
>>> calcsize('@11h')
18
>>> pack('@11h', 1, 2, 3) == pack('<qqh', 1, 2, 3)
True
>>> calcsize('<qqh6x')
24
>>> calcsize('@11h01')
24
>>> pack('@11h01', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
True
```

The above results (executed on a 64-bit machine) aren't guaranteed to match when executed on different machines. For example, the examples below were executed on a 32-bit machine:

```
>>> calcsize('<qqh6x')
24
>>> calcsize('@11h01')
12
>>> pack('@11h01', 1, 2, 3) == pack('<qqh6x', 1, 2, 3)
False
```

## 7.1.4 Classes

The `struct` module also defines the following type:

**class** `struct.Struct` (*format*)

Return a new Struct object which writes and reads binary data according to the format string *format*. Creating a Struct object once and calling its methods is more efficient than calling module-level functions with the same format since the format string is only compiled once.

### 備 F

The compiled versions of the most recent format strings passed to the module-level functions are cached, so programs that use only a few format strings needn't worry about reusing a single `Struct` instance.

Compiled Struct objects support the following methods and attributes:

**pack** (*v1*, *v2*, ...)

Identical to the `pack()` function, using the compiled format. (`len(result)` will equal *size*.)

**pack\_into** (*buffer*, *offset*, *v1*, *v2*, ...)

Identical to the `pack_into()` function, using the compiled format.

**unpack** (*buffer*)

Identical to the `unpack()` function, using the compiled format. The buffer's size in bytes must equal *size*.

**unpack\_from** (*buffer*, *offset*=0)

Identical to the `unpack_from()` function, using the compiled format. The buffer's size in bytes, starting at position *offset*, must be at least *size*.

**iter\_unpack** (*buffer*)

Identical to the `iter_unpack()` function, using the compiled format. The buffer's size in bytes must be a multiple of *size*.

在 3.4 版被加入。

**format**

The format string used to construct this Struct object.

在 3.7 版的變更: The format string type is now *str* instead of *bytes*.

**size**

The calculated size of the struct (and hence of the bytes object produced by the `pack()` method) corresponding to *format*.

在 3.13 版的變更: The `repr()` of structs has changed. It is now:

```
>>> Struct('i')
Struct('i')
```

## 7.2 codecs --- 編解碼器 F F 表和基底類 F

原始碼: [Lib/codecs.py](#)

This module defines base classes for standard Python codecs (encoders and decoders) and provides access to the internal Python codec registry, which manages the codec and error handling lookup process. Most standard codecs are *text encodings*, which encode text to bytes (and decode bytes to text), but there are also codecs provided that encode text to text, and bytes to bytes. Custom codecs may encode and decode between arbitrary types, but some module features are restricted to be used specifically with *text encodings* or with codecs that encode to *bytes*.

The module defines the following functions for encoding and decoding with any codec:

`codecs.encode` (*obj*, *encoding*='utf-8', *errors*='strict')

Encodes *obj* using the codec registered for *encoding*.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that encoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeEncodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

`codecs.decode` (*obj*, *encoding*='utf-8', *errors*='strict')

Decodes *obj* using the codec registered for *encoding*.

*Errors* may be given to set the desired error handling scheme. The default error handler is 'strict' meaning that decoding errors raise *ValueError* (or a more codec specific subclass, such as *UnicodeDecodeError*). Refer to *Codec Base Classes* for more information on codec error handling.

The full details for each codec can also be looked up directly:

`codecs.lookup(encoding)`

Looks up the codec info in the Python codec registry and returns a *CodecInfo* object as defined below.

Encodings are first looked up in the registry's cache. If not found, the list of registered search functions is scanned. If no *CodecInfo* object is found, a *LookupError* is raised. Otherwise, the *CodecInfo* object is stored in the cache and returned to the caller.

**class** `codecs.CodecInfo` (*encode, decode, streamreader=None, streamwriter=None, incrementalencoder=None, incrementaldecoder=None, name=None*)

Codec details when looking up the codec registry. The constructor arguments are stored in attributes of the same name:

**name**

The name of the encoding.

**encode**

**decode**

The stateless encoding and decoding functions. These must be functions or methods which have the same interface as the *encode()* and *decode()* methods of Codec instances (see *Codec Interface*). The functions or methods are expected to work in a stateless mode.

**incrementalencoder**

**incrementaldecoder**

Incremental encoder and decoder classes or factory functions. These have to provide the interface defined by the base classes *IncrementalEncoder* and *IncrementalDecoder*, respectively. Incremental codecs can maintain state.

**streamwriter**

**streamreader**

Stream writer and reader classes or factory functions. These have to provide the interface defined by the base classes *StreamWriter* and *StreamReader*, respectively. Stream codecs can maintain state.

To simplify access to the various codec components, the module provides these additional functions which use *lookup()* for the codec lookup:

`codecs.getencoder(encoding)`

Look up the codec for the given encoding and return its encoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getdecoder(encoding)`

Look up the codec for the given encoding and return its decoder function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getincrementalencoder(encoding)`

Look up the codec for the given encoding and return its incremental encoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental encoder.

`codecs.getincrementaldecoder(encoding)`

Look up the codec for the given encoding and return its incremental decoder class or factory function.

Raises a *LookupError* in case the encoding cannot be found or the codec doesn't support an incremental decoder.

`codecs.getreader(encoding)`

Look up the codec for the given encoding and return its *StreamReader* class or factory function.

Raises a *LookupError* in case the encoding cannot be found.

`codecs.getwriter(encoding)`

Look up the codec for the given encoding and return its `StreamWriter` class or factory function.

Raises a `LookupError` in case the encoding cannot be found.

Custom codecs are made available by registering a suitable codec search function:

`codecs.register(search_function)`

Register a codec search function. Search functions are expected to take one argument, being the encoding name in all lower case letters with hyphens and spaces converted to underscores, and return a `CodecInfo` object. In case a search function cannot find a given encoding, it should return `None`.

在 3.9 版的變更: Hyphens and spaces are converted to underscore.

`codecs.unregister(search_function)`

Unregister a codec search function and clear the registry's cache. If the search function is not registered, do nothing.

在 3.10 版被加入.

While the builtin `open()` and the associated `io` module are the recommended approach for working with encoded text files, this module provides additional utility functions and classes that allow the use of a wider range of codecs when working with binary files:

`codecs.open(filename, mode='r', encoding=None, errors='strict', buffering=-1)`

Open an encoded file using the given `mode` and return an instance of `StreamReaderWriter`, providing transparent encoding/decoding. The default file mode is 'r', meaning to open the file in read mode.

#### 備 F

If `encoding` is not `None`, then the underlying encoded files are always opened in binary mode. No automatic conversion of '\n' is done on reading and writing. The `mode` argument may be any binary mode acceptable to the built-in `open()` function; the 'b' is automatically added.

`encoding` specifies the encoding which is to be used for the file. Any encoding that encodes to and decodes from bytes is allowed, and the data types supported by the file methods depend on the codec used.

`errors` may be given to define the error handling. It defaults to 'strict' which causes a `ValueError` to be raised in case an encoding error occurs.

`buffering` has the same meaning as for the built-in `open()` function. It defaults to -1 which means that the default buffer size will be used.

在 3.11 版的變更: The 'U' mode has been removed.

`codecs.EncodedFile(file, data_encoding, file_encoding=None, errors='strict')`

Return a `StreamRecoder` instance, a wrapped version of `file` which provides transparent transcoding. The original file is closed when the wrapped version is closed.

Data written to the wrapped file is decoded according to the given `data_encoding` and then written to the original file as bytes using `file_encoding`. Bytes read from the original file are decoded according to `file_encoding`, and the result is encoded using `data_encoding`.

If `file_encoding` is not given, it defaults to `data_encoding`.

`errors` may be given to define the error handling. It defaults to 'strict', which causes `ValueError` to be raised in case an encoding error occurs.

`codecs.iterencode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental encoder to iteratively encode the input provided by `iterator`. This function is a `generator`. The `errors` argument (as well as any other keyword argument) is passed through to the incremental encoder.

This function requires that the codec accept text `str` objects to encode. Therefore it does not support bytes-to-bytes encoders such as `base64_codec`.

`codecs.iterdecode(iterator, encoding, errors='strict', **kwargs)`

Uses an incremental decoder to iteratively decode the input provided by *iterator*. This function is a *generator*. The *errors* argument (as well as any other keyword argument) is passed through to the incremental decoder.

This function requires that the codec accept *bytes* objects to decode. Therefore it does not support text-to-text encoders such as `rot_13`, although `rot_13` may be used equivalently with `iterencode()`.

The module also provides the following constants which are useful for reading and writing to platform dependent files:

```
codecs.BOM
codecs.BOM_BE
codecs.BOM_LE
codecs.BOM_UTF8
codecs.BOM_UTF16
codecs.BOM_UTF16_BE
codecs.BOM_UTF16_LE
codecs.BOM_UTF32
codecs.BOM_UTF32_BE
codecs.BOM_UTF32_LE
```

These constants define various byte sequences, being Unicode byte order marks (BOMs) for several encodings. They are used in UTF-16 and UTF-32 data streams to indicate the byte order used, and in UTF-8 as a Unicode signature. `BOM_UTF16` is either `BOM_UTF16_BE` or `BOM_UTF16_LE` depending on the platform's native byte order, `BOM` is an alias for `BOM_UTF16`, `BOM_LE` for `BOM_UTF16_LE` and `BOM_BE` for `BOM_UTF16_BE`. The others represent the BOM in UTF-8 and UTF-32 encodings.

## 7.2.1 Codec Base Classes

The `codecs` module defines a set of base classes which define the interfaces for working with codec objects, and can also be used as the basis for custom codec implementations.

Each codec has to define four interfaces to make it usable as codec in Python: stateless encoder, stateless decoder, stream reader and stream writer. The stream reader and writers typically reuse the stateless encoder/decoder to implement the file protocols. Codec authors also need to define how the codec will handle encoding and decoding errors.

### Error Handlers

To simplify and standardize error handling, codecs may implement different error handling schemes by accepting the *errors* string argument:

```
>>> 'German ß, ʃ'.encode(encoding='ascii', errors='backslashreplace')
b'German \\xdf, \\u266c'
>>> 'German ß, ʃ'.encode(encoding='ascii', errors='xmlcharrefreplace')
b'German &#223;;, &#9836;'
```

The following error handlers can be used with all Python *Standard Encodings* codecs:

Value	含義
'strict'	Raise <code>UnicodeError</code> (or a subclass), this is the default. Implemented in <code>strict_errors()</code> .
'ignore'	Ignore the malformed data and continue without further notice. Implemented in <code>ignore_errors()</code> .
'replace'	Replace with a replacement marker. On encoding, use <code>?</code> (ASCII character). On decoding, use <code>?</code> (U+FFFD, the official REPLACEMENT CHARACTER). Implemented in <code>replace_errors()</code> .
'backslashreplace'	Replace with backslashed escape sequences. On encoding, use hexadecimal form of Unicode code point with formats <code>\xhh \uxxxx \Uxxxxxxxx</code> . On decoding, use hexadecimal form of byte value with format <code>\xhh</code> . Implemented in <code>backslashreplace_errors()</code> .
'surrogateescape'	On decoding, replace byte with individual surrogate code ranging from U+DC80 to U+DCFF. This code will then be turned back into the same byte when the 'surrogateescape' error handler is used when encoding the data. (See <a href="#">PEP 383</a> for more.)

The following error handlers are only applicable to encoding (within *text encodings*):

Value	含義
'xmlcharref'	Replace with XML/HTML numeric character reference, which is a decimal form of Unicode code point with format <code>&amp;#num;</code> . Implemented in <code>xmlcharrefreplace_errors()</code> .
'namereplace'	Replace with <code>\N{...}</code> escape sequences, what appears in the braces is the Name property from Unicode Character Database. Implemented in <code>namereplace_errors()</code> .

In addition, the following error handler is specific to the given codecs:

Value	Codecs	含義
'surrog'	utf-8, utf-16, utf-32, utf-16-be, utf-16-le, utf-32-be, utf-32-le	Allow encoding and decoding surrogate code point (U+D800 - U+DFFF) as normal code point. Otherwise these codecs treat the presence of surrogate code point in <i>str</i> as an error.

在 3.1 版被加入: The 'surrogateescape' and 'surrogatepass' error handlers.

在 3.4 版的變更: The 'surrogatepass' error handler now works with utf-16\* and utf-32\* codecs.

在 3.5 版被加入: The 'namereplace' error handler.

在 3.5 版的變更: The 'backslashreplace' error handler now works with decoding and translating.

The set of allowed values can be extended by registering a new named error handler:

`codecs.register_error(name, error_handler)`

Register the error handling function *error\_handler* under the name *name*. The *error\_handler* argument will be called during encoding and decoding in case of an error, when *name* is specified as the errors parameter.

For encoding, *error\_handler* will be called with a `UnicodeEncodeError` instance, which contains information about the location of the error. The error handler must either raise this or a different exception, or return a tuple with a replacement for the unencodable part of the input and a position where encoding should continue. The replacement may be either *str* or *bytes*. If the replacement is bytes, the encoder will simply copy them into the output buffer. If the replacement is a string, the encoder will encode the replacement. Encoding continues on original input at the specified position. Negative position values will be treated as being relative to the end of the input string. If the resulting position is out of bound an `IndexError` will be raised.

Decoding and translating works similarly, except `UnicodeDecodeError` or `UnicodeTranslateError` will be passed to the handler and that the replacement from the error handler will be put into the output directly.

Previously registered error handlers (including the standard error handlers) can be looked up by name:

`codecs.lookup_error` (*name*)

Return the error handler previously registered under the name *name*.

Raises a `LookupError` in case the handler cannot be found.

The following standard error handlers are also made available as module level functions:

`codecs.strict_errors` (*exception*)

Implements the 'strict' error handling.

Each encoding or decoding error raises a `UnicodeError`.

`codecs.ignore_errors` (*exception*)

Implements the 'ignore' error handling.

Malformed data is ignored; encoding or decoding is continued without further notice.

`codecs.replace_errors` (*exception*)

Implements the 'replace' error handling.

Substitutes ? (ASCII character) for encoding errors or ◆ (U+FFFD, the official REPLACEMENT CHARACTER) for decoding errors.

`codecs.backslashreplace_errors` (*exception*)

Implements the 'backslashreplace' error handling.

Malformed data is replaced by a backslashed escape sequence. On encoding, use the hexadecimal form of Unicode code point with formats `\xhh` `\uxxxx` `\Uxxxxxxxx`. On decoding, use the hexadecimal form of byte value with format `\xhh`.

在 3.5 版的變更: Works with decoding and translating.

`codecs.xmlcharrefreplace_errors` (*exception*)

Implements the 'xmlcharrefreplace' error handling (for encoding within *text encoding* only).

The unencodable character is replaced by an appropriate XML/HTML numeric character reference, which is a decimal form of Unicode code point with format `&#num;`.

`codecs.namereplace_errors` (*exception*)

Implements the 'namereplace' error handling (for encoding within *text encoding* only).

The unencodable character is replaced by a `\N{...}` escape sequence. The set of characters that appear in the braces is the Name property from Unicode Character Database. For example, the German lowercase letter 'ß' will be converted to byte sequence `\N{LATIN SMALL LETTER SHARP S}`.

在 3.5 版被加入.

## Stateless Encoding and Decoding

The base `Codec` class defines these methods which also define the function interfaces of the stateless encoder and decoder:

**class** `codecs.Codec`

**encode** (*input*, *errors*='strict')

Encodes the object *input* and returns a tuple (output object, length consumed). For instance, *text encoding* converts a string object to a bytes object using a particular character set encoding (e.g., `cp1252` or `iso-8859-1`).

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the `Codec` instance. Use `StreamWriter` for codecs which have to keep state in order to make encoding efficient.

The encoder must be able to handle zero length input and return an empty object of the output object type in this situation.

**decode** (*input*, *errors*='strict')

Decodes the object *input* and returns a tuple (output object, length consumed). For instance, for a *text encoding*, decoding converts a bytes object encoded using a particular character set encoding to a string object.

For text encodings and bytes-to-bytes codecs, *input* must be a bytes object or one which provides the read-only buffer interface -- for example, buffer objects and memory mapped files.

The *errors* argument defines the error handling to apply. It defaults to 'strict' handling.

The method may not store state in the *Codec* instance. Use *StreamReader* for codecs which have to keep state in order to make decoding efficient.

The decoder must be able to handle zero length input and return an empty object of the output object type in this situation.

## Incremental Encoding and Decoding

The *IncrementalEncoder* and *IncrementalDecoder* classes provide the basic interface for incremental encoding and decoding. Encoding/decoding the input isn't done with one call to the stateless encoder/decoder function, but with multiple calls to the *encode()*/*decode()* method of the incremental encoder/decoder. The incremental encoder/decoder keeps track of the encoding/decoding process during method calls.

The joined output of calls to the *encode()*/*decode()* method is the same as if all the single inputs were joined into one, and this input was encoded/decoded with the stateless encoder/decoder.

### IncrementalEncoder 物件

The *IncrementalEncoder* class is used for encoding an input in multiple steps. It defines the following methods which every incremental encoder must define in order to be compatible with the Python codec registry.

**class** `codecs.IncrementalEncoder` (*errors*='strict')

Constructor for an *IncrementalEncoder* instance.

All incremental encoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalEncoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalEncoder* object.

**encode** (*object*, *final*=False)

Encodes *object* (taking the current state of the encoder into account) and returns the resulting encoded object. If this is the last call to *encode()* *final* must be true (the default is false).

**reset** ()

Reset the encoder to the initial state. The output is discarded: call `.encode(object, final=True)`, passing an empty byte or text string if necessary, to reset the encoder and to get the output.

**getstate** ()

Return the current state of the encoder which must be an integer. The implementation should make sure that 0 is the most common state. (States that are more complicated than integers can be converted into an integer by marshaling/pickling the state and encoding the bytes of the resulting string into an integer.)

**setstate** (*state*)

Set the state of the encoder to *state*. *state* must be an encoder state returned by *getstate()*.

## IncrementalDecoder 物件

The *IncrementalDecoder* class is used for decoding an input in multiple steps. It defines the following methods which every incremental decoder must define in order to be compatible with the Python codec registry.

**class** `codecs.IncrementalDecoder` (*errors*='strict')

Constructor for an *IncrementalDecoder* instance.

All incremental decoders must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *IncrementalDecoder* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for possible values.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *IncrementalDecoder* object.

**decode** (*object*, *final*=False)

Decodes *object* (taking the current state of the decoder into account) and returns the resulting decoded object. If this is the last call to *decode()* *final* must be true (the default is false). If *final* is true the decoder must decode the input completely and must flush all buffers. If this isn't possible (e.g. because of incomplete byte sequences at the end of the input) it must initiate error handling just like in the stateless case (which might raise an exception).

**reset** ()

Reset the decoder to the initial state.

**getstate** ()

Return the current state of the decoder. This must be a tuple with two items, the first must be the buffer containing the still undecoded input. The second must be an integer and can be additional state info. (The implementation should make sure that 0 is the most common additional state info.) If this additional state info is 0 it must be possible to set the decoder to the state which has no input buffered and 0 as the additional state info, so that feeding the previously buffered input to the decoder returns it to the previous state without producing any output. (Additional state info that is more complicated than integers can be converted into an integer by marshaling/pickling the info and encoding the bytes of the resulting string into an integer.)

**setstate** (*state*)

Set the state of the decoder to *state*. *state* must be a decoder state returned by *getstate()*.

## Stream Encoding and Decoding

The *StreamWriter* and *StreamReader* classes provide generic working interfaces which can be used to implement new encoding submodules very easily. See `encodings.utf_8` for an example of how this is done.

## StreamWriter 物件

The *StreamWriter* class is a subclass of *Codec* and defines the following methods which every stream writer must define in order to be compatible with the Python codec registry.

**class** `codecs.StreamWriter` (*stream*, *errors*='strict')

Constructor for a *StreamWriter* instance.

All stream writers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for writing text or binary data, as appropriate for the specific codec.

The *StreamWriter* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamWriter* object.

**write** (*object*)

Writes the object's contents encoded to the stream.

**writelines** (*list*)

Writes the concatenated iterable of strings to the stream (possibly by reusing the *write()* method). Infinite or very large iterables are not supported. The standard bytes-to-bytes codecs do not support this method.

**reset** ()

Resets the codec buffers used for keeping internal state.

Calling this method should ensure that the data on the output is put into a clean state that allows appending of new fresh data without having to rescan the whole stream to recover state.

In addition to the above methods, the *StreamWriter* must also inherit all other methods and attributes from the underlying stream.

## StreamReader 物件

The *StreamReader* class is a subclass of *Codec* and defines the following methods which every stream reader must define in order to be compatible with the Python codec registry.

**class** `codecs.StreamReader` (*stream*, *errors*='strict')

Constructor for a *StreamReader* instance.

All stream readers must provide this constructor interface. They are free to add additional keyword arguments, but only the ones defined here are used by the Python codec registry.

The *stream* argument must be a file-like object open for reading text or binary data, as appropriate for the specific codec.

The *StreamReader* may implement different error handling schemes by providing the *errors* keyword argument. See *Error Handlers* for the standard error handlers the underlying stream codec may support.

The *errors* argument will be assigned to an attribute of the same name. Assigning to this attribute makes it possible to switch between different error handling strategies during the lifetime of the *StreamReader* object.

The set of allowed values for the *errors* argument can be extended with *register\_error()*.

**read** (*size*=-1, *chars*=-1, *firstline*=False)

Decodes data from the stream and returns the resulting object.

The *chars* argument indicates the number of decoded code points or bytes to return. The *read()* method will never return more data than requested, but it might return less, if there is not enough available.

The *size* argument indicates the approximate maximum number of encoded bytes or code points to read for decoding. The decoder can modify this setting as appropriate. The default value -1 indicates to read and decode as much as possible. This parameter is intended to prevent having to decode huge files in one step.

The *firstline* flag indicates that it would be sufficient to only return the first line, if there are decoding errors on later lines.

The method should use a greedy read strategy meaning that it should read as much data as is allowed within the definition of the encoding and the given size, e.g. if optional encoding endings or state markers are available on the stream, these should be read too.

**readline** (*size*=None, *keepends*=True)

Read one line from the input stream and return the decoded data.

*size*, if given, is passed as size argument to the stream's *read()* method.

If *keepends* is false line-endings will be stripped from the lines returned.

**readlines** (*sizehint=None, keepends=True*)

Read all lines available on the input stream and return them as a list of lines.

Line-endings are implemented using the codec's *decode()* method and are included in the list entries if *keepends* is true.

*sizehint*, if given, is passed as the *size* argument to the stream's *read()* method.

**reset()**

Resets the codec buffers used for keeping internal state.

Note that no stream repositioning should take place. This method is primarily intended to be able to recover from decoding errors.

In addition to the above methods, the *StreamReader* must also inherit all other methods and attributes from the underlying stream.

### StreamReaderWriter 物件

The *StreamReaderWriter* is a convenience class that allows wrapping streams which work in both read and write modes.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

```
class codecs.StreamReaderWriter(stream, Reader, Writer, errors='strict')
```

Creates a *StreamReaderWriter* instance. *stream* must be a file-like object. *Reader* and *Writer* must be factory functions or classes providing the *StreamReader* and *StreamWriter* interface resp. Error handling is done in the same way as defined for the stream readers and writers.

*StreamReaderWriter* instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

### StreamRecoder 物件

The *StreamRecoder* translates data from one encoding to another, which is sometimes useful when dealing with different encoding environments.

The design is such that one can use the factory functions returned by the *lookup()* function to construct the instance.

```
class codecs.StreamRecoder(stream, encode, decode, Reader, Writer, errors='strict')
```

Creates a *StreamRecoder* instance which implements a two-way conversion: *encode* and *decode* work on the frontend —the data visible to code calling *read()* and *write()*, while *Reader* and *Writer* work on the backend —the data in *stream*.

You can use these objects to do transparent transcodings, e.g., from Latin-1 to UTF-8 and back.

The *stream* argument must be a file-like object.

The *encode* and *decode* arguments must adhere to the *Codec* interface. *Reader* and *Writer* must be factory functions or classes providing objects of the *StreamReader* and *StreamWriter* interface respectively.

Error handling is done in the same way as defined for the stream readers and writers.

*StreamRecoder* instances define the combined interfaces of *StreamReader* and *StreamWriter* classes. They inherit all other methods and attributes from the underlying stream.

## 7.2.2 Encodings and Unicode

Strings are stored internally as sequences of code points in range U+0000--U+10FFFF. (See [PEP 393](#) for more details about the implementation.) Once a string object is used outside of CPU and memory, endianness and how these arrays are stored as bytes become an issue. As with other codecs, serialising a string into a sequence of bytes

is known as *encoding*, and recreating the string from the sequence of bytes is known as *decoding*. There are a variety of different text serialisation codecs, which are collectively referred to as *text encodings*.

The simplest text encoding (called 'latin-1' or 'iso-8859-1') maps the code points 0--255 to the bytes 0x0-0xff, which means that a string object that contains code points above U+00FF can't be encoded with this codec. Doing so will raise a `UnicodeEncodeError` that looks like the following (although the details of the error message may differ): `UnicodeEncodeError: 'latin-1' codec can't encode character '\u1234' in position 3: ordinal not in range(256)`.

There's another group of encodings (the so called charmap encodings) that choose a different subset of all Unicode code points and how these code points are mapped to the bytes 0x0--0xff. To see how this is done simply open e.g. `encodings/cp1252.py` (which is an encoding that is used primarily on Windows). There's a string constant with 256 characters that shows you which character is mapped to which byte value.

All of these encodings can only encode 256 of the 1114112 code points defined in Unicode. A simple and straightforward way that can store each Unicode code point, is to store each code point as four consecutive bytes. There are two possibilities: store the bytes in big endian or in little endian order. These two encodings are called UTF-32-BE and UTF-32-LE respectively. Their disadvantage is that if e.g. you use UTF-32-BE on a little endian machine you will always have to swap bytes on encoding and decoding. UTF-32 avoids this problem: bytes will always be in natural endianness. When these bytes are read by a CPU with a different endianness, then bytes have to be swapped though. To be able to detect the endianness of a UTF-16 or UTF-32 byte sequence, there's the so called BOM ("Byte Order Mark"). This is the Unicode character U+FEFF. This character can be prepended to every UTF-16 or UTF-32 byte sequence. The byte swapped version of this character (0xFFFE) is an illegal character that may not appear in a Unicode text. So when the first character in a UTF-16 or UTF-32 byte sequence appears to be a U+FFFE the bytes have to be swapped on decoding. Unfortunately the character U+FEFF had a second purpose as a ZERO WIDTH NO-BREAK SPACE: a character that has no width and doesn't allow a word to be split. It can e.g. be used to give hints to a ligature algorithm. With Unicode 4.0 using U+FEFF as a ZERO WIDTH NO-BREAK SPACE has been deprecated (with U+2060 (WORD JOINER) assuming this role). Nevertheless Unicode software still must be able to handle U+FEFF in both roles: as a BOM it's a device to determine the storage layout of the encoded bytes, and vanishes once the byte sequence has been decoded into a string; as a ZERO WIDTH NO-BREAK SPACE it's a normal character that will be decoded like any other.

There's another encoding that is able to encode the full range of Unicode characters: UTF-8. UTF-8 is an 8-bit encoding, which means there are no issues with byte order in UTF-8. Each byte in a UTF-8 byte sequence consists of two parts: marker bits (the most significant bits) and payload bits. The marker bits are a sequence of zero to four 1 bits followed by a 0 bit. Unicode characters are encoded like this (with x being payload bits, which when concatenated give the Unicode character):

Range	Encoding
U-00000000 ... U-0000007F	0xxxxxxx
U-00000080 ... U-000007FF	110xxxxx 10xxxxxx
U-00000800 ... U-0000FFFF	1110xxxx 10xxxxxx 10xxxxxx
U-00010000 ... U-0010FFFF	11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

The least significant bit of the Unicode character is the rightmost x bit.

As UTF-8 is an 8-bit encoding no BOM is required and any U+FEFF character in the decoded string (even if it's the first character) is treated as a ZERO WIDTH NO-BREAK SPACE.

Without external information it's impossible to reliably determine which encoding was used for encoding a string. Each charmap encoding can decode any random byte sequence. However that's not possible with UTF-8, as UTF-8 byte sequences have a structure that doesn't allow arbitrary byte sequences. To increase the reliability with which a UTF-8 encoding can be detected, Microsoft invented a variant of UTF-8 (that Python calls "utf-8-sig") for its Notepad program: Before any of the Unicode characters is written to the file, a UTF-8 encoded BOM (which looks like this as a byte sequence: 0xef, 0xbb, 0xbf) is written. As it's rather improbable that any charmap encoded file starts with these byte values (which would e.g. map to

LATIN SMALL LETTER I WITH DIAERESIS  
 RIGHT-POINTING DOUBLE ANGLE QUOTATION MARK  
 INVERTED QUESTION MARK

in iso-8859-1), this increases the probability that a `utf-8-sig` encoding can be correctly guessed from the byte sequence. So here the BOM is not used to be able to determine the byte order used for generating the byte sequence, but as a signature that helps in guessing the encoding. On encoding the `utf-8-sig` codec will write `0xef, 0xbb, 0xbf` as the first three bytes to the file. On decoding `utf-8-sig` will skip those three bytes if they appear as the first three bytes in the file. In UTF-8, the use of the BOM is discouraged and should generally be avoided.

## 7.2.3 Standard Encodings

Python comes with a number of codecs built-in, either implemented as C functions or with dictionaries as mapping tables. The following table lists the codecs by name, together with a few common aliases, and the languages for which the encoding is likely used. Neither the list of aliases nor the list of languages is meant to be exhaustive. Notice that spelling alternatives that only differ in case or use a hyphen instead of an underscore are also valid aliases; therefore, e.g. `'utf-8'` is a valid alias for the `'utf_8'` codec.

**CPython 實作細節：** Some common encodings can bypass the codecs lookup machinery to improve performance. These optimization opportunities are only recognized by CPython for a limited set of (case insensitive) aliases: `utf-8`, `utf8`, `latin-1`, `latin1`, `iso-8859-1`, `iso8859-1`, `mbcs` (Windows only), `ascii`, `us-ascii`, `utf-16`, `utf16`, `utf-32`, `utf32`, and the same using underscores instead of dashes. Using alternative aliases for these encodings may result in slower execution.

在 3.6 版的變更: Optimization opportunity recognized for `us-ascii`.

Many of the character sets support the same languages. They vary in individual characters (e.g. whether the EURO SIGN is supported or not), and in the assignment of characters to code positions. For the European languages in particular, the following variants typically exist:

- an ISO 8859 codeset
- a Microsoft Windows code page, which is typically derived from an 8859 codeset, but replaces control characters with additional graphic characters
- an IBM EBCDIC code page
- an IBM PC code page, which is ASCII compatible

Codec	Aliases	語言

在 3.4 版的變更: The utf-16\* and utf-32\* encoders no longer allow surrogate code points (U+D800--U+DFFF) to be encoded. The utf-32\* decoders no longer decode byte sequences that correspond to surrogate code points.

在 3.8 版的變更: cp65001 is now an alias to utf\_8.

## 7.2.4 Python Specific Encodings

A number of predefined codecs are specific to Python, so their codec names have no meaning outside Python. These are listed in the tables below based on the expected input and output types (note that while text encodings are the most common use case for codecs, the underlying codec infrastructure supports arbitrary data transforms rather than just text encodings). For asymmetric codecs, the stated meaning describes the encoding direction.

## Text Encodings

The following codecs provide *str* to *bytes* encoding and *bytes-like object* to *str* decoding, similar to the Unicode text encodings.

Codec	Aliases	含義
idna		Implement <a href="#">RFC 3490</a> , see also <code>encodings.idna</code> . Only <code>errors='strict'</code> is supported.
mbscs	ansi, dbcs	Windows only: Encode the operand according to the ANSI codepage (CP_ACP).
oem		Windows only: Encode the operand according to the OEM codepage (CP_OEMCP). 在 3.6 版被加入。
palmos		Encoding of PalmOS 3.5.
punycode		Implement <a href="#">RFC 3492</a> . Stateful codecs are not supported.
raw_unicode_escape		Latin-1 encoding with <code>\uXXXX</code> and <code>\UXXXXXXXX</code> for other code points. Existing backslashes are not escaped in any way. It is used in the Python pickle protocol.
undefined		Raise an exception for all conversions, even empty strings. The error handler is ignored.
unicode_escape		Encoding suitable as the contents of a Unicode literal in ASCII-encoded Python source code, except that quotes are not escaped. Decode from Latin-1 source code. Beware that Python source code actually uses UTF-8 by default.

在 3.8 版的變更: "unicode\_internal" codec is removed.

## Binary Transforms

The following codecs provide binary transforms: *bytes-like object* to *bytes* mappings. They are not supported by `bytes.decode()` (which only produces *str* output).

Codec	Aliases	含義	Encoder / decoder
base64_codec <sup>1</sup>	base64, base_64	Convert the operand to multiline MIME base64 (the result always includes a trailing '\n'). 在 3.4 版的變更: accepts any <i>bytes-like object</i> as input for encoding and decoding	<code>base64.encodebytes()</code> / <code>base64.decodebytes()</code>
bz2_codec	bz2	Compress the operand using bz2.	<code>bz2.compress()</code> / <code>bz2.decompress()</code>
hex_codec	hex	Convert the operand to hexadecimal representation, with two digits per byte.	<code>binascii.b2a_hex()</code> / <code>binascii.a2b_hex()</code>
quopri_codec	quopri, quotedprintable, quoted_printable	Convert the operand to MIME quoted printable.	<code>quopri.encode()</code> with <code>quotetabs=True</code> / <code>quopri.decode()</code>
uu_codec	uu	Convert the operand using uuencode.	
zlib_codec	zip, zlib	Compress the operand using gzip.	<code>zlib.compress()</code> / <code>zlib.decompress()</code>

在 3.2 版被加入: Restoration of the binary transforms.

在 3.4 版的變更: Restoration of the aliases for the binary transforms.

## Text Transforms

The following codec provides a text transform: a *str* to *str* mapping. It is not supported by `str.encode()` (which only produces *bytes* output).

Codec	Aliases	含義
rot_13	rot13	Return the Caesar-cypher encryption of the operand.

在 3.2 版被加入: Restoration of the `rot_13` text transform.

在 3.4 版的變更: Restoration of the `rot13` alias.

## 7.2.5 encodings.idna --- Internationalized Domain Names in Applications

This module implements **RFC 3490** (Internationalized Domain Names in Applications) and **RFC 3492** (Nameprep: A Stringprep Profile for Internationalized Domain Names (IDN)). It builds upon the `punycode` encoding and `stringprep`.

If you need the IDNA 2008 standard from **RFC 5891** and **RFC 5895**, use the third-party `idna` module.

These RFCs together define a protocol to support non-ASCII characters in domain names. A domain name containing non-ASCII characters (such as `www.Alliancefrançaise.nu`) is converted into an ASCII-compatible encoding (ACE, such as `www.xn--alliancefranaise-npb.nu`). The ACE form of the domain name is then used in all places where arbitrary characters are not allowed by the protocol, such as DNS queries, HTTP *Host* fields, and so on. This conversion is carried out in the application; if possible invisible to the user: The application should transparently convert Unicode domain labels to IDNA on the wire, and convert back ACE labels to Unicode before presenting them to the user.

Python supports this conversion in several ways: the `idna` codec performs conversion between Unicode and ACE, separating an input string into labels based on the separator characters defined in **section 3.1 of RFC 3490** and converting each label to ACE as required, and conversely separating an input byte string into labels based on the .

<sup>1</sup> In addition to *bytes-like objects*, 'base64\_codec' also accepts ASCII-only instances of *str* for decoding

separator and converting any ACE labels found into unicode. Furthermore, the `socket` module transparently converts Unicode host names to ACE, so that applications need not be concerned about converting host names themselves when they pass them to the socket module. On top of that, modules that have host names as function parameters, such as `http.client` and `ftplib`, accept Unicode host names (`http.client` then also transparently sends an IDNA hostname in the `Host` field if it sends that field at all).

When receiving host names from the wire (such as in reverse name lookup), no automatic conversion to Unicode is performed: applications wishing to present such host names to the user should decode them to Unicode.

The module `encodings.idna` also implements the nameprep procedure, which performs certain normalizations on host names, to achieve case-insensitivity of international domain names, and to unify similar characters. The nameprep functions can be used directly if desired.

`encodings.idna.nameprep` (*label*)

Return the nameprepped version of *label*. The implementation currently assumes query strings, so `AllowUnassigned` is `true`.

`encodings.idna.ToASCII` (*label*)

Convert a label to ASCII, as specified in [RFC 3490](#). `UseSTD3ASCIIRules` is assumed to be `false`.

`encodings.idna.ToUnicode` (*label*)

Convert a label to Unicode, as specified in [RFC 3490](#).

## 7.2.6 `encodings.mbc`s --- Windows ANSI codepage

This module implements the ANSI codepage (CP\_ACP).

適用: Windows.

在 3.2 版的變更: Before 3.2, the `errors` argument was ignored; `'replace'` was always used to encode, and `'ignore'` to decode.

在 3.3 版的變更: Support any error handler.

## 7.2.7 `encodings.utf_8_sig` --- UTF-8 codec with BOM signature

This module implements a variant of the UTF-8 codec. On encoding, a UTF-8 encoded BOM will be prepended to the UTF-8 encoded bytes. For the stateful encoder this is only done once (on the first write to the byte stream). On decoding, an optional UTF-8 encoded BOM at the start of the data will be skipped.

本章節所描述的模組 (module) 提供了多樣的專門資料型，例如日期與時間、固定型陣列 (fixed-type arrays)、堆積列 (heap queues)、雙端列 (double-ended queues) 與列舉 (enumerations)。

Python 也有提供一些建資料型，特是 `dict`、`list`、`set` 與 `frozenset` 和 `tuple`。`str` 類是用來儲存 Unicode 字串，`bytes` 與 `bytearray` 類則是用來儲存二進位制資料。

本章節包含下列模組的文件：

## 8.1 `datetime` --- 日期與時間的基本型

原始碼：[Lib/datetime.py](#)

`datetime` 模組提供操作日期與時間的類。

While date and time arithmetic is supported, the focus of the implementation is on efficient attribute extraction for output formatting and manipulation.

### 💡 小訣竅

#### Package `dateutil`

帶有時區與剖析擴充支援的第三方函式庫。

**DateType 套件**

Third-party library that introduces distinct static types to e.g. allow *static type checkers* to differentiate between naive and aware datetimes.

## 8.1.1 Aware and Naive Objects

Date and time objects may be categorized as “aware” or “naive” depending on whether or not they include time zone information.

With sufficient knowledge of applicable algorithmic and political time adjustments, such as time zone and daylight saving time information, an **aware** object can locate itself relative to other aware objects. An aware object represents a specific moment in time that is not open to interpretation.<sup>1</sup>

A **naive** object does not contain enough information to unambiguously locate itself relative to other date/time objects. Whether a naive object represents Coordinated Universal Time (UTC), local time, or time in some other time zone is purely up to the program, just like it is up to the program whether a particular number represents metres, miles, or mass. Naive objects are easy to understand and to work with, at the cost of ignoring some aspects of reality.

For applications requiring aware objects, *datetime* and *time* objects have an optional time zone information attribute, *tzinfo*, that can be set to an instance of a subclass of the abstract *tzinfo* class. These *tzinfo* objects capture information about the offset from UTC time, the time zone name, and whether daylight saving time is in effect.

Only one concrete *tzinfo* class, the *timezone* class, is supplied by the *datetime* module. The *timezone* class can represent simple time zones with fixed offsets from UTC, such as UTC itself or North American EST and EDT time zones. Supporting time zones at deeper levels of detail is up to the application. The rules for time adjustment across the world are more political than rational, change frequently, and there is no standard suitable for every application aside from UTC.

## 8.1.2 常數

*datetime* 模組匯出以下常數：

`datetime.MINYEAR`

The smallest year number allowed in a *date* or *datetime* object. *MINYEAR* is 1.

`datetime.MAXYEAR`

The largest year number allowed in a *date* or *datetime* object. *MAXYEAR* is 9999.

`datetime.UTC`

Alias for the UTC time zone singleton `datetime.timezone.utc`.

在 3.11 版被加入。

## 8.1.3 Available Types

**class** `datetime.date`

An idealized naive date, assuming the current Gregorian calendar always was, and always will be, in effect. Attributes: *year*, *month*, and *day*.

**class** `datetime.time`

An idealized time, independent of any particular day, assuming that every day has exactly 24\*60\*60 seconds. (There is no notion of “leap seconds” here.) Attributes: *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

**class** `datetime.datetime`

A combination of a date and a time. Attributes: *year*, *month*, *day*, *hour*, *minute*, *second*, *microsecond*, and *tzinfo*.

<sup>1</sup> 也就是<sup>F</sup>，我們會忽略相對論的效應

**class** `datetime.timedelta`

表示兩個 *datetime* 或 *date* 實例之間時間的差 F，以微秒 F 解析度。

**class** `datetime.tzinfo`

An abstract base class for time zone information objects. These are used by the *datetime* and *time* classes to provide a customizable notion of time adjustment (for example, to account for time zone and/or daylight saving time).

**class** `datetime.timezone`

A class that implements the *tzinfo* abstract base class as a fixed offset from the UTC.

在 3.2 版被加入。

Objects of these types are immutable.

Subclass relationships:

```

object
  timedelta
  tzinfo
    timezone
  time
  date
  datetime

```

## 常見屬性

The *date*, *datetime*, *time*, and *timezone* types share these common features:

- Objects of these types are immutable.
- Objects of these types are *hashable*, meaning that they can be used as dictionary keys.
- Objects of these types support efficient pickling via the *pickle* module.

## Determining if an Object is Aware or Naive

Objects of the *date* type are always naive.

An object of type *time* or *datetime* may be aware or naive.

A *datetime* object *d* is aware if both of the following hold:

1. *d.tzinfo* 不是 `None`
2. *d.tzinfo.utcoffset(d)* 不會回傳 `None`

否則 *d* 會是 naive 的。

A *time* object *t* is aware if both of the following hold:

1. *t.tzinfo* 不是 `None`
2. *t.tzinfo.utcoffset(None)* F 有回傳 `None`。

否則 *t* 會是 naive 的。

The distinction between aware and naive doesn't apply to *timedelta* objects.

### 8.1.4 timedelta 物件

一個 *timedelta* 物件代表著一段持續時間，即兩個 *datetime* 或 *date* 之間的差 F。

**class** `datetime.timedelta` (*days=0, seconds=0, microseconds=0, milliseconds=0, minutes=0, hours=0, weeks=0*)

All arguments are optional and default to 0. Arguments may be integers or floats, and may be positive or negative.

Only *days*, *seconds* and *microseconds* are stored internally. Arguments are converted to those units:

- 一毫秒會被轉 1000 微秒。
- 一分鐘會被轉 60 秒。
- 一小時會被轉 3600 秒。
- 一週會被轉 7 天。

and *days*, *seconds* and *microseconds* are then normalized so that the representation is unique, with

- $0 \leq \text{microseconds} < 1000000$
- $0 \leq \text{seconds} < 3600 * 24$  (the number of seconds in one day)
- $-999999999 \leq \text{days} \leq 999999999$

The following example illustrates how any arguments besides *days*, *seconds* and *microseconds* are "merged" and normalized into those three resulting attributes:

```
>>> from datetime import timedelta
>>> delta = timedelta(
...     days=50,
...     seconds=27,
...     microseconds=10,
...     milliseconds=29000,
...     minutes=5,
...     hours=8,
...     weeks=2
... )
>>> # Only days, seconds, and microseconds remain
>>> delta
datetime.timedelta(days=64, seconds=29156, microseconds=10)
```

If any argument is a float and there are fractional microseconds, the fractional microseconds left over from all arguments are combined and their sum is rounded to the nearest microsecond using round-half-to-even tiebreaker. If no argument is a float, the conversion and normalization processes are exact (no information is lost).

If the normalized value of *days* lies outside the indicated range, *OverflowError* is raised.

Note that normalization of negative values may be surprising at first. For example:

```
>>> from datetime import timedelta
>>> d = timedelta(microseconds=-1)
>>> (d.days, d.seconds, d.microseconds)
(-1, 86399, 999999)
```

類屬性:

`timedelta.min`

The most negative *timedelta* object, `timedelta(-999999999)`.

`timedelta.max`

The most positive *timedelta* object, `timedelta(days=999999999, hours=23, minutes=59, seconds=59, microseconds=999999)`.

`timedelta.resolution`

The smallest possible difference between non-equal *timedelta* objects, `timedelta(microseconds=1)`.

Note that, because of normalization, `timedelta.max` is greater than `-timedelta.min`. `-timedelta.max` is not representable as a *timedelta* object.

Instance attributes (read-only):

`timedelta.days`

在 -999,999,999 到 999,999,999 (含) 之間

`timedelta.seconds`

在 0 到 86,399 (含) 之間

### ⚠ 警告

It is a somewhat common bug for code to unintentionally use this attribute when it is actually intended to get a `total_seconds()` value instead:

```
>>> from datetime import timedelta
>>> duration = timedelta(seconds=11235813)
>>> duration.days, duration.seconds
(130, 3813)
>>> duration.total_seconds()
11235813.0
```

`timedelta.microseconds`

在 0 到 999,999 (含) 之間

Supported operations:

Operation	Result
<code>t1 = t2 + t3</code>	Sum of <code>t2</code> and <code>t3</code> . Afterwards <code>t1 - t2 == t3</code> and <code>t1 - t3 == t2</code> are true. (1)
<code>t1 = t2 - t3</code>	Difference of <code>t2</code> and <code>t3</code> . Afterwards <code>t1 == t2 - t3</code> and <code>t2 == t1 + t3</code> are true. (1)(6)
<code>t1 = t2 * i</code> or <code>t1 = i * t2</code>	Delta multiplied by an integer. Afterwards <code>t1 // i == t2</code> is true, provided <code>i != 0</code> . In general, <code>t1 * i == t1 * (i-1) + t1</code> is true. (1)
<code>t1 = t2 * f</code> or <code>t1 = f * t2</code>	Delta multiplied by a float. The result is rounded to the nearest multiple of <code>timedelta.resolution</code> using round-half-to-even.
<code>f = t2 / t3</code>	Division (3) of overall duration <code>t2</code> by interval unit <code>t3</code> . Returns a <code>float</code> object.
<code>t1 = t2 / f</code> or <code>t1 = t2 / i</code>	Delta divided by a float or an int. The result is rounded to the nearest multiple of <code>timedelta.resolution</code> using round-half-to-even.
<code>t1 = t2 // i</code> or <code>t1 = t2 // t3</code>	The floor is computed and the remainder (if any) is thrown away. In the second case, an integer is returned. (3)
<code>t1 = t2 % t3</code>	The remainder is computed as a <code>timedelta</code> object. (3)
<code>q, r = divmod(t1, t2)</code>	Computes the quotient and the remainder: <code>q = t1 // t2</code> (3) and <code>r = t1 % t2</code> . <code>q</code> is an integer and <code>r</code> is a <code>timedelta</code> object.
<code>+t1</code>	Returns a <code>timedelta</code> object with the same value. (2)
<code>-t1</code>	等價於 <code>timedelta(-t1.days, -t1.seconds, -t1.microseconds)</code> , 也等價於 <code>t1 * -1</code> . (1)(4)
<code>abs(t)</code>	Equivalent to <code>+t</code> when <code>t.days &gt;= 0</code> , and to <code>-t</code> when <code>t.days &lt; 0</code> . (2)
<code>str(t)</code>	Returns a string in the form <code>[D] day[s], ][H]H:MM:SS[.UUUUUU]</code> , where <code>D</code> is negative for negative <code>t</code> . (5)
<code>repr(t)</code>	Returns a string representation of the <code>timedelta</code> object as a constructor call with canonical attribute values.

解:

- (1) 這是精確的, 但可能會溢位。
- (2) 這是精確的, 且不會溢位。
- (3) Division by zero raises `ZeroDivisionError`.

- (4) `-timedelta.max` is not representable as a *timedelta* object.
- (5) String representations of *timedelta* objects are normalized similarly to their internal representation. This leads to somewhat unusual results for negative timedeltas. For example:

```
>>> timedelta(hours=-5)
datetime.timedelta(days=-1, seconds=68400)
>>> print(_)
-1 day, 19:00:00
```

- (6) The expression `t2 - t3` will always be equal to the expression `t2 + (-t3)` except when `t3` is equal to `timedelta.max`; in that case the former will produce a result while the latter will overflow.

In addition to the operations listed above, *timedelta* objects support certain additions and subtractions with *date* and *datetime* objects (see below).

在 3.2 版的變更: Floor division and true division of a *timedelta* object by another *timedelta* object are now supported, as are remainder operations and the *divmod()* function. True division and multiplication of a *timedelta* object by a *float* object are now supported.

*timedelta* objects support equality and order comparisons.

In Boolean contexts, a *timedelta* object is considered to be true if and only if it isn't equal to `timedelta(0)`.

實例方法:

`timedelta.total_seconds()`

Return the total number of seconds contained in the duration. Equivalent to `td / timedelta(seconds=1)`. For interval units other than seconds, use the division form directly (e.g. `td / timedelta(microseconds=1)`).

Note that for very large time intervals (greater than 270 years on most platforms) this method will lose microsecond accuracy.

在 3.2 版被加入.

### 用法范例: `timedelta`

An additional example of normalization:

```
>>> # Components of another_year add up to exactly 365 days
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> another_year = timedelta(weeks=40, days=84, hours=23,
...                          minutes=50, seconds=600)
>>> year == another_year
True
>>> year.total_seconds()
31536000.0
```

Examples of *timedelta* arithmetic:

```
>>> from datetime import timedelta
>>> year = timedelta(days=365)
>>> ten_years = 10 * year
>>> ten_years
datetime.timedelta(days=3650)
>>> ten_years.days // 365
10
>>> nine_years = ten_years - year
>>> nine_years
datetime.timedelta(days=3285)
>>> three_years = nine_years // 3
>>> three_years, three_years.days // 365
(datetime.timedelta(days=1095), 3)
```

### 8.1.5 date 物件

A *date* object represents a date (year, month and day) in an idealized calendar, the current Gregorian calendar indefinitely extended in both directions.

January 1 of year 1 is called day number 1, January 2 of year 1 is called day number 2, and so on.<sup>2</sup>

**class** `datetime.date` (*year, month, day*)

All arguments are required. Arguments must be integers, in the following ranges:

- `MINYEAR <= year <= MAXYEAR`
- `1 <= month <= 12`
- `1 <= day <= number of days in the given month and year`

If an argument outside those ranges is given, *ValueError* is raised.

Other constructors, all class methods:

**classmethod** `date.today()`

回傳目前的本地日期。

這等同於 `date.fromtimestamp(time.time())`。

**classmethod** `date.fromtimestamp` (*timestamp*)

Return the local date corresponding to the POSIX timestamp, such as is returned by `time.time()`.

This may raise *OverflowError*, if the timestamp is out of the range of values supported by the platform C `localtime()` function, and *OSError* on `localtime()` failure. It's common for this to be restricted to years from 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`.

在 3.3 版的變更: Raise *OverflowError* instead of *ValueError* if the timestamp is out of the range of values supported by the platform C `localtime()` function. Raise *OSError* instead of *ValueError* on `localtime()` failure.

**classmethod** `date.fromordinal` (*ordinal*)

Return the date corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1.

*ValueError* is raised unless `1 <= ordinal <= date.max.toordinal()`. For any date `d`, `date.fromordinal(d.toordinal()) == d`.

**classmethod** `date.fromisoformat` (*date\_string*)

Return a *date* corresponding to a *date\_string* given in any valid ISO 8601 format, with the following exceptions:

1. Reduced precision dates are not currently supported (`YYYY-MM, YYYY`).
2. Extended date representations are not currently supported (`±YYYYYY-MM-DD`).
3. Ordinal dates are not currently supported (`YYYY-OOO`).

範例:

```
>>> from datetime import date
>>> date.fromisoformat('2019-12-04')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('20191204')
datetime.date(2019, 12, 4)
>>> date.fromisoformat('2021-W01-1')
datetime.date(2021, 1, 4)
```

在 3.7 版被加入。

在 3.11 版的變更: Previously, this method only supported the format `YYYY-MM-DD`.

<sup>2</sup> This matches the definition of the "proleptic Gregorian" calendar in Dershowitz and Reingold's book *Calendrical Calculations*, where it's the base calendar for all computations. See the book for algorithms for converting between proleptic Gregorian ordinals and many other calendar systems.

**classmethod** `date.fromisocalendar(year, week, day)`

Return a *date* corresponding to the ISO calendar date specified by year, week and day. This is the inverse of the function `date.isocalendar()`.

在 3.8 版被加入。

類 F 屬性：

`date.min`

The earliest representable date, `date(MINYEAR, 1, 1)`.

`date.max`

The latest representable date, `date(MAXYEAR, 12, 31)`.

`date.resolution`

The smallest possible difference between non-equal date objects, `timedelta(days=1)`.

Instance attributes (read-only):

`date.year`

Between *MINYEAR* and *MAXYEAR* inclusive.

`date.month`

在 1 到 12 (含) 之間。

`date.day`

Between 1 and the number of days in the given month of the given year.

Supported operations:

Operation	Result
<code>date2 = date1 + timedelta</code>	<code>date2</code> will be <code>timedelta.days</code> days after <code>date1</code> . (1)
<code>date2 = date1 - timedelta</code>	Computes <code>date2</code> such that <code>date2 + timedelta == date1</code> . (2)
<code>timedelta = date1 - date2</code>	(3)
<code>date1 == date2</code> <code>date1 != date2</code>	Equality comparison. (4)
<code>date1 &lt; date2</code> <code>date1 &gt; date2</code> <code>date1 &lt;= date2</code> <code>date1 &gt;= date2</code>	Order comparison. (5)

F 解：

- (1) *date2* is moved forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. Afterward `date2 - date1 == timedelta.days`, `timedelta.seconds` and `timedelta.microseconds` are ignored. `OverflowError` is raised if `date2.year` would be smaller than *MINYEAR* or larger than *MAXYEAR*.
- (2) `timedelta.seconds` 和 `timedelta.microseconds` 被忽略。
- (3) This is exact, and cannot overflow. `timedelta.seconds` and `timedelta.microseconds` are 0, and `date2 + timedelta == date1` after.

(4) `date` objects are equal if they represent the same date.

`date` objects that are not also `datetime` instances are never equal to `datetime` objects, even if they represent the same date.

(5) `date1` is considered less than `date2` when `date1` precedes `date2` in time. In other words, `date1 < date2` if and only if `date1.toordinal() < date2.toordinal()`.

Order comparison between a `date` object that is not also a `datetime` instance and a `datetime` object raises `TypeError`.

在 3.13 版的變更: Comparison between `datetime` object and an instance of the `date` subclass that is not a `datetime` subclass no longer converts the latter to `date`, ignoring the time part and the time zone. The default behavior can be changed by overriding the special comparison methods in subclasses.

In Boolean contexts, all `date` objects are considered to be true.

實例方法:

`date.replace(year=self.year, month=self.month, day=self.day)`

Return a date with the same value, except for those parameters given new values by whichever keyword arguments are specified.

範例:

```
>>> from datetime import date
>>> d = date(2002, 12, 31)
>>> d.replace(day=26)
datetime.date(2002, 12, 26)
```

`date` objects are also supported by generic function `copy.replace()`.

`date.timetuple()`

回傳一個 `time.struct_time`, 如同 `time.localtime()` 所回傳。

The hours, minutes and seconds are 0, and the DST flag is -1.

`d.timetuple()` 等價於:

```
time.struct_time((d.year, d.month, d.day, 0, 0, 0, d.weekday(), yday, -1))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st.

`date.toordinal()`

Return the proleptic Gregorian ordinal of the date, where January 1 of year 1 has ordinal 1. For any `date` object `d`, `date.fromordinal(d.toordinal()) == d`.

`date.weekday()`

回傳一個代表星期幾的整數, 星期一 F 0、星期日 F 6。例如 `date(2002, 12, 4).weekday() == 2` F 星期三。也請參考 `isoweekday()`。

`date.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. For example, `date(2002, 12, 4).isoweekday() == 3`, a Wednesday. See also `weekday()`, `isocalendar()`.

`date.isocalendar()`

Return a *named tuple* object with three components: `year`, `week` and `weekday`.

The ISO calendar is a widely used variant of the Gregorian calendar.<sup>3</sup>

The ISO year consists of 52 or 53 full weeks, and where a week starts on a Monday and ends on a Sunday. The first week of an ISO year is the first (Gregorian) calendar week of a year containing a Thursday. This is called week number 1, and the ISO year of that Thursday is the same as its Gregorian year.

<sup>3</sup> See R. H. van Gent's [guide to the mathematics of the ISO 8601 calendar](#) for a good explanation.

For example, 2004 begins on a Thursday, so the first week of ISO year 2004 begins on Monday, 29 Dec 2003 and ends on Sunday, 4 Jan 2004:

```
>>> from datetime import date
>>> date(2003, 12, 29).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=1)
>>> date(2004, 1, 4).isocalendar()
datetime.IsoCalendarDate(year=2004, week=1, weekday=7)
```

在 3.9 版的變更: Result changed from a tuple to a *named tuple*.

`date.isoformat()`

回傳一以 ISO 8601 格式 YYYY-MM-DD 表示的日期字串:

```
>>> from datetime import date
>>> date(2002, 12, 4).isoformat()
'2002-12-04'
```

`date.__str__()`

For a date `d`, `str(d)` is equivalent to `d.isoformat()`.

`date.ctime()`

Return a string representing the date:

```
>>> from datetime import date
>>> date(2002, 12, 4).ctime()
'Wed Dec 4 00:00:00 2002'
```

`d.ctime()` 等價於:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `date.ctime()` does not invoke) conforms to the C standard.

`date.strftime(format)`

Return a string representing the date, controlled by an explicit format string. Format codes referring to hours, minutes or seconds will see 0 values. See also `strftime()` 與 `strptime()` 的行 F 和 `date.isoformat()`.

`date.__format__(format)`

Same as `date.strftime()`. This makes it possible to specify a format string for a `date` object in formatted string literals and when using `str.format()`. See also `strftime()` 與 `strptime()` 的行 F 和 `date.isoformat()`.

### 用法范例: date

計算一個事件的天數的範例:

```
>>> import time
>>> from datetime import date
>>> today = date.today()
>>> today
datetime.date(2007, 12, 5)
>>> today == date.fromtimestamp(time.time())
True
>>> my_birthday = date(today.year, 6, 24)
>>> if my_birthday < today:
...     my_birthday = my_birthday.replace(year=today.year + 1)
...
>>> my_birthday
datetime.date(2008, 6, 24)
```

(繼續下一頁)

(繼續上一頁)

```
>>> time_to_birthday = abs(my_birthday - today)
>>> time_to_birthday.days
202
```

更多 `date` 的用法範例：

```
>>> from datetime import date
>>> d = date.fromordinal(730920) # 730920th day after 1. 1. 0001
>>> d
datetime.date(2002, 3, 11)

>>> # Methods related to formatting string output
>>> d.isoformat()
'2002-03-11'
>>> d.strftime("%d/%m/%y")
'11/03/02'
>>> d.strftime("%A %d. %B %Y")
'Monday 11. March 2002'
>>> d.ctime()
'Mon Mar 11 00:00:00 2002'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}.'.format(d, "day", "month")
'The day is 11, the month is March.'

>>> # Methods for extracting 'components' under different calendars
>>> t = d.timetuple()
>>> for i in t:
...     print(i)
2002          # year
3             # month
11            # day
0
0
0
0             # weekday (0 = Monday)
70            # 70th day in the year
-1

>>> ic = d.isocalendar()
>>> for i in ic:
...     print(i)
2002          # ISO year
11            # ISO week number
1             # ISO day number ( 1 = Monday )

>>> # A date object is immutable; all operations produce a new object
>>> d.replace(year=2005)
datetime.date(2005, 3, 11)
```

## 8.1.6 datetime 物件

A `datetime` object is a single object containing all the information from a `date` object and a `time` object.

Like a `date` object, `datetime` assumes the current Gregorian calendar extended in both directions; like a `time` object, `datetime` assumes there are exactly  $3600 \times 24$  seconds in every day.

Constructor:

```
class datetime.datetime(year, month, day, hour=0, minute=0, second=0, microsecond=0, tzinfo=None, *,
                        fold=0)
```

The `year`, `month` and `day` arguments are required. `tzinfo` may be `None`, or an instance of a `tzinfo` subclass. The remaining arguments must be integers in the following ranges:

- `MINYEAR <= year <= MAXYEAR`,

- `1 <= month <= 12`,
- `1 <= day <= number of days in the given month and year`,
- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- fold in `[0, 1]`.

If an argument outside those ranges is given, `ValueError` is raised.

在 3.6 版的變更: 新增 `fold` 參數。

Other constructors, all class methods:

**classmethod** `datetime.today()`

回傳目前的本地日期與時間, 且 `tzinfo` F None。

等價於:

```
datetime.fromtimestamp(time.time())
```

也請見 `now()`、`fromtimestamp()`。

This method is functionally equivalent to `now()`, but without a `tz` parameter.

**classmethod** `datetime.now(tz=None)`

Return the current local date and time.

如果選用的引數 `tz` F None 或未指定, 則會像是 `today()`, 但盡可能提供比透過 `time.time()` 取得的時間戳記更多位數的資訊 (例如, 這在有提供 `C gettimeofday()` 函式的平台上可能可行)。

If `tz` is not None, it must be an instance of a `tzinfo` subclass, and the current date and time are converted to `tz`'s time zone.

This function is preferred over `today()` and `utcnow()`.

#### 備 F

Subsequent calls to `datetime.now()` may return the same instant depending on the precision of the underlying clock.

**classmethod** `datetime.utcnow()`

Return the current UTC date and time, with `tzinfo` None.

This is like `now()`, but returns the current UTC date and time, as a naive `datetime` object. An aware current UTC datetime can be obtained by calling `datetime.now(timezone.utc)`. See also `now()`.

#### 警告

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing the current time in UTC is by calling `datetime.now(timezone.utc)`.

在 3.12 版之後被 F 用: Use `datetime.now()` with `UTC` instead.

**classmethod** `datetime.fromtimestamp(timestamp, tz=None)`

Return the local date and time corresponding to the POSIX timestamp, such as is returned by `time.time()`. If optional argument `tz` is `None` or not specified, the timestamp is converted to the platform's local date and time, and the returned `datetime` object is naive.

If `tz` is not `None`, it must be an instance of a `tzinfo` subclass, and the timestamp is converted to `tz`'s time zone.

`fromtimestamp()` may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions, and `OSError` on `localtime()` or `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038. Note that on non-POSIX systems that include leap seconds in their notion of a timestamp, leap seconds are ignored by `fromtimestamp()`, and then it's possible to have two timestamps differing by a second that yield identical `datetime` objects. This method is preferred over `utcfromtimestamp()`.

在 3.3 版的變更: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `localtime()` or `gmtime()` functions. Raise `OSError` instead of `ValueError` on `localtime()` or `gmtime()` failure.

在 3.6 版的變更: `fromtimestamp()` may return instances with `fold` set to 1.

**classmethod** `datetime.utcfromtimestamp(timestamp)`

Return the UTC `datetime` corresponding to the POSIX timestamp, with `tzinfo` `None`. (The resulting object is naive.)

This may raise `OverflowError`, if the timestamp is out of the range of values supported by the platform C `gmtime()` function, and `OSError` on `gmtime()` failure. It's common for this to be restricted to years in 1970 through 2038.

To get an aware `datetime` object, call `fromtimestamp()`:

```
datetime.fromtimestamp(timestamp, timezone.utc)
```

On the POSIX compliant platforms, it is equivalent to the following expression:

```
datetime(1970, 1, 1, tzinfo=timezone.utc) + timedelta(seconds=timestamp)
```

except the latter formula always supports the full years range: between `MINYEAR` and `MAXYEAR` inclusive.

警告

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC. As such, the recommended way to create an object representing a specific timestamp in UTC is by calling `datetime.fromtimestamp(timestamp, tz=timezone.utc)`.

在 3.3 版的變更: Raise `OverflowError` instead of `ValueError` if the timestamp is out of the range of values supported by the platform C `gmtime()` function. Raise `OSError` instead of `ValueError` on `gmtime()` failure.

在 3.12 版之後被 用: Use `datetime.fromtimestamp()` with `UTC` instead.

**classmethod** `datetime.fromordinal(ordinal)`

Return the `datetime` corresponding to the proleptic Gregorian ordinal, where January 1 of year 1 has ordinal 1. `ValueError` is raised unless  $1 \leq \text{ordinal} \leq \text{datetime.max.toordinal}()$ . The hour, minute, second and microsecond of the result are all 0, and `tzinfo` is `None`.

**classmethod** `datetime.combine(date, time, tzinfo=time.tzinfo)`

Return a new `datetime` object whose date components are equal to the given `date` object's, and whose time components are equal to the given `time` object's. If the `tzinfo` argument is provided, its value is used to set the `tzinfo` attribute of the result, otherwise the `tzinfo` attribute of the `time` argument is used. If the `date` argument is a `datetime` object, its time components and `tzinfo` attributes are ignored.

For any *datetime* object *d*, `d == datetime.combine(d.date(), d.time(), d.tzinfo)`.

在 3.6 版的變更: 新增 *tzinfo* 引數。

**classmethod** `datetime.fromisoformat(date_string)`

Return a *datetime* corresponding to a *date\_string* in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The T separator may be replaced by any single unicode character.
3. Fractional hours and minutes are not supported.
4. Reduced precision dates are not currently supported (YYYY-MM, YYYY).
5. Extended date representations are not currently supported (±YYYYYY-MM-DD).
6. Ordinal dates are not currently supported (YYYY-OOO).

範例:

```
>>> from datetime import datetime
>>> datetime.fromisoformat('2011-11-04')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('20111104')
datetime.datetime(2011, 11, 4, 0, 0)
>>> datetime.fromisoformat('2011-11-04T00:05:23')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-11-04T00:05:23Z')
datetime.datetime(2011, 11, 4, 0, 5, 23, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('20111104T000523')
datetime.datetime(2011, 11, 4, 0, 5, 23)
>>> datetime.fromisoformat('2011-W01-2T00:05:23.283')
datetime.datetime(2011, 1, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000)
>>> datetime.fromisoformat('2011-11-04 00:05:23.283+00:00')
datetime.datetime(2011, 11, 4, 0, 5, 23, 283000, tzinfo=datetime.timezone.utc)
>>> datetime.fromisoformat('2011-11-04T00:05:23+04:00')
datetime.datetime(2011, 11, 4, 0, 5, 23,
tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
```

在 3.7 版被加入。

在 3.11 版的變更: Previously, this method only supported formats that could be emitted by `date.isoformat()` or `datetime.isoformat()`.

**classmethod** `datetime.fromisocalendar(year, week, day)`

Return a *datetime* corresponding to the ISO calendar date specified by year, week and day. The non-date components of the datetime are populated with their normal default values. This is the inverse of the function `datetime.isocalendar()`.

在 3.8 版被加入。

**classmethod** `datetime.strptime(date_string, format)`

Return a *datetime* corresponding to *date\_string*, parsed according to *format*.

If *format* does not contain microseconds or time zone information, this is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

*ValueError* is raised if the *date\_string* and *format* can't be parsed by `time.strptime()` or if it returns a value which isn't a time tuple. See also `strptime()` 與 `strptime()` 的行 和 `datetime.fromisoformat()`.

在 3.13 版的變更: If *format* specifies a day of month without a year a *DeprecationWarning* is now emitted. This is to avoid a quadrennial leap year bug in code seeking to parse only a month and day as the default year used in absence of one in the format is not a leap year. Such *format* values may raise an error as of Python

3.15. The workaround is to always include a year in your *format*. If parsing *date\_string* values that do not have a year, explicitly add a year that is a leap year before parsing:

```
>>> from datetime import datetime
>>> date_string = "02/29"
>>> when = datetime.strptime(f"{date_string};1984", "%m/%d;%Y") # Avoids leap year bug.
>>> when.strftime("%B %d")
'February 29'
```

類屬性:

`datetime.min`

The earliest representable *datetime*, `datetime(MINYEAR, 1, 1, tzinfo=None)`.

`datetime.max`

The latest representable *datetime*, `datetime(MAXYEAR, 12, 31, 23, 59, 59, 999999, tzinfo=None)`.

`datetime.resolution`

The smallest possible difference between non-equal *datetime* objects, `timedelta(microseconds=1)`.

Instance attributes (read-only):

`datetime.year`

Between *MINYEAR* and *MAXYEAR* inclusive.

`datetime.month`

在 1 到 12 (含) 之間。

`datetime.day`

Between 1 and the number of days in the given month of the given year.

`datetime.hour`

In range (24).

`datetime.minute`

In range (60).

`datetime.second`

In range (60).

`datetime.microsecond`

In range (1000000).

`datetime.tzinfo`

The object passed as the *tzinfo* argument to the *datetime* constructor, or `None` if none was passed.

`datetime.fold`

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

在 3.6 版被加入。

Supported operations:

Operation	Result
<code>datetime2 = datetime1 + timedelta</code>	(1)
<code>datetime2 = datetime1 - timedelta</code>	(2)
<code>timedelta = datetime1 - datetime2</code>	(3)
<code>datetime1 == datetime2</code> <code>datetime1 != datetime2</code>	Equality comparison. (4)
<code>datetime1 &lt; datetime2</code> <code>datetime1 &gt; datetime2</code> <code>datetime1 &lt;= datetime2</code> <code>datetime1 &gt;= datetime2</code>	Order comparison. (5)

(1) `datetime2` is a duration of `timedelta` removed from `datetime1`, moving forward in time if `timedelta.days > 0`, or backward if `timedelta.days < 0`. The result has the same `tzinfo` attribute as the input `datetime`, and `datetime2 - datetime1 == timedelta` after. `OverflowError` is raised if `datetime2.year` would be smaller than `MINYEAR` or larger than `MAXYEAR`. Note that no time zone adjustments are done even if the input is an aware object.

(2) Computes the `datetime2` such that `datetime2 + timedelta == datetime1`. As for addition, the result has the same `tzinfo` attribute as the input `datetime`, and no time zone adjustments are done even if the input is aware.

(3) Subtraction of a `datetime` from a `datetime` is defined only if both operands are naive, or if both are aware. If one is aware and the other is naive, `TypeError` is raised.

If both are naive, or both are aware and have the same `tzinfo` attribute, the `tzinfo` attributes are ignored, and the result is a `timedelta` object `t` such that `datetime2 + t == datetime1`. No time zone adjustments are done in this case.

If both are aware and have different `tzinfo` attributes, `a-b` acts as if `a` and `b` were first converted to naive UTC datetimes. The result is `(a.replace(tzinfo=None) - a.utcoffset()) - (b.replace(tzinfo=None) - b.utcoffset())` except that the implementation never overflows.

(4) `datetime` objects are equal if they represent the same date and time, taking into account the time zone.

Naive and aware `datetime` objects are never equal.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and `fold` attributes are ignored and the base datetimes are compared. If both comparands are aware and have different `tzinfo` attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows. `datetime` instances in a repeated interval are never equal to `datetime` instances in other time zone.

(5) `datetime1` is considered less than `datetime2` when `datetime1` precedes `datetime2` in time, taking into account the time zone.

Order comparison between naive and aware `datetime` objects raises `TypeError`.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and `fold` attributes are ignored and the base datetimes are compared. If both comparands are aware and have different `tzinfo` attributes, the comparison acts as comparands were first converted to UTC datetimes except that the implementation never overflows.

在 3.3 版的變更: Equality comparisons between aware and naive `datetime` instances don't raise `TypeError`.

在 3.13 版的變更: Comparison between `datetime` object and an instance of the `date` subclass that is not a `datetime` subclass no longer converts the latter to `date`, ignoring the time part and the time zone. The default behavior can be changed by overriding the special comparison methods in subclasses.

實例方法：

`datetime.date()`

Return *date* object with same year, month and day.

`datetime.time()`

Return *time* object with same hour, minute, second, microsecond and fold. *tzinfo* is `None`. See also method `timetz()`.

在 3.6 版的變更: The fold value is copied to the returned *time* object.

`datetime.timetz()`

Return *time* object with same hour, minute, second, microsecond, fold, and tzinfo attributes. See also method `time()`.

在 3.6 版的變更: The fold value is copied to the returned *time* object.

`datetime.replace(year=self.year, month=self.month, day=self.day, hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a datetime with the same attributes, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive datetime from an aware datetime with no conversion of date and time data.

*datetime* objects are also supported by generic function `copy.replace()`.

在 3.6 版的變更: 新增 *fold* 參數。

`datetime.astimezone(tz=None)`

Return a *datetime* object with new *tzinfo* attribute *tz*, adjusting the date and time data so the result is the same UTC time as *self*, but in *tz*'s local time.

If provided, *tz* must be an instance of a *tzinfo* subclass, and its `utcoffset()` and `dst()` methods must not return `None`. If *self* is naive, it is presumed to represent time in the system time zone.

If called without arguments (or with `tz=None`) the system local time zone is assumed for the target time zone. The `.tzinfo` attribute of the converted datetime instance will be set to an instance of *timezone* with the zone name and offset obtained from the OS.

If `self.tzinfo` is *tz*, `self.astimezone(tz)` is equal to *self*: no adjustment of date or time data is performed. Else the result is local time in the time zone *tz*, representing the same UTC time as *self*: after `astz = dt.astimezone(tz)`, `astz - astz.utcoffset()` will have the same date and time data as `dt - dt.utcoffset()`.

If you merely want to attach a *timezone* object *tz* to a datetime *dt* without adjustment of date and time data, use `dt.replace(tzinfo=tz)`. If you merely want to remove the *timezone* object from an aware datetime *dt* without conversion of date and time data, use `dt.replace(tzinfo=None)`.

Note that the default *tzinfo.fromutc()* method can be overridden in a *tzinfo* subclass to affect the result returned by `astimezone()`. Ignoring error cases, `astimezone()` acts like:

```
def astimezone(self, tz):
    if self.tzinfo is tz:
        return self
    # Convert self to UTC, and attach the new timezone object.
    utc = (self - self.utcoffset()).replace(tzinfo=tz)
    # Convert from UTC to tz's local time.
    return tz.fromutc(utc)
```

在 3.3 版的變更: *tz* now can be omitted.

在 3.6 版的變更: The `astimezone()` method can now be called on naive instances that are presumed to represent system local time.

`datetime.utcoffset()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.utcoffset(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

`datetime.dst()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.dst(self)`, and raises an exception if the latter doesn't return `None` or a `timedelta` object with magnitude less than one day.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

`datetime.tzname()`

If `tzinfo` is `None`, returns `None`, else returns `self.tzinfo.tzname(self)`, raises an exception if the latter doesn't return `None` or a string object,

`datetime.timetuple()`

回傳一個 `time.struct_time`, 如同 `time.localtime()` 所回傳。

`d.timetuple()` 等價於:

```
time.struct_time((d.year, d.month, d.day,
                 d.hour, d.minute, d.second,
                 d.weekday(), yday, dst))
```

where `yday = d.toordinal() - date(d.year, 1, 1).toordinal() + 1` is the day number within the current year starting with 1 for January 1st. The `tm_isdst` flag of the result is set according to the `dst()` method: `tzinfo` is `None` or `dst()` returns `None`, `tm_isdst` is set to `-1`; else if `dst()` returns a non-zero value, `tm_isdst` is set to `1`; else `tm_isdst` is set to `0`.

`datetime.utctimetuple()`

If `datetime` instance `d` is naive, this is the same as `d.timetuple()` except that `tm_isdst` is forced to `0` regardless of what `d.dst()` returns. DST is never in effect for a UTC time.

If `d` is aware, `d` is normalized to UTC time, by subtracting `d.utcoffset()`, and a `time.struct_time` for the normalized time is returned. `tm_isdst` is forced to `0`. Note that an `OverflowError` may be raised if `d.year` was `MINYEAR` or `MAXYEAR` and UTC adjustment spills over a year boundary.

#### 警告

Because naive `datetime` objects are treated by many `datetime` methods as local times, it is preferred to use aware datetimes to represent times in UTC; as a result, using `datetime.utctimetuple()` may give misleading results. If you have a naive `datetime` representing UTC, use `datetime.replace(tzinfo=timezone.utc)` to make it aware, at which point you can use `datetime.timetuple()`.

`datetime.toordinal()`

Return the proleptic Gregorian ordinal of the date. The same as `self.date().toordinal()`.

`datetime.timestamp()`

Return POSIX timestamp corresponding to the `datetime` instance. The return value is a `float` similar to that returned by `time.time()`.

Naive `datetime` instances are assumed to represent local time and this method relies on the platform `C mktime()` function to perform the conversion. Since `datetime` supports wider range of values than `mktime()` on many platforms, this method may raise `OverflowError` or `OSError` for times far in the past or far in the future.

For aware `datetime` instances, the return value is computed as:

```
(dt - datetime(1970, 1, 1, tzinfo=timezone.utc)).total_seconds()
```

在 3.3 版被加入。

在 3.6 版的變更: The `timestamp()` method uses the `fold` attribute to disambiguate the times during a repeated interval.

### 備 F

There is no method to obtain the POSIX timestamp directly from a naive `datetime` instance representing UTC time. If your application uses this convention and your system time zone is not set to UTC, you can obtain the POSIX timestamp by supplying `tzinfo=timezone.utc`:

```
timestamp = dt.replace(tzinfo=timezone.utc).timestamp()
```

or by calculating the timestamp directly:

```
timestamp = (dt - datetime(1970, 1, 1)) / timedelta(seconds=1)
```

`datetime.weekday()`

Return the day of the week as an integer, where Monday is 0 and Sunday is 6. The same as `self.date().weekday()`. See also `isoweekday()`.

`datetime.isoweekday()`

Return the day of the week as an integer, where Monday is 1 and Sunday is 7. The same as `self.date().isoweekday()`. See also `weekday()`, `isocalendar()`.

`datetime.isocalendar()`

Return a *named tuple* with three components: `year`, `week` and `weekday`. The same as `self.date().isocalendar()`.

`datetime.isoformat(sep='T', timespec='auto')`

Return a string representing the date and time in ISO 8601 format:

- YYYY-MM-DDTHH:MM:SS.ffffff, 如果 *microsecond* 不是 0
- YYYY-MM-DDTHH:MM:SS, 如果 *microsecond* 是 0

如果 `utcoffset()` 沒有回傳 `None`, 則會附加一个字串, 給出 UTC 偏移:

- YYYY-MM-DDTHH:MM:SS.ffffff+HH:MM[:SS[.ffffff]], 如果 *microsecond* 不是 0
- YYYY-MM-DDTHH:MM:SS+HH:MM[:SS[.ffffff]], 如果 *microsecond* 是 0

範例:

```
>>> from datetime import datetime, timezone
>>> datetime(2019, 5, 18, 15, 17, 8, 132263).isoformat()
'2019-05-18T15:17:08.132263'
>>> datetime(2019, 5, 18, 15, 17, tzinfo=timezone.utc).isoformat()
'2019-05-18T15:17:00+00:00'
```

The optional argument `sep` (default `'T'`) is a one-character separator, placed between the date and time portions of the result. For example:

```
>>> from datetime import tzinfo, timedelta, datetime
>>> class TZ(tzinfo):
...     """A time zone with an arbitrary, constant -06:39 offset."""
...     def utcoffset(self, dt):
...         return timedelta(hours=-6, minutes=-39)
...
>>> datetime(2002, 12, 25, tzinfo=TZ()).isoformat(' ')
```

(繼續下一頁)

(繼續上一頁)

```
'2002-12-25 00:00:00-06:39'
>>> datetime(2009, 11, 27, microsecond=100, tzinfo=TZ()).isoformat()
'2009-11-27T00:00:00.000100-06:39'
```

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if *microsecond* is 0, same as 'microseconds' otherwise.
- 'hours': Include the *hour* in the two-digit HH format.
- 'minutes': Include *hour* and *minute* in HH:MM format.
- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

### 備 F

Excluded time components are truncated, not rounded.

*ValueError* will be raised on an invalid *timespec* argument:

```
>>> from datetime import datetime
>>> datetime.now().isoformat(timespec='minutes')
'2002-12-25T00:00'
>>> dt = datetime(2015, 1, 1, 12, 30, 59, 0)
>>> dt.isoformat(timespec='microseconds')
'2015-01-01T12:30:59.000000'
```

在 3.6 版的變更: 新增 *timespec* 參數。

`datetime.__str__()`

For a *datetime* instance *d*, `str(d)` is equivalent to `d.isoformat('')`.

`datetime.ctime()`

Return a string representing the date and time:

```
>>> from datetime import datetime
>>> datetime(2002, 12, 4, 20, 30, 40).ctime()
'Wed Dec 4 20:30:40 2002'
```

The output string will *not* include time zone information, regardless of whether the input is aware or naive.

`d.ctime()` 等價於:

```
time.ctime(time.mktime(d.timetuple()))
```

on platforms where the native C `ctime()` function (which `time.ctime()` invokes, but which `datetime.ctime()` does not invoke) conforms to the C standard.

`datetime.strftime(format)`

Return a string representing the date and time, controlled by an explicit format string. See also `strftime()` 與 `strptime()` 的行 F 和 `datetime.isoformat()`.

`datetime.__format__(format)`

Same as `datetime.strftime()`. This makes it possible to specify a format string for a *datetime* object in formatted string literals and when using `str.format()`. See also `strftime()` 與 `strptime()` 的行 F 和 `datetime.isoformat()`.

**用法范例: datetime**

更多 *datetime* 的用法範例:

```
>>> from datetime import datetime, date, time, timezone

>>> # Using datetime.combine()
>>> d = date(2005, 7, 14)
>>> t = time(12, 30)
>>> datetime.combine(d, t)
datetime.datetime(2005, 7, 14, 12, 30)

>>> # Using datetime.now()
>>> datetime.now()
datetime.datetime(2007, 12, 6, 16, 29, 43, 79043) # GMT +1
>>> datetime.now(timezone.utc)
datetime.datetime(2007, 12, 6, 15, 29, 43, 79060, tzinfo=datetime.timezone.utc)

>>> # Using datetime.strptime()
>>> dt = datetime.strptime("21/11/06 16:30", "%d/%m/%y %H:%M")
>>> dt
datetime.datetime(2006, 11, 21, 16, 30)

>>> # Using datetime.timetuple() to get tuple of all attributes
>>> tt = dt.timetuple()
>>> for it in tt:
...     print(it)
...
2006 # year
11 # month
21 # day
16 # hour
30 # minute
0 # second
1 # weekday (0 = Monday)
325 # number of days since 1st January
-1 # dst - method tzinfo.dst() returned None

>>> # Date in ISO format
>>> ic = dt.isocalendar()
>>> for it in ic:
...     print(it)
...
2006 # ISO year
47 # ISO week
2 # ISO weekday

>>> # Formatting a datetime
>>> dt.strftime("%A, %d. %B %Y %I:%M%p")
'Tuesday, 21. November 2006 04:30PM'
>>> 'The {1} is {0:%d}, the {2} is {0:%B}, the {3} is {0:%I:%M%p}.'.format(dt, "day", "month", "time")
'The day is 21, the month is November, the time is 04:30PM.'
```

The example below defines a *tzinfo* subclass capturing time zone information for Kabul, Afghanistan, which used +4 UTC until 1945 and then +4:30 UTC thereafter:

```
from datetime import timedelta, datetime, tzinfo, timezone

class KabulTz(tzinfo):
    # Kabul used +4 until 1945, when they moved to +4:30
    UTC_MOVE_DATE = datetime(1944, 12, 31, 20, tzinfo=timezone.utc)
```

(繼續下一頁)

```

def utcoffset(self, dt):
    if dt.year < 1945:
        return timedelta(hours=4)
    elif (1945, 1, 1, 0, 0) <= dt.timetuple()[5] < (1945, 1, 1, 0, 30):
        # An ambiguous ("imaginary") half-hour range representing
        # a 'fold' in time due to the shift from +4 to +4:30.
        # If dt falls in the imaginary range, use fold to decide how
        # to resolve. See PEP495.
        return timedelta(hours=4, minutes=(30 if dt.fold else 0))
    else:
        return timedelta(hours=4, minutes=30)

def fromutc(self, dt):
    # Follow same validations as in datetime.tzinfo
    if not isinstance(dt, datetime):
        raise TypeError("fromutc() requires a datetime argument")
    if dt.tzinfo is not self:
        raise ValueError("dt.tzinfo is not self")

    # A custom implementation is required for fromutc as
    # the input to this function is a datetime with utc values
    # but with a tzinfo set to self.
    # See datetime.astimezone or fromtimestamp.
    if dt.replace(tzinfo=timezone.utc) >= self.UTC_MOVE_DATE:
        return dt + timedelta(hours=4, minutes=30)
    else:
        return dt + timedelta(hours=4)

def dst(self, dt):
    # Kabul does not observe daylight saving time.
    return timedelta(0)

def tzname(self, dt):
    if dt >= self.UTC_MOVE_DATE:
        return "+04:30"
    return "+04"

```

Usage of KabulTz from above:

```

>>> tz1 = KabulTz()

>>> # Datetime before the change
>>> dt1 = datetime(1900, 11, 21, 16, 30, tzinfo=tz1)
>>> print(dt1.utcoffset())
4:00:00

>>> # Datetime after the change
>>> dt2 = datetime(2006, 6, 14, 13, 0, tzinfo=tz1)
>>> print(dt2.utcoffset())
4:30:00

>>> # Convert datetime to another time zone
>>> dt3 = dt2.astimezone(timezone.utc)
>>> dt3
datetime.datetime(2006, 6, 14, 8, 30, tzinfo=datetime.timezone.utc)
>>> dt2
datetime.datetime(2006, 6, 14, 13, 0, tzinfo=KabulTz())
>>> dt2 == dt3
True

```

### 8.1.7 `time` 物件

A `time` object represents a (local) time of day, independent of any particular day, and subject to adjustment via a `tzinfo` object.

**class** `datetime.time` (*hour=0, minute=0, second=0, microsecond=0, tzinfo=None, \*, fold=0*)

All arguments are optional. `tzinfo` may be `None`, or an instance of a `tzinfo` subclass. The remaining arguments must be integers in the following ranges:

- `0 <= hour < 24`,
- `0 <= minute < 60`,
- `0 <= second < 60`,
- `0 <= microsecond < 1000000`,
- `fold` in `[0, 1]`.

If an argument outside those ranges is given, `ValueError` is raised. All default to 0 except `tzinfo`, which defaults to `None`.

類 F 屬性:

`time.min`

The earliest representable `time`, `time(0, 0, 0, 0)`.

`time.max`

The latest representable `time`, `time(23, 59, 59, 999999)`.

`time.resolution`

The smallest possible difference between non-equal `time` objects, `timedelta(microseconds=1)`, although note that arithmetic on `time` objects is not supported.

Instance attributes (read-only):

`time.hour`

In range (24).

`time.minute`

In range (60).

`time.second`

In range (60).

`time.microsecond`

In range (1000000).

`time.tzinfo`

The object passed as the `tzinfo` argument to the `time` constructor, or `None` if none was passed.

`time.fold`

In `[0, 1]`. Used to disambiguate wall times during a repeated interval. (A repeated interval occurs when clocks are rolled back at the end of daylight saving time or when the UTC offset for the current zone is decreased for political reasons.) The values 0 and 1 represent, respectively, the earlier and later of the two moments with the same wall time representation.

在 3.6 版被加入。

`time` objects support equality and order comparisons, where `a` is considered less than `b` when `a` precedes `b` in time.

Naive and aware `time` objects are never equal. Order comparison between naive and aware `time` objects raises `TypeError`.

If both comparands are aware, and have the same `tzinfo` attribute, the `tzinfo` and `fold` attributes are ignored and the base times are compared. If both comparands are aware and have different `tzinfo` attributes, the comparands are first adjusted by subtracting their UTC offsets (obtained from `self.utcoffset()`).

在 3.3 版的變更: Equality comparisons between aware and naive `time` instances don't raise `TypeError`.

In Boolean contexts, a `time` object is always considered to be true.

在 3.5 版的變更: Before Python 3.5, a `time` object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See [bpo-13936](#) for full details.

Other constructor:

**classmethod** `time.fromisoformat(time_string)`

Return a `time` corresponding to a `time_string` in any valid ISO 8601 format, with the following exceptions:

1. Time zone offsets may have fractional seconds.
2. The leading `T`, normally required in cases where there may be ambiguity between a date and a time, is not required.
3. Fractional seconds may have any number of digits (anything beyond 6 will be truncated).
4. Fractional hours and minutes are not supported.

範例:

```
>>> from datetime import time
>>> time.fromisoformat('04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T04:23:01')
datetime.time(4, 23, 1)
>>> time.fromisoformat('T042301')
datetime.time(4, 23, 1)
>>> time.fromisoformat('04:23:01.000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01,000384')
datetime.time(4, 23, 1, 384)
>>> time.fromisoformat('04:23:01+04:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone(datetime.timedelta(seconds=14400)))
>>> time.fromisoformat('04:23:01Z')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
>>> time.fromisoformat('04:23:01+00:00')
datetime.time(4, 23, 1, tzinfo=datetime.timezone.utc)
```

在 3.7 版被加入.

在 3.11 版的變更: Previously, this method only supported formats that could be emitted by `time.isoformat()`.

實例方法:

`time.replace(hour=self.hour, minute=self.minute, second=self.second, microsecond=self.microsecond, tzinfo=self.tzinfo, *, fold=0)`

Return a `time` with the same value, except for those attributes given new values by whichever keyword arguments are specified. Note that `tzinfo=None` can be specified to create a naive `time` from an aware `time`, without conversion of the time data.

`time` objects are also supported by generic function `copy.replace()`.

在 3.6 版的變更: 新增 `fold` 參數。

`time.isoformat(timespec='auto')`

Return a string representing the time in ISO 8601 format, one of:

- HH:MM:SS.ffffff, if `microsecond` is not 0
- HH:MM:SS, if `microsecond` is 0
- HH:MM:SS.ffffff+HH:MM[:SS[.ffffff]], if `utcoffset()` does not return None

- HH:MM:SS+HH:MM[:SS[.ffffff]], if *microsecond* is 0 and *utcoffset()* does not return None

The optional argument *timespec* specifies the number of additional components of the time to include (the default is 'auto'). It can be one of the following:

- 'auto': Same as 'seconds' if *microsecond* is 0, same as 'microseconds' otherwise.
- 'hours': Include the *hour* in the two-digit HH format.
- 'minutes': Include *hour* and *minute* in HH:MM format.
- 'seconds': Include *hour*, *minute*, and *second* in HH:MM:SS format.
- 'milliseconds': Include full time, but truncate fractional second part to milliseconds. HH:MM:SS.sss format.
- 'microseconds': Include full time in HH:MM:SS.ffffff format.

#### 備

Excluded time components are truncated, not rounded.

*ValueError* will be raised on an invalid *timespec* argument.

範例:

```
>>> from datetime import time
>>> time(hour=12, minute=34, second=56, microsecond=123456).isoformat(timespec='minutes
↪')
'12:34'
>>> dt = time(hour=12, minute=34, second=56, microsecond=0)
>>> dt.isoformat(timespec='microseconds')
'12:34:56.000000'
>>> dt.isoformat(timespec='auto')
'12:34:56'
```

在 3.6 版的變更: 新增 *timespec* 參數。

`time.__str__()`

For a time *t*, `str(t)` is equivalent to `t.isoformat()`.

`time.strftime(format)`

Return a string representing the time, controlled by an explicit format string. See also *strftime()* 與 *strptime()* 的行 和 *time.isoformat()*.

`time.__format__(format)`

Same as *time.strftime()*. This makes it possible to specify a format string for a *time* object in formatted string literals and when using *str.format()*. See also *strftime()* 與 *strptime()* 的行 和 *time.isoformat()*.

`time.utcoffset()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.utcoffset(None)`, and raises an exception if the latter doesn't return None or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

`time.dst()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.dst(None)`, and raises an exception if the latter doesn't return None, or a *timedelta* object with magnitude less than one day.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

`time.tzname()`

If *tzinfo* is None, returns None, else returns `self.tzinfo.tzname(None)`, or raises an exception if the latter doesn't return None or a string object.

用法范例: `time`Examples of working with a `time` object:

```

>>> from datetime import time, tzinfo, timedelta
>>> class TZ1(tzinfo):
...     def utcoffset(self, dt):
...         return timedelta(hours=1)
...     def dst(self, dt):
...         return timedelta(0)
...     def tzname(self, dt):
...         return "+01:00"
...     def __repr__(self):
...         return f"{self.__class__.__name__}()"
...
>>> t = time(12, 10, 30, tzinfo=TZ1())
>>> t
datetime.time(12, 10, 30, tzinfo=TZ1())
>>> t.isoformat()
'12:10:30+01:00'
>>> t.dst()
datetime.timedelta(0)
>>> t.tzname()
'+01:00'
>>> t.strftime("%H:%M:%S %Z")
'12:10:30 +01:00'
>>> 'The {} is {:%H:%M}.'.format("time", t)
'The time is 12:10.'

```

8.1.8 `tzinfo` 物件`class datetime.tzinfo`

This is an abstract base class, meaning that this class should not be instantiated directly. Define a subclass of `tzinfo` to capture information about a particular time zone.

An instance of (a concrete subclass of) `tzinfo` can be passed to the constructors for `datetime` and `time` objects. The latter objects view their attributes as being in local time, and the `tzinfo` object supports methods revealing offset of local time from UTC, the name of the time zone, and DST offset, all relative to a date or time object passed to them.

You need to derive a concrete subclass, and (at least) supply implementations of the standard `tzinfo` methods needed by the `datetime` methods you use. The `datetime` module provides `timezone`, a simple concrete subclass of `tzinfo` which can represent time zones with fixed offset from UTC such as UTC itself or North American EST and EDT.

Special requirement for pickling: A `tzinfo` subclass must have an `__init__()` method that can be called with no arguments, otherwise it can be pickled but possibly not unpickled again. This is a technical requirement that may be relaxed in the future.

A concrete subclass of `tzinfo` may need to implement the following methods. Exactly which methods are needed depends on the uses made of aware `datetime` objects. If in doubt, simply implement all of them.

`tzinfo.utcoffset(dt)`

Return offset of local time from UTC, as a `timedelta` object that is positive east of UTC. If local time is west of UTC, this should be negative.

This represents the *total* offset from UTC; for example, if a `tzinfo` object represents both time zone and DST adjustments, `utcoffset()` should return their sum. If the UTC offset isn't known, return `None`. Else the value returned must be a `timedelta` object strictly between `-timedelta(hours=24)` and `timedelta(hours=24)` (the magnitude of the offset must be less than one day). Most implementations of `utcoffset()` will probably look like one of these two:

```

return CONSTANT # fixed-offset class
return CONSTANT + self.dst(dt) # daylight-aware class

```

If `utcoffset()` does not return `None`, `dst()` should not return `None` either.

The default implementation of `utcoffset()` raises `NotImplementedError`.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

`tzinfo.dst(dt)`

Return the daylight saving time (DST) adjustment, as a `timedelta` object or `None` if DST information isn't known.

Return `timedelta(0)` if DST is not in effect. If DST is in effect, return the offset as a `timedelta` object (see `utcoffset()` for details). Note that DST offset, if applicable, has already been added to the UTC offset returned by `utcoffset()`, so there's no need to consult `dst()` unless you're interested in obtaining DST info separately. For example, `datetime.timetuple()` calls its `tzinfo` attribute's `dst()` method to determine how the `tm_isdst` flag should be set, and `tzinfo.fromutc()` calls `dst()` to account for DST changes when crossing time zones.

An instance `tz` of a `tzinfo` subclass that models both standard and daylight times must be consistent in this sense:

```
tz.utcoffset(dt) - tz.dst(dt)
```

must return the same result for every `datetime dt` with `dt.tzinfo == tz`. For sane `tzinfo` subclasses, this expression yields the time zone's "standard offset", which should not depend on the date or the time, but only on geographic location. The implementation of `datetime.astimezone()` relies on this, but cannot detect violations; it's the programmer's responsibility to ensure it. If a `tzinfo` subclass cannot guarantee this, it may be able to override the default implementation of `tzinfo.fromutc()` to work correctly with `astimezone()` regardless.

Most implementations of `dst()` will probably look like one of these two:

```

def dst(self, dt):
    # a fixed-offset class: doesn't account for DST
    return timedelta(0)

```

或是:

```

def dst(self, dt):
    # Code to set dston and dstoff to the time zone's DST
    # transition times based on the input dt.year, and expressed
    # in standard local time.

    if dston <= dt.replace(tzinfo=None) < dstoff:
        return timedelta(hours=1)
    else:
        return timedelta(0)

```

The default implementation of `dst()` raises `NotImplementedError`.

在 3.7 版的變更: The DST offset is not restricted to a whole number of minutes.

`tzinfo.tzname(dt)`

Return the time zone name corresponding to the `datetime` object `dt`, as a string. Nothing about string names is defined by the `datetime` module, and there's no requirement that it mean anything in particular. For example, "GMT", "UTC", "-500", "-5:00", "EDT", "US/Eastern", "America/New York" are all valid replies. Return `None` if a string name isn't known. Note that this is a method rather than a fixed string primarily because some `tzinfo` subclasses will wish to return different names depending on the specific value of `dt` passed, especially if the `tzinfo` class is accounting for daylight time.

The default implementation of `tzname()` raises `NotImplementedError`.

These methods are called by a *datetime* or *time* object, in response to their methods of the same names. A *datetime* object passes itself as the argument, and a *time* object passes `None` as the argument. A *tzinfo* subclass's methods should therefore be prepared to accept a *dt* argument of `None`, or of class *datetime*.

When `None` is passed, it's up to the class designer to decide the best response. For example, returning `None` is appropriate if the class wishes to say that time objects don't participate in the *tzinfo* protocols. It may be more useful for `utcoffset(None)` to return the standard UTC offset, as there is no other convention for discovering the standard offset.

When a *datetime* object is passed in response to a *datetime* method, `dt.tzinfo` is the same object as *self*. *tzinfo* methods can rely on this, unless user code calls *tzinfo* methods directly. The intent is that the *tzinfo* methods interpret *dt* as being in local time, and not need worry about objects in other time zones.

There is one more *tzinfo* method that a subclass may wish to override:

`tzinfo.fromutc(dt)`

This is called from the default *datetime.astimezone()* implementation. When called from that, `dt.tzinfo` is *self*, and *dt*'s date and time data are to be viewed as expressing a UTC time. The purpose of *fromutc()* is to adjust the date and time data, returning an equivalent datetime in *self*'s local time.

Most *tzinfo* subclasses should be able to inherit the default *fromutc()* implementation without problems. It's strong enough to handle fixed-offset time zones, and time zones accounting for both standard and daylight time, and the latter even if the DST transition times differ in different years. An example of a time zone the default *fromutc()* implementation may not handle correctly in all cases is one where the standard offset (from UTC) depends on the specific date and time passed, which can happen for political reasons. The default implementations of *astimezone()* and *fromutc()* may not produce the result you want if the result is one of the hours straddling the moment the standard offset changes.

Skipping code for error cases, the default *fromutc()* implementation acts like:

```
def fromutc(self, dt):
    # raise ValueError error if dt.tzinfo is not self
    dtoff = dt.utcoffset()
    dtdst = dt.dst()
    # raise ValueError if dtoff is None or dtdst is None
    delta = dtoff - dtdst # this is self's standard offset
    if delta:
        dt += delta # convert to standard local time
        dtdst = dt.dst()
        # raise ValueError if dtdst is None
    if dtdst:
        return dt + dtdst
    else:
        return dt
```

In the following `tzinfo_examples.py` file there are some examples of *tzinfo* classes:

```
from datetime import tzinfo, timedelta, datetime

ZERO = timedelta(0)
HOUR = timedelta(hours=1)
SECOND = timedelta(seconds=1)

# A class capturing the platform's idea of local time.
# (May result in wrong values on historical times in
# timezones where UTC offset and/or the DST rules had
# changed in the past.)
import time as _time

STDOFFSET = timedelta(seconds = -_time.timezone)
if _time.daylight:
    DSTOFFSET = timedelta(seconds = -_time.altzone)
else:
```

        return dst_time

Eastern = USTimeZone(-5, "Eastern", "EST", "EDT")
Central = USTimeZone(-6, "Central", "CST", "CDT")
Mountain = USTimeZone(-7, "Mountain", "MST", "MDT")
Pacific = USTimeZone(-8, "Pacific", "PST", "PDT")

```

Note that there are unavoidable subtleties twice per year in a `tzinfo` subclass accounting for both standard and daylight time, at the DST transition points. For concreteness, consider US Eastern (UTC -0500), where EDT begins the minute after 1:59 (EST) on the second Sunday in March, and ends the minute after 1:59 (EDT) on the first Sunday in November:

```

UTC    3:MM  4:MM  5:MM  6:MM  7:MM  8:MM
EST   22:MM 23:MM  0:MM  1:MM  2:MM  3:MM
EDT   23:MM  0:MM  1:MM  2:MM  3:MM  4:MM

start 22:MM 23:MM  0:MM  1:MM  3:MM  4:MM

end   23:MM  0:MM  1:MM  1:MM  2:MM  3:MM

```

When DST starts (the "start" line), the local wall clock leaps from 1:59 to 3:00. A wall time of the form 2:MM doesn't really make sense on that day, so `astimezone(Eastern)` won't deliver a result with `hour == 2` on the day DST begins. For example, at the Spring forward transition of 2016, we get:

```

>>> from datetime import datetime, timezone
>>> from tzinfo_examples import HOUR, Eastern
>>> u0 = datetime(2016, 3, 13, 5, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)

```

(繼續下一頁)

(繼續上一頁)

```

...     print(u.time(), 'UTC =', t.time(), t.tzname())
...
05:00:00 UTC = 00:00:00 EST
06:00:00 UTC = 01:00:00 EST
07:00:00 UTC = 03:00:00 EDT
08:00:00 UTC = 04:00:00 EDT

```

When DST ends (the "end" line), there's a potentially worse problem: there's an hour that can't be spelled unambiguously in local wall time: the last hour of daylight time. In Eastern, that's times of the form 5:MM UTC on the day daylight time ends. The local wall clock leaps from 1:59 (daylight time) back to 1:00 (standard time) again. Local times of the form 1:MM are ambiguous. `astimezone()` mimics the local clock's behavior by mapping two adjacent UTC hours into the same local hour then. In the Eastern example, UTC times of the form 5:MM and 6:MM both map to 1:MM when converted to Eastern, but earlier times have the `fold` attribute set to 0 and the later times have it set to 1. For example, at the Fall back transition of 2016, we get:

```

>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...     u = u0 + i*HOUR
...     t = u.astimezone(Eastern)
...     print(u.time(), 'UTC =', t.time(), t.tzname(), t.fold)
...
04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0

```

Note that the `datetime` instances that differ only by the value of the `fold` attribute are considered equal in comparisons.

Applications that can't bear wall-time ambiguities should explicitly check the value of the `fold` attribute or avoid using hybrid `tzinfo` subclasses; there are no ambiguities when using `timezone`, or any other fixed-offset `tzinfo` subclass (such as a class representing only EST (fixed offset -5 hours), or only EDT (fixed offset -4 hours)).

## 也參考

### `zoneinfo`

The `datetime` module has a basic `timezone` class (for handling arbitrary fixed offsets from UTC) and its `timezone.utc` attribute (a UTC `timezone` instance).

`zoneinfo` brings the *IANA time zone database* (also known as the Olson database) to Python, and its usage is recommended.

### IANA 時區資料庫

The Time Zone Database (often called `tz`, `tzdata` or `zoneinfo`) contains code and data that represent the history of local time for many representative locations around the globe. It is updated periodically to reflect changes made by political bodies to time zone boundaries, UTC offsets, and daylight-saving rules.

## 8.1.9 `timezone` 物件

The `timezone` class is a subclass of `tzinfo`, each instance of which represents a time zone defined by a fixed offset from UTC.

Objects of this class cannot be used to represent time zone information in the locations where different offsets are used in different days of the year or where historical changes have been made to civil time.

**class** `datetime.timezone` (*offset*, *name=None*)

The *offset* argument must be specified as a `timedelta` object representing the difference between the local time and UTC. It must be strictly between `-timedelta(hours=24)` and `timedelta(hours=24)`, otherwise `ValueError` is raised.

The *name* argument is optional. If specified it must be a string that will be used as the value returned by the `datetime.tzname()` method.

在 3.2 版被加入。

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

`timezone.utcoffset(dt)`

Return the fixed value specified when the `timezone` instance is constructed.

The *dt* argument is ignored. The return value is a `timedelta` instance equal to the difference between the local time and UTC.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

`timezone.tzname(dt)`

Return the fixed value specified when the `timezone` instance is constructed.

If *name* is not provided in the constructor, the name returned by `tzname(dt)` is generated from the value of the *offset* as follows. If *offset* is `timedelta(0)`, the name is "UTC", otherwise it is a string in the format `UTC±HH:MM`, where  $\pm$  is the sign of *offset*, HH and MM are two digits of `offset.hours` and `offset.minutes` respectively.

在 3.6 版的變更: Name generated from `offset=timedelta(0)` is now plain 'UTC', not 'UTC+00:00'.

`timezone.dst(dt)`

總是回傳 `None`。

`timezone.fromutc(dt)`

Return `dt + offset`. The *dt* argument must be an aware `datetime` instance, with `tzinfo` set to `self`.

類 F 屬性:

`timezone.utc`

UTC 時區, `timezone(timedelta(0))`。

### 8.1.10 `strftime()` 與 `strptime()` 的行 F

`date`, `datetime`, and `time` objects all support a `strftime(format)` method, to create a string representing the time under the control of an explicit format string.

Conversely, the `datetime.strptime()` class method creates a `datetime` object from a string representing a date and time and a corresponding format string.

The table below provides a high-level comparison of `strftime()` versus `strptime()`:

	<code>strftime</code>	<code>strptime</code>
用法	Convert object to a string according to a given format	Parse a string into a <code>datetime</code> object given a corresponding format
Type of method	實例方法	類 F 方法
Method of	<code>date</code> ; <code>datetime</code> ; <code>time</code>	<code>datetime</code>
Signature	<code>strftime(format)</code>	<code>strptime(date_string, format)</code>

#### `strftime()` 與 `strptime()` 格式碼

These methods accept format codes that can be used to parse and format dates:

```
>>> datetime.strptime('31/01/22 23:59:59.999999',
...                    '%d/%m/%y %H:%M:%S.%f')
datetime.datetime(2022, 1, 31, 23, 59, 59, 999999)
>>> _.strftime('%a %d %b %Y, %I:%M%p')
'Mon 31 Jan 2022, 11:59PM'
```

The following is a list of all the format codes that the 1989 C standard requires, and these work on all platforms with a standard C implementation.

Directive	含義	範例	解
%a	Weekday as locale's abbreviated name.	Sun, Mon, ..., Sat (en_US); So, Mo, ..., Sa (de_DE)	(1)
%A	Weekday as locale's full name.	Sunday, Monday, ..., Saturday (en_US); Sonntag, Montag, ..., Samstag (de_DE)	(1)
%w	Weekday as a decimal number, where 0 is Sunday and 6 is Saturday.	0, 1, ..., 6	
%d	Day of the month as a zero-padded decimal number.	01, 02, ..., 31	(9)
%b	Month as locale's abbreviated name.	Jan, Feb, ..., Dec (en_US); Jan, Feb, ..., Dez (de_DE)	(1)
%B	Month as locale's full name.	January, February, ..., December (en_US); Januar, Februar, ..., Dezember (de_DE)	(1)
%m	以零填充的以十進位數字表示的月份。	01, 02, ..., 12	(9)
%y	Year without century as a zero-padded decimal number.	00, 01, ..., 99	(9)
%Y	Year with century as a decimal number.	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(2)
%H	Hour (24-hour clock) as a zero-padded decimal number.	00, 01, ..., 23	(9)
%I	Hour (12-hour clock) as a zero-padded decimal number.	01, 02, ..., 12	(9)
%p	Locale's equivalent of either AM or PM.	AM, PM (en_US); am, pm (de_DE)	(1), (3)
%M	Minute as a zero-padded decimal number.	00, 01, ..., 59	(9)
%S	Second as a zero-padded decimal number.	00, 01, ..., 59	(4), (9)
%f	Microsecond as a decimal number, zero-padded to 6 digits.	000000, 000001, ..., 999999	(5)
%z	UTC offset in the form	(empty), +0000, -0400,	(6)
<b>8.1. datetime --- 日期與時間的基本型</b>	<b>日期與時間的基本型</b>	<b>日期與時間的基本型</b>	<b>233</b>
	(empty string if the object is naive).	+1030, +063415, - 030712.345216	
%Z	Time zone name (empty	(empty), UTC, GMT	(6)

Several additional directives not required by the C89 standard are included for convenience. These parameters all correspond to ISO 8601 date values.

Di- rec- tive	含義	範例	解
%G	ISO 8601 year with century representing the year that contains the greater part of the ISO week (%V).	0001, 0002, ..., 2013, 2014, ..., 9998, 9999	(8)
%u	ISO 8601 weekday as a decimal number where 1 is Monday.	1, 2, ..., 7	
%V	ISO 8601 week as a decimal number with Monday as the first day of the week. Week 01 is the week containing Jan 4.	01, 02, ..., 53	(8), (9)
:%:z	UTC offset in the form ±HH:MM[:SS[.ffffff]] (empty string if the object is naive).	(empty), +00:00, -04:00, +10:30, +06:34:15, -03:07:12.345216	(6)

These may not be available on all platforms when used with the `strftime()` method. The ISO 8601 year and ISO 8601 week directives are not interchangeable with the year and week number directives above. Calling `strptime()` with incomplete or ambiguous ISO 8601 directives will raise a `ValueError`.

The full set of format codes supported varies across platforms, because Python calls the platform C library's `strftime()` function, and platform variations are common. To see the full set of format codes supported on your platform, consult the `strftime(3)` documentation. There are also differences between platforms in handling of unsupported format specifiers.

在 3.6 版被加入: 新增 %G、%u 與 %V。

在 3.12 版被加入: 新增 %:z。

### 技術細節

Broadly speaking, `d.strftime(fmt)` acts like the `time` module's `time.strftime(fmt, d.timetuple())` although not all objects support a `timetuple()` method.

For the `datetime.strptime()` class method, the default value is `1900-01-01T00:00:00.000`: any components not specified in the format string will be pulled from the default value.<sup>4</sup>

Using `datetime.strptime(date_string, format)` is equivalent to:

```
datetime(*(time.strptime(date_string, format)[0:6]))
```

except when the format includes sub-second components or time zone offset information, which are supported in `datetime.strptime` but are discarded by `time.strptime`.

對 `time` 物件來 F，不應該使用年、月、日的格式碼，因 F `time` 物件 F F 有這些值。如果使用這些格式碼，年份會以 1900 代替、月及日會以 1 代替。

對 `date` 物件來 F，不應該使用時、分、秒、微秒的格式碼，因 F `date` 物件 F F 有這些值。如果使用這些格式碼，這些值都會以 0 代替。

For the same reason, handling of format strings containing Unicode code points that can't be represented in the charset of the current locale is also platform-dependent. On some platforms such code points are preserved intact in the output, while on others `strftime` may raise `UnicodeError` or return an empty string instead.

F 解:

- (1) Because the format depends on the current locale, care should be taken when making assumptions about the output value. Field orderings will vary (for example, "month/day/year" versus "day/month/year"), and the output may contain non-ASCII characters.
- (2) The `strptime()` method can parse years in the full [1, 9999] range, but years < 1000 must be zero-filled to 4-digit width.

在 3.2 版的變更: In previous versions, `strftime()` method was restricted to years >= 1900.

<sup>4</sup> Passing `datetime.strptime('Feb 29', '%b %d')` will fail since 1900 is not a leap year.

在 3.3 版的變更: In version 3.2, `strftime()` method was restricted to years  $\geq 1000$ .

- (3) When used with the `strptime()` method, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
- (4) Unlike the `time` module, the `datetime` module does not support leap seconds.
- (5) When used with the `strptime()` method, the `%f` directive accepts from one to six digits and zero pads on the right. `%f` is an extension to the set of format characters in the C standard (but implemented separately in `datetime` objects, and therefore always available).
- (6) For a naive object, the `%z`, `:%z` and `%Z` format codes are replaced by empty strings.

For an aware object:

**%z**

`utcoffset()` is transformed into a string of the form `±HHMM[SS[.ffffff]]`, where `HH` is a 2-digit string giving the number of UTC offset hours, `MM` is a 2-digit string giving the number of UTC offset minutes, `SS` is a 2-digit string giving the number of UTC offset seconds and `ffffff` is a 6-digit string giving the number of UTC offset microseconds. The `ffffff` part is omitted when the offset is a whole number of seconds and both the `ffffff` and the `SS` part is omitted when the offset is a whole number of minutes. For example, if `utcoffset()` returns `timedelta(hours=-3, minutes=-30)`, `%z` is replaced with the string `'-0330'`.

在 3.7 版的變更: The UTC offset is not restricted to a whole number of minutes.

在 3.7 版的變更: When the `%z` directive is provided to the `strptime()` method, the UTC offsets can have a colon as a separator between hours, minutes and seconds. For example, `'+01:00:00'` will be parsed as an offset of one hour. In addition, providing `'Z'` is identical to `'+00:00'`.

**:%z**

Behaves exactly as `%z`, but has a colon separator added between hours, minutes and seconds.

**%Z**

In `strftime()`, `%Z` is replaced by an empty string if `tzname()` returns `None`; otherwise `%Z` is replaced by the returned value, which must be a string.

`strptime()` only accepts certain values for `%Z`:

1. any value in `time.tzname` for your machine's locale
2. the hard-coded values `UTC` and `GMT`

So someone living in Japan may have `JST`, `UTC`, and `GMT` as valid values, but probably not `EST`. It will raise `ValueError` for invalid values.

在 3.2 版的變更: When the `%z` directive is provided to the `strptime()` method, an aware `datetime` object will be produced. The `tzinfo` of the result will be set to a `timezone` instance.

- (7) When used with the `strptime()` method, `%U` and `%W` are only used in calculations when the day of the week and the calendar year (`%Y`) are specified.
- (8) Similar to `%U` and `%W`, `%V` is only used in calculations when the day of the week and the ISO year (`%G`) are specified in a `strptime()` format string. Also note that `%G` and `%Y` are not interchangeable.
- (9) When used with the `strptime()` method, the leading zero is optional for formats `%d`, `%m`, `%H`, `%I`, `%M`, `%S`, `%j`, `%U`, `%W`, and `%V`. Format `%y` does require a leading zero.
- (10) When parsing a month and day using `strptime()`, always include a year in the format. If the value you need to parse lacks a year, append an explicit dummy leap year. Otherwise your code will raise an exception when it encounters leap day because the default year used by the parser is not a leap year. Users run into this bug every four years...

```
>>> month_day = "02/29"
>>> datetime.strptime(f"{month_day};1984", "%m/%d;%Y") # No leap year bug.
datetime.datetime(1984, 2, 29, 0, 0)
```

Deprecated since version 3.13, will be removed in version 3.15: `strptime()` calls using a format string containing a day of month without a year now emit a `DeprecationWarning`. In 3.15 or later we may change this into an error or change the default year to a leap year. See [gh-70647](#).

 解

## 8.2 zoneinfo --- IANA 時區支援

在 3.9 版被加入。

原始碼: [Lib/zoneinfo](#)

The `zoneinfo` module provides a concrete time zone implementation to support the IANA time zone database as originally specified in [PEP 615](#). By default, `zoneinfo` uses the system's time zone data if available; if no system time zone data is available, the library will fall back to using the first-party `tzdata` package available on PyPI.

### 也參考

#### `datetime` 模組

Provides the `time` and `datetime` types with which the `ZoneInfo` class is designed to be used.

#### `tzdata` 套件

First-party package maintained by the CPython core developers to supply time zone data via PyPI.

適用: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參  [WebAssembly](#) 平台。

### 8.2.1 Using ZoneInfo

`ZoneInfo` is a concrete implementation of the `datetime.tzinfo` abstract base class, and is intended to be attached to `tzinfo`, either via the constructor, the `datetime.replace` method or `datetime.astimezone`:

```
>>> from zoneinfo import ZoneInfo
>>> from datetime import datetime, timedelta

>>> dt = datetime(2020, 10, 31, 12, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-10-31 12:00:00-07:00

>>> dt.tzname()
'PDT'
```

Datetimes constructed in this way are compatible with datetime arithmetic and handle daylight saving time transitions with no further intervention:

```
>>> dt_add = dt + timedelta(days=1)

>>> print(dt_add)
2020-11-01 12:00:00-08:00

>>> dt_add.tzname()
'PST'
```

These time zones also support the `fold` attribute introduced in [PEP 495](#). During offset transitions which induce ambiguous times (such as a daylight saving time to standard time transition), the offset from *before* the transition is used when `fold=0`, and the offset *after* the transition is used when `fold=1`, for example:

```
>>> dt = datetime(2020, 11, 1, 1, tzinfo=ZoneInfo("America/Los_Angeles"))
>>> print(dt)
2020-11-01 01:00:00-07:00

>>> print(dt.replace(fold=1))
2020-11-01 01:00:00-08:00
```

When converting from another time zone, the fold will be set to the correct value:

```
>>> from datetime import timezone
>>> LOS_ANGELES = ZoneInfo("America/Los_Angeles")
>>> dt_utc = datetime(2020, 11, 1, 8, tzinfo=timezone.utc)

>>> # Before the PDT -> PST transition
>>> print(dt_utc.astimezone(LOS_ANGELES))
2020-11-01 01:00:00-07:00

>>> # After the PDT -> PST transition
>>> print((dt_utc + timedelta(hours=1)).astimezone(LOS_ANGELES))
2020-11-01 01:00:00-08:00
```

## 8.2.2 Data sources

The `zoneinfo` module does not directly provide time zone data, and instead pulls time zone information from the system time zone database or the first-party PyPI package `tzdata`, if available. Some systems, including notably Windows systems, do not have an IANA database available, and so for projects targeting cross-platform compatibility that require time zone data, it is recommended to declare a dependency on `tzdata`. If neither system data nor `tzdata` are available, all calls to `ZoneInfo` will raise `ZoneInfoNotFoundError`.

### Configuring the data sources

When `ZoneInfo(key)` is called, the constructor first searches the directories specified in `TZPATH` for a file matching `key`, and on failure looks for a match in the `tzdata` package. This behavior can be configured in three ways:

1. The default `TZPATH` when not otherwise specified can be configured at *compile time*.
2. `TZPATH` can be configured using *an environment variable*.
3. At *runtime*, the search path can be manipulated using the `reset_tzpath()` function.

### Compile-time configuration

The default `TZPATH` includes several common deployment locations for the time zone database (except on Windows, where there are no “well-known” locations for time zone data). On POSIX systems, downstream distributors and those building Python from source who know where their system time zone data is deployed may change the default time zone path by specifying the compile-time option `TZPATH` (or, more likely, the configure flag `--with-tzpath`), which should be a string delimited by `os.pathsep`.

On all platforms, the configured value is available as the `TZPATH` key in `sysconfig.get_config_var()`.

### Environment configuration

When initializing `TZPATH` (either at import time or whenever `reset_tzpath()` is called with no arguments), the `zoneinfo` module will use the environment variable `PYTHONTZPATH`, if it exists, to set the search path.

#### PYTHONTZPATH

This is an `os.pathsep`-separated string containing the time zone search path to use. It must consist of only absolute rather than relative paths. Relative components specified in `PYTHONTZPATH` will not be used, but otherwise the behavior when a relative path is specified is implementation-defined; CPython will raise `InvalidTZPathWarning`, but other implementations are free to silently ignore the erroneous component or raise an exception.

To set the system to ignore the system data and use the tzdata package instead, set `PYTHONTZPATH=""`.

## Runtime configuration

The TZ search path can also be configured at runtime using the `reset_tzpath()` function. This is generally not an advisable operation, though it is reasonable to use it in test functions that require the use of a specific time zone path (or require disabling access to the system time zones).

### 8.2.3 The `ZoneInfo` class

**class** `zoneinfo.ZoneInfo` (*key*)

A concrete `datetime.tzinfo` subclass that represents an IANA time zone specified by the string *key*. Calls to the primary constructor will always return objects that compare identically; put another way, barring cache invalidation via `ZoneInfo.clear_cache()`, for all values of *key*, the following assertion will always be true:

```
a = ZoneInfo(key)
b = ZoneInfo(key)
assert a is b
```

*key* must be in the form of a relative, normalized POSIX path, with no up-level references. The constructor will raise `ValueError` if a non-conforming key is passed.

If no file matching *key* is found, the constructor will raise `ZoneInfoNotFoundError`.

The `ZoneInfo` class has two alternate constructors:

**classmethod** `ZoneInfo.from_file` (*fobj*, *l*, *key=None*)

Constructs a `ZoneInfo` object from a file-like object returning bytes (e.g. a file opened in binary mode or an `io.BytesIO` object). Unlike the primary constructor, this always constructs a new object.

The *key* parameter sets the name of the zone for the purposes of `__str__()` and `__repr__()`.

Objects created via this constructor cannot be pickled (see *pickling*).

**classmethod** `ZoneInfo.no_cache` (*key*)

An alternate constructor that bypasses the constructor's cache. It is identical to the primary constructor, but returns a new object on each call. This is most likely to be useful for testing or demonstration purposes, but it can also be used to create a system with a different cache invalidation strategy.

Objects created via this constructor will also bypass the cache of a deserializing process when unpickled.

Using this constructor may change the semantics of your datetimes in surprising ways, only use it if you know that you need to.

The following class methods are also available:

**classmethod** `ZoneInfo.clear_cache` (\*, *only\_keys=None*)

A method for invalidating the cache on the `ZoneInfo` class. If no arguments are passed, all caches are invalidated and the next call to the primary constructor for each key will return a new instance.

If an iterable of key names is passed to the *only\_keys* parameter, only the specified keys will be removed from the cache. Keys passed to *only\_keys* but not found in the cache are ignored.

Invoking this function may change the semantics of datetimes using `ZoneInfo` in surprising ways; this modifies module state and thus may have wide-ranging effects. Only use it if you know that you need to.

The class has one attribute:

`ZoneInfo.key`

This is a read-only *attribute* that returns the value of `key` passed to the constructor, which should be a lookup key in the IANA time zone database (e.g. `America/New_York`, `Europe/Paris` or `Asia/Tokyo`).

For zones constructed from file without specifying a `key` parameter, this will be set to `None`.

#### 備註

Although it is a somewhat common practice to expose these to end users, these values are designed to be primary keys for representing the relevant zones and not necessarily user-facing elements. Projects like CLDR (the Unicode Common Locale Data Repository) can be used to get more user-friendly strings from these keys.

## String representations

The string representation returned when calling `str` on a `ZoneInfo` object defaults to using the `ZoneInfo.key` attribute (see the note on usage in the attribute documentation):

```
>>> zone = ZoneInfo("Pacific/Kwajalein")
>>> str(zone)
'Pacific/Kwajalein'

>>> dt = datetime(2020, 4, 1, 3, 15, tzinfo=zone)
>>> f"{dt.isoformat()} [{dt.tzinfo}]"
'2020-04-01T03:15:00+12:00 [Pacific/Kwajalein]'
```

For objects constructed from a file without specifying a `key` parameter, `str` falls back to calling `repr()`. `ZoneInfo`'s `repr` is implementation-defined and not necessarily stable between versions, but it is guaranteed not to be a valid `ZoneInfo` key.

## Pickle serialization

Rather than serializing all transition data, `ZoneInfo` objects are serialized by key, and `ZoneInfo` objects constructed from files (even those with a value for `key` specified) cannot be pickled.

The behavior of a `ZoneInfo` file depends on how it was constructed:

1. `ZoneInfo(key)`: When constructed with the primary constructor, a `ZoneInfo` object is serialized by key, and when deserialized, the deserializing process uses the primary and thus it is expected that these are expected to be the same object as other references to the same time zone. For example, if `europe_berlin_pkl` is a string containing a pickle constructed from `ZoneInfo("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl)
>>> a is b
True
```

2. `ZoneInfo.no_cache(key)`: When constructed from the cache-bypassing constructor, the `ZoneInfo` object is also serialized by key, but when deserialized, the deserializing process uses the cache bypassing constructor. If `europe_berlin_pkl_nc` is a string containing a pickle constructed from `ZoneInfo.no_cache("Europe/Berlin")`, one would expect the following behavior:

```
>>> a = ZoneInfo("Europe/Berlin")
>>> b = pickle.loads(europe_berlin_pkl_nc)
>>> a is b
False
```

3. `ZoneInfo.from_file(fobj, /, key=None)`: When constructed from a file, the `ZoneInfo` object raises an exception on pickling. If an end user wants to pickle a `ZoneInfo` constructed from a file, it is recommended that they use a wrapper type or a custom serialization function: either serializing by key or storing the contents of the file object and serializing that.

This method of serialization requires that the time zone data for the required key be available on both the serializing and deserializing side, similar to the way that references to classes and functions are expected to exist in both the serializing and deserializing environments. It also means that no guarantees are made about the consistency of results when unpickling a `ZoneInfo` pickled in an environment with a different version of the time zone data.

## 8.2.4 函式

`zoneinfo.available_timezones()`

Get a set containing all the valid keys for IANA time zones available anywhere on the time zone path. This is recalculated on every call to the function.

This function only includes canonical zone names and does not include "special" zones such as those under the `posix/` and `right/` directories, or the `posixrules` zone.

警告

This function may open a large number of files, as the best way to determine if a file on the time zone path is a valid time zone is to read the "magic string" at the beginning.

備F

These values are not designed to be exposed to end-users; for user facing elements, applications should use something like CLDR (the Unicode Common Locale Data Repository) to get more user-friendly strings. See also the cautionary note on `ZoneInfo.key`.

`zoneinfo.reset_tzpath(to=None)`

Sets or resets the time zone search path (`TZPATH`) for the module. When called with no arguments, `TZPATH` is set to the default value.

Calling `reset_tzpath` will not invalidate the `ZoneInfo` cache, and so calls to the primary `ZoneInfo` constructor will only use the new `TZPATH` in the case of a cache miss.

The `to` parameter must be a *sequence* of strings or `os.PathLike` and not a string, all of which must be absolute paths. `ValueError` will be raised if something other than an absolute path is passed.

## 8.2.5 Globals

`zoneinfo.TZPATH`

A read-only sequence representing the time zone search path -- when constructing a `ZoneInfo` from a key, the key is joined to each entry in the `TZPATH`, and the first file found is used.

`TZPATH` may contain only absolute paths, never relative paths, regardless of how it is configured.

The object that `zoneinfo.TZPATH` points to may change in response to a call to `reset_tzpath()`, so it is recommended to use `zoneinfo.TZPATH` rather than importing `TZPATH` from `zoneinfo` or assigning a long-lived variable to `zoneinfo.TZPATH`.

For more information on configuring the time zone search path, see *Configuring the data sources*.

## 8.2.6 Exceptions and warnings

**exception** `zoneinfo.ZoneInfoNotFoundError`

Raised when construction of a `ZoneInfo` object fails because the specified key could not be found on the system. This is a subclass of `KeyError`.

**exception** `zoneinfo.InvalidTZPathWarning`

Raised when `PYTHONTZPATH` contains an invalid component that will be filtered out, such as a relative path.

## 8.3 calendar --- 日 相關函式

原始碼: `Lib/calendar.py`

這個模組讓你可以像 Unix 的 `cal` 程式一樣輸出日，額外提供有用的日相關函式。這些日預設把一當作一的第一天，而日當作最後一天（歐洲的慣例）。可以使用 `setfirstweekday()` 設定一的第一天日 (6) 或一的其它任一天，其中指定日期的參數是整數。相關功能參考 `datetime` 和 `time` 模組。

這個模組定義的函式和類使用理想化的日，也就是公 (Gregorian calendar) 無限往前後兩個方向延伸。這符合 Dershowitz 和 Reingold 在「*Calendrical Calculations*」這本書定義的「逆推公」(proleptic Gregorian)，是做所有計算的基礎日。0 及負數年份的解讀跟 ISO 8601 標準規定的一樣，0 年是公元前 1 年，-1 年是公元前 2 年依此類推。

**class** `calendar.Calendar` (*firstweekday=0*)

建立 `Calendar` 物件。*firstweekday* 是一個指定一第一天的整數，`MONDAY` 是 0 (預設值)，`SUNDAY` 是 6。

`Calendar` 物件提供一些方法來日資料的格式化做準備。這個類本身不做任何格式化，這是子類的工作。

`Calendar` 實例有以下方法與屬性：

**firstweekday**

The first weekday as an integer (0--6).

This property can also be set and read using `setfirstweekday()` and `getfirstweekday()` respectively.

**getfirstweekday()**

Return an `int` for the current first weekday (0--6).

Identical to reading the `firstweekday` property.

**setfirstweekday** (*firstweekday*)

Set the first weekday to *firstweekday*, passed as an `int` (0--6)

Identical to setting the `firstweekday` property.

**iterweekdays()**

回傳一個以數字代表一的每一天的代器 (iterator)。代器的第一個值和 `firstweekday` 屬性的值一樣。

**itermonthdates** (*year*, *month*)

回傳一個在 *year* 年 *month* (1--12) 月的代器。這個代器會回傳該月的所有日期 (`datetime.date` 物件) 以及在該月之前及之後用來組成完整一的日期。

**itermonthdays** (*year*, *month*)

類似 `itermonthdates()`，回傳一個在 *year* 年 *month* 月的代器，但不受限於 `datetime.date` 的範圍。回傳的日期單純是該月當日的數字，對於該月之外的日期數字會是 0。

**itermonthdays2**(*year, month*)

類似 `itermonthdates()`，回傳一個在 *year* 年 *month* 月的迭代器，但不受限於 `datetime.date` 的範圍。回傳的日期是一個由該月當日的數字及代表幾的數字組成的元組。

**itermonthdays3**(*year, month*)

類似 `itermonthdates()`，回傳一個在 *year* 年 *month* 月的迭代器，但不受限於 `datetime.date` 的範圍。回傳的日期是一個由年、月、日的數字組成的元組。

在 3.7 版被加入。

**itermonthdays4**(*year, month*)

類似 `itermonthdates()`，回傳一個在 *year* 年 *month* 月的迭代器，但不受限於 `datetime.date` 的範圍。回傳的日期是一個由年、月、日及代表幾的數字組成的元組。

在 3.7 版被加入。

**monthdatescalendar**(*year, month*)

回傳一個在 *year* 年 *month* 月每一組成的串列。每一組是一個串列，包含七個 `datetime.date` 物件。

**monthdays2calendar**(*year, month*)

回傳一個在 *year* 年 *month* 月每一組成的串列。每一組是一個串列，包含七個該月當日的數字及代表幾的數字組成的元組。

**monthdayscalendar**(*year, month*)

回傳一個在 *year* 年 *month* 月每一組成的串列。每一組是一個串列，包含七個該月當日的數字。

**yeardatescalendar**(*year, width=3*)

回傳用來格式化的指定年份的資料。回傳值是月份列的串列，每個月份列最多由 *width* 個月份組成（預設 3）。每個月份包含四到六，每一包含一到七天，每一天則是一個 `datetime.date` 物件。

**yeardays2calendar**(*year, width=3*)

回傳用來格式化的指定年份的資料（類似 `yeardatescalendar()`）。每一天是一個該月當日的數字及代表幾的數字組成的元組，該月外的日期的該月當日數字 0。

**yeardayscalendar**(*year, width=3*)

回傳用來格式化的指定年份的資料（類似 `yeardatescalendar()`）。每一天是一個該月當日的數字，該月外的日期的該月當日數字 0。

**class** `calendar.TextCalendar`(*firstweekday=0*)

這個類用來生成純文字的日。

`TextCalendar` 實例有以下方法：

**formatday**(*theday, weekday, width*)

Return a string representing a single day formatted with the given *width*. If *theday* is 0, return a string of spaces of the specified width, representing an empty day. The *weekday* parameter is unused.

**formatweek**(*theweek, w=0*)

Return a single week in a string with no newline. If *w* is provided, it specifies the width of the date columns, which are centered. Depends on the first weekday as specified in the constructor or set by the `setfirstweekday()` method.

**formatweekday**(*weekday, width*)

Return a string representing the name of a single weekday formatted to the specified *width*. The *weekday* parameter is an integer representing the day of the week, where 0 is Monday and 6 is Sunday.

**formatweekheader**(*width*)

Return a string containing the header row of weekday names, formatted with the given *width* for each column. The names depend on the locale settings and are padded to the specified width.

**formatmonth** (*theyear, themonth, w=0, l=0*)

以多行字串的形式回傳一個月份的日。如果給定 *w*，它會指定置中的日期欄的寬度。如果給定 *l*，它會指定每一行使用的行數。這個日會依據在建構函式中指定或者透過 `setfirstweekday()` 方法設定的一的第一天來輸出。

**formatmonthname** (*theyear, themonth, width=0, withyear=True*)

Return a string representing the month's name centered within the specified *width*. If *withyear* is `True`, include the year in the output. The *theyear* and *themoth* parameters specify the year and month for the name to be formatted respectively.

**prmonth** (*theyear, themonth, w=0, l=0*)

印出一個月份的日，容和 `formatmonth()` 回傳的一樣。

**formatyear** (*theyear, w=2, l=1, c=6, m=3*)

以多行字串的形式回傳有 *m* 欄的一整年的日。可選的參數 *w*、*l* 及 *c* 分別是日期欄寬度、每行行數及月份欄中間的空白數。這個日會依據在建構函式中指定或者透過 `setfirstweekday()` 方法設定的一的第一天來輸出。最早可以生日的年份會依據平台而不同。

**pryear** (*theyear, w=2, l=1, c=6, m=3*)

印出一整年的日，容和 `formatyear()` 回傳的一樣。

**class** `calendar.HTMLCalendar` (*firstweekday=0*)

這個類用來生日 HTML 日。

`HTMLCalendar` 實例有以下方法：

**formatmonth** (*theyear, themonth, withyear=True*)

以 HTML 表格的形式回傳一個月份的日。如果 *withyear* 是 `true` 則標題會包含年份，否則只會有月份名稱。

**formatyear** (*theyear, width=3*)

以 HTML 表格的形式回傳一整年的日。*width* (預設 3) 指定一列有幾個月。

**formatyearpage** (*theyear, width=3, css='calendar.css', encoding=None*)

以完整 HTML 頁面的形式回傳一整年的日。*width* (預設 3) 指定一列有幾個月。*css* 是要使用的 CSS (cascading style sheet) 名稱，可以給 `None` 表示不使用任何 CSS。*encoding* 指定輸出使用的編碼 (預設使用系統預設編碼)。

**formatmonthname** (*theyear, themonth, withyear=True*)

以 HTML 表列的形式回傳一個月份的名稱。如果 *withyear* 是 `true` 則該列會包含年份，否則只會有月份名稱。

`HTMLCalendar` 可以覆寫以下屬性來客生日所使用的 CSS 類：

**cssclasses**

對應一每一天的 CSS 類的串列。預設的串列容：

```
cssclasses = ["mon", "tue", "wed", "thu", "fri", "sat", "sun"]
```

可以針對每一天增加更多樣式：

```
cssclasses = ["mon text-bold", "tue", "wed", "thu", "fri", "sat", "sun red"]
```

注意這個串列的長度必須是七個項目。

**cssclass\_noday**

跟當月同一且屬於前一個或下一個月份的日期使用的 CSS 類。

在 3.7 版被加入。

**cssclasses\_weekday\_head**

在標題列中一 每一天的名稱的 CSS 類 (由 `formatweekday()` 所使用), 預設值和 `cssclasses` 相同。  
在 3.7 版被加入。

**cssclass\_month\_head**

月份標題的 CSS 類 (由 `formatmonthname()` 所使用), 預設值是 "month"。  
在 3.7 版被加入。

**cssclass\_month**

整個月份表格的 CSS 類 (由 `formatmonth()` 所使用), 預設值是 "month"。  
在 3.7 版被加入。

**cssclass\_year**

整年表格的 CSS 類 (由 `formatyear()` 所使用), 預設值是 "year"。  
在 3.7 版被加入。

**cssclass\_year\_head**

整年表格標題的 CSS 類 (由 `formatyear()` 所使用), 預設值是 "year"。  
在 3.7 版被加入。

注意雖然上面提到的 CSS 屬性名稱是單數 (例如 `cssclass_month`、`cssclass_noday`), 你可以使用多個以空格隔開的 CSS 類取代單一 CSS 類, 例如:

```
"text-bold text-red"
```

以下是客 化 `HTMLCalendar` 的範例:

```
class CustomHTMLCal(calendar.HTMLCalendar):
    cssclasses = [style + " text-nowrap" for style in
                  calendar.HTMLCalendar.cssclasses]
    cssclass_month_head = "text-center month-head"
    cssclass_month = "text-center month"
    cssclass_year = "text-italic lead"
```

**class calendar.LocaleTextCalendar (firstweekday=0, locale=None)**

`TextCalendar` 的子類, 可以在建構函式傳入語系名稱, 它會回傳指定語系的月份及一 每一天的名稱。

**class calendar.LocaleHTMLCalendar (firstweekday=0, locale=None)**

`HTMLCalendar` 的子類, 可以在建構函式傳入語系名稱, 它會回傳指定語系的月份及一 每一天的名稱。

**備**

這兩個類的建構函式、`formatweekday()` 及 `formatmonthname()` 方法會把 `LC_TIME` 語系暫時改成給定的 `locale`。因 目前的語系是屬於整個行程 (`process-wide`) 的設定, 它們不是執行緒安全的。

這個模組提供以下函式給單純的文字日 使用。

**calendar.setfirstweekday (weekday)**

設定一 的第一天 (0 是 一、6 是 日)。提供 `MONDAY`、`TUESDAY`、`WEDNESDAY`、`THURSDAY`、`FRIDAY`、`SATURDAY` 及 `SUNDAY` 可以方便設定。例如設定一 的第一天 日:

```
import calendar
calendar.setfirstweekday(calendar.SUNDAY)
```

`calendar.firstweekday()`

回傳目前設定的一星期的第一天。

`calendar.isleap(year)`

如果 `year` 是閏年回傳 `True`，否則回傳 `False`。

`calendar.leapdays(y1, y2)`

回傳從 `y1` 到 `y2`（不包含）間有幾個閏年，其中 `y1` 和 `y2` 是年份。

這個函式也適用在跨越世紀的時間範圍。

`calendar.weekday(year, month, day)`

回傳 `year` 年 (1970---...) `month` 月 (1--12) `day` 日 (1--31) 是星期幾 (0 是星期一)。

`calendar.weekheader(n)`

回傳包含一星期的每一天的名稱縮寫的標題。`n` 指定每一天的字元寬度。

`calendar.monthrange(year, month)`

回傳指定 `year` 年 `month` 月該月第一天代表星期幾的數字及該月有多少天。

`calendar.monthcalendar(year, month)`

回傳代表一個月份日星期的矩陣。每一列一星期；該月以外的日期以 0 表示。每一星期以星期一開始，除非有使用 `setfirstweekday()` 改變設定。

`calendar.prmnth(theyear, themonth, w=0, l=0)`

印出一個月份的日星期，跟 `month()` 回傳的日星期內容一樣。

`calendar.month(theyear, themonth, w=0, l=0)`

以多行字串的形式回傳一個月的日星期，使用 `TextCalendar` 類 `formatmonth()`。

`calendar.prcal(year, w=0, l=0, c=6, m=3)`

印出一整年的日星期，跟 `calendar()` 回傳的日星期內容一樣。

`calendar.calendar(year, w=2, l=1, c=6, m=3)`

以多行字串回傳三欄形式的一整年日星期，使用 `TextCalendar` 類 `formatyear()`。

`calendar.timegm(tuple)`

一個跟日星期無關但方便的函式，它接受一個像 `time` 模組 `gmtime()` 函式回傳的元組，日星期回傳對應的 Unix 時間戳，假設從 1970 開始及 POSIX 編碼。事實上，`time.gmtime()` 和 `timegm()` 是彼此相反的。

`calendar` 模組匯出以下資料屬性：

`calendar.day_name`

以目前語系來表示的一星期的每一天名稱的序列，其中星期一為第 0 天。

```
>>> import calendar
>>> list(calendar.day_name)
['Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday', 'Saturday', 'Sunday']
```

`calendar.day_abbr`

以目前語系來表示的一星期的每一天縮寫名稱的序列，其中 Mon 為第 0 天。

```
>>> import calendar
>>> list(calendar.day_abbr)
['Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat', 'Sun']
```

`calendar.MONDAY`

`calendar.TUESDAY`

`calendar.WEDNESDAY`

`calendar.THURSDAY`

`calendar.FRIDAY`

`calendar.SATURDAY`

`calendar.SUNDAY`

一 每一天的 名，其中 `MONDAY` 是 0 而 `SUNDAY` 是 6。

在 3.12 版被加入。

**class** `calendar.Day`

將一 中的幾天定義 整數常數的列舉。此列舉的成員將作 `MONDAY` 到 `SUNDAY` 匯出到模組作用域。

在 3.12 版被加入。

`calendar.month_name`

以目前語系來表示的一年每個月份名稱的序列。它按照一般慣例以數字 1 代表一月，因此它的長度 13，而 `month_name[0]` 是空字串。

```
>>> import calendar
>>> list(calendar.month_name)
['', 'January', 'February', 'March', 'April', 'May', 'June', 'July', 'August',
↵ 'September', 'October', 'November', 'December']
```

`calendar.month_abbr`

以目前語系來表示的一年每個月份縮寫名稱的序列。它按照一般慣例以數字 1 代表一月，因此它的長度 13，而 `month_abbr[0]` 是空字串。

```
>>> import calendar
>>> list(calendar.month_abbr)
['', 'Jan', 'Feb', 'Mar', 'Apr', 'May', 'Jun', 'Jul', 'Aug', 'Sep', 'Oct', 'Nov', 'Dec']
```

`calendar.JANUARY`

`calendar.FEBRUARY`

`calendar.MARCH`

`calendar.APRIL`

`calendar.MAY`

`calendar.JUNE`

`calendar.JULY`

`calendar.AUGUST`

`calendar.SEPTEMBER`

`calendar.OCTOBER`

`calendar.NOVEMBER`

`calendar.DECEMBER`

一年 每個月的 名，其中 `JANUARY` 是 1 而 `DECEMBER` 是 12。

在 3.12 版被加入。

**class** `calendar.Month`

將一年中的月份定義 整數常數的列舉。此列舉的成員將作 `JANUARY` 到 `DECEMBER` 匯出到模組作用域。

在 3.12 版被加入。

`calendar` 模組定義了以下例外：

**exception** `calendar.IllegalMonthError(month)`

`ValueError` 的子類，當給定的月份數字超出 1-12 範圍（含）時引發。

**month**

無效的月份號。

**exception** `calendar.IllegalWeekdayError` (*weekday*)

`ValueError` 的子類，當給定的幾的數字超出 0-6 (含) 範圍時引發。

**weekday**

無效的幾編號。

### 也參考

**`datetime` 模組**

日期與時間的物件導向介面，和 `time` 模組有相似的功能。

**`time` 模組**

底層的時間相關函式。

## 8.3.1 命令列用法

在 2.5 版被加入。

`calendar` 模組可以作本從命令列執行，以互動方式列印日。

```
python -m calendar [-h] [-L LOCALE] [-e ENCODING] [-t {text,html}]
                  [-w WIDTH] [-l LINES] [-s SPACING] [-m MONTHS] [-c CSS]
                  [-f FIRST_WEEKDAY] [year] [month]
```

例如，要列印 2000 年的日：

```
$ python -m calendar 2000

                2000

    January                February                March
Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su
                        1 2                    1 2 3 4 5 6
    3 4 5 6 7 8 9        7 8 9 10 11 12 13        6 7 8 9 10 11 12
    10 11 12 13 14 15 16  14 15 16 17 18 19 20        13 14 15 16 17 18 19
    17 18 19 20 21 22 23  21 22 23 24 25 26 27        20 21 22 23 24 25 26
    24 25 26 27 28 29 30  28 29                                27 28 29 30 31
    31

    April                    May                    June
Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su
                        1 2                    1 2 3 4 5 6 7
    3 4 5 6 7 8 9        8 9 10 11 12 13 14        5 6 7 8 9 10 11
    10 11 12 13 14 15 16  15 16 17 18 19 20 21        12 13 14 15 16 17 18
    17 18 19 20 21 22 23  22 23 24 25 26 27 28        19 20 21 22 23 24 25
    24 25 26 27 28 29 30  29 30 31                                26 27 28 29 30

    July                    August                September
Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su
                        1 2                    1 2 3 4 5 6
    3 4 5 6 7 8 9        7 8 9 10 11 12 13        4 5 6 7 8 9 10
    10 11 12 13 14 15 16  14 15 16 17 18 19 20        11 12 13 14 15 16 17
    17 18 19 20 21 22 23  21 22 23 24 25 26 27        18 19 20 21 22 23 24
    24 25 26 27 28 29 30  28 29 30 31                                25 26 27 28 29 30
    31

    October                November                December
Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su    Mo Tu We Th Fr Sa Su
                        1                    1 2 3 4 5
    2 3 4 5 6 7 8        6 7 8 9 10 11 12        4 5 6 7 8 9 10
    9 10 11 12 13 14 15  13 14 15 16 17 18 19        11 12 13 14 15 16 17
    16 17 18 19 20 21 22  20 21 22 23 24 25 26        18 19 20 21 22 23 24
```

(繼續下一頁)

```
23 24 25 26 27 28 29      27 28 29 30      25 26 27 28 29 30 31
30 31
```

接受以下選項：

**--help, -h**

顯示幫助訊息並退出。

**--locale LOCALE, -L LOCALE**

用於月份和星期名稱的語系。預設為英語。

**--encoding ENCODING, -e ENCODING**

用於輸出的編碼。如有設定 `--locale` 則必須給定 `--encoding`。

**--type {text,html}, -t {text,html}**

將日期以文字或 HTML 文件的形式印出到終端機。

**--first-weekday FIRST\_WEEKDAY, -f FIRST\_WEEKDAY**

一週起始的日子。必須是 0 (週一) 到 6 (週日) 之間的數字。預設為 0。

在 3.13 版被加入。

**year**

印出日期的年份。預設為當前年份。

**month**

要列印日期的指定 `year` 的月份。必須是 1 到 12 之間的數字，且只能在文字模式下使用。預設列印全年日期。

文字模式選項：

**--width WIDTH, -w WIDTH**

終端機行中日期行的寬度。日期印出在行的中央。任何小於 2 的值都會被忽略。預設為 2。

**--lines LINES, -l LINES**

終端機列中每行的列數。日期印出時頂部會對齊。任何小於 1 的值都會被忽略。預設為 1。

**--spacing SPACING, -s SPACING**

行中月份之間的時間距。任何小於 2 的值都會被忽略。預設為 6。

**--months MONTHS, -m MONTHS**

每列印出的月份數量。預設為 3。

HTML 模式選項：

**--css CSS, -c CSS**

用於日期的 CSS 樣式表路徑。這必須是相對於生成之 HTML 的，或者對的 HTTP 或 `file:///` URL。

## 8.4 collections --- 容器資料型態

原始碼：[Lib/collections/\\_init\\_.py](#)

這個模組實作了一些特殊的容器資料型態，用來替代 Python 一般建立的容器，例如 `dict` (字典)、`list` (串列)、`set` (集合) 和 `tuple` (元組)。

<code>namedtuple()</code>	用來建立具名欄位的 <code>tuple</code> 子類化的工廠函式
<code>deque</code>	一個類似 <code>list</code> 的容器，可以快速的在頭尾加入 ( <code>append</code> ) 元素與移除 ( <code>pop</code> ) 元素
<code>ChainMap</code>	一個類似 <code>dict</code> 的類，用來多個對映 ( <code>mapping</code> ) 建立單一的視圖 ( <code>view</code> )
<code>Counter</code>	<code>dict</code> 的子類，用來計算可雜物件的數量
<code>OrderedDict</code>	<code>dict</code> 的子類，會記物件被加入的順序
<code>defaultdict</code>	<code>dict</code> 的子類，當值不存在 <code>dict</code> 中時會呼叫一個提供預設值的工廠函式
<code>UserDict</code>	<code>dict</code> 物件的包裝器 ( <code>wrapper</code> )，簡化了 <code>dict</code> 的子類化過程
<code>UserList</code>	<code>list</code> 物件的包裝器，簡化了 <code>list</code> 的子類化過程
<code>UserString</code>	字串物件的包裝器，簡化了字串的子類化過程

### 8.4.1 ChainMap 物件

在 3.3 版被加入。

`ChainMap` (對映鏈結) 類化的目的是快速將數個對映連結在一起，讓它們可以被當作一個單元來處理。它通常會比建立一個新的字典多次呼叫 `update()` 來得更快。

這個類化可用於模擬巢狀作用域 (`nested scopes`)，且在模板化 (`templating`) 時能派上用場。

**class** `collections.ChainMap(*maps)`

一個 `ChainMap` 將多個 `dict` 或其他對映組合在一起，建立一個獨立、可更新的視圖。如果化有指定 `maps`，預設會提供一個空字典讓每個新鏈結都至少有一個對映。

底層的對映儲存於一個 `list` 中，這個 `list` 是公開的且可透過 `maps` 屬性存取或更新，化有其他狀態 (`state`)。

檢索 (`lookup`) 陸續查詢底層對映，直到鍵被找到，然而讀取、更新和化除就只會對第一個對映操作。

`ChainMap` 透過參照將底層對映合化，所以當一個底層對映被更新，這些改變也會反映到 `ChainMap`。

所有常見的字典方法都有支援。此外，還有一個 `maps` 屬性 (`attribute`)、一個建立子上下文 (`subcontext`) 的方法、和一個能化存取除了第一個以外其他所有對映的特性 (`property`):

#### **maps**

一個可被更新的對映列表，這個列表是按照被搜索的順序來排列，在 `ChainMap` 中它是唯一被儲存的狀態，可被修改來變化搜索順序。回傳的列表都至少包含一個對映。

**new\_child** (`m=None, **kwargs`)

回傳包含一個新對映的 `ChainMap`，新對映後面接著當前實例的所有現存對映。如果有給定 `m`，`m` 會成化那個最前面的新對映；若化有指定，則會加上一個空 `dict`，如此一來呼叫 `d.new_child()` 就等同於 `ChainMap({}, *d.maps)`。這個方法用於建立子上下文，而保持父對映的不變。

在 3.4 版的變更: 加入可選參數 `m`。

在 3.10 版的變更: 增加了對關鍵字引數的支援。

#### **parents**

回傳一個包含除了第一個以外所有其他對映的新 `ChainMap` 的特性，可用於需要跳過第一個對映的搜索。使用情境類似於在巢狀作用域當中使用 `nonlocal` 關鍵字，也可與化建函式 `super()` 做類比。引用 `d.parents` 等同於 `ChainMap(*d.maps[1:])`。

注意，一個 `ChainMap` 的化代順序是透過由後往前掃描對映而定:

```
>>> baseline = {'music': 'bach', 'art': 'rembrandt'}
>>> adjustments = {'art': 'van gogh', 'opera': 'carmen'}
>>> list(ChainMap(adjustments, baseline))
['music', 'art', 'opera']
```

這和呼叫 `dict.update()` 結果的順序一樣是從最後一個對映開始:

```
>>> combined = baseline.copy()
>>> combined.update(adjustments)
>>> list(combined)
['music', 'art', 'opera']
```

在 3.9 版的變更: 支援 `|` 和 `|=` 運算子, 詳見 [PEP 584](#)。

### 也參考

- Enthought CodeTools package 中的 `MultiContext` class 支援在鏈中選定任意對映寫入。
- Django 中用於模板的 `Context` class 是唯讀的對映鏈, 也具有加入 (push) 和移除 (pop) 上下文的功能, 與 `new_child()` 方法和 `parents` 特性類似。
- [Nested Contexts recipe](#) 提供了控制是否只對鏈中第一個或其他對映做寫入或其他操作的選項。
- 一個極度簡化、唯讀版本的 `Chainmap`。

### ChainMap 范例和用法

此章節提供了多種操作 `ChainMap` 的案例。

模擬 Python 內部檢索鏈結的例子:

```
import builtins
pylookup = ChainMap(locals(), globals(), vars(builtins))
```

讓使用者指定的命令列引數優先於環境變數、再優先於預設值的範例:

```
import os, argparse

defaults = {'color': 'red', 'user': 'guest'}

parser = argparse.ArgumentParser()
parser.add_argument('-u', '--user')
parser.add_argument('-c', '--color')
namespace = parser.parse_args()
command_line_args = {k: v for k, v in vars(namespace).items() if v is not None}

combined = ChainMap(command_line_args, os.environ, defaults)
print(combined['color'])
print(combined['user'])
```

用 `ChainMap` 類模擬巢狀上下文的範例模式:

```
c = ChainMap()           # Create root context
d = c.new_child()       # Create nested child context
e = c.new_child()       # Child of c, independent from d
e.maps[0]               # Current context dictionary -- like Python's locals()
e.maps[-1]              # Root context -- like Python's globals()
e.parents               # Enclosing context chain -- like Python's nonlocals

d['x'] = 1               # Set value in current context
d['x']                  # Get first key in the chain of contexts
del d['x']              # Delete from current context
list(d)                 # All nested values
k in d                  # Check all nested values
len(d)                 # Number of nested values
d.items()              # All nested items
dict(d)                 # Flatten into a regular dictionary
```

`ChainMap` 類只對鏈結中第一個對映來做寫入或刪除，但檢索則會掃過整個鏈結。但如果需要對更深層的鍵寫入或刪除，透過定義一個子類來實作也不困難：

```
class DeepChainMap(ChainMap):
    'Variant of ChainMap that allows direct updates to inner scopes'

    def __setitem__(self, key, value):
        for mapping in self.maps:
            if key in mapping:
                mapping[key] = value
                return
        self.maps[0][key] = value

    def __delitem__(self, key):
        for mapping in self.maps:
            if key in mapping:
                del mapping[key]
                return
        raise KeyError(key)

>>> d = DeepChainMap({'zebra': 'black'}, {'elephant': 'blue'}, {'lion': 'yellow'})
>>> d['lion'] = 'orange'           # update an existing key two levels down
>>> d['snake'] = 'red'            # new keys get added to the topmost dict
>>> del d['elephant']             # remove an existing key one level down
>>> d                             # display result
DeepChainMap({'zebra': 'black', 'snake': 'red'}, {}, {'lion': 'orange'})
```

## 8.4.2 Counter 物件

提供一個支援方便且快速計數的計數器工具，例如：

```
>>> # Tally occurrences of words in a list
>>> cnt = Counter()
>>> for word in ['red', 'blue', 'red', 'green', 'blue', 'blue']:
...     cnt[word] += 1
...
>>> cnt
Counter({'blue': 3, 'red': 2, 'green': 1})

>>> # Find the ten most common words in Hamlet
>>> import re
>>> words = re.findall(r'\w+', open('hamlet.txt').read().lower())
>>> Counter(words).most_common(10)
[('the', 1143), ('and', 966), ('to', 762), ('of', 669), ('i', 631),
 ('you', 554), ('a', 546), ('my', 514), ('hamlet', 471), ('in', 451)]
```

`class collections.Counter([iterable-or-mapping])`

`Counter` 是 `dict` 的子類，用來計算可雜物件的數量。它是將物件與其計數作字典的鍵值對儲存的集合容器。計數可以是包含 0 與負數的任何整數值。`Counter` 類類似其他程式語言中的 `bags` 或 `multisets`。

被計數的元素來自一個 `iterable` 或是被其他的 `mapping` (或 `Counter`) 初始化：

```
>>> c = Counter()                # a new, empty counter
>>> c = Counter('gallahad')     # a new counter from an iterable
>>> c = Counter({'red': 4, 'blue': 2}) # a new counter from a mapping
>>> c = Counter(cats=4, dogs=8)  # a new counter from keyword args
```

`Counter` 物件擁有一個字典的使用介面，除了遇到 `Counter` 中有的值時會回傳計數 0 取代 `KeyError` 這點不同：

```
>>> c = Counter(['eggs', 'ham'])
>>> c['bacon'] # count of a missing element is zero
0
```

將一個值的計數設 0 不會真的從 `Counter` 中除這個元素，要使用 `del` 來將其除：

```
>>> c['sausage'] = 0 # counter entry with a zero count
>>> del c['sausage'] # del actually removes the entry
```

在 3.1 版被加入。

在 3.7 版的變更：作 `dict` 的子類，`Counter` 繼承了記憶插入順序的功能。對 `Counter` 做數學運算後同樣保留順序性，其結果是依照各個元素在運算元左邊出現的時間先後、再按照運算元右邊出現的時間先後來排列。

除了字典原本就有的方法外，`Counter` 物件額外支援數個新方法：

#### `elements()`

回傳每個元素都重現出現計算次數的 `iterator` (代器) 物件，其中元素的回傳順序是依照各元素首次出現的時間先後。如果元素的出現次數小於 1，`elements()` 方法會忽略這些元素。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> sorted(c.elements())
['a', 'a', 'a', 'a', 'b', 'b']
```

#### `most_common([n])`

回傳一個 `list`，包含出現最多次的  $n$  個元素及其出現次數，按照出現次數排序。如果  $n$  被省略或者 `None`，`most_common()` 會回傳所有 `counter` 中的元素。出現次數相同的元素會按照首次出現的時間先後來排列：

```
>>> Counter('abracadabra').most_common(3)
[('a', 5), ('b', 2), ('r', 2)]
```

#### `subtract([iterable-or-mapping])`

去自一個 `iterable` 或另一個對映 (或 `Counter`) 中的計數元素，行類似 `dict.update()` 但是是去了計數而非取代其值。輸入和輸出都可以是 0 或是負數。

```
>>> c = Counter(a=4, b=2, c=0, d=-2)
>>> d = Counter(a=1, b=2, c=3, d=4)
>>> c.subtract(d)
>>> c
Counter({'a': 3, 'b': 0, 'c': -3, 'd': -6})
```

在 3.2 版被加入。

#### `total()`

計算總計數值。

```
>>> c = Counter(a=10, b=5, c=0)
>>> c.total()
15
```

在 3.10 版被加入。

通常來字典方法也可以用於 `Counter` 物件，除了以下兩個作用方式與計數器不同。

#### `fromkeys(iterable)`

此類方法有被實作於 `Counter` 物件中。

#### `update([iterable-or-mapping])`

加上自一個 `iterable` 計算出的計數或加上另一個 `mapping` (或 `Counter`) 中的計數，行類似 `dict.update()` 但是是加了計數而非取代其值。另外，`iterable` 需要是一串將被計算個數元素的序列，而非元素 (key, value) 形式的序列。

`Counter` 支援相等性、子集和超集關係的 rich comparison 運算子：`==`、`!=`、`<`、`<=`、`>`、`>=`。這些檢測會將不存在的元素之計數值當作零，因此 `Counter(a=1) == Counter(a=1, b=0)` 將回傳真值。

在 3.10 版的變更: 增加了 rich comparison 運算。

在 3.10 版的變更: 在相等性運算中，不存在的元素之計數值會被當作零。在此之前，`Counter(a=3)` 和 `Counter(a=3, b=0)` 被視爲不同。

使用 `Counter` 物件的常見使用模式:

```
c.total()           # total of all counts
c.clear()           # reset all counts
list(c)             # list unique elements
set(c)              # convert to a set
dict(c)             # convert to a regular dictionary
c.items()           # access the (elem, cnt) pairs
Counter(dict(list_of_pairs)) # convert from a list of (elem, cnt) pairs
c.most_common()[:n-1:-1] # n least common elements
+c                  # remove zero and negative counts
```

結合多個 `Counter` 物件以生成 multiset (多重集合，擁有大於 0 計數元素的計數器)，有提供了幾種數學操作。加法和法是根據各個對應元素分將 `Counter` 加上和去計數，交集和聯集分回傳各個元素最小和最大計數，相等性與包含性運算則會比較對應的計數。每一個操作都可以接受輸入帶有正負號的計數，但輸出的 `Counter` 則會將擁有小於或等於 0 計數的元素剔除。

```
>>> c = Counter(a=3, b=1)
>>> d = Counter(a=1, b=2)
>>> c + d           # add two counters together: c[x] + d[x]
Counter({'a': 4, 'b': 3})
>>> c - d           # subtract (keeping only positive counts)
Counter({'a': 2})
>>> c & d           # intersection: min(c[x], d[x])
Counter({'a': 1, 'b': 1})
>>> c | d           # union: max(c[x], d[x])
Counter({'a': 3, 'b': 2})
>>> c == d         # equality: c[x] == d[x]
False
>>> c <= d         # inclusion: c[x] <= d[x]
False
```

加法的一元運算子分是加上空的 `Counter` 和從空 `Counter` 去的簡寫。

```
>>> c = Counter(a=2, b=-4)
>>> +c
Counter({'a': 2})
>>> -c
Counter({'b': 4})
```

在 3.3 版被加入: 開始支援加一元運算子和 multiset 的原地 (in-place) 操作。

### 備

`Counter` 主要是被設計來操作正整數以當作使用中的計數，但了某些會用到計數之值負數或其他型的案例中，`Counter` 也小心地被設計成不會預先排除這些特殊元素。了輔助使用於上述案例，這一小節記了最小範圍和型限制。

- `Counter` 類本身是字典的子類，且不限制其鍵與值。值被用來表示計數，但實際上你可以儲存任何值。
- 使用 `most_common()` 方法的唯一條件是其值要是可被排序的。
- 像是 `c[key] += 1` 的原地操作中，其值之型只必須支援加，所以分數、浮點數、十進位數與其負值都可以使用。同理，`update()` 和 `subtract()` 也都允許 0 或負值輸入或輸出。

- Multiset 相關方法只處理正值而設計，其輸入允許是 0 或負值但只有正值會被輸出。無型限制，但其值的型須支援加、及比較運算。
- `elements()` 方法需要其計數正值，如 0 或負值則忽略。

### 也參考

- 維基百科上的多重集合條目。
- C++ multisets 教學與範例。
- Multiset 的數學運算及其使用時機，參考 Knuth, Donald. *The Art of Computer Programming Volume II, Section 4.6.3, Exercise 19*。
- 若要根據給定的元素集合來列舉出所有不重且擁有指定元素數量的 multiset，請見 `itertools.combinations_with_replacement()`：

```
map(Counter, combinations_with_replacement('ABC', 2)) # --> AA AB AC BB BC CC
```

## 8.4.3 deque 物件

`class collections.deque([iterable[, maxlen]])`

回傳一個新的 deque (雙端列) 物件，將 `iterable` 中的資料由左至右 (使用 `append()`) 加入來做初始化。如果 `iterable` 未給定，回傳的則是一個空的 deque。

Deque (發音 “deck”，“double-ended queue” 的簡稱) stack 和 queue 的一般化。deque 支援執行緒安全 (thread-safe)，且能有效率地節省記憶體在頭和尾加入和移除元素，兩個方向表現都大致  $O(1)$  複雜度。

雖然 list 物件也支援類似操作，但 list 優化了長度固定時的操作，而會改變底層資料的長度及位置的 `pop(0)` 和 `insert(0, v)` 操作，記憶體移動則  $O(n)$  複雜度。

如果 `maxlen` 有給定或者 None，deque 可以增長到任意長度；但若有給定的話，deque 的最大長度就會被限制。一個被限制長度的 deque 一旦滿了，若在一端加入數個新元素，則同時會在另一端移除相同數量的元素。限定長度的 deque 提供了和 Unix tail filter 類似的功能，可用於追蹤使用者在意的那些最新執行事項或數據源。

Deque 物件支援以下方法：

**append(x)**

將 `x` 自 deque 的右側加入。

**appendleft(x)**

將 `x` 自 deque 的左側加入。

**clear()**

將所有元素從 deque 中移除，使其長度 0。

**copy()**

建立一個 deque 的淺 (shallow copy)。

在 3.5 版被加入。

**count(x)**

計算 deque 元素 `x` 的個數。

在 3.2 版被加入。

**extend(iterable)**

將 `iterable` 引數加入 deque 的右側。

**extendleft** (*iterable*)

將 *iterable* 引數加入 deque 的左側。要注意的是，加入後的元素順序和 *iterable* 參數是相反的。

**index** (*x* [, *start* [, *stop* ]])

回傳 deque 中 *x* 的位置 (或在索引 *start* 之後、索引 *stop* 之前的位置)。回傳第一個匹配的位置，如果找不到就引發 *ValueError*。

在 3.5 版被加入。

**insert** (*i*, *x*)

在 deque 位置 *i* 中插入 *x*。

如果此插入操作導致 deque 超過其長度上限 *maxlen* 的話，會引發 *IndexError* 例外。

在 3.5 版被加入。

**pop** ()

移除回傳 deque 的最右側元素，若本來就沒有任何元素，則會引發 *IndexError*。

**popleft** ()

移除回傳 deque 的最左側元素，若本來就沒有任何元素，則會引發 *IndexError*。

**remove** (*value*)

移除第一個出現的 *value*，如果找不到的話就引發一個 *ValueError*。

**reverse** ()

將 deque 中的元素原地 (in-place) 倒序排列回傳 *None*。

在 3.2 版被加入。

**rotate** (*n=1*)

將 deque 向右輪轉 *n* 步。若 *n* 負值則向左輪轉。

當 deque 不是空的，向右輪轉一步和 `d.appendleft(d.pop())` 有相同意義，而向左輪轉亦等價於 `d.append(d.popleft())`。

Deque 物件也提供了一個唯讀屬性：

**maxlen**

Deque 的最大長度，如果不限制長度的話則回傳 *None*。

在 3.1 版被加入。

除了以上使用方式，deque 亦支援了迭代、pickle、`len(d)`、`reversed(d)`、`copy.copy(d)`、`copy.deepcopy(d)`、用 `in` 運算子來作隸屬資格檢測以及像是 `d[0]` 的標號引用來取得第一個元素。在兩端做索引存取的回雜度  $O(1)$  但越靠近中間則慢至  $O(n)$ 。若想要隨機而快速的存取，使用 `list` 會較合適。

自從 3.5 版本起，deque 開始支援 `__add__()`、`__mul__()` 和 `__imul__()`。

範例：

```
>>> from collections import deque
>>> d = deque('ghi')           # make a new deque with three items
>>> for elem in d:           # iterate over the deque's elements
...     print(elem.upper())
G
H
I

>>> d.append('j')            # add a new entry to the right side
>>> d.appendleft('f')        # add a new entry to the left side
>>> d                        # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])
```

(繼續下一頁)

(繼續上一頁)

```

>>> d.pop() # return and remove the rightmost item
'j'
>>> d.popleft() # return and remove the leftmost item
'f'
>>> list(d) # list the contents of the deque
['g', 'h', 'i']
>>> d[0] # peek at leftmost item
'g'
>>> d[-1] # peek at rightmost item
'i'

>>> list(reversed(d)) # list the contents of a deque in reverse
['i', 'h', 'g']
>>> 'h' in d # search the deque
True
>>> d.extend('jkl') # add multiple elements at once
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])
>>> d.rotate(1) # right rotation
>>> d
deque(['l', 'g', 'h', 'i', 'j', 'k'])
>>> d.rotate(-1) # left rotation
>>> d
deque(['g', 'h', 'i', 'j', 'k', 'l'])

>>> deque(reversed(d)) # make a new deque in reverse order
deque(['l', 'k', 'j', 'i', 'h', 'g'])
>>> d.clear() # empty the deque
>>> d.pop() # cannot pop from an empty deque
Traceback (most recent call last):
  File "<pyshell#6>", line 1, in <code>-toplevel-
    d.pop()
IndexError: pop from an empty deque

>>> d.extendleft('abc') # extendleft() reverses the input order
>>> d
deque(['c', 'b', 'a'])

```

### deque 用法

這一章節提供了多種操作 deque 的案例。

被限制長度的 deque 功能類似 Unix 中的 tail filter:

```

def tail(filename, n=10):
    'Return the last n lines of a file'
    with open(filename) as f:
        return deque(f, n)

```

另一用法是透過從右邊加入、從左邊移除來維護最近加入元素的 list:

```

def moving_average(iterable, n=3):
    # moving_average([40, 30, 50, 46, 39, 44]) --> 40.0 42.0 45.0 43.0
    # https://en.wikipedia.org/wiki/Moving_average
    it = iter(iterable)
    d = deque(itertools.islice(it, n-1))
    d.appendleft(0)
    s = sum(d)
    for elem in it:
        s += elem - d.popleft()
        d.append(elem)

```

(繼續下一頁)

(繼續上一頁)

`yield s / n`

一個輪詢調度器可以透過在 `deque` 中放入 `iterator` 來實現，值自當前 `iterator` 的位置 0 取出，如果 `iterator` 已經消耗完畢就用 `popleft()` 將其從 `deque` 中移除，否則利用 `rotate()` 來將其移至 `deque` 列尾端：

```
def roundrobin(*iterables):
    "roundrobin('ABC', 'D', 'EF') --> A D E B F C"
    iterators = deque(map(iter, iterables))
    while iterators:
        try:
            while True:
                yield next(iterators[0])
                iterators.rotate(-1)
        except StopIteration:
            # Remove an exhausted iterator.
            iterators.popleft()
```

`rotate()` 提供了可以用來實作 `deque` 切片和 `pop` 的方法。舉例來說，用純 Python 實作 `del d[n]` 需要用 `rotate()` 來定位要被移除的元素：

```
def delete_nth(d, n):
    d.rotate(-n)
    d.popleft()
    d.rotate(n)
```

要實現 `deque` 切片，可使用近似以下方法：使用 `rotate()` 來將目標元素移動到 `deque` 最左側，用 `popleft()` 移除舊元素，用 `extend()` 加入新元素，最後再反向 `rotate`。在這個方法上做小小的更動就能簡單地實現 Forth 風格的 `stack` 操作，例如 `dup`、`drop`、`swap`、`over`、`pick`、`rot` 和 `roll`。

## 8.4.4 defaultdict 物件

`class collections.defaultdict (default_factory=None, [, ...])`

回傳一個新的類似字典的物件。`defaultdict` 是 `dict` 的子類。它覆蓋掉了一個方法，添加了一個可寫入的實例變數。其餘功能與 `dict` 相同，此文件不再贅述。

第一個引數 `default_factory` 屬性提供了初始值，他被預設為 `None`，所有其他的引數（包括關鍵字引數）都會被傳遞給 `dict` 的建構函式 (constructor)。

`defaultdict` 物件支援以下 `dict` 所擁有的方法：

`__missing__(key)`

如果 `default_factory` 屬性為 `None`，呼叫此方法會引發一個附帶引數 `key` 的 `KeyError` 例外。

如果 `default_factory` 不為 `None`，它會不帶引數地被呼叫來給定的 `key` 提供一個預設值，這個值和 `key` 被作鍵值對來插入到字典中，且被此方法所回傳。

如果呼叫 `default_factory` 時發生例外，則該例外將會保持不變地向外傳遞。

在無法找到所要求的鍵時，此方法會被 `dict` 類型的 `__getitem__()` 方法呼叫。無論此方法回傳了值還是引發了例外，都會被 `__getitem__()` 所傳遞。

Note that `__missing__()` is not called for any operations besides `__getitem__()`. This means that `get()` will, like normal dictionaries, return `None` as a default rather than using `default_factory`.

`defaultdict` 物件支援以下實例變數：

`default_factory`

此屬性由 `__missing__()` 方法所使用。如果有引數被傳入建構函式，則此屬性會被初始化成第一個引數，如未提供引數則被初始化為 `None`。

在 3.9 版的變更：新增合 (`|`) 和更新 (`|=`) 運算子，請見 [PEP 584](#)。

**defaultdict 范例**

使用 `list` 作 `default_factory` 可以很輕鬆地將鍵值對序列轉成包含 `list` 之字典：

```
>>> s = [('yellow', 1), ('blue', 2), ('yellow', 3), ('blue', 4), ('red', 1)]
>>> d = defaultdict(list)
>>> for k, v in s:
...     d[k].append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

當每個鍵第一次被存取時，它還不存在於對映中，所以會自動呼叫 `default_factory` 方法來回傳一個空的 `list` 以建立一個條目，`list.append()` 操作後續會再新增值到這個新的列表。當再次存取該鍵時，就如普通字典般操作（回傳該鍵所對應到的 `list`），`list.append()` 也會新增另一個值到 `list` 中。和使用與其等價的 `dict.setdefault()` 相比，這個技巧更加快速和簡單：

```
>>> d = {}
>>> for k, v in s:
...     d.setdefault(k, []).append(v)
...
>>> sorted(d.items())
[('blue', [2, 4]), ('red', [1]), ('yellow', [1, 3])]
```

設定 `default_factory` 成 `int` 使得 `defaultdict` 可被用於計數（類似其他語言中的 `bag` 或 `multiset`）：

```
>>> s = 'mississippi'
>>> d = defaultdict(int)
>>> for k in s:
...     d[k] += 1
...
>>> sorted(d.items())
[('i', 4), ('m', 1), ('p', 2), ('s', 4)]
```

當一個字母首次被存取時，它不存在於對映中，則 `default_factory` 函式會呼叫 `int()` 來提供一個整數 `0` 作預設值。後續的增加操作繼續對每個字母做計數。

函式 `int()` 總是回傳 `0`，這是常數函式的特殊情況。一個更快、更有彈性的方法是使用 `lambda` 函式來提供任何常數值（不用一定要是 `0`）：

```
>>> def constant_factory(value):
...     return lambda: value
...
>>> d = defaultdict(constant_factory('<missing>'))
>>> d.update(name='John', action='ran')
>>> '%(name)s %(action)s to %(object)s' % d
'John ran to <missing>'
```

將 `default_factory` 設成 `set` 使 `defaultdict` 可用於構建一個值 `set` 的字典：

```
>>> s = [('red', 1), ('blue', 2), ('red', 3), ('blue', 4), ('red', 1), ('blue', 4)]
>>> d = defaultdict(set)
>>> for k, v in s:
...     d[k].add(v)
...
>>> sorted(d.items())
[('blue', {2, 4}), ('red', {1, 3})]
```

### 8.4.5 namedtuple() 擁有具名欄位之 tuple 的工廠函式

Named tuple (具名元組) 賦予 tuple 中各個位置意義, 使程式碼更有可讀性與自我文件性。它們可以用於任何普通 tuple 可使用的場合, 賦予其透過名稱 (而非位置索引) 來存取欄位的能力。

`collections.namedtuple (typename, field_names, *, rename=False, defaults=None, module=None)`

Returns a new tuple subclass named *typename*. The new subclass is used to create tuple-like objects that have fields accessible by attribute lookup as well as being indexable and iterable. Instances of the subclass also have a helpful docstring (with *typename* and *field\_names*) and a helpful `__repr__()` method which lists the tuple contents in a `name=value` format.

*field\_names* 是一個像 ['x', 'y'] 一樣的字串序列。 *field\_names* 也可以是一個用空白或逗號分隔各個欄位名稱的字串, 比如 'x y' 或者 'x, y'。

除了底 `_` 開頭以外的其他任何有效 Python 識字 (identifier) 都可以作欄位名稱, 有效識字由字母、數字、底 `_` 所組成, 但不能是數字或底 `_` 開頭, 也不能是關鍵詞 *keyword*, 例如 *class*、*for*、*return*、*global*、*pass* 或 *raise*。

如果 *rename* 為真值, 無效的欄位名稱會自動被位置名稱取代。比如 ['abc', 'def', 'ghi', 'abc'] 會被轉成 ['abc', '\_1', 'ghi', '\_3'], 移除了關鍵字 *def* 和重欄位名 *abc*。

*defaults* 可以為 `None` 或者是一個預設值的 *iterable*。因有預設值的欄位必須出現在那些有預設值的欄位之後, *defaults* 是被應用在右側的引數。例如 *fieldnames* ['x', 'y', 'z'] 且 *defaults* (1, 2), 那 *x* 就必須被給定一個引數, *y* 被預設 1, *z* 則被預設 2。

如果 *module* 值有被定義, `namedtuple` 的 `__module__` 屬性就被設定該值。

Named tuple 實例中有字典, 所以它們更加輕量, 且和一般 tuple 相比用更少記憶體。

要支援 pickle, 應將 `namedtuple` 類賦值給一個符合 *typename* 的變數。

在 3.1 版的變更: 新增對於 *rename* 的支援。

在 3.6 版的變更: *verbose* 和 *rename* 參數成僅限關鍵字引數。

在 3.6 版的變更: 新增 *module* 參數。

在 3.7 版的變更: Removed the *verbose* parameter and the `_source` attribute.

在 3.7 版的變更: Added the *defaults* parameter and the `_field_defaults` attribute.

```
>>> # Basic example
>>> Point = namedtuple('Point', ['x', 'y'])
>>> p = Point(11, y=22)           # instantiate with positional or keyword arguments
>>> p[0] + p[1]                  # indexable like the plain tuple (11, 22)
33
>>> x, y = p                     # unpack like a regular tuple
>>> x, y
(11, 22)
>>> p.x + p.y                    # fields also accessible by name
33
>>> p                             # readable __repr__ with a name=value style
Point(x=11, y=22)
```

Named tuple 在賦予欄位名稱於 *csv* 或 *sqlite3* 模組回傳之 tuple 時相當有用:

```
EmployeeRecord = namedtuple('EmployeeRecord', 'name, age, title, department, paygrade')

import csv
for emp in map(EmployeeRecord._make, csv.reader(open("employees.csv", "rb"))):
    print(emp.name, emp.title)

import sqlite3
conn = sqlite3.connect('/companydata')
cursor = conn.cursor()
cursor.execute('SELECT name, age, title, department, paygrade FROM employees')
```

(繼續下一頁)

```
for emp in map(EmployeeRecord._make, cursor.fetchall()):
    print(emp.name, emp.title)
```

除了繼承自 `tuple` 的方法，`named tuple` 還支援三個額外的方法和兩個屬性。為了防止欄位名稱有衝突，方法和屬性的名稱以底開頭。

**classmethod** `somenamedtuple._make(iterable)`

從已存在的序列或可代物件建立一個新實例的類方法。

```
>>> t = [11, 22]
>>> Point._make(t)
Point(x=11, y=22)
```

`somenamedtuple._asdict()`

回傳一個將欄位名稱對映至對應值的 `dict`：

```
>>> p = Point(x=11, y=22)
>>> p._asdict()
{'x': 11, 'y': 22}
```

在 3.1 版的變更：回傳一個 `OrderedDict` 而非 `dict`。

在 3.8 版的變更：回傳一個常規 `dict` 而非 `OrderedDict`，自從 Python 3.7 開始，`dict` 已經保證有順序性，如果需要 `OrderedDict` 所專屬的特性，推薦的解法是將結果專成所需的類型：`OrderedDict(nt._asdict())`。

`somenamedtuple._replace(**kwargs)`

回傳一個新的 `named tuple` 實例，將指定欄位替新的值：

```
>>> p = Point(x=11, y=22)
>>> p._replace(x=33)
Point(x=33, y=22)

>>> for partnum, record in inventory.items():
...     inventory[partnum] = record._replace(price=newprices[partnum], timestamp=time.
↪now())
```

`Named tuples` are also supported by generic function `copy.replace()`.

在 3.13 版的變更：Raise `TypeError` instead of `ValueError` for invalid keyword arguments.

`somenamedtuple._fields`

列出 `tuple` 欄位名稱的字串，用於自我檢查或是從現有 `named tuple` 建立一個新的 `named tuple` 型。

```
>>> p._fields           # view the field names
('x', 'y')

>>> Color = namedtuple('Color', 'red green blue')
>>> Pixel = namedtuple('Pixel', Point._fields + Color._fields)
>>> Pixel(11, 22, 128, 255, 0)
Pixel(x=11, y=22, red=128, green=255, blue=0)
```

`somenamedtuple._field_defaults`

將欄位名稱對映至預設值的字典。

```
>>> Account = namedtuple('Account', ['type', 'balance'], defaults=[0])
>>> Account._field_defaults
{'balance': 0}
>>> Account('premium')
Account(type='premium', balance=0)
```

要取得這個名稱存於字串的欄位，要使用 `getattr()` 函式：

```
>>> getattr(p, 'x')
11
```

(如 [tut-unpacking-arguments](#) 所述) 將一個字典轉成 named tuple, 要使用 `**` 雙星號運算子:

```
>>> d = {'x': 11, 'y': 22}
>>> Point(**d)
Point(x=11, y=22)
```

因一個 named tuple 是一個常規的 Python 類, 我們可以很容易的透過子類來新增或更改功能, 以下是如何新增一個計算得到的欄位和固定寬度的輸出列印格式:

```
>>> class Point(namedtuple('Point', ['x', 'y'])):
...     __slots__ = ()
...     @property
...     def hypot(self):
...         return (self.x ** 2 + self.y ** 2) ** 0.5
...     def __str__(self):
...         return 'Point: x=%6.3f y=%6.3f hypot=%6.3f' % (self.x, self.y, self.hypot)

>>> for p in Point(3, 4), Point(14, 5/7):
...     print(p)
Point: x= 3.000 y= 4.000 hypot= 5.000
Point: x=14.000 y= 0.714 hypot=14.018
```

上面的子類將 `__slots__` 設定成空 tuple, 這樣一來就防止了字典實例被建立, 因而保持了較低的記憶體用量。

子類化無法用於增加新的、已被儲存的欄位, 應當透過 `_fields` 屬性以建立一個新的 named tuple 來實現:

```
>>> Point3D = namedtuple('Point3D', Point._fields + ('z',))
```

透過直接賦值給 `__doc__`, 可以自訂明文件字串:

```
>>> Book = namedtuple('Book', ['id', 'title', 'authors'])
>>> Book.__doc__ += ': Hardcover book in active collection'
>>> Book.id.__doc__ = '13-digit ISBN'
>>> Book.title.__doc__ = 'Title of first printing'
>>> Book.authors.__doc__ = 'List of authors sorted by last name'
```

在 3.5 版的變更: 文件字串屬性變成可寫入。

## 也參考

- 關於 named tuple 新增型提示的方法, 請參 `typing.NamedTuple`, 它運用 `class` 關鍵字以提供了一個簡潔的表示法:

```
class Component(NamedTuple):
    part_number: int
    weight: float
    description: Optional[str] = None
```

- 關於以 dict 而非 tuple 底層的可變命名空間, 請參考 `types.SimpleNamespace()`。
- `dataclasses` 模組提供了一個裝飾器和一些函式, 用於自動將被生成的特殊方法新增到使用者定義的類中。

### 8.4.6 OrderedDict 物件

Ordered dictionary (有序字典) 就像常規字典一樣，但有一些與排序操作相關的額外功能，但由於 3.7 版的 `dict` 類現在已經有記憶插入順序的能力 (Python 3.7 中確保了這種新行)，它們變得不那麼重要了。

仍存在一些與 `dict` 的不同之處：

- 常規的 `dict` 被設計成非常擅長於對映相關操作，追插入的順序次要目標。
- `OrderedDict` 則被設計成擅長於重新排序相關的操作，空間效率、迭代速度和更新操作的效能則次要設計目標。
- `OrderedDict` 比起 `dict` 更適合處理頻繁的重新排序操作，如在下方用法中所示，這讓它適合用於多種 LRU cache 的實作中。
- `OrderedDict` 之相等性運算會檢查順序是否相同。

一個一般的 `dict` 可以用 `p == q and all(k1 == k2 for k1, k2 in zip(p, q))` 來效仿有檢查順序的相等性運算。

- The `popitem()` method of `OrderedDict` has a different signature. It accepts an optional argument to specify which item is popped.

一個一般的 `dict` 可以用 `d.popitem()` 來效仿 `OrderedDict` 的 `od.popitem(last=True)`，這保證會移除最右邊 (最後一個) 的元素。

一個一般的 `dict` 可以用 `(k := next(iter(d)), d.pop(k))` 來效仿 `OrderedDict` 的 `od.popitem(last=False)`，若最左邊 (第一個) 的元素存在，則將其回傳移除。

- `OrderedDict` has a `move_to_end()` method to efficiently reposition an element to an endpoint.

一個一般的 `dict` 可以用 `d[k] = d.pop(k)` 來效仿 `OrderedDict` 的 `od.move_to_end(k, last=True)`，這會將該鍵與其對應到的值移動至最右 (最後面) 的位置。

一個一般的 `dict` 有和 `OrderedDict` 的 `od.move_to_end(k, last=False)` 等價的有效方式，這是將鍵與其對應到的值移動至最左 (最前面) 位置的方法。

- Until Python 3.8, `dict` lacked a `__reversed__()` method.

`class collections.OrderedDict([items])`

回傳一個 `dict` 子類的實例，它具有專門用於重新排列字典順序的方法。

在 3.1 版被加入。

`popitem(last=True)`

`Ordered dictionary` 的 `popitem()` 方法移除回傳一個鍵值 (key, value) 對。如果 `last` 真值，則按 LIFO 後進先出的順序回傳鍵值對，否則就按 FIFO (first-in, first-out) 先進先出的順序回傳鍵值對。

`move_to_end(key, last=True)`

將現有的 `key` 移動到 `ordered dictionary` 的任一端。如果 `last` 真值 (此預設值) 則將元素移至右端；如果 `last` 假值則將元素移至左端。如果 `key` 不存在則會引發 `KeyError`：

```
>>> d = OrderedDict.fromkeys('abcde')
>>> d.move_to_end('b')
>>> ''.join(d)
'acdeb'
>>> d.move_to_end('b', last=False)
>>> ''.join(d)
'bacde'
```

在 3.2 版被加入。

除了普通的對映方法，`ordered dictionary` 還支援了透過 `reversed()` 來做倒序迭代。

`OrderedDict` 物件之間的相等性運算是會檢查順序是否相同的，大致等價於 `list(od1.items()) == list(od2.items())`。

`OrderedDict` 物件和其他 `Mapping` 物件間的相等性運算則像普通字典一樣不考慮順序性，這使得 `OrderedDict` 可於任何字典可使用的時機中被替換掉。

在 3.5 版的變更: `OrderedDict` 的項 (item)、鍵與值之視圖現在可透過 `reversed()` 來倒序代。

在 3.6 版的變更: With the acceptance of **PEP 468**, order is retained for keyword arguments passed to the `OrderedDict` constructor and its `update()` method.

在 3.9 版的變更: 新增合 (|) 和更新 (|=) 運算子，請見 **PEP 584**。

### OrderedDict 范例與用法

建立一個能記住鍵最後插入順序的 ordered dictionary 變體很簡單。如果新條目覆蓋了現有條目，則原本插入位置會被更改移動至末端：

```
class LastUpdatedOrderedDict(OrderedDict):
    'Store items in the order the keys were last added'

    def __setitem__(self, key, value):
        super().__setitem__(key, value)
        self.move_to_end(key)
```

`OrderedDict` 在實現一個 `functools.lru_cache()` 的變形版本時也非常有用：

```
from collections import OrderedDict
from time import time

class TimeBoundedLRU:
    "LRU Cache that invalidates and refreshes old entries."

    def __init__(self, func, maxsize=128, maxage=30):
        self.cache = OrderedDict() # { args : (timestamp, result) }
        self.func = func
        self.maxsize = maxsize
        self.maxage = maxage

    def __call__(self, *args):
        if args in self.cache:
            self.cache.move_to_end(args)
            timestamp, result = self.cache[args]
            if time() - timestamp <= self.maxage:
                return result
        result = self.func(*args)
        self.cache[args] = time(), result
        if len(self.cache) > self.maxsize:
            self.cache.popitem(last=False)
        return result
```

```
class MultiHitLRUCache:
    """ LRU cache that defers caching a result until
        it has been requested multiple times.

        To avoid flushing the LRU cache with one-time requests,
        we don't cache until a request has been made more than once.

    """

    def __init__(self, func, maxsize=128, maxrequests=4096, cache_after=1):
        self.requests = OrderedDict() # { uncached_key : request_count }
        self.cache = OrderedDict() # { cached_key : function_result }
        self.func = func
        self.maxrequests = maxrequests # max number of uncached requests
        self.maxsize = maxsize # max number of stored return values
```

(繼續下一頁)

```

self.cache_after = cache_after

def __call__(self, *args):
    if args in self.cache:
        self.cache.move_to_end(args)
        return self.cache[args]
    result = self.func(*args)
    self.requests[args] = self.requests.get(args, 0) + 1
    if self.requests[args] <= self.cache_after:
        self.requests.move_to_end(args)
        if len(self.requests) > self.maxrequests:
            self.requests.popitem(last=False)
    else:
        self.requests.pop(args, None)
        self.cache[args] = result
        if len(self.cache) > self.maxsize:
            self.cache.popitem(last=False)
    return result

```

### 8.4.7 UserDict 物件

`UserDict` 類是作 `dict` 物件的包裝器。因已經可以直接自 `dict` 建立子類，這個類的需求已部分被滿足，不過這個類使用起來更方便，因被包裝的字典可以作其屬性來存取。

```
class collections.UserDict([initialdata])
```

模擬字典的類。實例的內容被存於一個字典，可透過 `UserDict` 的 `data` 屬性來做存取。如果有提供 `initialdata`，`data` 屬性會被初始化其值；要注意指到 `initialdata` 的參照不會被保留，使其可被用於其他目的。

除了支援作對映所需的方法與操作，`UserDict` 實例提供了以下屬性：

**data**

一個真實的字典，用於儲存 `UserDict` 類的資料內容。

### 8.4.8 UserList 物件

此類是 `list` 物件的包裝器。它是個方便的基礎類，可繼承它覆寫現有方法或加入新方法來定義你所需的一個類似於 `list` 的類。如此一來，我們可以 `list` 加入新的特性。

因已經可以直接自 `list` 建立子類，這個類的需求已部分被滿足，不過這個類使用起來更方便，因被包裝的 `list` 可以作其屬性來存取。

```
class collections.UserList([list])
```

模擬 `list` 的類。實例的內容被存於一個 `list`，可透過 `UserList` 的 `data` 屬性來做存取。實例內容被初始化 `list` 的內容，預設一個空的 `list []`。`list` 可以是任何 `iterable`，例如一個真實的 Python `list` 或是一個 `UserList` 物件。

除了支援可變序列的方法與操作，`UserList` 實例提供了以下屬性：

**data**

一個真實的 `list` 物件，用於儲存 `UserList` 類的資料內容。

**子類化的條件：** `UserList` 的子類應該要提供一個不需要引數或一個引數的建構函式。回傳一個新序列的 `list` 操作會從那些實作出來的類建立一個實例，為了達成上述目的，它假設建構函式可傳入單一參數來呼叫，該參數即是做數據來源的一個序列物件。

如果希望一個自此獲得的子類不遵從上述要求，那所有該類支援的特殊方法則必須被覆寫；請參考原始碼來理解在這種情況下哪些方法是必須提供的。

## 8.4.9 UserString 物件

`UserString` 類是字串物件的包裝器，因為已經可以從 `str` 直接建立子類，這個類的需求已經部分被滿足，不過這個類使用起來更方便，因為被包裝的字串可以作為其屬性來存取。

**class** `collections.UserString(seq)`

模擬字串物件的類。實例的內容被存於一個字串物件，可透過 `UserString` 的 `data` 屬性來做存取。實例內容被初始化 `seq` 的內容，`seq` 引數可以是任何可被建函式 `str()` 轉成字串的物件。

除了支援字串的方法和操作以外，`UserString` 實例也提供了以下屬性：

**data**

一個真實的 `str` 物件，用來儲存 `UserString` 類的資料內容。

在 3.5 版的變更：新增方法 `__getnewargs__`、`__rmod__`、`casefold`、`format_map`、`isprintable` 以及 `maketrans`。

## 8.5 collections.abc --- 容器的抽象基底類

在 3.3 版被加入：Formerly, this module was part of the `collections` module.

原始碼：Lib/\_collections\_abc.py

This module provides *abstract base classes* that can be used to test whether a class provides a particular interface; for example, whether it is *hashable* or whether it is a *mapping*.

An `issubclass()` or `isinstance()` test for an interface works in one of three ways.

- 1) A newly written class can inherit directly from one of the abstract base classes. The class must supply the required abstract methods. The remaining mixin methods come from inheritance and can be overridden if desired. Other methods may be added as needed:

```
class C(Sequence):
    def __init__(self): ...
    def __getitem__(self, index): ...
    def __len__(self): ...
    def count(self, value): ...
```

# Direct inheritance  
# Extra method not required by the ABC  
# Required abstract method  
# Required abstract method  
# Optionally override a mixin method

```
>>> issubclass(C, Sequence)
True
>>> isinstance(C(), Sequence)
True
```

- 2) Existing classes and built-in classes can be registered as "virtual subclasses" of the ABCs. Those classes should define the full API including all of the abstract methods and all of the mixin methods. This lets users rely on `issubclass()` or `isinstance()` tests to determine whether the full interface is supported. The exception to this rule is for methods that are automatically inferred from the rest of the API:

```
class D:
    def __init__(self): ...
    def __getitem__(self, index): ...
    def __len__(self): ...
    def count(self, value): ...
    def index(self, value): ...
```

# No inheritance  
# Extra method not required by the ABC  
# Abstract method  
# Abstract method  
# Mixin method  
# Mixin method

```
Sequence.register(D)
# Register instead of inherit
```

```
>>> issubclass(D, Sequence)
True
>>> isinstance(D(), Sequence)
True
```

In this example, class `D` does not need to define `__contains__`, `__iter__`, and `__reversed__` because the in-operator, the *iteration* logic, and the `reversed()` function automatically fall back to using `__getitem__` and `__len__`.

- 3) Some simple interfaces are directly recognizable by the presence of the required methods (unless those methods have been set to `None`):

```
class E:
    def __iter__(self): ...
    def __next__(self): ...
```

```
>>> isinstance(E, Iterable)
True
>>> isinstance(E(), Iterable)
True
```

Complex interfaces do not support this last technique because an interface is more than just the presence of method names. Interfaces specify semantics and relationships between methods that cannot be inferred solely from the presence of specific method names. For example, knowing that a class supplies `__getitem__`, `__len__`, and `__iter__` is insufficient for distinguishing a *Sequence* from a *Mapping*.

在 3.9 版被加入: These abstract classes now support []. See 泛型 名型和 PEP 585.

### 8.5.1 Collections Abstract Base Classes

The collections module offers the following *ABCs*:

ABC	Inherits from	Abstract Methods	Mixin Methods
<i>Container</i> <sup>1</sup>		<code>__contains__</code>	
<i>Hashable</i> <sup>1</sup>		<code>__hash__</code>	
<i>Iterable</i> <sup>12</sup>		<code>__iter__</code>	
<i>Iterator</i> <sup>1</sup>	<i>Iterable</i>	<code>__next__</code>	<code>__iter__</code>
<i>Reversible</i> <sup>1</sup>	<i>Iterable</i>	<code>__reversed__</code>	
<i>Generator</i> <sup>1</sup>	<i>Iterator</i>	<code>send</code> , <code>throw</code>	<code>close</code> , <code>__iter__</code> , <code>__next__</code>
<i>Sized</i> <sup>1</sup>		<code>__len__</code>	
<i>Callable</i> <sup>1</sup>		<code>__call__</code>	
<i>Collection</i> <sup>1</sup>	<i>Sized</i> , <i>Iterable</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code>	
<i>Sequence</i>	<i>Reversible</i> , <i>Collection</i>	<code>__getitem__</code> , <code>__len__</code>	<code>__contains__</code> , <code>__iter__</code> , <code>__reversed__</code> , <code>index</code> 和 <code>count</code>
<i>MutableSequence</i>	<i>Sequence</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__len__</code> , <code>insert</code>	Inherited <i>Sequence</i> methods and <code>append</code> , <code>clear</code> , <code>reverse</code> , <code>extend</code> , <code>pop</code> , <code>remove</code> , and <code>__iadd__</code>
<i>ByteString</i>	<i>Sequence</i>	<code>__getitem__</code> , <code>__len__</code>	Inherited <i>Sequence</i> methods
<i>Set</i>	<i>Collection</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__le__</code> , <code>__lt__</code> , <code>__eq__</code> , <code>__ne__</code> , <code>__gt__</code> , <code>__ge__</code> , <code>__and__</code> , <code>__or__</code> , <code>__sub__</code> , <code>__rsub__</code> , <code>__xor__</code> , <code>__rxor__</code> 和 <code>isdisjoint</code>
<i>MutableSet</i>	<i>Set</i>	<code>__contains__</code> , <code>__iter__</code> , <code>__len__</code> , <code>add</code> , <code>discard</code>	Inherited <i>Set</i> methods and <code>clear</code> , <code>pop</code> , <code>remove</code> , <code>__ior__</code> , <code>__iand__</code> , <code>__ixor__</code> , and <code>__isub__</code>
<i>Mapping</i>	<i>Collection</i>	<code>__getitem__</code> , <code>__iter__</code> , <code>__len__</code>	<code>__contains__</code> , <code>keys</code> , <code>items</code> , <code>values</code> , <code>get</code> , <code>__eq__</code> 和 <code>__ne__</code>
<i>MutableMapping</i>	<i>Mapping</i>	<code>__getitem__</code> , <code>__setitem__</code> , <code>__delitem__</code> , <code>__iter__</code> , <code>__len__</code>	Inherited <i>Mapping</i> methods and <code>pop</code> , <code>popitem</code> , <code>clear</code> , <code>update</code> , and <code>setdefault</code>
<i>MappingView</i>	<i>Sized</i>		<code>__init__</code> , <code>__len__</code> 和 <code>__repr__</code>
<i>ItemsView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>KeysView</i>	<i>MappingView</i> , <i>Set</i>		<code>__contains__</code> , <code>__iter__</code>
<i>ValuesView</i>	<i>MappingView</i> , <i>Collection</i>		<code>__contains__</code> , <code>__iter__</code>
<i>Awaitable</i> <sup>1</sup>		<code>__await__</code>	
<i>Coroutine</i> <sup>1</sup>	<i>Awaitable</i>	<code>send</code> , <code>throw</code>	<code>close</code>
<i>AsyncIterable</i> <sup>1</sup>		<code>__aiter__</code>	
<i>AsyncIterator</i> <sup>1</sup>	<i>AsyncIte</i>	<code>__anext__</code>	<code>__aiter__</code>
<i>AsyncGenerator</i> <sup>1</sup>	<i>AsyncIte</i>	<code>asend</code> , <code>athrow</code>	<code>aclose</code> , <code>__aiter__</code> , <code>__anext__</code>
<i>Buffer</i> <sup>1</sup>		<code>__buffer__</code>	

<sup>1</sup> These ABCs override `__subclasshook__()` to support testing an interface by verifying the required methods are present and have not been set to `None`. This only works for simple interfaces. More complex interfaces require registration or direct subclassing.

<sup>2</sup> Checking `isinstance(obj, Iterable)` detects classes that are registered as *Iterable* or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

## 8.5.2 Collections Abstract Base Classes -- Detailed Descriptions

**class** `collections.abc.Container`

ABC for classes that provide the `__contains__()` method.

**class** `collections.abc.Hashable`

ABC for classes that provide the `__hash__()` method.

**class** `collections.abc.Sized`

ABC for classes that provide the `__len__()` method.

**class** `collections.abc.Callable`

ABC for classes that provide the `__call__()` method.

See [F釋 callable 物件](#) for details on how to use `Callable` in type annotations.

**class** `collections.abc.Iterable`

ABC for classes that provide the `__iter__()` method.

Checking `isinstance(obj, Iterable)` detects classes that are registered as `Iterable` or that have an `__iter__()` method, but it does not detect classes that iterate with the `__getitem__()` method. The only reliable way to determine whether an object is *iterable* is to call `iter(obj)`.

**class** `collections.abc.Collection`

ABC for sized iterable container classes.

在 3.6 版被加入.

**class** `collections.abc.Iterator`

ABC for classes that provide the `__iter__()` and `__next__()` methods. See also the definition of *iterator*.

**class** `collections.abc.Reversible`

ABC for iterable classes that also provide the `__reversed__()` method.

在 3.6 版被加入.

**class** `collections.abc.Generator`

ABC for *generator* classes that implement the protocol defined in [PEP 342](#) that extends *iterators* with the `send()`, `throw()` and `close()` methods.

See [Annotating generators and coroutines](#) for details on using `Generator` in type annotations.

在 3.5 版被加入.

**class** `collections.abc.Sequence`

**class** `collections.abc.MutableSequence`

**class** `collections.abc.ByteString`

ABCs for read-only and mutable *sequences*.

Implementation note: Some of the mixin methods, such as `__iter__()`, `__reversed__()` and `index()`, make repeated calls to the underlying `__getitem__()` method. Consequently, if `__getitem__()` is implemented with constant access speed, the mixin methods will have linear performance; however, if the underlying method is linear (as it would be with a linked list), the mixins will have quadratic performance and will likely need to be overridden.

在 3.5 版的變更: The `index()` method added support for *stop* and *start* arguments.

Deprecated since version 3.12, will be removed in version 3.14: The `ByteString` ABC has been deprecated. For use in typing, prefer a union, like `bytes | bytearray`, or `collections.abc.Buffer`. For use as an ABC, prefer `Sequence` or `collections.abc.Buffer`.

**class** `collections.abc.Set`

**class** `collections.abc.MutableSet`

ABCs for read-only and mutable *sets*.

**class** `collections.abc.Mapping`

**class** `collections.abc.MutableMapping`

ABCs for read-only and mutable *mappings*.

**class** `collections.abc.MappingView`

**class** `collections.abc.ItemsView`

**class** `collections.abc.KeysView`

**class** `collections.abc.ValuesView`

ABCs for mapping, items, keys, and values *views*.

**class** `collections.abc.Awaitable`

ABC for *awaitable* objects, which can be used in `await` expressions. Custom implementations must provide the `__await__()` method.

*Coroutine* objects and instances of the *Coroutine* ABC are all instances of this ABC.

**備 F**

In CPython, generator-based coroutines (*generators* decorated with `@types.coroutine`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Awaitable)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

在 3.5 版被加入。

**class** `collections.abc.Coroutine`

ABC for *coroutine* compatible classes. These implement the following methods, defined in *coroutine-objects*: `send()`, `throw()`, and `close()`. Custom implementations must also implement `__await__()`. All *Coroutine* instances are also instances of *Awaitable*.

**備 F**

In CPython, generator-based coroutines (*generators* decorated with `@types.coroutine`) are *awaitables*, even though they do not have an `__await__()` method. Using `isinstance(gencoro, Coroutine)` for them will return `False`. Use `inspect.isawaitable()` to detect them.

See *Annotating generators and coroutines* for details on using *Coroutine* in type annotations. The variance and order of type parameters correspond to those of *Generator*.

在 3.5 版被加入。

**class** `collections.abc.AsyncIterable`

ABC for classes that provide an `__aiter__` method. See also the definition of *asynchronous iterable*.

在 3.5 版被加入。

**class** `collections.abc.AsyncIterator`

ABC for classes that provide `__aiter__` and `__anext__` methods. See also the definition of *asynchronous iterator*.

在 3.5 版被加入。

**class** `collections.abc.AsyncGenerator`

ABC for *asynchronous generator* classes that implement the protocol defined in **PEP 525** and **PEP 492**.

See *Annotating generators and coroutines* for details on using *AsyncGenerator* in type annotations.

在 3.6 版被加入。

`class collections.abc.Buffer`

ABC for classes that provide the `__buffer__()` method, implementing the buffer protocol. See [PEP 688](#).  
在 3.12 版被加入。

### 8.5.3 Examples and Recipes

ABCs allow us to ask classes or instances if they provide particular functionality, for example:

```
size = None
if isinstance(myvar, collections.abc.Sized):
    size = len(myvar)
```

Several of the ABCs are also useful as mixins that make it easier to develop classes supporting container APIs. For example, to write a class supporting the full `Set` API, it is only necessary to supply the three underlying abstract methods: `__contains__()`, `__iter__()`, and `__len__()`. The ABC supplies the remaining methods such as `__and__()` and `isdisjoint()`:

```
class ListBasedSet(collections.abc.Set):
    ''' Alternate set implementation favoring space over speed
        and not requiring the set elements to be hashable. '''
    def __init__(self, iterable):
        self.elements = lst = []
        for value in iterable:
            if value not in lst:
                lst.append(value)

    def __iter__(self):
        return iter(self.elements)

    def __contains__(self, value):
        return value in self.elements

    def __len__(self):
        return len(self.elements)

s1 = ListBasedSet('abcdef')
s2 = ListBasedSet('defghi')
overlap = s1 & s2           # The __and__() method is supported automatically
```

Notes on using `Set` and `MutableSet` as a mixin:

- (1) Since some set operations create new sets, the default mixin methods need a way to create new instances from an *iterable*. The class constructor is assumed to have a signature in the form `ClassName(iterable)`. That assumption is factored-out to an internal *classmethod* called `_from_iterable()` which calls `cls(iterable)` to produce a new set. If the `Set` mixin is being used in a class with a different constructor signature, you will need to override `_from_iterable()` with a classmethod or regular method that can construct new instances from an iterable argument.
- (2) To override the comparisons (presumably for speed, as the semantics are fixed), redefine `__le__()` and `__ge__()`, then the other operations will automatically follow suit.
- (3) The `Set` mixin provides a `_hash()` method to compute a hash value for the set; however, `__hash__()` is not defined because not all sets are *hashable* or immutable. To add set hashability using mixins, inherit from both `Set()` and `Hashable()`, then define `__hash__ = Set._hash`.

## 8.6 heapq --- 堆積列 (heap queue) 演算法

原始碼: Lib/heapq.py

這個模組實作了堆積列 (heap queue) 演算法，亦被稱優先列 (priority queue) 演算法。

Heap (堆積) 是一顆二元樹，樹上所有父節點的值都小於等於他的子節點的值，我們將這種情況稱堆積的性質不變。

使用陣列實作，對於所有從 0 開始的  $k$  都滿足  $\text{heap}[k] \leq \text{heap}[2*k+1]$  和  $\text{heap}[k] \leq \text{heap}[2*k+2]$ 。比較節點的值，不存在的元素被視無限大。heap 存在一個有趣的性質：樹上最小的元素永遠會在根節點  $\text{heap}[0]$  上。

下方的 API 跟一般教科書的 heap queue 演算法有兩個方面不同：第一，我們的索引從 0 開始計算，這會父節點與子節點之間的關係生很微小的差別，但更符合 Python 從 0 開始索引的設計。第二，我們的 pop 方法會回傳最小的元素而不是最大的元素（在教科書中被稱作“min heap”，而“max heap”因他很適合做原地排序，所以更常出現在教科書中）。

這兩個特性使得把 heap 當作一個標準的 Python list 檢視時不會出現意外： $\text{heap}[0]$  是最小的物件， $\text{heap.sort}()$  能保持 heap 的性質不變！

建立一個 heap 可以使用 list 初始化  $[],$  或者使用函式  $\text{heapify}()$  將一個已經有元素的 list 轉成一個 heap。

此模組提供下面的函式

$\text{heapq.heappush}(\text{heap}, \text{item})$

把  $\text{item}$  放進  $\text{heap}$ ，保持 heap 性質不變。

$\text{heapq.heappop}(\text{heap})$

從  $\text{heap}$  取出回傳最小的元素，同時保持 heap 性質不變。如果  $\text{heap}$  是空的會生  $\text{IndexError}$  錯誤。只存取最小元素但不取出可以使用  $\text{heap}[0]$ 。

$\text{heapq.heappushpop}(\text{heap}, \text{item})$

將  $\text{item}$  放入  $\text{heap}$ ，接著從  $\text{heap}$  取出回傳最小的元素。這個組合函式比呼叫  $\text{heappush}()$  之後呼叫  $\text{heappop}()$  更有效率。

$\text{heapq.heapify}(x)$

在時間上將 list  $x$  轉成 heap，且過程不會申請額外記憶體。

$\text{heapq.heapreplace}(\text{heap}, \text{item})$

從  $\text{heap}$  取出回傳最小的元素，接著將新的  $\text{item}$  放進  $\text{heap}$ 。 $\text{heap}$  的大小不會改變。如果  $\text{heap}$  是空的會生  $\text{IndexError}$  錯誤。

這個一次完成的操作會比呼叫  $\text{heappop}()$  之後呼叫  $\text{heappush}()$  更有效率，在維護  $\text{heap}$  的大小不變時更適當，取出/放入的組合函式一定會從  $\text{heap}$  回傳一個元素用  $\text{item}$  取代他。

函式的回傳值可能會大於被加入的  $\text{item}$ 。如果這不是你期望發生的，可以考慮使用  $\text{heappushpop}()$  替代，他會回傳  $\text{heap}$  的最小值和  $\text{item}$  兩個當中比較小的那個，將大的留在  $\text{heap}$ 。

這個模組也提供三個利用 heap 實作的一般用途函式

$\text{heapq.merge}(*\text{iterables}, \text{key}=\text{None}, \text{reverse}=\text{False})$

合多個已排序的輸入生單一旦已排序的輸出（舉例：合來自多個 log 檔中有時間戳記的項目）。回傳一個 *iterator* 包含已經排序的值。

和  $\text{sorted}(\text{itertools.chain}(*\text{iterables}))$  類似但回傳值是一個 *iterable*，不會一次把所有資料都放進記憶體中，且假設每一個輸入都已經（由小到大）排序過了。

有兩個選用參數，指定時必須被當作關鍵字參數指定。

$\text{key}$  參數指定了一個 *key function* 引數，用來從每一個輸入的元素中定一個比較的依據。預設的值是  $\text{None}$ （直接比較元素）。

`reverse` 是一個布林值，如果設定為 `True`，則輸入的元素將以相反的比較順序進行合併。為了達成類似 `sorted(itertools.chain(*iterables), reverse=True)` 的行為，所有 `iterables` 必須由大到小排序。

在 3.5 版的變更: 加入選用參數 `key` 和 `reverse`。

`heapq.nlargest(n, iterable, key=None)`

回傳一個包含資料 `iterable` 中前 `n` 大元素的 `list`。如果有指定 `key` 引數，`key` 會是只有一個引數的函式，用來從每一個在 `iterable` 中的元素提取一個比較的依據（例如 `key=str.lower`）。效果相當於 `sorted(iterable, key=key, reverse=True)[:n]`。

`heapq.nsmallest(n, iterable, key=None)`

回傳一個包含資料 `iterable` 中前 `n` 小元素的 `list`。如果有指定 `key` 引數，`key` 會是只有一個引數的函式，用來從每一個在 `iterable` 中的元素提取一個比較的依據（例如 `key=str.lower`）。效果相當於 `sorted(iterable, key=key)[:n]`。

後兩個函式在 `n` 值比較小時有最好的表現。對於較大的 `n` 值，只用 `sorted()` 函式會更有效率。同樣地，當 `n=1` 時，使用內建函式 `min()` 和 `max()` 會有更好的效率。如果需要重用這些函式，可以考慮將 `iterable` 轉成真正的 `heap`。

## 8.6.1 基礎范例

堆積排序 (`heapsort`) 可以透過將所有的值推入一個 `heap`，且從 `heap` 中一個接一個彈出最小元素來實作：

```
>>> def heapsort(iterable):
...     h = []
...     for value in iterable:
...         heappush(h, value)
...     return [heappop(h) for i in range(len(h))]
...
>>> heapsort([1, 3, 5, 7, 9, 2, 4, 6, 8, 0])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

雖然類似 `sorted(iterable)`，但跟 `sorted()` 不同的是，這個實作不是 `stable` 的排序。

`Heap` 中的元素可以是 `tuple`。這有利於將要比較的值（例如一個 `task` 的優先度）和主要資料放在一起排序：

```
>>> h = []
>>> heappush(h, (5, 'write code'))
>>> heappush(h, (7, 'release product'))
>>> heappush(h, (1, 'write spec'))
>>> heappush(h, (3, 'create tests'))
>>> heappop(h)
(1, 'write spec')
```

## 8.6.2 優先列實作細節

優先列 (`priority queue`) 是 `heap` 的常見用途之一，實作優先列伴隨著下列挑戰：

- 排序的穩定性：如何將兩個擁有相同優先次序 (`priority`) 的 `task` 按照他們被加入的順序回傳？
- `Tuple` 的排序在某些情況下會壞掉，例如當 `Tuple (priority, task)` 的 `priorities` 相等且 `tasks` 有一個預設的排序時。
- 當一個 `heap` 中 `task` 的 `priority` 改變時，如何將它移到 `heap` 正確的位置上？
- 或者一個還未被解鎖的 `task` 需要被解除時，要如何從列中找到解除指定的 `task`？

一個針對前兩個問題的解法是：儲存一個包含 `priority`、`entry count` 和 `task` 三個元素的 `tuple`。兩個 `task` 有相同 `priority` 時，`entry count` 會讓兩個 `task` 能根據加入的順序排序。因此沒有任何兩個 `task` 擁有相同的 `entry count`，所以永遠不會直接使用 `task` 做比較。

`task` 無法比較的另一個解方案是建立一個包裝器類，該類忽略 `task` 項目，只比較優先等級：

```

from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)

```

剩下的問題可以藉由找到要刪除的 task 更改它的 priority 或者直接將它移除。尋找一個 task 可以使用一個 dictionary 指向列當中的 entry。

移除 entry 或更改它的 priority 更困難，因為這會破壞 heap 的性質。所以一個可行的方案是將原本的 entry 做一個標記表示它已經被刪除，新增一個擁有新的 priority 的 entry：

```

pq = [] # list of entries arranged in a heap
entry_finder = {} # mapping of tasks to entries
REMOVED = '<removed-task>' # placeholder for a removed task
counter = itertools.count() # unique sequence count

def add_task(task, priority=0):
    'Add a new task or update the priority of an existing task'
    if task in entry_finder:
        remove_task(task)
    count = next(counter)
    entry = [priority, count, task]
    entry_finder[task] = entry
    heappush(pq, entry)

def remove_task(task):
    'Mark an existing task as REMOVED. Raise KeyError if not found.'
    entry = entry_finder.pop(task)
    entry[-1] = REMOVED

def pop_task():
    'Remove and return the lowest priority task. Raise KeyError if empty.'
    while pq:
        priority, count, task = heappop(pq)
        if task is not REMOVED:
            del entry_finder[task]
            return task
    raise KeyError('pop from an empty priority queue')

```

### 8.6.3 原理

Heap 是一個陣列對於所有從 0 開始的 index  $k$  都存在性質  $a[k] \leq a[2k+1]$  和  $a[k] \leq a[2k+2]$ 。為了方便比較，不存在的元素被視為無限大。Heap 的一個有趣的性質是： $a[0]$  永遠是最小的元素。

上述乍看之下有些奇怪的不變式，是為了實作一個對記憶體來有效率的方法，其表示方式如同錦標賽一般。下列的數字  $k$ ，而不是  $a[k]$ ：

```

      0
    1   2
  3   4   5   6
7  8  9  10  11  12  13  14
15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30

```

在上面的樹當中，每個單元  $k$  都會位在  $2k+1$  與  $2k+2$  上方。如同體育賽事常見的錦標賽般，每個單元可視為其下方兩個單元當中的贏家，我們可以透過追溯整棵樹來找到該贏家曾經對戰過的所有對手。然

而，在許多電腦應用中，我們不需要追溯贏家的完整對戰歷史。了能更有效率地使用記憶體，當一個贏家級勝出時，我們用下方較低層級的另一個項目來取代它，至此規則變一個單元以及它下方兩個單元，包含三個不同項目，但是最上方的單元「勝過」下方兩個單元。

如果能確保滿足這個 heap 的不變式，那索引 0 顯然是最終的贏家。移除找到「下一個」贏家最簡單的演算法：將一個輸家（例如上圖中的單元 30）移動到位置 0，然後從新的位置 0 不斷與下方的位置交值來向下傳遞，直到滿足不變式止。這個過程的難度顯然是樹的節點數目的對數級。透過對所有項目代，可以得到一個複雜度  $O(n \log n)$  的排序。

這種排序有個好處，只要插入的項目有「贏過」你最後提取、索引 0 的元素，你就可以在排序進行的同時有效率地插入新項目。這在模擬情境當中特有用，其中樹能保存所有輸入事件，而「贏」意味著最小排程時間。當一個事件排程其它事件的執行時，因這些事件仍在等待進行，所以很容易將它們插入 heap 當中。因此，heap 是一個實現排程器的優秀資料結構（這就是我用以實作 MIDI 編曲器的方法:-)。

多種用於實作排程器的結構現今已被廣泛研究，heap 對此非常有用，因它們速度相當快，且速度幾乎不受其他因素影響，最壞情況與平均狀況差無幾。也有其它整體來更有效率的方法，然而它們的最壞情況可能會非常糟糕。

Heap 在儲存於硬碟上的大量資料進行排序也非常有用。你可能已經知道，大量資料排序涉及“runs”的生成（也就是預先排序的序列，其大小通常與 CPU 記憶體的大小有關），之後再對這些 run 合併，而這些合併的過程通常相當巧妙<sup>1</sup>。很重要的一點是，初始排序生成的 run 越長越好。錦標賽是達成這一點的好方法，若你用所有可用記憶體來舉行一場錦標賽，透過替與向下交來處理所有適配當前 run 的值，那對於隨機生成的輸入，將可以生成長度兩倍於記憶體大小的 run。對於已模糊排序過的輸入，效果更好。

此外，若你將索引 0 的項目輸出至磁碟，取得一個無法適配當前錦標賽的輸入（因該值「勝過」最後的輸出值），則該輸入值就無法插入至 heap 當中，因此 heap 的大小會小。釋放出來的記憶體可以巧妙地立即再被運用，逐步建構出第二個 heap，其大小增加的速度會與第一個 heap 少的速度一致。當第一個 heap 完全消失時，你可以切至第二個 heap 開一個新 run。這真是個聰明且相當有效率的做法！

總結來，heap 是值得了解的有用記憶體結構。我在一些應用中使用它們，我認能有一個‘heap’模組是很棒的。:-)

## 解

## 8.7 bisect --- 陣列二分演算法 (Array bisection algorithm)

原始碼：Lib/bisect.py

這個模組維護一個已經排序過的 list，當我們每次做完插入後不需要再次排序整個 list。一個很長的 list 的比較操作很花費時間，可以透過性搜索或頻繁地詢問來改善。

這個模組被稱 `bisect` 是因它使用基本二分演算法來完成其工作。不像其它搜尋特定值的二分法工具，本模組中的函式旨在定位插入點。因此，這些函式永遠不會呼叫 `__eq__()` 方法來確認是否找到一個值。相反地，這些函式只呼叫 `__lt__()` 方法，在陣列中的值回傳一個插入點。

此模組提供下面的函式：

```
bisect.bisect_left(a, x, lo=0, hi=len(a), *, key=None)
```

在 `a` 當中找到一個位置，讓 `x` 插入後 `a` 仍然是排序好的。參數 `lo` 和 `hi` 用來指定 list 中應該被考慮的子區間，預設是考慮整個 list。如果 `a` 面已經有 `x` 出現，插入的位置會在所有 `x` 的前面（左邊）。回傳值可以被當作 `list.insert()` 的第一個參數，但列表 `a` 必須先排序過。

回傳的插入點 `ip` 將陣列 `a` 劃分左右兩個切片，使得對於左切片而言 `all(elem < x for elem in a[lo : ip])` 真，對於右切片而言 `all(elem >= x for elem in a[ip : hi])` 真。

`key` 可指定一個單一參數的 *key function*。函式將套用此 function 在陣列所有元素以得到比較值來計算順位。注意此 function 只會套用在陣列中的元素，不會套用在 `x`。

<sup>1</sup> 現今的磁碟平衡演算法因硬碟查找能力而更加難解。在有查找功能的裝置如大型磁帶機，狀況又不一样了，人們必須機智地確保（遠遠提前）每次於磁帶上移動都盡可能是最有效率的（也就是盡可能更好地「推進」合併的過程）。有些磁帶甚至能向後讀取，這也被用來避免倒轉的時間。相信我，真正優秀的磁帶排序看起來相當壯觀！排序一直以來都是一門偉大的藝術！:-)

若 `key` 為 `None`，元素將直接進行比較，不會呼叫任何鍵函式。

在 3.10 版的變更: 新增 `key` 參數。

```
bisect.bisect_right(a, x, lo=0, hi=len(a), *, key=None)
```

```
bisect.bisect(a, x, lo=0, hi=len(a), *, key=None)
```

類似 `bisect_left()`，但回傳的插入位置會在所有 `a` 當中的 `x` 的後面（右邊）。

回傳的插入點 `ip` 將陣列 `a` 劃分為左右兩個切片，使得對於左切片而言 `all(elem <= x for elem in a[lo : ip])` 為真，對於右切片而言 `all(elem > x for elem in a[ip : hi])` 為真。

在 3.10 版的變更: 新增 `key` 參數。

```
bisect.insort_left(a, x, lo=0, hi=len(a), *, key=None)
```

將元素 `x` 插入 list `a`，維持順序。

此函式先使用 `bisect_left()` 搜索插入位置，接著用 `insert()` 於 `a` 以將 `x` 插入，維持添加元素後的順序。

此函式只有在搜索時會使用 `key` 函式，插入時不會。

注意雖然搜索是  $O(\log n)$ ，但插入是  $O(n)$ ，因此此函式整體時間複雜度是  $O(n)$ 。

在 3.10 版的變更: 新增 `key` 參數。

```
bisect.insort_right(a, x, lo=0, hi=len(a), *, key=None)
```

```
bisect.insort(a, x, lo=0, hi=len(a), *, key=None)
```

類似 `insort_left()`，但插入的位置會在所有 `a` 當中的 `x` 的後面（右邊）。

此函式先使用 `bisect_right()` 搜索插入位置，接著用 `insert()` 於 `a` 以將 `x` 插入，維持添加元素後的順序。

此函式只有在搜索時會使用 `key` 函式，插入時不會。

注意雖然搜索是  $O(\log n)$ ，但插入是  $O(n)$ ，因此此函式整體時間複雜度是  $O(n)$ 。

在 3.10 版的變更: 新增 `key` 參數。

## 8.7.1 效能考量

若在需要關注寫入時間的程式當中使用 `bisect()` 和 `insort()`，請特別注意幾個事項：

- 二分法在一段範圍的數值中做搜索的效率較佳，但若是存取特定數值，使用字典的表現還是比較好。
- `insort()` 函式的時間複雜度是  $O(n)$ ，因為對數搜尋是以線性時間的插入步驟所主導 (dominate)。
- 搜索函式是無狀態的 (stateless)，且鍵函式會在使用過後被回收。因此，如果搜索函式被使用於循環當中，鍵函式會不斷被重呼叫於相同的 list 元素。如果鍵函式執行速度不快，請考慮將其以 `functools.cache()` 包裝起來以減少重計算。另外，也可以透過搜尋預先計算好的鍵列表 (array of precomputed keys) 來定位插入點（如下方範例所示）。

### 也參考

- 有序容器 (Sorted Collections) 是一個使用 `bisect` 來管理資料之有序集合的高效能模組。
- `SortedCollection recipe` 使用二分法來建立一個功能完整的集合類 (collection class) 帶有符合直覺的搜索方法 (search methods) 與支援鍵函式。鍵會預先被計算好，以減少搜索過程中多余的鍵函式呼叫。

## 8.7.2 搜尋一個已排序的 list

上面的 *bisect functions* 在找到數值插入點上很有用，但一般的數值搜尋任務上就不是那麼的方便。以下的五個函式展示了如何將其轉成標準的有序列表查找函式：

```
def index(a, x):
    'Locate the leftmost value exactly equal to x'
    i = bisect_left(a, x)
    if i != len(a) and a[i] == x:
        return i
    raise ValueError

def find_lt(a, x):
    'Find rightmost value less than x'
    i = bisect_left(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_le(a, x):
    'Find rightmost value less than or equal to x'
    i = bisect_right(a, x)
    if i:
        return a[i-1]
    raise ValueError

def find_gt(a, x):
    'Find leftmost value greater than x'
    i = bisect_right(a, x)
    if i != len(a):
        return a[i]
    raise ValueError

def find_ge(a, x):
    'Find leftmost item greater than or equal to x'
    i = bisect_left(a, x)
    if i != len(a):
        return a[i]
    raise ValueError
```

## 8.7.3 范例

*bisect()* 函式可用於數值表中的查找 (numeric table lookup)，這個範例使用 *bisect()* 以基於一組有序的數值分界點來一個考試成績找到相對應的字母等級：90 以上是 'A'、80 到 89 是 'B'，依此類推：

```
>>> def grade(score, breakpoints=[60, 70, 80, 90], grades='FDCBA'):
...     i = bisect(breakpoints, score)
...     return grades[i]
...
>>> [grade(score) for score in [33, 99, 77, 70, 89, 90, 100]]
['F', 'A', 'C', 'C', 'B', 'A', 'A']
```

*bisect()* 與 *insort()* 函式也適用於容 tuples (元組) 的 lists，*key* 引數可被用以取出在數值表中作排序依據的欄位：

```
>>> from collections import namedtuple
>>> from operator import attrgetter
>>> from bisect import bisect, insort
>>> from pprint import pprint

>>> Movie = namedtuple('Movie', ('name', 'released', 'director'))
```

(繼續下一頁)

(繼續上一頁)

```

>>> movies = [
...     Movie('Jaws', 1975, 'Spielberg'),
...     Movie('Titanic', 1997, 'Cameron'),
...     Movie('The Birds', 1963, 'Hitchcock'),
...     Movie('Aliens', 1986, 'Cameron')
... ]

>>> # Find the first movie released after 1960
>>> by_year = attrgetter('released')
>>> movies.sort(key=by_year)
>>> movies[bisect(movies, 1960, key=by_year)]
Movie(name='The Birds', released=1963, director='Hitchcock')

>>> # Insert a movie while maintaining sort order
>>> romance = Movie('Love Story', 1970, 'Hiller')
>>> insort(movies, romance, key=by_year)
>>> pprint(movies)
[Movie(name='The Birds', released=1963, director='Hitchcock'),
 Movie(name='Love Story', released=1970, director='Hiller'),
 Movie(name='Jaws', released=1975, director='Spielberg'),
 Movie(name='Aliens', released=1986, director='Cameron'),
 Movie(name='Titanic', released=1997, director='Cameron')]

```

如果鍵函式會消耗較多運算資源，那可以在預先計算好的鍵列表中搜索該紀元的索引值，以減少重覆的函式呼叫：

```

>>> data = [('red', 5), ('blue', 1), ('yellow', 8), ('black', 0)]
>>> data.sort(key=lambda r: r[1])           # Or use operator.itemgetter(1).
>>> keys = [r[1] for r in data]           # Precompute a list of keys.
>>> data[bisect_left(keys, 0)]
('black', 0)
>>> data[bisect_left(keys, 1)]
('blue', 1)
>>> data[bisect_left(keys, 5)]
('red', 5)
>>> data[bisect_left(keys, 8)]
('yellow', 8)

```

## 8.8 array --- 高效率的數值型陣列

這個模組定義了一個物件型，可以簡潔的表達一個包含基本數值的陣列：字元、整數、浮點數。陣列是一個非常類似 list (串列) 的序列型，除了陣列會限制儲存的物件型。在建立陣列時可以使用一個字元的 *type code* 來指定儲存的資料型。以下有被定義的 type codes：

Type code	C Type	Python Type	所需的最小位元組 (bytes)	解
'b'	signed char	int	1	
'B'	unsigned char	int	1	
'u'	wchar_t	Unicode character	2	(1)
'w'	Py_UCS4	Unicode character	4	
'h'	signed short	int	2	
'H'	unsigned short	int	2	
'i'	signed int	int	2	
'I'	unsigned int	int	2	
'l'	signed long	int	4	
'L'	unsigned long	int	4	
'q'	signed long long	int	8	
'Q'	unsigned long long	int	8	
'f'	float	float	4	
'd'	double	float	8	

解:

(1) 根據平台的不同，它有可能是 16 位元或者 32 位元。

在 3.9 版的變更: 目前 `array('u')` 使用 `wchar_t` 取代已用的 `Py_UNICODE` 作 C type。這個動有影響到它的作用，因為自從 Python 3.3 開始 `Py_UNICODE` 即 `wchar_t` 的代名。

Deprecated since version 3.3, will be removed in version 3.16: Please migrate to 'w' typecode.

實際上數值的表示方法是被機器的架構所定 (更精準地, 被 C 的實作方法定)。實際的大小可以透過 `array.itemsize` 屬性存取。

這個模組定義了以下項目:

`array.typecodes`

一個包含所有可用的 type codes 的字串。

這個模組定義了下方的型:

`class array.array (typecode[, initializer])`

一個新的陣列中的元素被 `typecode` 限制, 由選用的 `initializer` 參數初始化, `initializer` 必須是一個 `bytes` 或 `bytearray` 物件、一個 Unicode 字串或包含適當型元素的可代物件 (iterable)。

如果給定的是一個 `bytes` 或 `bytearray` 物件, 新的陣列初始化時會傳入 `frombytes()` 方法; 如 Unicode 字串則會傳入 `fromunicode()` 方法; 其他情況時, 一個 `initializer` 的可代物件將被傳入 `extend()` 方法之中來將初始項目新增至陣列。

陣列支援常見的序列操作, 包含索引 (indexing)、切片 (slicing)、串接 (concatenation)、相乘 (multiplication) 等。當使用切片進行賦值時, 賦值的陣列必須具備相同的 type code, 其他型的數值將導致 `TypeError`。陣列同時也實作了緩衝區介面, 可以在任何支援 `bytes-like objects` 的地方使用。

引發稽核事件 (auditing event) `array.__new__` 附帶引數 `typecode`、`initializer`。

`typecode`

`typecode` 字元被用在建立陣列時。

`itemsize`

陣列當中的一個元素在部需要的位元組長度。

`append(x)`

新增一個元素 `x` 到陣列的最尾端。

`buffer_info()`

回傳一個 tuple (address, length) 表示當前的記憶體位置和陣列儲存元素的緩衝區記憶體長度。緩衝區的長度單位是位元組, 可以用 `array.buffer_info()[1] * array.itemsize`

計算得到。這偶爾會在底層操作需要記憶體位置的輸出輸入時很有用，例如 `ioctl()` 指令。只要陣列存在且有使用任何更改長度的操作時，回傳的數值就有效。

### 備註

當使用來自 C 或 C++ 程式碼（這是唯一使得這個資訊有效的途徑）的陣列物件時，更適當的做法是使用陣列物件支援的緩衝區介面。這個方法維護了向後兼容性，應該在新的程式碼中避免。關於緩衝區介面的文件在 `bufferobjects`。

#### `byteswap()`

“Byteswap” 所有陣列中的物件。這只有支援物件長度 1、2、4 或 8 位元組的陣列，其他型的值會導致 `RuntimeError`。這在從機器讀取位元順序不同的檔案時很有用。

#### `count(x)`

回傳 `x` 在陣列中出現了幾次。

#### `extend(iterable)`

從 `iterable` 中新增元素到陣列的尾端，如果 `iterable` 是另一個陣列，它必須有完全相同的 type code，如果不同會導致 `TypeError`。如果 `iterable` 不是一個陣列，它必須可以被迭代 (`iterable`) 且其中的元素必須是可以被加入陣列中的正確型。

#### `frombytes(buffer)`

從 `bytes-like object` 中新增元素。讀取時會將其內容當作一個機器數值組成的陣列（就像從檔案中使用 `fromfile()` 方法讀出的資料）。

在 3.2 版被加入：將 `fromstring()` 更名 `frombytes()`，使其更加清晰易懂。

#### `fromfile(f, n)`

從 `file object` `f` 讀取 `n` 個元素（作機器數值），接著將這些元素加入陣列的最尾端。如果只有少於 `n` 個有效的元素會導致 `EOFError`，但有效的元素仍然會被加入陣列中。

#### `fromlist(list)`

從 `list` 中新增元素。這等價於 `for x in list: a.append(x)`，除了有型錯誤發生時，陣列會保持原狀不會被更改。

#### `fromunicode(s)`

Extends this array with data from the given Unicode string. The array must have type code 'u' or 'w'; otherwise a `ValueError` is raised. Use `array.frombytes(unicodestring.encode(enc))` to append Unicode data to an array of some other type.

#### `index(x[, start[, stop]])`

回傳 `i` 的最小數值，使得 `i` 成陣列之中第一次出現 `x` 的索引。選擇性的引數 `start` 及 `stop` 則可以被用來在指定的陣列空間中搜尋 `x`。如果 `x` 不存在將導致 `ValueError`。

在 3.10 版的變更：新增選擇性的參數 `start` 及 `stop`。

#### `insert(i, x)`

在位置 `i` 之前插入一個元素 `x`。負數的索引值會從陣列尾端開始數。

#### `pop([i])`

移除回傳陣列索引值 `i` 的元素。選擇性的引數 `i` 預設 `-1`，所以預設會刪除回傳最後一個元素。

#### `remove(x)`

從陣列中刪除第一個出現的 `x`。

#### `clear()`

Remove all elements from the array.

在 3.13 版被加入。

**reverse()**

反轉陣列中元素的順序。

**tobytes()**

將陣列轉成另一個機器數值組成的陣列回傳它的位元組表示（跟用 `tofile()` 方法寫入檔案時的位元序列相同）。

在 3.2 版被加入：為了明確性，過去的 `tostring()` 已更名 `tobytes()`。

**tofile(f)**

將所有元素（作機器數值）寫入 *file object* `f`。

**tolist()**

不更改元素，將陣列轉成一般的 `list`。

**tounicode()**

Convert the array to a Unicode string. The array must have a type 'u' or 'w'; otherwise a `ValueError` is raised. Use `array.tobytes().decode(enc)` to obtain a Unicode string from an array of some other type.

The string representation of array objects has the form `array(typecode, initializer)`. The *initializer* is omitted if the array is empty, otherwise it is a Unicode string if the *typecode* is 'u' or 'w', otherwise it is a list of numbers. The string representation is guaranteed to be able to be converted back to an array with the same type and value using `eval()`, so long as the `array` class has been imported using `from array import array`. Variables `inf` and `nan` must also be defined if it contains corresponding floating-point values. Examples:

```
array('l')
array('w', 'hello \u2641')
array('l', [1, 2, 3, 4, 5])
array('d', [1.0, 2.0, 3.14, -inf, nan])
```

將包含不同資料類型的二進位資料包裝與解開包裝。

#### **NumPy**

NumPy 套件定義了另一個陣列型。

## 8.9 weakref --- 弱參照

原始碼：[Lib/weakref.py](#)

`weakref` 模組允許 Python 程式設計師建立對物件的弱參照。

在以下文章中，術語參照目標 (*referent*) 表示被弱參照所參考的物件。

對物件的弱參照不足以使物件保持存在：當對參照目標的唯一剩下的參照是弱參照時，*garbage collection* 可以自由地銷參照目標將其記憶體重新用於其他用途。然而，在物件被確實銷之前，即使有對該物件的參照 (strong reference)，弱參照也可能會回傳該物件。

弱參照的主要用途是實作保存大型物件的快取或對映，其不希望大型物件僅僅因它出現在快取或對映中而保持存在。

例如，如果你有許多大型的二進位影像物件，你可能會想要每個物件關聯 (associate) 一個名稱。如果你使用 Python 字典將名稱對映到影像，或將影像對映到名稱，則影像物件將保持存活，僅因它們在字典中作值 (value) 或鍵 (key) 出現。`weakref` 模組提供的 `WeakKeyDictionary` 和 `WeakValueDictionary` 類是另一種選擇，它們使用弱參照來建構對映，這些對映不會僅因物件出現在對映物件中而使物件保持存活。例如，如果一個影像物件是 `WeakValueDictionary` 中的一個值，那當對該影像物件最後的

參照是弱對映 (weak mapping) 所持有的弱參照時，垃圾回收 (garbage collection) 可以回收該物件，且其對應的條目在弱對映中會被完全地刪除。

`WeakKeyDictionary` 和 `WeakValueDictionary` 在其實作中使用弱參照，在弱參照上設定回呼函式，此弱參照在垃圾回收取回鍵或值時通知弱字典。`WeakSet` 實作了 `set` 介面，但保留對其元素的弱參照，就像 `WeakKeyDictionary` 一樣。

`finalize` 提供了一種直接的方法來在物件被垃圾回收時呼叫的清理函式。這比在原始弱參照上設定回呼函式更容易使用，因 `weakref` 模組在物件被回收前會自動確保最終化器 (finalizer) 保持存活。

大多數程式應該發現使用這些弱容器種類之一或 `finalize` 就足了一通常不需要直接建立自己的弱參照。低層級的機制由 `weakref` 模組公開，以利於進階用途。

非所有物件都可以被弱參照。支援弱參照的物件包括類實例、用 Python (但不是 C) 編寫的函式、實例方法、集合、凍結集合 (frozenset)、一些檔案物件、生成器、類型物件、socket、陣列、雙向列、正規表示式模式物件和程式碼物件。

在 3.2 版的變更: 新增了對 `thread.lock`、`threading.Lock` 和程式碼物件的支援。

一些建型，例如 `list` 和 `dict` 不直接支援弱參照，但可以透過子類化來支援：

```
class Dict(dict):
    pass

obj = Dict(red=1, green=2, blue=3)  # 這個物件是可被弱參照的
```

其他建型，例如 `tuple` 和 `int` 即使在子類化時也不支援弱參照。

擴充型 (extension type) 可以輕易地支援弱參照；請參 `weakref-support`。

當給定的型定義 `__slots__` 時，弱參照支援將被停用，除非 `'__weakref__'` 字串也存在於 `__slots__` 宣告的字串序列中。詳情請參 `__slots__` 文件。

`class weakref.ref(object[, callback])`

回傳對 `object` 的弱參照。如果參照目標仍存活，則可以透過呼叫參照物件來取回原始物件；如果參照目標已不存活，呼叫參照物件將導致 `None` 被回傳。如果 `callback` 被提供而非 `None`，且回傳的弱參照物件仍存活，那當物件即將被最終化 (finalize) 時，回呼將被呼叫；弱參照物件將作唯一的參數傳遞給回呼；參照物件將不再可用。

同一個物件建構多個弱參照是可行的。每個弱參照的回呼將按照最新到最舊的回呼順序來被呼叫。

回呼引發的例外將在標準錯誤輸出中被明，但無法被傳播；它們的處理方式與物件的 `__del__()` 方法引發的例外完全相同。

如果 `object` 是可雜的，那弱參照就是可雜的。即使在 `object` 被除後，它們仍將保留其雜值。如果僅在 `object` 除後才第一次呼叫 `hash()`，則該呼叫將引發 `TypeError`。

弱參照支援相等性的測試，但不支援排序。如果參照目標仍存活，則兩個參照與其參照目標具有相同的相等關 (無論 `callback` 如何)。如果任一參照目標已被除，則僅當參照物件是同一物件時，參照才相等。

這是一個可子類化的型，而不是一個工廠函式。

`__callback__`

此唯讀屬性回傳目前與弱參照關聯的回呼。如果有回呼或弱參照的參照目標已不存活，那該屬性的值 `None`。

在 3.4 版的變更: 新增 `__callback__` 屬性。

`weakref.proxy(object[, callback])`

回傳一個使用弱參照的 `object` 的代理 (proxy)。這支援在大多數情境中使用代理，而不需要對弱參照物件明確地取消參照。回傳的物件將具有 `ProxyType` 或 `CallableProxyType` 型，具體取於 `object` 是否可呼叫物件。無論參照目標如何，代理物件都不是 `hashable`；這避免了與其基本可變物件本質相關的許多問題，阻止它們作字典的鍵被使用。`callback` 與 `ref()` 函式的同名參數是相同的。

在參照目標被垃圾回收後存取代理物件的屬性會引發 `ReferenceError`。

在 3.8 版的變更: 提供對代理物件的運算子支援, 以包括矩陣乘法運算子 `@` 和 `@=`。

`weakref.getweakrefcount(object)`

回傳參照 `object` 的弱參照和代理的數量。

`weakref.getweakrefs(object)`

回傳參照 `object` 的所有弱參照和代理物件的一個串列。

`class weakref.WeakKeyDictionary([dict])`

弱參照鍵的對映類。當不再有對鍵的參照時, 字典中的條目將被刪除。這可用於將附加資料與應用程式其他部分擁有的物件相關聯, 而無需向這些物件新增屬性。這對於覆蓋屬性存取的物件特別有用。

請注意, 當將與現有鍵具有相同值的鍵 (但識別性不相等) 插入字典時, 它會替換該值, 但不會替換現有鍵。因此, 當刪除對原始鍵的參照時, 它也會刪除字典中的條目:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1 # d = {k1: 1}
>>> d[k2] = 2 # d = {k1: 2}
>>> del k1 # d = {}
```

一個變通的解法是在重新賦值 (reassignment) 之前刪除鍵:

```
>>> class T(str): pass
...
>>> k1, k2 = T(), T()
>>> d = weakref.WeakKeyDictionary()
>>> d[k1] = 1 # d = {k1: 1}
>>> del d[k1]
>>> d[k2] = 2 # d = {k2: 2}
>>> del k1 # d = {k2: 2}
```

在 3.9 版的變更: 新增對 `|` 和 `|=` 運算子的支持, 如 [PEP 584](#) 中所說明。

`WeakKeyDictionary` 物件有一個直接公開內部參照的附加方法。參照在被使用時不保證是“存活的”, 因此在使用之前需要檢查呼叫參照的結果。這可以用來防止建立會導致垃圾回收器保留鍵的時間超過其所需時間的參照。

`WeakKeyDictionary.keyrefs()`

回傳對鍵的弱參照的可代理物件。

`class weakref.WeakValueDictionary([dict])`

弱參照值的對映類。當不再存在對值的參照時, 字典中的條目將被刪除。

在 3.9 版的變更: 新增對 `|` 和 `|=` 運算子的支持, 如 [PEP 584](#) 中所說明。

`WeakValueDictionary` 物件有一個附加方法, 它與 `WeakKeyDictionary.keyrefs()` 方法有相同的問題。

`WeakValueDictionary.valuerefs()`

回傳對值的弱參照的可代理物件。

`class weakref.WeakSet([elements])`

保留對其元素的弱參照的集合類。當不再存在對某個元素的參照時, 該元素將被刪除。

`class weakref.WeakMethod(method[, callback])`

一個特別的 `ref` 子類, 其模擬對結方法 (bound method) (即在類上定義在實例上查找的方法) 的弱參照。由於結方法是短暫存在的, 因此標準弱參照無法保留它。 `WeakMethod` 有特殊的程式碼來重新建立結方法, 直到物件或原始函式死亡:

```

>>> class C:
...     def method(self):
...         print("method called!")
...
>>> c = C()
>>> r = weakref.ref(c.method)
>>> r()
>>> r = weakref.WeakMethod(c.method)
>>> r()
<bound method C.method of <__main__.C object at 0x7fc859830220>>
>>> r() ()
method called!
>>> del c
>>> gc.collect()
0
>>> r()
>>>

```

`callback` 與 `ref()` 函式的同名參數是相同的。

在 3.4 版被加入。

**class** `weakref.finalize(obj, func, /, *args, **kwargs)`

回傳可呼叫的最終化器物件，此物件在 `obj` 被垃圾回收時會被呼叫。與一般的弱參照不同，最終化器將始終存在，直到參照物件被回收<sup>[F]</sup>止，從而大大簡化了生命<sup>[F]</sup>期管理。

最終化器在被呼叫（明確呼叫或在垃圾回收時）之前被視<sup>[F]</sup>存活，之後它就會死亡。呼叫存活的最終化器會回傳 `func(*arg, **kwargs)` 的計算結果，而呼叫死亡的最終化器會回傳 `None`。

垃圾回收期間最終化器回呼引發的例外會在標準錯誤輸出中顯示，但無法傳播。它們的處理方式與從物件的 `__del__()` 方法或弱參照的回呼引發的例外相同。

當程式結束時，除非該最終化器的 `atexit` 屬性已被設定<sup>[F]</sup> `false`，否則每個存活的最終化器會被呼叫。它們以與建立相反的順序被呼叫。

當模組的 `globals` 可能被 `None` 取代時，最終化器永遠不會在 *interpreter shutdown* 的後期調用（`invoke`）其回呼。

**\_\_call\_\_()**

如果 `self` 仍存活，則將其標記<sup>[F]</sup>死亡<sup>[F]</sup>回傳呼叫 `func(*args, **kwargs)` 的結果。如果 `self` 已死亡，則回傳 `None`。

**detach()**

如果 `self` 仍存活，則將其標記<sup>[F]</sup>死亡<sup>[F]</sup>回傳元組 `(obj, func, args, kwargs)`。如果 `self` 已死亡，則回傳 `None`。

**peek()**

如果 `self` 仍存活，則回傳元組 `(obj, func, args, kwargs)`。如果 `self` 已死亡，則回傳 `None`。

**alive**

如果最終化器仍存活，則屬性<sup>[F]</sup> `true`，否則<sup>[F]</sup> `false`。

**atexit**

一個可寫的布林屬性，預設<sup>[F]</sup> `true`。當程式結束時，它會呼叫 `atexit` <sup>[F]</sup> `true` 的所有剩余且仍存活的最終化器。它們以與建立相反的順序被呼叫。

#### 備<sup>[F]</sup>

確保 `func`、`args` 和 `kwargs` 不直接或間接擁有對 `obj` 的任何參照非常重要，否則 `obj` 將永遠不會被垃圾回收。尤其 `func` 不應該是 `obj` 的<sup>[F]</sup>結方法。

在 3.4 版被加入。

`weakref.ReferenceType`

弱參照物件的型物件。

`weakref.ProxyType`

非可呼叫物件的代理的型物件。

`weakref.CallableProxyType`

可呼叫物件的代理的型物件。

`weakref.ProxyTypes`

包含代理的所有型物件的序列。這可以讓測試物件是否代理變得更簡單，而無需依賴命名兩種代理型。

### 也參考

#### PEP 205 - 弱參照

此功能的提案和理由，包括早期實作的連結以及其他語言中類似功能的資訊。

## 8.9.1 弱參照物件

弱參照物件除了 `ref.__callback__` 之外沒有任何方法和屬性。弱參照物件允許透過呼叫來獲取參照目標（如果它仍然存在）：

```
>>> import weakref
>>> class Object:
...     pass
...
>>> o = Object()
>>> r = weakref.ref(o)
>>> o2 = r()
>>> o is o2
True
```

如果參照目標不再存活，則呼叫參照物件將回傳 `None`：

```
>>> del o, o2
>>> print(r())
None
```

應該使用運算式 `ref() is not None` 來測試弱參照物件是否仍然存活。需要使用參照物件的應用程式碼通常應遵循以下模式：

```
# r is a weak reference object
o = r()
if o is None:
    # referent has been garbage collected
    print("Object has been deallocated; can't frobnicate.")
else:
    print("Object is still live!")
    o.do_something_useful()
```

使用對「活性 (liveness)」的單獨測試會在執行緒應用程式中建立競條件 (race condition)；另一個執行緒可能在弱參照被呼叫之前讓該弱參照失效；上方顯示的慣用作法在執行緒應用程式和單執行緒應用程式中都是安全的。

可以透過子類化來建立 `ref` 物件的特殊版本。這在 `WeakValueDictionary` 的實作中被使用，以減少對映中每個條目的記憶體開銷。這對於將附加資訊與參照相關聯最有用，但也可用於在呼叫上插入附加處理以檢索參照目標。

這個範例展示如何使用 `ref` 的子類來儲存有關物件的附加資訊影響存取參照目標時回傳的值：

```
import weakref

class ExtendedRef(weakref.ref):
    def __init__(self, ob, callback=None, /, **annotations):
        super().__init__(ob, callback)
        self.__counter = 0
        for k, v in annotations.items():
            setattr(self, k, v)

    def __call__(self):
        """Return a pair containing the referent and the number of
        times the reference has been called.
        """
        ob = super().__call__()
        if ob is not None:
            self.__counter += 1
            ob = (ob, self.__counter)
        return ob
```

## 8.9.2 范例

這個簡單的範例展示了應用程式如何使用物件 ID 來檢索它以前見過 的物件。物件的 ID 之後可以在其他資料結構中使用，而不必限制物件保持存活，但如果這樣做，仍然可以透過 ID 檢索物件。

```
import weakref

_id2obj_dict = weakref.WeakValueDictionary()

def remember(obj):
    oid = id(obj)
    _id2obj_dict[oid] = obj
    return oid

def id2obj(oid):
    return _id2obj_dict[oid]
```

## 8.9.3 最終化器物件

使用 `finalize` 的最大優點是可以輕鬆回呼，而無需保留回傳的最終化器物件。例如

```
>>> import weakref
>>> class Object:
...     pass
...
>>> kenny = Object()
>>> weakref.finalize(kenny, print, "You killed Kenny!")
<finalize object at ...; for 'Object' at ...>
>>> del kenny
You killed Kenny!
```

最終化器也可以直接被呼叫。然而，最終化器最多會調用回呼一次。

```
>>> def callback(x, y, z):
...     print("CALLBACK")
...     return x + y + z
...
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> assert f.alive
>>> assert f() == 6
```

(繼續下一頁)

(繼續上一頁)

```
CALLBACK
>>> assert not f.alive
>>> f() # callback not called because finalizer dead
>>> del obj # callback not called because finalizer dead
```

你可以使用最終化器的 `detach()` 方法來取消最終化器。這會殺死最終化器回傳建立建構函式時傳遞給建構函式的引數。

```
>>> obj = Object()
>>> f = weakref.finalize(obj, callback, 1, 2, z=3)
>>> f.detach()
(<...Object object ...>, <function callback ...>, (1, 2), {'z': 3})
>>> newobj, func, args, kwargs = _
>>> assert not f.alive
>>> assert newobj is obj
>>> assert func(*args, **kwargs) == 6
CALLBACK
```

除非你將 `atexit` 屬性設 `False`，否則當程式結束時，最終化器將會被呼叫如果其仍然存在。例如

```
>>> obj = Object()
>>> weakref.finalize(obj, print, "obj dead or exiting")
<finalize object at ...; for 'Object' at ...>
>>> exit()
obj dead or exiting
```

## 8.9.4 最終化器與 `__del__()` 方法的比較

假設我們要建立一個類，其實例代表臨時目錄。當以下任一事件發生時，應除目錄及其內容：

- 該物件被垃圾回收，
- 該物件的 `remove()` 方法被呼叫，或者
- 程式結束。

我們可以用以下的方式來嘗試使用 `__del__()` 方法實作該類：

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()

    def remove(self):
        if self.name is not None:
            shutil.rmtree(self.name)
            self.name = None

    @property
    def removed(self):
        return self.name is None

    def __del__(self):
        self.remove()
```

從 Python 3.4 開始，`__del__()` 方法不再阻止參照循環 (reference cycle) 被垃圾回收，且在 *interpreter shutdown* 期間不再制將模組的 `globals` 設 `None`。所以這段程式碼在 CPython 上應該可以正常運作。

然而，所周知，對 `__del__()` 方法的處理是特地實作的，因它依賴於直譯器的垃圾回收器實作的內部細節。

更耐用的替代方案可以是定義一個最終化器，其僅參照需要的特定函式和物件，而不是存取物件的完整狀態：

```
class TempDir:
    def __init__(self):
        self.name = tempfile.mkdtemp()
        self._finalizer = weakref.finalize(self, shutil.rmtree, self.name)

    def remove(self):
        self._finalizer()

    @property
    def removed(self):
        return not self._finalizer.alive
```

定義如下，我們的最終化器僅接收對適當清理目所需的詳細資訊的參照。如果物件從未被垃圾回收，則最終化器仍將在結束時被呼叫。

基於 `weakref` 的最終化器的另一個優點是它們可用於定義由第三方控制的類最終化器，例如在卸載模組時執行程式碼：

```
import weakref, sys
def unloading_module():
    # implicit reference to the module globals from the function body
    weakref.finalize(sys.modules[__name__], unloading_module)
```

### 備

如果在程式結束時在常駐的 (daemon) 執行緒中建立最終化器物件，則最終化器有可能在結束時不會被呼叫。然而，在常駐的執行緒中 `atexit.register()`、`try: ... finally: ...` 和 `with: ...` 也不保證清理會發生。

## 8.10 types --- 動態型建立與建型名稱

原始碼：Lib/types.py

This module defines utility functions to assist in dynamic creation of new types.

It also defines names for some object types that are used by the standard Python interpreter, but not exposed as builtins like `int` or `str` are.

Finally, it provides some additional type-related utility classes and functions that are not fundamental enough to be builtins.

### 8.10.1 Dynamic Type Creation

`types.new_class` (*name*, *bases*=(), *kwds*=None, *exec\_body*=None)

Creates a class object dynamically using the appropriate metaclass.

The first three arguments are the components that make up a class definition header: the class name, the base classes (in order), the keyword arguments (such as `metaclass`).

The `exec_body` argument is a callback that is used to populate the freshly created class namespace. It should accept the class namespace as its sole argument and update the namespace directly with the class contents. If no callback is provided, it has the same effect as passing in `lambda ns: None`.

在 3.3 版被加入。

`types.prepare_class` (*name*, *bases*=(), *kwds*=None)

Calculates the appropriate metaclass and creates the class namespace.

The arguments are the components that make up a class definition header: the class name, the base classes (in order) and the keyword arguments (such as `metaclass`).

The return value is a 3-tuple: `metaclass`, `namespace`, `kwds`

`metaclass` is the appropriate metaclass, `namespace` is the prepared class namespace and `kwds` is an updated copy of the passed in `kwds` argument with any 'metaclass' entry removed. If no `kwds` argument is passed in, this will be an empty dict.

在 3.3 版被加入.

在 3.6 版的變更: The default value for the `namespace` element of the returned tuple has changed. Now an insertion-order-preserving mapping is used when the metaclass does not have a `__prepare__` method.

#### metaclasses

Full details of the class creation process supported by these functions

#### PEP 3115 - Metaclasses in Python 3000

Introduced the `__prepare__` namespace hook

`types.resolve_bases` (*bases*)

Resolve MRO entries dynamically as specified by [PEP 560](#).

This function looks for items in *bases* that are not instances of *type*, and returns a tuple where each such object that has an `__mro_entries__()` method is replaced with an unpacked result of calling this method. If a *bases* item is an instance of *type*, or it doesn't have an `__mro_entries__()` method, then it is included in the return tuple unchanged.

在 3.7 版被加入.

`types.get_original_bases` (*cls*, /)

Return the tuple of objects originally given as the bases of *cls* before the `__mro_entries__()` method has been called on any bases (following the mechanisms laid out in [PEP 560](#)). This is useful for introspecting *Generics*.

For classes that have an `__orig_bases__` attribute, this function returns the value of `cls.__orig_bases__`. For classes without the `__orig_bases__` attribute, `cls.__bases__` is returned.

舉例來 F:

```
from typing import TypeVar, Generic, NamedTuple, TypedDict

T = TypeVar("T")
class Foo(Generic[T]): ...
class Bar(Foo[int], float): ...
class Baz(list[str]): ...
Eggs = NamedTuple("Eggs", [("a", int), ("b", str)])
Spam = TypedDict("Spam", {"a": int, "b": str})

assert Bar.__bases__ == (Foo, float)
assert get_original_bases(Bar) == (Foo[int], float)

assert Baz.__bases__ == (list,)
assert get_original_bases(Baz) == (list[str],)

assert Eggs.__bases__ == (tuple,)
assert get_original_bases(Eggs) == (NamedTuple,)

assert Spam.__bases__ == (dict,)
assert get_original_bases(Spam) == (TypedDict,)
```

(繼續下一頁)

(繼續上一頁)

```

## 8.10.2 Standard Interpreter Types

This module provides names for many of the types that are required to implement a Python interpreter. It deliberately avoids including some of the types that arise only incidentally during processing such as the `listiterator` type.

Typical use of these names is for `isinstance()` or `issubclass()` checks.

If you instantiate any of these types, note that signatures may vary between Python versions.

Standard names are defined for the following types:

`types.NoneType`

The type of `None`.

在 3.10 版被加入。

`types.FunctionType`

`types.LambdaType`

The type of user-defined functions and functions created by `lambda` expressions.

引發一個附帶引數 `code` 的稽核事件 `function.__new__`。

The audit event only occurs for direct instantiation of function objects, and is not raised for normal compilation.

`types.GeneratorType`

The type of *generator*-iterator objects, created by generator functions.

`types.CoroutineType`

The type of *coroutine* objects, created by `async def` functions.

在 3.5 版被加入。

`types.AsyncGeneratorType`

The type of *asynchronous generator*-iterator objects, created by asynchronous generator functions.

在 3.6 版被加入。

`class types.CodeType (**kwargs)`

The type of code objects such as returned by `compile()`.

引發一個附帶引數 `code`、`filename`、`name`、`argcount`、`posonlyargcount`、`kwonlyargcount`、`nlocals`、`stacksize`、`flags` 的稽核事件 `code.__new__`。

Note that the audited arguments may not match the names or positions required by the initializer. The audit event only occurs for direct instantiation of code objects, and is not raised for normal compilation.

`types.CellType`

The type for cell objects: such objects are used as containers for a function's *closure variables*.

在 3.8 版被加入。

`types.MethodType`

The type of methods of user-defined class instances.

`types.BuiltinFunctionType`

**types.BuiltinMethodType**

The type of built-in functions like `len()` or `sys.exit()`, and methods of built-in classes. (Here, the term "built-in" means "written in C".)

**types WrapperDescriptorType**

The type of methods of some built-in data types and base classes such as `object.__init__()` or `object.__lt__()`.

在 3.7 版被加入。

**types.MethodWrapperType**

The type of *bound* methods of some built-in data types and base classes. For example it is the type of `object().__str__`.

在 3.7 版被加入。

**types.NotImplementedType**

The type of `NotImplemented`.

在 3.10 版被加入。

**types.MethodDescriptorType**

The type of methods of some built-in data types such as `str.join()`.

在 3.7 版被加入。

**types.ClassMethodDescriptorType**

The type of *unbound* class methods of some built-in data types such as `dict.__dict__['fromkeys']`.

在 3.7 版被加入。

**class types.ModuleType (name, doc=None)**

The type of *modules*. The constructor takes the name of the module to be created and optionally its *docstring*.

 **也參考**
**Documentation on module objects**

Provides details on the special attributes that can be found on instances of `ModuleType`.

**`importlib.util.module_from_spec()`**

Modules created using the `ModuleType` constructor are created with many of their special attributes unset or set to default values. `module_from_spec()` provides a more robust way of creating `ModuleType` instances which ensures the various attributes are set appropriately.

**types.EllipsisType**

The type of `Ellipsis`.

在 3.10 版被加入。

**class types.GenericAlias (t\_origin, t\_args)**

The type of *parameterized generics* such as `list[int]`.

`t_origin` should be a non-parameterized generic class, such as `list`, `tuple` or `dict`. `t_args` should be a *tuple* (possibly of length 1) of types which parameterize `t_origin`:

```
>>> from types import GenericAlias
>>> list[int] == GenericAlias(list, (int,))
True
>>> dict[str, int] == GenericAlias(dict, (str, int))
True
```

在 3.9 版被加入。

在 3.9.2 版的變更: This type can now be subclassed.

### 也參考

#### *Generic Alias Types*

In-depth documentation on instances of `types.GenericAlias`

#### **PEP 585 - Type Hinting Generics In Standard Collections**

Introducing the `types.GenericAlias` class

**class** `types.UnionType`

The type of *union type expressions*.

在 3.10 版被加入。

**class** `types.TracebackType` (*tb\_next*, *tb\_frame*, *tb\_lasti*, *tb\_lineno*)

The type of traceback objects such as found in `sys.exception().__traceback__`.

See the language reference for details of the available attributes and operations, and guidance on creating tracebacks dynamically.

`types.FrameType`

The type of frame objects such as found in `tb.tb_frame` if `tb` is a traceback object.

`types.GetSetDescriptorType`

The type of objects defined in extension modules with `PyGetSetDef`, such as `FrameType.f_locals` or `array.array.typecode`. This type is used as descriptor for object attributes; it has the same purpose as the *property* type, but for classes defined in extension modules.

`types.MemberDescriptorType`

The type of objects defined in extension modules with `PyMemberDef`, such as `datetime.timedelta.days`. This type is used as descriptor for simple C data members which use standard conversion functions; it has the same purpose as the *property* type, but for classes defined in extension modules.

In addition, when a class is defined with a `__slots__` attribute, then for each slot, an instance of `MemberDescriptorType` will be added as an attribute on the class. This allows the slot to appear in the class's `__dict__`.

**CPython 實作細節:** In other implementations of Python, this type may be identical to `GetSetDescriptorType`.

**class** `types.MappingProxyType` (*mapping*)

Read-only proxy of a mapping. It provides a dynamic view on the mapping's entries, which means that when the mapping changes, the view reflects these changes.

在 3.3 版被加入。

在 3.9 版的變更: Updated to support the new union (`|`) operator from **PEP 584**, which simply delegates to the underlying mapping.

**key in proxy**

Return `True` if the underlying mapping has a key *key*, else `False`.

**proxy[key]**

Return the item of the underlying mapping with key *key*. Raises a `KeyError` if *key* is not in the underlying mapping.

**iter(proxy)**

Return an iterator over the keys of the underlying mapping. This is a shortcut for `iter(proxy.keys())`.

**len(proxy)**

Return the number of items in the underlying mapping.

**copy()**

Return a shallow copy of the underlying mapping.

**get(key[, default])**

Return the value for *key* if *key* is in the underlying mapping, else *default*. If *default* is not given, it defaults to *None*, so that this method never raises a *KeyError*.

**items()**

Return a new view of the underlying mapping's items ((*key*, *value*) pairs).

**keys()**

Return a new view of the underlying mapping's keys.

**values()**

Return a new view of the underlying mapping's values.

**reversed(proxy)**

Return a reverse iterator over the keys of the underlying mapping.

在 3.9 版被加入。

**hash(proxy)**

Return a hash of the underlying mapping.

在 3.12 版被加入。

**class types.CapsuleType**

The type of capsule objects.

在 3.13 版被加入。

### 8.10.3 Additional Utility Classes and Functions

**class types.SimpleNamespace**

A simple *object* subclass that provides attribute access to its namespace, as well as a meaningful repr.

Unlike *object*, with *SimpleNamespace* you can add and remove attributes.

*SimpleNamespace* objects may be initialized in the same way as *dict*: either with keyword arguments, with a single positional argument, or with both. When initialized with keyword arguments, those are directly added to the underlying namespace. Alternatively, when initialized with a positional argument, the underlying namespace will be updated with key-value pairs from that argument (either a mapping object or an *iterable* object producing key-value pairs). All such keys must be strings.

The type is roughly equivalent to the following code:

```
class SimpleNamespace:
    def __init__(self, mapping_or_iterable=(), /, **kwargs):
        self.__dict__.update(mapping_or_iterable)
        self.__dict__.update(kwargs)

    def __repr__(self):
        items = (f"{k}={v!r}" for k, v in self.__dict__.items())
        return "{}({})".format(type(self).__name__, ".join(items))

    def __eq__(self, other):
        if isinstance(self, SimpleNamespace) and isinstance(other, SimpleNamespace):
            return self.__dict__ == other.__dict__
        return NotImplemented
```

`SimpleNamespace` may be useful as a replacement for `class NS: pass`. However, for a structured record type use `namedtuple()` instead.

`SimpleNamespace` objects are supported by `copy.replace()`.

在 3.3 版被加入。

在 3.9 版的變更: Attribute order in the repr changed from alphabetical to insertion (like dict).

在 3.13 版的變更: Added support for an optional positional argument.

`types.DynamicClassAttribute` (*fget=None, fset=None, fdel=None, doc=None*)

Route attribute access on a class to `__getattr__`.

This is a descriptor, used to define attributes that act differently when accessed through an instance and through a class. Instance access remains normal, but access to an attribute through a class will be routed to the class's `__getattr__` method; this is done by raising `AttributeError`.

This allows one to have properties active on an instance, and have virtual attributes on the class with the same name (see `enum.Enum` for an example).

在 3.4 版被加入。

## 8.10.4 Coroutine Utility Functions

`types.coroutine` (*gen\_func*)

This function transforms a *generator* function into a *coroutine function* which returns a generator-based coroutine. The generator-based coroutine is still a *generator iterator*, but is also considered to be a *coroutine* object and is *awaitable*. However, it may not necessarily implement the `__await__()` method.

If *gen\_func* is a generator function, it will be modified in-place.

If *gen\_func* is not a generator function, it will be wrapped. If it returns an instance of `collections.abc.Generator`, the instance will be wrapped in an *awaitable* proxy object. All other types of objects will be returned as is.

在 3.5 版被加入。

## 8.11 copy --- 淺層 (shallow) 和深層 (deep) 操作

原始碼: [Lib/copy.py](#)

Python 的賦值陳述式不物件，而是建立目標和物件的結 (binding) 關係。對於可變 (mutable) 或包含可變項目 (mutable item) 的集合，有時會需要一份副本來改變特定副本，而不必改變其他副本。本模組提供了通用的淺層和深層操作 (如下所述)。

介面摘要：

`copy.copy` (*obj*)

Return a shallow copy of *obj*.

`copy.deepcopy` (*obj*, [*memo*])

Return a deep copy of *obj*.

`copy.replace` (*obj*, /, *\*\*changes*)

Creates a new object of the same type as *obj*, replacing fields with values from *changes*.

在 3.13 版被加入。

**exception** `copy.Error`

引發針對特定模組的錯誤。

淺層與深層的區別僅與物件 (即包含 list 或類的實例等其他物件的物件) 相關：

- 淺層複製建構一個新的複合物件，然後（在可能的範圍內）將原始物件中找到的物件的參照插入其中。
- 深層複製建構一個新的複合物件，然後遞迴地將在原始物件中找到的物件的副本插入其中。

深層複製操作通常存在兩個問題，而淺層複製操作不存在這些問題：

- 遞迴物件（直接或間接包含對自身參照的複合物件）可能會導致遞迴圈。
- 由於深層複製會複製所有內容，因此可能有過多副本（例如應該在副本之間共享的資料）。

`deepcopy()` 函式用以下方式避免了這些問題：

- 保留在當前複製過程中已複製的物件的 `memo` 字典；以及
- 允許使用者定義的類覆寫（override）複製操作或複製的元件集合。

該模組不複製模組、方法、堆疊追跡（stack trace）、堆疊框（stack frame）、檔案、socket、視窗、陣列以及任何類似的型別。它透過不變更原始物件將其回傳來（淺層或深層地）”複製”函式和類；這與 `pickle` 模組處理這類問題的方式是相似的。

字典的淺層複製可以使用 `dict.copy()`，而 list 的淺層複製可以透過賦值整個 list 的切片（slice）完成，例如，`copied_list = original_list[:]`。

類可以使用與操作 `pickle` 相同的介面來控制複製操作，關於這些方法的描述資訊請參考 `pickle` 模組。實際上，`copy` 模組使用的正是從 `copyreg` 模組中複製的 `pickle` 函式。

In order for a class to define its own copy implementation, it can define special methods `__copy__()` and `__deepcopy__()`.

`object.__copy__(self)`

Called to implement the shallow copy operation; no additional arguments are passed.

`object.__deepcopy__(self, memo)`

Called to implement the deep copy operation; it is passed one argument, the `memo` dictionary. If the `__deepcopy__` implementation needs to make a deep copy of a component, it should call the `deepcopy()` function with the component as first argument and the `memo` dictionary as second argument. The `memo` dictionary should be treated as an opaque object.

Function `copy.replace()` is more limited than `copy()` and `deepcopy()`, and only supports named tuples created by `namedtuple()`, `dataclasses`, and other classes which define method `__replace__()`.

`object.__replace__(self, /, **changes)`

This method should create a new object of the same type, replacing fields with values from `changes`.

## 8.12 pprint --- 資料美化列印器

原始碼：[Lib/pprint.py](#)

The `pprint` module provides a capability to ”pretty-print” arbitrary Python data structures in a form which can be used as input to the interpreter. If the formatted structures include objects which are not fundamental Python types, the representation may not be loadable. This may be the case if objects such as files, sockets or classes are included, as well as many other objects which are not representable as Python literals.

The formatted representation keeps objects on a single line if it can, and breaks them onto multiple lines if they don't fit within the allowed width, adjustable by the `width` parameter defaulting to 80 characters.

Dictionaries are sorted by key before the display is computed.

在 3.9 版的變更: Added support for pretty-printing `types.SimpleNamespace`.

在 3.10 版的變更: Added support for pretty-printing `dataclasses.dataclass`.

### 8.12.1 函式

`pprint.pp` (*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, \*, *compact=False*, *sort\_dicts=False*, *underscore\_numbers=False*)

Prints the formatted representation of *object*, followed by a newline. This function may be used in the interactive interpreter instead of the `print()` function for inspecting values. Tip: you can reassign `print = pprint.pp` for use within a scope.

#### 參數

- **object** -- 將被印出的物件。
- **stream** (*file-like object* | `None`) -- A file-like object to which the output will be written by calling its `write()` method. If `None` (the default), `sys.stdout` is used.
- **indent** (*int*) -- The amount of indentation added for each nesting level.
- **width** (*int*) -- The desired maximum number of characters per line in the output. If a structure cannot be formatted within the width constraint, a best effort will be made.
- **depth** (*int* | `None`) -- The number of nesting levels which may be printed. If the data structure being printed is too deep, the next contained level is replaced by `...`. If `None` (the default), there is no constraint on the depth of the objects being formatted.
- **compact** (*bool*) -- Control the way long *sequences* are formatted. If `False` (the default), each item of a sequence will be formatted on a separate line, otherwise as many items as will fit within the *width* will be formatted on each output line.
- **sort\_dicts** (*bool*) -- If `True`, dictionaries will be formatted with their keys sorted, otherwise they will be displayed in insertion order (the default).
- **underscore\_numbers** (*bool*) -- If `True`, integers will be formatted with the `_` character for a thousands separator, otherwise underscores are not displayed (the default).

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff)
>>> pprint.pp(stuff)
[<Recursion on list with id=...>,
 'spam',
 'eggs',
 'lumberjack',
 'knights',
 'ni']
```

在 3.8 版被加入。

`pprint.pprint` (*object*, *stream=None*, *indent=1*, *width=80*, *depth=None*, \*, *compact=False*, *sort\_dicts=True*, *underscore\_numbers=False*)

Alias for `pp()` with *sort\_dicts* set to `True` by default, which would automatically sort the dictionaries' keys, you might want to use `pp()` instead where it is `False` by default.

`pprint.pformat` (*object*, *indent=1*, *width=80*, *depth=None*, \*, *compact=False*, *sort\_dicts=True*, *underscore\_numbers=False*)

Return the formatted representation of *object* as a string. *indent*, *width*, *depth*, *compact*, *sort\_dicts* and *underscore\_numbers* are passed to the `PrettyPrinter` constructor as formatting parameters and their meanings are as described in the documentation above.

`pprint.isreadable` (*object*)

Determine if the formatted representation of *object* is "readable", or can be used to reconstruct the value using `eval()`. This always returns `False` for recursive objects.

```
>>> pprint.isreadable(stuff)
False
```

`pprint.isrecursive(object)`

Determine if *object* requires a recursive representation. This function is subject to the same limitations as noted in `saferepr()` below and may raise an `RecursionError` if it fails to detect a recursive object.

`pprint.saferepr(object)`

Return a string representation of *object*, protected against recursion in some common data structures, namely instances of *dict*, *list* and *tuple* or subclasses whose `__repr__` has not been overridden. If the representation of *object* exposes a recursive entry, the recursive reference will be represented as `<Recursion on typename with id=number>`. The representation is not otherwise formatted.

```
>>> pprint.saferepr(stuff)
"<Recursion on list with id=...>, 'spam', 'eggs', 'lumberjack', 'knights', 'ni'"
```

## 8.12.2 PrettyPrinter 物件

```
class pprint.PrettyPrinter(indent=1, width=80, depth=None, stream=None, *, compact=False,
                           sort_dicts=True, underscore_numbers=False)
```

建立一個 `PrettyPrinter` 實例。

Arguments have the same meaning as for `pp()`. Note that they are in a different order, and that `sort_dicts` defaults to `True`.

```
>>> import pprint
>>> stuff = ['spam', 'eggs', 'lumberjack', 'knights', 'ni']
>>> stuff.insert(0, stuff[:])
>>> pp = pprint.PrettyPrinter(indent=4)
>>> pp.pprint(stuff)
[ ['spam', 'eggs', 'lumberjack', 'knights', 'ni'],
  'spam',
  'eggs',
  'lumberjack',
  'knights',
  'ni']
>>> pp = pprint.PrettyPrinter(width=41, compact=True)
>>> pp.pprint(stuff)
[['spam', 'eggs', 'lumberjack',
  'knights', 'ni'],
 'spam', 'eggs', 'lumberjack', 'knights',
 'ni']
>>> tup = ('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead',
... ('parrot', ('fresh fruit',))))))))
>>> pp = pprint.PrettyPrinter(depth=6)
>>> pp.pprint(tup)
('spam', ('eggs', ('lumberjack', ('knights', ('ni', ('dead', (...))))))
```

在 3.4 版的變更: 新增 `compact` 參數。

在 3.8 版的變更: 新增 `sort_dicts` 參數。

在 3.10 版的變更: 新增 `underscore_numbers` 參數。

在 3.11 版的變更: No longer attempts to write to `sys.stdout` if it is `None`.

`PrettyPrinter` 實例有以下方法:

`PrettyPrinter.pformat(object)`

Return the formatted representation of *object*. This takes into account the options passed to the `PrettyPrinter` constructor.

`PrettyPrinter.pprint(object)`

Print the formatted representation of *object* on the configured stream, followed by a newline.

The following methods provide the implementations for the corresponding functions of the same names. Using these methods on an instance is slightly more efficient since new `PrettyPrinter` objects don't need to be created.

`PrettyPrinter.isreadable(object)`

Determine if the formatted representation of the object is "readable," or can be used to reconstruct the value using `eval()`. Note that this returns `False` for recursive objects. If the `depth` parameter of the `PrettyPrinter` is set and the object is deeper than allowed, this returns `False`.

`PrettyPrinter.isrecursive(object)`

Determine if the object requires a recursive representation.

This method is provided as a hook to allow subclasses to modify the way objects are converted to strings. The default implementation uses the internals of the `saferepr()` implementation.

`PrettyPrinter.format(object, context, maxlevels, level)`

Returns three values: the formatted version of *object* as a string, a flag indicating whether the result is readable, and a flag indicating whether recursion was detected. The first argument is the object to be presented. The second is a dictionary which contains the `id()` of objects that are part of the current presentation context (direct and indirect containers for *object* that are affecting the presentation) as the keys; if an object needs to be presented which is already represented in *context*, the third return value should be `True`. Recursive calls to the `format()` method should add additional entries for containers to this dictionary. The third argument, *maxlevels*, gives the requested limit to recursion; this will be 0 if there is no requested limit. This argument should be passed unmodified to recursive calls. The fourth argument, *level*, gives the current level; recursive calls should be passed a value less than that of the current call.

### 8.12.3 范例

To demonstrate several uses of the `pp()` function and its parameters, let's fetch information about a project from PyPI:

```
>>> import json
>>> import pprint
>>> from urllib.request import urlopen
>>> with urlopen('https://pypi.org/pypi/sampleproject/1.2.0/json') as resp:
...     project_info = json.load(resp)['info']
```

In its basic form, `pp()` shows the whole object:

```
>>> pprint.pp(project_info)
{'author': 'The Python Packaging Authority',
 'author_email': 'pypa-dev@googlegroups.com',
 'bugtrack_url': None,
 'classifiers': ['Development Status :: 3 - Alpha',
                 'Intended Audience :: Developers',
                 'License :: OSI Approved :: MIT License',
                 'Programming Language :: Python :: 2',
                 'Programming Language :: Python :: 2.6',

## 8.13 reprlib --- repr() 的替代實作

原始碼: [Lib/reprlib.py](#)

The `reprlib` module provides a means for producing object representations with limits on the size of the resulting strings. This is used in the Python debugger and may be useful in other contexts as well.

This module provides a class, an instance, and a function:

```
class reprlib.Repr(*, maxlevel=6, maxtuple=6, maxlist=6, maxarray=5, maxdict=4, maxset=6,
                  maxfrozenset=6, maxdeque=6, maxstring=30, maxlong=40, maxother=30, fillvalue='...',
                  indent=None)
```

Class which provides formatting services useful in implementing functions similar to the built-in `repr()`; size limits for different object types are added to avoid the generation of representations which are excessively long.

The keyword arguments of the constructor can be used as a shortcut to set the attributes of the `Repr` instance. Which means that the following initialization:

```
aRepr = reprlib.Repr(maxlevel=3)
```

等價於:

```
aRepr = reprlib.Repr()
aRepr.maxlevel = 3
```

See section *Repr Objects* for more information about `Repr` attributes.

在 3.12 版的變更: Allow attributes to be set via keyword arguments.

`reprlib.aRepr`

This is an instance of `Repr` which is used to provide the `repr()` function described below. Changing the attributes of this object will affect the size limits used by `repr()` and the Python debugger.

`reprlib.repr(obj)`

This is the `repr()` method of `aRepr`. It returns a string similar to that returned by the built-in function of the same name, but with limits on most sizes.

In addition to size-limiting tools, the module also provides a decorator for detecting recursive calls to `__repr__()` and substituting a placeholder string instead.

`@reprlib.recursive_repr(fillvalue='...')`

Decorator for `__repr__()` methods to detect recursive calls within the same thread. If a recursive call is made, the `fillvalue` is returned, otherwise, the usual `__repr__()` call is made. For example:

```
>>> from reprlib import recursive_repr
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|'.join(map(repr, self)) + '>'
...
>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
```

(繼續下一頁)

(繼續上一頁)

```
>>> print(m)
<'a'|'b'|'c'|...|'x'>
```

在 3.2 版被加入。

### 8.13.1 Repr 物件

*Repr* instances provide several attributes which can be used to provide size limits for the representations of different object types, and methods which format specific object types.

*Repr*.**fillvalue**

This string is displayed for recursive references. It defaults to . . .

在 3.11 版被加入。

*Repr*.**maxlevel**

Depth limit on the creation of recursive representations. The default is 6.

*Repr*.**maxdict**

*Repr*.**maxlist**

*Repr*.**maxtuple**

*Repr*.**maxset**

*Repr*.**maxfrozenset**

*Repr*.**maxdeque**

*Repr*.**maxarray**

Limits on the number of entries represented for the named object type. The default is 4 for *maxdict*, 5 for *maxarray*, and 6 for the others.

*Repr*.**maxlength**

Maximum number of characters in the representation for an integer. Digits are dropped from the middle. The default is 40.

*Repr*.**maxstring**

Limit on the number of characters in the representation of the string. Note that the "normal" representation of the string is used as the character source: if escape sequences are needed in the representation, these may be mangled when the representation is shortened. The default is 30.

*Repr*.**maxother**

This limit is used to control the size of object types for which no specific formatting method is available on the *Repr* object. It is applied in a similar manner as *maxstring*. The default is 20.

*Repr*.**indent**

If this attribute is set to `None` (the default), the output is formatted with no line breaks or indentation, like the standard *repr()*. For example:

```
>>> example = [
...     1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
>>> import reprlib
>>> aRepr = reprlib.Repr()
>>> print(aRepr.repr(example))
[1, 'spam', {'a': 2, 'b': 'spam eggs', 'c': {3: 4.5, 6: []}}, 'ham']
```

If *indent* is set to a string, each recursion level is placed on its own line, indented by that string:

```
>>> aRepr.indent = '-->'
>>> print(aRepr.repr(example))
[
-->1,
```

(繼續下一頁)

(繼續上一頁)

```
-->'spam',
-->{
-->-->'a': 2,
-->-->'b': 'spam eggs',
-->-->'c': {
-->-->-->3: 4.5,
-->-->-->6: [],
-->-->}},
-->},
-->'ham',
]
```

Setting *indent* to a positive integer value behaves as if it was set to a string with that number of spaces:

```
>>> aRepr.indent = 4
>>> print(aRepr.repr(example))
[
    1,
    'spam',
    {
        'a': 2,
        'b': 'spam eggs',
        'c': {
            3: 4.5,
            6: [],
        },
    },
    'ham',
]
```

在 3.12 版被加入。

Repr.**repr**(*obj*)

The equivalent to the built-in *repr()* that uses the formatting imposed by the instance.

Repr.**repr1**(*obj*, *level*)

Recursive implementation used by *repr()*. This uses the type of *obj* to determine which formatting method to call, passing it *obj* and *level*. The type-specific methods should call *repr1()* to perform recursive formatting, with *level - 1* for the value of *level* in the recursive call.

Repr.**repr\_TYPE**(*obj*, *level*)

Formatting methods for specific types are implemented as methods with a name based on the type name. In the method name, **TYPE** is replaced by `'_'.join(type(obj).__name__.split())`. Dispatch to these methods is handled by *repr1()*. Type-specific methods which need to recursively format a value should call `self.repr1(subobj, level - 1)`.

## 8.13.2 Subclassing Repr Objects

The use of dynamic dispatching by *Repr.repr1()* allows subclasses of *Repr* to add support for additional built-in object types or to modify the handling of types already supported. This example shows how special support for file objects could be added:

```
import reprlib
import sys

class MyRepr(reprlib.Repr):

    def repr_TextIOWrapper(self, obj, level):
        if obj.name in {'<stdin>', '<stdout>', '<stderr>'}:
            return obj.name
```

(繼續下一頁)

(繼續上一頁)

```

    return repr(obj)

aRepr = MyRepr()
print(aRepr.repr(sys.stdin))      # 印出 '<stdin>'

```

&lt;stdin&gt;

## 8.14 enum --- 對列舉的支援

在 3.4 版被加入。

原始碼: [Lib/enum.py](#)

### Important

本頁包含 API 的參考資訊。關於教學資訊及更多進階主題的討論請參考

- 基本教學
- 進階教學
- 列舉指南

列舉:

- 是一組綁定唯一值的代表名稱 (成員)
- 可以用 `[]` 代的方式以定義的順序回傳其正式 (canonical) (即非 `[]` 名) 成員
- 使用 `call` 語法來透過值回傳成員
- 使用 `index` 語法來透過名稱回傳成員

列舉透過 `class` 語法或函式呼叫的語法來建立:

```

>>> from enum import Enum

>>> # class 語法
>>> class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3

>>> # 函式語法
>>> Color = Enum('Color', [('RED', 1), ('GREEN', 2), ('BLUE', 3)])

```

雖然我們可以用 `class` 語法來建立列舉，列舉 `Enum` 不是標準的 Python 類 `Enum`。參考列舉有何差別以取得更多細節。

### 備註

命名方式

- `Color` 類 `Enum` 是一個列舉 (或 `enum`)
- `Color.RED`、`Color.GREEN` 等屬性是列舉成員 (或成員)，`Enum` 且使用上可以看作常數。
- 列舉成員有名義和值 (`Color.RED` 的名稱是 `RED`，`Color.BLUE` 的值是 `3` 諸如此類)

## 8.14.1 模組內容

*EnumType*`Enum` 及其子類的 `type`。*Enum*

用來建立列舉常數的基礎類。

*IntEnum*用來建立列舉常數的基礎類，同時也是 `int` 的子類。(備)*StrEnum*用來建立列舉常數的基礎類，同時也是 `str` 的子類。(備)*Flag*用來建立列舉常數的基礎類，可以使用位元操作來結合成員且其結果不失去 `Flag` 的成員資格。*IntFlag*用來建立列舉常數的基礎類，可以使用位元操作來結合成員且其結果不失去 `IntFlag` 的成員資格。`IntFlag` 的成員也是 `int` 的子類。(備)*ReprEnum*由 `IntEnum`、`StrEnum` 及 `IntFlag` 所使用來保留這些混合型 `str()`。*EnumCheck*一個有 `CONTINUOUS`、`NAMED_FLAGS` 及 `UNIQUE` 這些值的列舉，和 `verify()` 一起使用來確保給定的列舉符合多種限制。*FlagBoundary*一個有 `STRICT`、`CONFORM`、`EJECT` 及 `KEEP` 這些值的列舉，允許列舉對如何處理非法值做更細微的控制。*EnumDict*`dict` 的子類，用於當作 `EnumType` 的子類時使用。*auto*列舉成員的實例會被取代成合適的值。`StrEnum` 預設是小寫版本的成員名稱，其它列舉則預設是 1 且往後遞增。*property()*允許 `Enum` 成員擁有屬性且不會與成員名稱有衝突。`value` 及 `name` 屬性是用這個方式來實作。*unique()*`Enum` 類的裝飾器，用來確保任何值只有綁定到一個名稱上。*verify()*`Enum` 類的裝飾器，用來檢查列舉上使用者所選的限制。*member()*讓 `obj` 變成成員。可以當作裝飾器使用。*nonmember()*不讓 `obj` 變成成員。可以當作裝飾器使用。*global\_enum()*

修改列舉上的 `str()` 及 `repr()`，讓成員顯示屬於模組而不是類，將該列舉成員匯出到全域命名空間。

```
show_flag_values()
```

回傳旗標 (flag) 包含的所有 2 的次方的整數串列。

在 3.6 版被加入: `Flag`, `IntFlag`, `auto`

在 3.11 版被加入: `StrEnum`, `EnumCheck`, `ReprEnum`, `FlagBoundary`, `property`, `member`, `nonmember`, `global_enum`, `show_flag_values`

在 3.13 版被加入: `EnumDict`

## 8.14.2 資料型

**class** `enum.EnumType`

`EnumType` 是 `enum` 列舉的 *metaclass*。 `EnumType` 可以有子類 -- 細節請參考 建立 `EnumType` 的子類。

`EnumType` 負責在最後的列舉上面設定正確的 `__repr__()`、`__str__()`、`__format__()` 及 `__reduce__()` 方法，以及建立列舉成員、正確處理重、提供列舉類的代等等。

```
__call__(cls, value, names=None, *, module=None, qualname=None, type=None, start=1,
         boundary=None)
```

這個方法可以用兩種不同的方式呼叫：

- 查詢已存在的成員：

**cls**  
所呼叫的列舉類。

**value**  
要查詢的值。

- 使用 `cls` 列舉來建立新列舉（只有在現有列舉有任何成員時）

**cls**  
所呼叫的列舉類。

**value**  
要建立的新列舉的名稱。

**names**  
新列舉的成員的名稱/值。

**module**  
新列舉要建立在哪個模組名稱下。

**qualname**  
這個列舉在模組實際上的位置。

**type**  
新列舉的混合型。

**start**  
列舉的第一個整數值（由 `auto` 所使用）

**boundary**  
在位元操作時處理範圍外的值（只有 `Flag` 會用到）

```
__contains__(cls, member)
```

如果 `member` 屬於 `cls` 則回傳 `True`：

```
>>> some_var = Color.RED
>>> some_var in Color
True
>>> Color.RED.value in Color
True
```

在 3.12 版的變更: 在 Python 3.12 之前, 如果用非列舉成員做屬於檢查 (containment check) 會引發 `TypeError`。

`__dir__ (cls)`

回傳 ['\_\_class\_\_', '\_\_doc\_\_', '\_\_members\_\_', '\_\_module\_\_'] 及 `cls` 的成員名稱:

```
>>> dir(Color)
['BLUE', 'GREEN', 'RED', '__class__', '__contains__', '__doc__', '__getitem__', '__init_subclass__', '__iter__', '__len__', '__members__', '__module__', '__name__', '__qualname__']
```

`__getitem__ (cls, name)`

回傳 `cls` 中符合 `name` 的列舉成員, 或引發 `KeyError`:

```
>>> Color['BLUE']
<Color.BLUE: 3>
```

`__iter__ (cls)`

以定義的順序回傳在 `cls` 中的每個成員:

```
>>> list(Color)
[<Color.RED: 1>, <Color.GREEN: 2>, <Color.BLUE: 3>]
```

`__len__ (cls)`

回傳 `cls` 的成員數量:

```
>>> len(Color)
3
```

`__members__`

回傳每個列舉名稱到其成員的對映, 包括 名稱

`__reversed__ (cls)`

以跟定義相反的順序回傳 `cls` 的每個成員:

```
>>> list(reversed(Color))
[<Color.BLUE: 3>, <Color.GREEN: 2>, <Color.RED: 1>]
```

`__add_alias_ ()`

新增一個名稱作 現有成員的 名稱。如果該名稱已被指派給不同的成員, 則會引發 `NameError`。

`__add_value_alias_ ()`

新增一個值作 現有成員的 名稱。如果該值已與不同成員連結, 則會引發 `ValueError`。

在 3.11 版被加入: 在 3.11 之前, `EnumType` 稱作 `EnumMeta`, 其目前仍可作 名稱使用。

`class enum.Enum`

`Enum` 是所有 `enum` 列舉的基礎類。

`name`

用來定義 `Enum` 成員的名稱:

```
>>> Color.BLUE.name
'BLUE'
```

**value**

Enum 成員給定的值：

```
>>> Color.RED.value
1
```

成員的值，可以在 `__new__()` 設定。

**備註**

## 列舉成員的值

成員的值可以是任何值：`int`、`str` 等等。如果實際使用什麼值不重要，你可以使用 `auto` 實例，它會為你選擇合適的值。更多細節請參考 `auto`。

雖然可以使用可變的 (mutable) / 不可雜的 (unhashable) 值，例如 `dict`、`list` 或可變的 `dataclass`，它們在建立期間會對效能產生相對於列舉中可變的 / 不可雜的值總數量的二次方影響。

**\_\_name\_\_**

成員名稱。

**\_\_value\_\_**

成員的值，可以在 `__new__()` 設定。

**\_\_order\_\_**

已不再使用，只為了向後相容而保留（類屬性，在類建立時移除）

**\_\_ignore\_\_**

`__ignore__` 只有在建立的時候用到，在列舉建立完成後會被移除。

`__ignore__` 是一個不會變成成員的名稱串列，在列舉建立完成後其名稱會被移除。範例請參考 `TimePeriod`。

**\_\_dir\_\_(self)**

回傳 ['\_\_class\_\_', '\_\_doc\_\_', '\_\_module\_\_', 'name', 'value'] 及任何 `self.__class__` 上定義的公開方法：

```
>>> from datetime import date
>>> class Weekday(Enum):
...     MONDAY = 1
...     TUESDAY = 2
...     WEDNESDAY = 3
...     THURSDAY = 4
...     FRIDAY = 5
...     SATURDAY = 6
...     SUNDAY = 7
...     @classmethod
...     def today(cls):
...         print('today is %s' % cls(date.today().isoweekday()).name)
...
>>> dir(Weekday.SATURDAY)
['__class__', '__doc__', '__eq__', '__hash__', '__module__', 'name', 'today',
↪ 'value']
```

**\_\_generate\_next\_value\_\_(name, start, count, last\_values)****name**

定義的成員名稱（例如 'RED'）。

**start**

列舉的開始值，預設 1。

**count**

已定義的成員數量，不包含目前這一個。

**last\_values**

一個之前值的串列。

一個 *staticmethod*，用來固定 *auto* 下一個要回傳的值的：

```
>>> from enum import auto
>>> class PowersOfThree(Enum):
...     @staticmethod
...     def _generate_next_value_(name, start, count, last_values):
...         return 3 ** (count + 1)
...     FIRST = auto()
...     SECOND = auto()
...
>>> PowersOfThree.SECOND.value
9
```

**\_\_init\_\_(self, \*args, \*\*kwargs)**

預設情況下，不執行任何操作。如果在成員賦值中給出多個值，這些值將成與 `__init__` 分

```
>>> from enum import Enum
>>> class Weekday(Enum):
...     MONDAY = 1, 'Mon'
```

`Weekday.__init__()` 將被稱 `Weekday.__init__(self, 1, 'Mon')`

**\_\_init\_subclass\_\_(cls, \*\*kwargs)**

一個 *classmethod*，用來進一步設定後續的子類，預設不做任何事。

**\_\_missing\_\_(cls, value)**

一個 *classmethod*，用來查詢在 *cls* 找不到的值。預設不做任何事，但可以被覆寫以實作客化的搜尋行：

```
>>> from enum import StrEnum
>>> class Build(StrEnum):
...     DEBUG = auto()
...     OPTIMIZED = auto()
...     @classmethod
...     def _missing_(cls, value):
...         value = value.lower()
...         for member in cls:
...             if member.value == value:
...                 return member
...         return None
...
>>> Build.DEBUG.value
'debug'
>>> Build('deBUG')
<Build.DEBUG: 'debug'>
```

**\_\_new\_\_(cls, \*args, \*\*kwargs)**

預設情況下不存在。如果有指定，無論是在列舉類定義中還是在 *mixin* 類中（例如 `int`），都將傳遞成員賦值中給出的所有值；例如

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     TWENTYSIX = '1a', 16
```

會生呼叫 `int('1a', 16)` 而該成員的值 26。

**備**

當寫自訂的 `__new__` 時，不要使用 `super().__new__`，而是要呼叫適當的 `__new__`。

`__repr__(self)`

回傳呼叫 `repr()` 時使用的字串。預設回傳 `Enum` 名稱、成員名稱及值，但可以被覆寫：

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __repr__(self):
...         cls_name = self.__class__.__name__
...         return f'{cls_name}.{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"OtherStyle.ALTERNATE"
(OtherStyle.ALTERNATE, 'OtherStyle.ALTERNATE', 'OtherStyle.ALTERNATE')
```

`__str__(self)`

回傳呼叫 `str()` 時使用的字串。預設回傳 `Enum` 名稱及成員名稱，但可以被覆寫：

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __str__(self):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"OtherStyle.ALTERNATE"
(<OtherStyle.ALTERNATE: 1>, 'ALTERNATE', 'ALTERNATE')
```

`__format__(self)`

回傳呼叫 `format()` 及 *f-string* 時使用的字串。預設回傳 `__str__()` 的回傳值，但可以被覆寫：

```
>>> class OtherStyle(Enum):
...     ALTERNATE = auto()
...     OTHER = auto()
...     SOMETHING_ELSE = auto()
...     def __format__(self, spec):
...         return f'{self.name}'
...
>>> OtherStyle.ALTERNATE, str(OtherStyle.ALTERNATE), f"OtherStyle.ALTERNATE"
(<OtherStyle.ALTERNATE: 1>, 'OtherStyle.ALTERNATE', 'ALTERNATE')
```

**備**

`Enum` 使用 `auto` 會生從 1 開始遞增的整數。

在 3.12 版的變更: 新增 `enum-dataclass-support`

`class enum.IntEnum`

`IntEnum` 和 `Enum` 一樣，但其成員同時也是整數而可以被用在任何使用整數的地方。如果 `IntEnum` 成員經過任何整數運算，結果值會失去其列舉狀態。

```
>>> from enum import IntEnum
>>> class Number(IntEnum):
...     ONE = 1
...     TWO = 2
```

(繼續下一頁)

(繼續上一頁)

```

...     THREE = 3
...
>>> Number.THREE
<Number.THREE: 3>
>>> Number.ONE + Number.TWO
3
>>> Number.THREE + 5
8
>>> Number.THREE == 3
True

```

**備**

`IntEnum` 使用 `auto` 會生從 1 開始遞增的整數。

在 3.11 版的變更: 了更好地支援現存常數取代 (*replacement of existing constants*) 的使用情境, `__str__()` 現在會是 `int.__str__()`。了同樣的理由, `__format__()` 已經是 `int.__format__()`。

**class** `enum.StrEnum`

`StrEnum` 和 `Enum` 一樣, 但其成員同時也是字串而可以被用在幾乎所有使用字串的地方。 `StrEnum` 成員經過任何字串操作的結果會不再是列舉的一部份。

**備**

`stdlib` 有些地方會檢查只能是 `str` 而不是 `str` 的子類 (也就是 `type(unknown) == str` 而不是 `isinstance(unknown, str)`), 在這些地方你需要使用 `str(StrEnum.member)`。

**備**

`StrEnum` 使用 `auto` 會生小寫的成員名稱當作值。

**備**

了更好地支援現存常數取代 (*replacement of existing constants*) 的使用情境, `__str__()` 現在會是 `str.__str__()`。了同樣的理由, `__format__()` 也會是 `str.__format__()`。

在 3.11 版被加入。

**class** `enum.Flag`

`Flag` 與 `Enum` 相同, 但其成員支援位元運算子 `&` (*AND*)、`|` (*OR*)、`^` (*XOR*) 和 `~` (*INVERT*); 這些操作的結果是列舉的成員 (的 名)。

`__contains__` (`self, value`)

如果 `value` 在 `self` 則回傳 `True`:

```

>>> from enum import Flag, auto
>>> class Color(Flag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> purple = Color.RED | Color.BLUE

```

(繼續下一頁)

(繼續上一頁)

```

>>> white = Color.RED | Color.GREEN | Color.BLUE
>>> Color.GREEN in purple
False
>>> Color.GREEN in white
True
>>> purple in white
True
>>> white in purple
False

```

**`__iter__(self):`**

回傳所有包含的非名成員：

```

>>> list(Color.RED)
[<Color.RED: 1>]
>>> list(purple)
[<Color.RED: 1>, <Color.BLUE: 4>]

```

在 3.11 版被加入。

**`__len__(self):`**

回傳旗標的成員數量：

```

>>> len(Color.GREEN)
1
>>> len(white)
3

```

在 3.11 版被加入。

**`__bool__(self):`**如果成員在旗標則回傳 *True*，否則回傳 *False*：

```

>>> bool(Color.GREEN)
True
>>> bool(white)
True
>>> black = Color(0)
>>> bool(black)
False

```

**`__or__(self, other)`**回傳和 *other* 做 OR 過後的二進位旗標：

```

>>> Color.RED | Color.GREEN
<Color.RED|GREEN: 3>

```

**`__and__(self, other)`**回傳和 *other* 做 AND 過後的二進位旗標：

```

>>> purple & white
<Color.RED|BLUE: 5>
>>> purple & Color.GREEN
<Color: 0>

```

**`__xor__(self, other)`**回傳和 *other* 做 XOR 過後的二進位旗標：

```
>>> purple ^ white
<Color.GREEN: 2>
>>> purple ^ Color.GREEN
<Color.RED|GREEN|BLUE: 7>
```

**\_\_invert\_\_(self):**

回傳所有在 `type(self)` 但不在 `self` 的旗標:

```
>>> ~white
<Color: 0>
>>> ~purple
<Color.GREEN: 2>
>>> ~Color.RED
<Color.GREEN|BLUE: 6>
```

**\_\_numeric\_repr\_\_()**

用來格式化任何剩下未命名數值的函式。預設是值的 `repr`，常見選擇是 `hex()` 和 `oct()`。

**備**

`Flag` 使用 `auto` 會生從 1 開始 2 的次方的整數。

在 3.11 版的變更: 值 0 的旗標的 `repr()` 已改變。現在是:

```
>>> Color(0)
<Color: 0>
```

**class enum.IntFlag**

`IntFlag` 和 `Flag` 一樣，但其成員同時也是整數而可以被用在任何使用整數的地方。

```
>>> from enum import IntFlag, auto
>>> class Color(IntFlag):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> Color.RED & 2
<Color: 0>
>>> Color.RED | 2
<Color.RED|GREEN: 3>
```

如果 `IntFlag` 成員經過任何整數運算，其結果不是 `IntFlag`:

```
>>> Color.RED + 2
3
```

如果 `IntFlag` 成員經過 `Flag` 操作且:

- 結果是合法的 `IntFlag`: 回傳 `IntFlag`
- 結果不是合法的 `IntFlag`: 結果會根據 `FlagBoundary` 的設定

未命名且值 0 的旗標的 `repr()` 已改變。現在是:

```
>>> Color(0)
<Color: 0>
```

**備**

`IntFlag` 使用 `auto` 會生從 1 開始 2 的次方的整數。

在 3.11 版的變更: 了更好地支援現存常數取代 (*replacement of existing constants*) 的使用情境, `__str__()` 現在會是 `int.__str__()`。了同樣的理由, `__format__()` 已經是 `int.__format__()`。

`IntFlag` 的反轉 (*inversion*) 現在會回傳正值, 該值是不在給定旗標的所有旗標聯集, 而不是一個負值。這符合現有 `Flag` 的行。

**class enum.ReprEnum**

`ReprEnum` 使用 `Enum` 的 `repr()`, 但使用混合資料型的 `str()`:

- 對 `IntEnum` 和 `IntFlag` 是 `int.__str__()`
- 對 `StrEnum` 是 `str.__str__()`

繼承 `ReprEnum` 來保留混合資料型的 `str()` / `format()`, 而不是使用 `Enum` 預設的 `str()`。

在 3.11 版被加入。

**class enum.EnumCheck**

`EnumCheck` 包含 `verify()` 裝飾器使用的選項, 以確保多樣的限制, 不符合限制會生 `ValueError`。

**UNIQUE**

確保每個值只有一個名稱:

```
>>> from enum import Enum, verify, UNIQUE
>>> @verify(UNIQUE)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 3
...     CRIMSON = 1
Traceback (most recent call last):
...
ValueError: aliases found in <enum 'Color'>: CRIMSON -> RED
```

**CONTINUOUS**

確保在最小值成員跟最大值成員間有缺少值:

```
>>> from enum import Enum, verify, CONTINUOUS
>>> @verify(CONTINUOUS)
... class Color(Enum):
...     RED = 1
...     GREEN = 2
...     BLUE = 5
Traceback (most recent call last):
...
ValueError: invalid enum 'Color': missing values 3, 4
```

**NAMED\_FLAGS**

確保任何旗標群組 / 遮罩只包含命名旗標 -- 當值是用指定而不是透過 `auto()` 生時是很實用的:

```
>>> from enum import Flag, verify, NAMED_FLAGS
>>> @verify(NAMED_FLAGS)
... class Color(Flag):
...     RED = 1
```

(繼續下一頁)

(繼續上一頁)

```

...     GREEN = 2
...     BLUE = 4
...     WHITE = 15
...     NEON = 31
Traceback (most recent call last):
...
ValueError: invalid Flag 'Color': aliases WHITE and NEON are missing combined_
↪ values of 0x18 [use enum.show_flag_values(value) for details]

```

**i 備 F**

CONTINUOUS 和 NAMED\_FLAGS 是設計用來運作在整數值的成員上。

在 3.11 版被加入。

**class enum.FlagBoundary**

FlagBoundary 控制在 *Flag* 及其子類 F 中如何處理範圍外的值。

**STRICT**

範圍外的值會引發 *ValueError*。這是 *Flag* 的預設行 F：

```

>>> from enum import Flag, STRICT, auto
>>> class StrictFlag(Flag, boundary=STRICT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> StrictFlag(2**2 + 2**4)
Traceback (most recent call last):
...
ValueError: <flag 'StrictFlag'> invalid value 20
        given 0b0 10100
        allowed 0b0 00111

```

**CONFORM**

會移除範圍外的值中的非法值，留下合法的 *Flag* 值：

```

>>> from enum import Flag, CONFORM, auto
>>> class ConformFlag(Flag, boundary=CONFORM):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> ConformFlag(2**2 + 2**4)
<ConformFlag.BLUE: 4>

```

**EJECT**

範圍外的值會失去它們的 *Flag* 成員資格且恢復成 *int*。

```

>>> from enum import Flag, EJECT, auto
>>> class EjectFlag(Flag, boundary=EJECT):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> EjectFlag(2**2 + 2**4)
20

```

**KEEP**

範圍外的值會被保留，*Flag* 成員資格也會被保留。這是 *IntFlag* 的預設行：

```
>>> from enum import Flag, KEEP, auto
>>> class KeepFlag(Flag, boundary=KEEP):
...     RED = auto()
...     GREEN = auto()
...     BLUE = auto()
...
>>> KeepFlag(2**2 + 2**4)
<KeepFlag.BLUE|16: 20>
```

在 3.11 版被加入。

**class enum.EnumDict**

*EnumDict* 是 *dict* 的子類，用來作定義列舉類的命名空間（參見 *prepare*）。它被公開來使得 *EnumType* 的子類能具有進階行，例如讓每個成員有多個值。它應該在被呼叫時帶上正在建立的列舉類名稱，否則私有名稱和部類將無法被正確處理。

注意只有 *MutableMapping* 介面（*\_\_setitem\_\_()* 和 *update()*）被覆寫。可能可以使用其他 *dict* 操作來繞過檢查，例如 *|=*。

**member\_names**

一個成員名稱的串列。

在 3.13 版被加入。

**支援的 \_\_dunder\_\_ 名稱**

*\_\_members\_\_* 是一個唯讀有序的成員名稱：成員項目的對映。只有在類上可用。

*\_\_new\_\_()*，如果有指定，它必須建立回傳列舉成員；適當地設定成員的 *\_value\_* 也是一個很好的主意。一旦所有成員都建立之後就不會再被用到。

**支援的 \_sunder\_ 名稱**

- *\_\_add\_alias\_\_()* -- 新增一個名稱作現有成員的名。
- *\_\_add\_value\_alias\_\_()* -- 新增一個值作現有成員的名。
- *\_\_name\_\_* -- 成員名稱
- *\_\_value\_\_* -- 成員的值；可以在 *\_\_new\_\_* 設定
- *\_\_missing\_\_()* -- 當值有被找到時會使用的查詢函式；可以被覆寫
- *\_\_ignore\_\_* -- 一個名稱的串列，可以是 *list* 或 *str*，它不會被轉成成員，且在最後的類上會被移除
- *\_\_order\_\_* -- 不再被使用，僅了向後相容而保留（類屬性，在類建立時移除）
- *\_\_generate\_next\_value\_\_()* -- 用來列舉成員取得合適的值；可以被覆寫

**備**

對標準的 *Enum* 類來，下一個被選擇的值是所看過的最大值加一。

對 *Flag* 類來，下一個被選擇的值是下一個最大的 2 的次方的數字。

- 雖然 *\_sunder\_* 名稱通常保留用於 *Enum* 類的進一步開發而不能被使用，但有些是明確允許的：
  - *\_\_repr\_\_\**（例如 *\_\_repr\_html\_\_*），例如用於 *IPython* 的豐富顯示

在 3.6 版被加入: `_missing_`、`_order_`、`_generate_next_value_`

在 3.7 版被加入: `_ignore_`

在 3.13 版被加入: `_add_alias_`、`_add_value_alias_`、`_repr_*`

### 8.14.3 通用項目與裝飾器

**class** `enum.auto`

`auto` 可以用來取代給值。如果使用的話, `Enum` 系統會呼叫 `Enum` 的 `_generate_next_value_()` 來取得合適的值。對 `Enum` 和 `IntEnum` 來, 合適的值是最後一個值加一; 對 `Flag` 和 `IntFlag` 來, 是第一個比最大值還大的 2 的次方的數字; 對 `StrEnum` 來, 是成員名稱的小寫版本。如果混用 `auto()` 和手動指定值的話要特別注意。

`auto` 實例只有在最上層的賦值時才會被解析:

- `FIRST = auto()` 可以運作 (`auto()` 會被取代成 1)
- `SECOND = auto(), -2` 可以運作 (`auto` 會被取代成 2, 因此 2, -2 會被用來建立列舉成員 `SECOND`;
- `THREE = [auto(), -3]` 無法運作 (<`auto` 實例>, -3 會被用來建立列舉成員 `THREE`)

在 3.11.1 版的變更: 在之前的版本中, `auto()` 必須是賦值行的唯一內容才能運作正確。

可以覆寫 `_generate_next_value_` 來客 `auto` 使用的值。

#### 備

在 3.13 預設 `_generate_next_value_` 總是回傳最大的成員值加一, 如果任何成員是不相容的型就會失敗。

**@enum.property**

和建的 `property` 相似的裝飾器, 但只專門針對列舉。它允許成員屬性和成員本身有相同名稱。

#### 備

屬性和成員必須定義在分開的類; 例如 `value` 和 `name` 屬性定義在 `Enum` 類而 `Enum` 子類可以定義成員名稱 `value` 和 `name`。

在 3.11 版被加入。

**@enum.unique**

專門針對列舉的 `class` 裝飾器。它搜尋列舉的 `__members__`, 集任何它找到的名; 如果有找到任何名則引發 `ValueError` 附上細節:

```
>>> from enum import Enum, unique
>>> @unique
... class Mistake(Enum):
...     ONE = 1
...     TWO = 2
...     THREE = 3
...     FOUR = 3
...
Traceback (most recent call last):
...
ValueError: duplicate values found in <enum 'Mistake'>: FOUR -> THREE
```

**@enum.verify**

專門針對列舉的 `class` 裝飾器。使用 `EnumCheck` 的成員來指定在裝飾的列舉上應該檢查什麼限制。

在 3.11 版被加入。

**@enum.member**

列舉所使用的裝飾器：其目標會變成成員。

在 3.11 版被加入。

**@enum.nonmember**

列舉所使用的裝飾器：其目標不會變成成員。

在 3.11 版被加入。

**@enum.global\_enum**

修改列舉的 `str()` 及 `repr()` 的裝飾器，讓成員顯示屬於模組而不是其類。應該只有當列舉成員被匯出到模組的全域命名空間才使用（範例請參考 `re.RegexFlag`）。

在 3.11 版被加入。

**enum.show\_flag\_values (value)**

回傳在旗標值中包含的所有 2 的次方的整數串列。

在 3.11 版被加入。

## 8.14.4 備

`IntEnum`、`StrEnum` 及 `IntFlag`

這三種列舉型是設計來直接取代現有以整數及字串為基底的值；因此它們有額外的限制：

- `__str__` 使用值而不是列舉成員的名稱
- `__format__` 因使用 `__str__`，也會使用值而不是列舉成員的名稱

如果你不需要或不想要這些限制，你可以透過混合 `int` 或 `str` 型來建立自己的基礎類：

```
>>> from enum import Enum
>>> class MyIntEnum(int, Enum):
...     pass
```

或者你也可以在你的列舉重新給定合適的 `str()`：

```
>>> from enum import Enum, IntEnum
>>> class MyIntEnum(IntEnum):
...     __str__ = Enum.__str__
```

## 8.15 graphlib —— 使用類圖 (graph-like) 結構進行操作的功能

原始碼：Lib/graphlib.py

**class graphlib.TopologicalSorter (graph=None)**

提供對包含可雜節點之圖 (`graph`) 進行拓撲排序 (topologically sort) 的功能。

拓撲排序是圖中頂點 (vertex) 的性排序，使得對於從頂點 `u` 到頂點 `v` 的每條有向邊 (directed edge) `u -> v`，頂點 `u` 在排序中會位於頂點 `v` 之前。例如，圖的頂點可能代表要執行的任務，而邊可能代表一個任務必須在另一個任務之前執行的限制；在此範例中，拓撲排序只是任務的一種有效序列。

若且唯若 (if and only if) 圖有有向環 (directed cycle) 時，即如果它是個有向無環圖 (directed acyclic graph)，則完整的拓撲排序才是可行的。

如果提供了可選的 `graph` 引數，它必須是表示有向無環圖的字典，其中鍵是節點，值是圖中該節點的包含所有前驅節點 (predecessor) 之可代物件 (這些前驅節點具有指向以鍵表示之節點的邊)。可以使用 `add()` 方法將其他節點新增到圖中。

在一般情況下，對給定的圖執行排序所需的步驟如下：

- 以選用的初始圖建立 `TopologicalSorter` 的實例。
- 在圖中新增其他節點。
- 呼叫圖的 `prepare()`。
- 當 `is_active()` 為 `True` 時，代物件 `get_ready()` 回傳的節點處理它們。在每個節點完成處理時呼叫 `done()`。

如果只需要立即對圖中的節點進行排序且不涉及平行性 (parallelism)，則可以直接使用便捷方法 `TopologicalSorter.static_order()`：

```
>>> graph = {"D": {"B", "C"}, "C": {"A"}, "B": {"A"}}
>>> ts = TopologicalSorter(graph)
>>> tuple(ts.static_order())
('A', 'C', 'B', 'D')
```

該類設計在節點準備就緒時，簡單支援節點的平行處理。例如：

```
topological_sorter = TopologicalSorter()

# Add nodes to 'topological_sorter'...

topological_sorter.prepare()
while topological_sorter.is_active():
    for node in topological_sorter.get_ready():
        # Worker threads or processes take nodes to work on off the
        # 'task_queue' queue.
        task_queue.put(node)

    # When the work for a node is done, workers put the node in
    # 'finalized_tasks_queue' so we can get more nodes to work on.
    # The definition of 'is_active()' guarantees that, at this point, at
    # least one node has been placed on 'task_queue' that hasn't yet
    # been passed to 'done()', so this blocking 'get()' must (eventually)
    # succeed. After calling 'done()', we loop back to call 'get_ready()'
    # again, so put newly freed nodes on 'task_queue' as soon as
    # logically possible.
    node = finalized_tasks_queue.get()
    topological_sorter.done(node)
```

**add (node, \*predecessors)**

向圖中新增新節點及其前驅節點。 `node` 和 `predecessors` 中的所有元素都必須是可雜的。

如果以相同節點引數多次呼叫，則依賴項的集合將會是傳入的所有依賴項的聯集。

可以新增一個有依賴的節點 (`predecessors` 未提供) 或提供兩次依賴。如果有之前未曾提供的節點被包含在 `predecessors` 中，它將自動新增到有前驅節點的圖中。

如果在 `prepare()` 之後呼叫，則引發 `ValueError`。

**prepare()**

將圖標記為已完成檢查圖中的循環。如果檢測到任何循環，將引發 `CycleError`，但 `get_ready()` 仍可用於盡可能獲得更多的節點，直到循環阻塞了進度。呼叫此函式後就無法修改圖，因此無法使用 `add()` 來新增更多節點。

**is\_active()**

如果有更多進度則回傳 True，否則回傳 False。如果循環不阻塞解析 (resolution) 且仍有節點準備就緒但尚未由 `TopologicalSorter.get_ready()` 回傳或標記 `TopologicalSorter.done()` 的節點數量較 `TopologicalSorter.get_ready()` 所回傳的少，則可以繼續取得進度。

此類 `is_active()` 方法遵循此函式，因此以下做法：

```
if ts.is_active():
    ...
```

可以簡單地用以下方式替：

```
if ts:
    ...
```

如果呼叫之前有先呼叫 `prepare()` 則引發 `ValueError`。

**done(\*nodes)**

將 `TopologicalSorter.get_ready()` 回傳的一組節點標記已處理，停止阻塞 `nodes` 中每個節點的任何後繼節點 (successor)，以便將來通過呼叫 `TopologicalSorter.get_ready()` 回傳。

若有和該呼叫一起呼叫 `prepare()` 或節點還未被 `get_ready()` 回傳，且如果 `nodes` 中有任何節點已被先前對此方法的呼叫標記已處理、或者未使用 `TopologicalSorter.add()` 將節點新增到圖中，則引發 `ValueError`。

**get\_ready()**

回傳一個包含所有準備就緒節點的 tuple。最初它回傳有前驅節點的所有節點，一旦通過呼叫 `TopologicalSorter.done()` 來將這些節點標記已處理後，進一步的呼叫將回傳所有其全部前驅節點都已被處理的新節點。若無法取得更多進度，將回傳空 tuple。

如果呼叫之前有先呼叫 `prepare()` 則引發 `ValueError`。

**static\_order()**

回傳一個可迭代物件，它將按拓撲排序代節點。使用此方法時，不應呼叫 `prepare()` 和 `done()`。此方法等效於：

```
def static_order(self):
    self.prepare()
    while self.is_active():
        node_group = self.get_ready()
        yield from node_group
        self.done(*node_group)
```

回傳的特定順序可能取於將項目插入圖中的特定順序。例如：

```
>>> ts = TopologicalSorter()
>>> ts.add(3, 2, 1)
>>> ts.add(1, 0)
>>> print(list(ts.static_order()))
[2, 0, 1, 3]

>>> ts2 = TopologicalSorter()
>>> ts2.add(1, 0)
>>> ts2.add(3, 2, 1)
>>> print(list(ts2.static_order()))
[0, 2, 1, 3]
```

這是因“0”和“2”在圖中處於同一級（它們將在對 `get_ready()` 的同一呼叫中回傳）且它們之間的順序取於插入順序。

如果檢測到任何循環，則引發 `CycleError`。

在 3.9 版被加入。

### 8.15.1 例外

`graphlib` 模組定義了以下例外類：

**exception** `graphlib.CycleError`

`ValueError` 的子類，如果作用的圖中存在循環則由 `TopologicalSorter.prepare()` 引發。如果存在多個循環，則只會報告未定義的其中一個包含在例外中。

檢測到的循環可以通過例外實例的 `args` 屬性中第二個元素來存取，其一個節點列表，每個節點在圖中都是列表中下一個節點的直接前驅節點（`immediate predecessor`，即父節點）。在報告列表中，第一個和最後一個節點將會是相同的，用以明確表示它是循環的。

---

 數值與數學模組
 

---

本章所描述的模組提供了數值和與數學相關的函式和資料型 $\mathbb{F}$ 。 `numbers` 模組定義了數值型 $\mathbb{F}$ 的抽象階層結構。 `math` 和 `cmath` 模組包含了用於浮點數和 $\mathbb{F}$ 數的各種數學函式。 `decimal` 模組支援對十進位數字的精確表示以及任意精度的算術運算。

本章節包含下列的模組：

## 9.1 `numbers` --- 數值的抽象基底類 $\mathbb{F}$

原始碼：[Lib/numbers.py](#)

---

`numbers` 模組 ([PEP 3141](#)) 定義了數值抽象基底類 $\mathbb{F}$ 的階層結構，其中逐一定義了更多操作。此模組中定義的型 $\mathbb{F}$ 都不可被實例化。

**class** `numbers.Number`

數值階層結構的基礎。如果你只想確認引數 `x` 是不是數值、 $\mathbb{F}$ 不關心其型 $\mathbb{F}$ ，請使用 `isinstance(x, Number)`。

### 9.1.1 數值的階層

**class** `numbers.Complex`

這個型 $\mathbb{F}$ 的子類 $\mathbb{F}$ 描述了 $\mathbb{F}$ 數 $\mathbb{F}$ 包含適用於 $\mathbb{F}$ 建`complex`型 $\mathbb{F}$ 的操作。這些操作有：`complex`和`bool`的轉 $\mathbb{F}$ 、`real`、`imag`、`+`、`-`、`*`、`/`、`**`、`abs()`、`conjugate()`、`==`以及`!=`。除`-`和`!=`之外所有操作都是抽象的。

**real**

$\mathbb{F}$ 抽象的。取得該數值的實數部分。

**imag**

$\mathbb{F}$ 抽象的。取得該數值的 $\mathbb{F}$ 數部分。

**abstractmethod** `conjugate()`

$\mathbb{F}$ 抽象的。回傳共 $\mathbb{F}$  $\mathbb{F}$ 數，例如 `(1+3j).conjugate() == (1-3j)`。

**class numbers.Real**

相對於 `Complex`, `Real` 加入了只有實數才能進行的操作。

簡單的, 有 `float` 的轉, `math.trunc()`、`round()`、`math.floor()`、`math.ceil()`、`divmod()`、`//`、`%`、`<`、`<=`、`>`、和 `>=`。

實數同樣提供 `complex()`、`real`、`imag` 和 `conjugate()` 的預設值。

**class numbers.Rational**

`Real` 的子型, 增加了 `numerator` 和 `denominator` 這兩種特性。它也會提供 `float()` 的預設值。`numerator` 和 `denominator` 的值必須是 `Integral` 的實例且 `denominator` 要是正數。

**numerator**

抽象的。

**denominator**

抽象的。

**class numbers.Integral**

`Rational` 的子型, 增加了 `int` 的轉操作。 `float()`、`numerator` 和 `denominator` 提供了預設值。 `pow()` 方法增加了求余 (modulus) 和位元字串運算 (bit-string operations) 的抽象方法: `<<`、`>>`、`&`、`^`、`|`、`~`。

### 9.1.2 給型實作者的記

實作者需注意, 相等的數值除了大小相等外, 還必須擁有同樣的雜值。當使用兩個不同的實數擴充時, 這可能是很微妙的。例如, `fractions.Fraction` 底下的 `hash()` 實作如下:

```
def __hash__(self):
    if self.denominator == 1:
        # Get integers right.
        return hash(self.numerator)
    # Expensive check, but definitely correct.
    if self == float(self):
        return hash(float(self))
    else:
        # Use tuple's hash to avoid a high collision rate on
        # simple fractions.
        return hash((self.numerator, self.denominator))
```

### 加入更多數值 ABC

當然, 還有更多用於數值的 ABC, 如果不加入它們就不會有健全的階層。你可以在 `Complex` 和 `Real` 中加入 `MyFoo`, 像是:

```
class MyFoo(Complex): ...
MyFoo.register(Real)
```

### 實作算術操作

我們想要實作算術操作, 來使得混合模式操作要呼叫一個作者知道兩個引數之型的實作, 要將其轉成最接近的型執行這個操作。對於 `Integral` 的子型, 這意味著 `__add__()` 和 `__radd__()` 必須用如下方式定義:

```
class MyIntegral(Integral):

    def __add__(self, other):
        if isinstance(other, MyIntegral):
            return do_my_adding_stuff(self, other)
        elif isinstance(other, OtherTypeIKnowAbout):
```

(繼續下一頁)

(繼續上一頁)

```

        return do_my_other_adding_stuff(self, other)
    else:
        return NotImplemented

def __radd__(self, other):
    if isinstance(other, MyIntegral):
        return do_my_adding_stuff(other, self)
    elif isinstance(other, OtherTypeIKnowAbout):
        return do_my_other_adding_stuff(other, self)
    elif isinstance(other, Integral):
        return int(other) + int(self)
    elif isinstance(other, Real):
        return float(other) + float(self)
    elif isinstance(other, Complex):
        return complex(other) + complex(self)
    else:
        return NotImplemented

```

`Complex` 的子類有 5 種不同的混合型操作。我將上面提到所有不涉及 `MyIntegral` 和 `OtherTypeIKnowAbout` 的程式碼稱作「模板 (boilerplate)」。`a` 是 `Complex` 之子型 `A` 的實例 (`a : A <: Complex`)，同時 `b : B <: Complex`。我將要計算 `a + b`：

1. 如果 `A` 有定義成一個接受 `b` 的 `__add__()`，不會發生問題。
2. 如果 `A` 回退成模板程式碼，它將回傳一個來自 `__add__()` 的值，喪失讓 `B` 定義一個更完善的 `__radd__()` 的機會，因此模板需要回傳一個來自 `__add__()` 的 `NotImplemented`。(或者 `A` 可能完全不實作 `__add__()`。)
3. 接著看 `B` 的 `__radd__()`。如果它接受 `a`，不會發生問題。
4. 如果 `B` 有成功回退到模板，就 `B` 有更多的方法可以去嘗試，因此這 `B` 將使用預設的實作。
5. 如果 `B <: A`，`Python` 會在 `A.__add__` 之前嘗試 `B.__radd__`。這是可行的，因為它是透過對 `A` 的理解而實作的，所以這可以在交給 `Complex` 之前處理好這些實例。

如果 `A <: Complex` 和 `B <: Real` 且 `B` 有共享任何其他型上的理解，那 `B` 適當的共享操作會涉及 `B` 的 `complex`，且 `B` 用到 `__radd__()`，因此 `a+b == b+a`。

由於大部分對任意給定類型的操作都十分相似的，定義一個任意給定運算子生成向前 (forward) 與向後 (reverse) 實例的輔助函式可能會非常有用。例如，`fractions.Fraction` 使用了：

```

def _operator_fallbacks(monomorphic_operator, fallback_operator):
    def forward(a, b):
        if isinstance(b, (int, Fraction)):
            return monomorphic_operator(a, b)
        elif isinstance(b, float):
            return fallback_operator(float(a), b)
        elif isinstance(b, complex):
            return fallback_operator(complex(a), b)
        else:
            return NotImplemented
    forward.__name__ = '__' + fallback_operator.__name__ + '__'
    forward.__doc__ = monomorphic_operator.__doc__

    def reverse(b, a):
        if isinstance(a, Rational):
            # 包含整數。
            return monomorphic_operator(a, b)
        elif isinstance(a, Real):
            return fallback_operator(float(a), float(b))
        elif isinstance(a, Complex):
            return fallback_operator(complex(a), complex(b))
        else:

```

(繼續下一頁)

```

        return NotImplemented
    reverse.__name__ = '__r' + fallback_operator.__name__ + '__'
    reverse.__doc__ = monomorphic_operator.__doc__

    return forward, reverse

def _add(a, b):
    """a + b"""
    return Fraction(a.numerator * b.denominator +
                    b.numerator * a.denominator,
                    a.denominator * b.denominator)

__add__, __radd__ = _operator_fallbacks(_add, operator.add)

# ...

```

## 9.2 math --- 數學函式

此模組提供對 C 標準中定義的數學相關函式的存取。

這些函式不支援  $\mathbb{F}$  數；若你需要計算  $\mathbb{F}$  數，請使用 `cmath` 模組的同名函式。這是因  $\mathbb{F}$  大多數的使用者  $\mathbb{F}$  不想學習那  $\mathbb{F}$  多理解  $\mathbb{F}$  數所需的數學概念，所以根據支援  $\mathbb{F}$  數與否分  $\mathbb{F}$  兩種函式。收到一個例外而非  $\mathbb{F}$  數回傳值，有助於程式設計師提早察覺參數中包含非預期的  $\mathbb{F}$  數，進而從源頭查出導致此情  $\mathbb{F}$  的原因。

此模組提供下列函式。除非特意  $\mathbb{F}$  明，否則回傳值皆  $\mathbb{F}$  浮點數。

<b>數論函式</b>	
<code>comb(n, k)</code>	從 $n$ 個物品中不重 $\mathbb{F}$ 且不考慮排序地取出 $k$ 個物品的方法數。
<code>factorial(n)</code>	$n$ factorial
<code>gcd(*integers)</code>	Greatest common divisor of the integer arguments
<code>isqrt(n)</code>	Integer square root of a nonnegative integer $n$
<code>lcm(*integers)</code>	Least common multiple of the integer arguments
<code>perm(n, k)</code>	從 $n$ 個物品中不重 $\mathbb{F}$ 但考慮排序地取出 $k$ 個物品的方法數。
<b>Floating point arithmetic</b>	
<code>ceil(x)</code>	Ceiling of $x$ , the smallest integer greater than or equal to $x$
<code>fabs(x)</code>	$x$ 的 $\mathbb{F}$ 對值。
<code>floor(x)</code>	Floor of $x$ , the largest integer less than or equal to $x$
<code>fma(x, y, z)</code>	Fused multiply-add operation: $(x * y) + z$
<code>fmod(x, y)</code>	Remainder of division $x / y$
<code>modf(x)</code>	Fractional and integer parts of $x$
<code>remainder(x, y)</code>	Remainder of $x$ with respect to $y$
<code>trunc(x)</code>	Integer part of $x$
<b>浮點數操作函式</b>	
<code>copysign(x, y)</code>	Magnitude (absolute value) of $x$ with the sign of $y$
<code>frexp(x)</code>	Mantissa and exponent of $x$
<code>isclose(a, b, rel_tol, abs_tol)</code>	Check if the values $a$ and $b$ are close to each other
<code>isfinite(x)</code>	Check if $x$ is neither an infinity nor a NaN
<code>isinf(x)</code>	Check if $x$ is a positive or negative infinity
<code>isnan(x)</code>	Check if $x$ is a NaN (not a number)
<code>ldexp(x, i)</code>	$x * (2^{**i})$ , inverse of function <code>frexp()</code>
<code>nextafter(x, y, steps)</code>	Floating-point value $steps$ steps after $x$ towards $y$
<code>ulp(x)</code>	Value of the least significant bit of $x$
<b>Power, exponential and logarithmic functions</b>	
<code>cbt(x)</code>	Cube root of $x$

繼續

表格 1 - 繼續上一頁

<code>exp(x)</code>	$e$ raised to the power $x$
<code>exp2(x)</code>	2 raised to the power $x$
<code>expm1(x)</code>	$e$ raised to the power $x$ , minus 1
<code>log(x, base)</code>	Logarithm of $x$ to the given base ( $e$ by default)
<code>log1p(x)</code>	Natural logarithm of $1+x$ (base $e$ )
<code>log2(x)</code>	Base-2 logarithm of $x$
<code>log10(x)</code>	Base-10 logarithm of $x$
<code>pow(x, y)</code>	$x$ raised to the power $y$
<code>sqrt(x)</code>	$x$ 的平方根
<b>Summation and product functions</b>	
<code>dist(p, q)</code>	Euclidean distance between two points $p$ and $q$ given as an iterable of coordinates
<code>fsum(iterable)</code>	Sum of values in the input <i>iterable</i>
<code>hypot(*coordinates)</code>	Euclidean norm of an iterable of coordinates
<code>prod(iterable, start)</code>	Product of elements in the input <i>iterable</i> with a <i>start</i> value
<code>sumprod(p, q)</code>	Sum of products from two iterables $p$ and $q$
<b>Angular conversion</b>	
<code>degrees(x)</code>	Convert angle $x$ from radians to degrees
<code>radians(x)</code>	Convert angle $x$ from degrees to radians
<b>Trigonometric functions</b>	
<code>acos(x)</code>	Arc cosine of $x$
<code>asin(x)</code>	Arc sine of $x$
<code>atan(x)</code>	Arc tangent of $x$
<code>atan2(y, x)</code>	$\text{atan}(y / x)$
<code>cos(x)</code>	Cosine of $x$
<code>sin(x)</code>	Sine of $x$
<code>tan(x)</code>	Tangent of $x$
<b>Hyperbolic functions</b>	
<code>acosh(x)</code>	Inverse hyperbolic cosine of $x$
<code>asinh(x)</code>	Inverse hyperbolic sine of $x$
<code>atanh(x)</code>	Inverse hyperbolic tangent of $x$
<code>cosh(x)</code>	Hyperbolic cosine of $x$
<code>sinh(x)</code>	Hyperbolic sine of $x$
<code>tanh(x)</code>	Hyperbolic tangent of $x$
<b>Special functions</b>	
<code>erf(x)</code>	Error function at $x$
<code>erfc(x)</code>	Complementary error function at $x$
<code>gamma(x)</code>	Gamma function at $x$
<code>lgamma(x)</code>	Natural logarithm of the absolute value of the Gamma function at $x$
<b>常數</b>	
<code>pi</code>	$\pi = 3.141592\dots$
<code>e</code>	$e = 2.718281\dots$
<code>tau</code>	$\tau = 2\pi = 6.283185\dots$
<code>inf</code>	正無限大
<code>nan</code>	"Not a number" (NaN)

## 9.2.1 數論函式

`math.comb(n, k)`

回傳從  $n$  個物品中不重且不用考慮排序地取出  $k$  個物品的方法數。

當  $k \leq n$  時其值  $n! / (k! * (n - k)!)$ ，否則其值 0。

因此此值等同於  $(1 + x)^n$  進行多項式展開後第  $k$  項的係數，所以又稱二項式係數。

當任一參數非整數型時會引發 `TypeError`。當任一參數負數時會引發 `ValueError`。

在 3.8 版被加入。

`math.factorial(n)`

以整數回傳  $n$  的階乘。若  $n$  非整數型或其值負會引發 `ValueError`。

在 3.10 版的變更: 其值整數的浮點數 (如: 5.0) 已不再被接受。

`math.gcd(*integers)`

回傳指定整數引數的最大公因數。若存在任一非零引數, 回傳值所有引數共有因數中最大的正整數。若所有引數皆零, 則回傳值 0。gcd() 若未傳入任何引數也將回傳 0。

在 3.5 版被加入。

在 3.9 版的變更: 新增支援任意數量的引數。先前僅支援兩個引數。

`math.isqrt(n)`

回傳非負整數  $n$  的整數平方根。此值  $n$  精確平方根經下取整的值, 亦等同於滿足  $a^2 \leq n$  的最大整數值  $a$ 。

於有些應用程式中, 取得滿足  $n \leq a^2$  的最小整數值  $a$  —— 或者  $n$  精確平方根經上取整的值 —— 會更加方便。對正數  $n$ , 此值可使用 `a = 1 + isqrt(n - 1)` 計算。

在 3.8 版被加入。

`math.lcm(*integers)`

回傳指定整數引數的最小公倍數。若所有引數皆非零, 回傳值所有引數共有倍數中最小的正整數。若存在任一引數值零, 則回傳值 0。lcm() 若未傳入任何引數將回傳 1。

在 3.9 版被加入。

`math.perm(n, k=None)`

Return the number of ways to choose  $k$  items from  $n$  items without repetition and with order.

Evaluates to  $n! / (n - k)!$  when  $k \leq n$  and evaluates to zero when  $k > n$ .

If  $k$  is not specified or is `None`, then  $k$  defaults to  $n$  and the function returns  $n!$ .

當任一參數非整數型時會引發 `TypeError`。當任一參數負數時會引發 `ValueError`。

在 3.8 版被加入。

## 9.2.2 Floating point arithmetic

`math.ceil(x)`

回傳  $x$  經上取整的值, 即大於或等於  $x$  的最小整數。若  $x$  非浮點數, 此函式將委派給 `x.__ceil__`, 回傳 `Integral` 型的值。

`math.fabs(x)`

回傳  $x$  的絕對值。

`math.floor(x)`

回傳  $x$  經下取整的值, 即小於或等於  $x$  的最大整數。若  $x$  非浮點數, 此函式將委派給 `x.__floor__`, 回傳 `Integral` 型的值。

`math.fma(x, y, z)`

Fused multiply-add operation. Return  $(x * y) + z$ , computed as though with infinite precision and range followed by a single round to the `float` format. This operation often provides better accuracy than the direct expression  $(x * y) + z$ .

This function follows the specification of the fusedMultiplyAdd operation described in the IEEE 754 standard. The standard leaves one case implementation-defined, namely the result of `fma(0, inf, nan)` and `fma(inf, 0, nan)`. In these cases, `math.fma` returns a NaN, and does not raise any exception.

在 3.13 版被加入。

`math.fmod(x, y)`

回傳  $x / y$  的浮點數余數，其以平臺上的 C 函式庫 `fmod(x, y)` 函式定義。請注意此函式與 Python 運算式  $x \% y$  可能不會回傳相同結果。C 标准要求 `fmod(x, y)` 的回傳值完全等同（數學定義上，即無限精度）於  $x - n*y$ ， $n$  可使回傳值與  $x$  同號且長度小於  $\text{abs}(y)$  的整數。Python 運算式  $x \% y$  的回傳值則與  $y$  同號，且可能無法精確地計算浮點數引數。例如：`fmod(-1e-100, 1e100)` 的值  $-1e-100$ ，但 Python 運算式  $-1e-100 \% 1e100$  的結果  $1e100-1e-100$ ，此值無法準確地表示成浮點數，會四舍五入出乎意料的  $1e100$ 。因此，處理浮點數時通常會選擇函式 `fmod()`，而處理整數時會選擇 Python 運算式  $x \% y$ 。

`math.modf(x)`

Return the fractional and integer parts of  $x$ . Both results carry the sign of  $x$  and are floats.

Note that `modf()` has a different call/return pattern than its C equivalents: it takes a single argument and return a pair of values, rather than returning its second return value through an 'output parameter' (there is no such thing in Python).

`math.remainder(x, y)`

Return the IEEE 754-style remainder of  $x$  with respect to  $y$ . For finite  $x$  and finite nonzero  $y$ , this is the difference  $x - n*y$ , where  $n$  is the closest integer to the exact value of the quotient  $x / y$ . If  $x / y$  is exactly halfway between two consecutive integers, the nearest *even* integer is used for  $n$ . The remainder  $r = \text{remainder}(x, y)$  thus always satisfies  $\text{abs}(r) \leq 0.5 * \text{abs}(y)$ .

Special cases follow IEEE 754: in particular, `remainder(x, math.inf)` is  $x$  for any finite  $x$ , `remainder(x, 0)` and `remainder(math.inf, x)` raise `ValueError` for any non-NaN  $x$ . If the result of the remainder operation is zero, that zero will have the same sign as  $x$ .

On platforms using IEEE 754 binary floating point, the result of this operation is always exactly representable: no rounding error is introduced.

在 3.7 版被加入。

`math.trunc(x)`

Return  $x$  with the fractional part removed, leaving the integer part. This rounds toward 0: `trunc()` is equivalent to `floor()` for positive  $x$ , and equivalent to `ceil()` for negative  $x$ . If  $x$  is not a float, delegates to `x.__trunc__`, which should return an *Integral* value.

For the `ceil()`, `floor()`, and `modf()` functions, note that *all* floating-point numbers of sufficiently large magnitude are exact integers. Python floats typically carry no more than 53 bits of precision (the same as the platform C double type), in which case any float  $x$  with  $\text{abs}(x) \geq 2^{52}$  necessarily has no fractional bits.

## 9.2.3 Floating point manipulation functions

`math.copysign(x, y)`

回傳與  $x$  相同長度（對值）且與  $y$  同號的浮點數。在支援帶符號零的平臺上，`copysign(1.0, -0.0)` 回傳  $-1.0$ 。

`math.frexp(x)`

以  $(m, e)$  對的格式回傳  $x$  的尾數  $m$  及指數  $e$ 。 $m$  是浮點數而  $e$  是整數，且兩者精確地使  $x == m * 2^{*e}$ 。若  $x$  零，回傳  $(0.0, 0)$ ，否則令  $0.5 \leq \text{abs}(m) < 1$ 。此函式用於以可「分割」浮點數部表示法。

Note that `frexp()` has a different call/return pattern than its C equivalents: it takes a single argument and return a pair of values, rather than returning its second return value through an 'output parameter' (there is no such thing in Python).

`math.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

若  $a$  及  $b$  兩值足接近便回傳 `True`，否則回傳 `False`。

兩數是否足接近取於給定的對及相對容許偏差 (tolerance)。如果有錯誤發生，結果將： $\text{abs}(a-b) \leq \max(\text{rel\_tol} * \max(\text{abs}(a), \text{abs}(b)), \text{abs\_tol})$ 。

`rel_tol` 相對容許偏差 ——  $a$  與  $b$  兩數差的最大容許值，與  $a$  及  $b$  兩數的絕對值中較大者相關。例如欲設置 5% 的容許偏差，則傳入 `rel_tol=0.05`。其預設值 `1e-09`，該值可確保兩數於大約 9 個十進數位相同。`rel_tol` 須不負且小於 1.0。

`abs_tol` is the absolute tolerance; it defaults to 0.0 and it must be nonnegative. When comparing  $x$  to 0.0, `isclose(x, 0)` is computed as `abs(x) <= rel_tol * abs(x)`, which is `False` for any  $x$  and `rel_tol` less than 1.0. So add an appropriate positive `abs_tol` argument to the call.

定義於 IEEE 754 浮點標準中的特殊值 `NaN`、`inf` 和 `-inf` 會根據該標準處理。更明確地，`NaN` 不會與包含自身在任何數字足接近，而 `inf` 及 `-inf` 皆只與自身接近。

在 3.5 版被加入。

### 也參考

**PEP 485** —— 用於測試近似相等的函式

`math.isfinite(x)`

若  $x$  不是無限值或 `NaN` 便回傳 `True`，否則回傳 `False`。（注意 0.0 被視有限數。）

在 3.2 版被加入。

`math.isinf(x)`

若  $x$  是正無限值或負無限值便回傳 `True`，否則回傳 `False`。

`math.isnan(x)`

若  $x$  是 `NaN` —— 即非數字 (`NaN, not a number`) —— 便回傳 `True`，否則回傳 `False`。

`math.ldexp(x, i)`

回傳  $x * (2^{**i})$ 。此函式本質上 `frexp()` 的反函式。

`math.nextafter(x, y, steps=1)`

Return the floating-point value `steps` steps after  $x$  towards  $y$ .

If  $x$  is equal to  $y$ , return  $y$ , unless `steps` is zero.

範例：

- `math.nextafter(x, math.inf)` goes up: towards positive infinity.
- `math.nextafter(x, -math.inf)` goes down: towards minus infinity.
- `math.nextafter(x, 0.0)` goes towards zero.
- `math.nextafter(x, math.copysign(math.inf, x))` goes away from zero.

另請參 `math.ulp()`。

在 3.9 版被加入。

在 3.12 版的變更: 新增 `steps` 引數。

`math.ulp(x)`

Return the value of the least significant bit of the float  $x$ :

- If  $x$  is a `NaN` (not a number), return  $x$ .
- 若  $x$  負值，回傳 `ulp(-x)`。
- 若  $x$  正無限值，回傳  $x$ 。
- If  $x$  is equal to zero, return the smallest positive *denormalized* representable float (smaller than the minimum positive *normalized* float, `sys.float_info.min`).
- If  $x$  is equal to the largest positive representable float, return the value of the least significant bit of  $x$ , such that the first float smaller than  $x$  is  $x - \text{ulp}(x)$ .

- Otherwise ( $x$  is a positive finite number), return the value of the least significant bit of  $x$ , such that the first float bigger than  $x$  is  $x + \text{ulp}(x)$ .

ULP stands for "Unit in the Last Place".

See also `math.nextafter()` and `sys.float_info.epsilon`.

在 3.9 版被加入。

## 9.2.4 Power, exponential and logarithmic functions

`math.cbrt(x)`

Return the cube root of  $x$ .

在 3.11 版被加入。

`math.exp(x)`

Return  $e$  raised to the power  $x$ , where  $e = 2.718281\dots$  is the base of natural logarithms. This is usually more accurate than `math.e ** x` or `pow(math.e, x)`.

`math.exp2(x)`

Return 2 raised to the power  $x$ .

在 3.11 版被加入。

`math.expm1(x)`

Return  $e$  raised to the power  $x$ , minus 1. Here  $e$  is the base of natural logarithms. For small floats  $x$ , the subtraction in `exp(x) - 1` can result in a significant loss of precision; the `expm1()` function provides a way to compute this quantity to full precision:

```
>>> from math import exp, expm1
>>> exp(1e-5) - 1 # gives result accurate to 11 places
1.0000050000069649e-05
>>> expm1(1e-5) # result accurate to full precision
1.0000050000166668e-05
```

在 3.2 版被加入。

`math.log(x[, base])`

With one argument, return the natural logarithm of  $x$  (to base  $e$ ).

With two arguments, return the logarithm of  $x$  to the given *base*, calculated as  $\log(x) / \log(\text{base})$ .

`math.log1p(x)`

Return the natural logarithm of  $1+x$  (base  $e$ ). The result is calculated in a way which is accurate for  $x$  near zero.

`math.log2(x)`

Return the base-2 logarithm of  $x$ . This is usually more accurate than `log(x, 2)`.

在 3.3 版被加入。

### 也參考

`int.bit_length()` returns the number of bits necessary to represent an integer in binary, excluding the sign and leading zeros.

`math.log10(x)`

Return the base-10 logarithm of  $x$ . This is usually more accurate than `log(x, 10)`.

`math.pow(x, y)`

Return  $x$  raised to the power  $y$ . Exceptional cases follow the IEEE 754 standard as far as possible. In particular, `pow(1.0, x)` and `pow(x, 0.0)` always return `1.0`, even when  $x$  is a zero or a NaN. If both  $x$  and  $y$  are finite,  $x$  is negative, and  $y$  is not an integer then `pow(x, y)` is undefined, and raises `ValueError`.

Unlike the built-in `**` operator, `math.pow()` converts both its arguments to type `float`. Use `**` or the built-in `pow()` function for computing exact integer powers.

在 3.11 版的變更: The special cases `pow(0.0, -inf)` and `pow(-0.0, -inf)` were changed to return `inf` instead of raising `ValueError`, for consistency with IEEE 754.

`math.sqrt(x)`

Return the square root of  $x$ .

## 9.2.5 Summation and product functions

`math.dist(p, q)`

Return the Euclidean distance between two points  $p$  and  $q$ , each given as a sequence (or iterable) of coordinates. The two points must have the same dimension.

Roughly equivalent to:

```
sqrt(sum((px - qx) ** 2.0 for px, qx in zip(p, q)))
```

在 3.8 版被加入。

`math.fsum(iterable)`

回傳可 [F](#) 代物件 (iterable) 中所有值的精確浮點數和。透過追 [F](#) 過程中多個部分和 (partial sum) 以避免精確度損失。

此演算法準確性奠基於保證 IEEE-754 浮點標準及典型奇進偶舍 (half-even) 模式。於有些非 Windows 平台建置時，底層 C 函式庫使用延伸精度加法運算，而可能導致對過程中同一部分和重 [F](#) 舍入，[F](#) 使其最低有效位不如預期。

更深入的討論及兩種替代做法請參 [F](#) [ASPN cookbook recipes](#) 精準的浮點數總和。

`math.hypot(*coordinates)`

Return the Euclidean norm, `sqrt(sum(x**2 for x in coordinates))`. This is the length of the vector from the origin to the point given by the coordinates.

For a two dimensional point  $(x, y)$ , this is equivalent to computing the hypotenuse of a right triangle using the Pythagorean theorem, `sqrt(x*x + y*y)`.

在 3.8 版的變更: Added support for n-dimensional points. Formerly, only the two dimensional case was supported.

在 3.10 版的變更: Improved the algorithm's accuracy so that the maximum error is under 1 ulp (unit in the last place). More typically, the result is almost always correctly rounded to within 1/2 ulp.

`math.prod(iterable, *, start=1)`

Calculate the product of all the elements in the input *iterable*. The default *start* value for the product is 1.

When the iterable is empty, return the start value. This function is intended specifically for use with numeric values and may reject non-numeric types.

在 3.8 版被加入。

`math.sumprod(p, q)`

Return the sum of products of values from two iterables  $p$  and  $q$ .

Raises `ValueError` if the inputs do not have the same length.

Roughly equivalent to:

```
sum(itertools.starmap(operator.mul, zip(p, q, strict=True)))
```

For float and mixed int/float inputs, the intermediate products and sums are computed with extended precision.  
在 3.12 版被加入.

## 9.2.6 Angular conversion

`math.degrees(x)`

Convert angle  $x$  from radians to degrees.

`math.radians(x)`

Convert angle  $x$  from degrees to radians.

## 9.2.7 Trigonometric functions

`math.acos(x)`

Return the arc cosine of  $x$ , in radians. The result is between 0 and  $\pi$ .

`math.asin(x)`

Return the arc sine of  $x$ , in radians. The result is between  $-\pi/2$  and  $\pi/2$ .

`math.atan(x)`

Return the arc tangent of  $x$ , in radians. The result is between  $-\pi/2$  and  $\pi/2$ .

`math.atan2(y, x)`

Return  $\text{atan}(y / x)$ , in radians. The result is between  $-\pi$  and  $\pi$ . The vector in the plane from the origin to point  $(x, y)$  makes this angle with the positive X axis. The point of `atan2()` is that the signs of both inputs are known to it, so it can compute the correct quadrant for the angle. For example, `atan(1)` and `atan2(1, 1)` are both  $\pi/4$ , but `atan2(-1, -1)` is  $-3\pi/4$ .

`math.cos(x)`

Return the cosine of  $x$  radians.

`math.sin(x)`

Return the sine of  $x$  radians.

`math.tan(x)`

Return the tangent of  $x$  radians.

## 9.2.8 Hyperbolic functions

Hyperbolic functions are analogs of trigonometric functions that are based on hyperbolas instead of circles.

`math.acosh(x)`

Return the inverse hyperbolic cosine of  $x$ .

`math.asinh(x)`

Return the inverse hyperbolic sine of  $x$ .

`math.atanh(x)`

Return the inverse hyperbolic tangent of  $x$ .

`math.cosh(x)`

Return the hyperbolic cosine of  $x$ .

`math.sinh(x)`

Return the hyperbolic sine of  $x$ .

`math.tanh(x)`

Return the hyperbolic tangent of  $x$ .

## 9.2.9 特殊函式

`math.erf(x)`

Return the error function at  $x$ .

The `erf()` function can be used to compute traditional statistical functions such as the cumulative standard normal distribution:

```
def phi(x):
    'Cumulative distribution function for the standard normal distribution'
    return (1.0 + erf(x / sqrt(2.0))) / 2.0
```

在 3.2 版被加入。

`math.erfc(x)`

Return the complementary error function at  $x$ . The complementary error function is defined as  $1.0 - \text{erf}(x)$ . It is used for large values of  $x$  where a subtraction from one would cause a loss of significance.

在 3.2 版被加入。

`math.gamma(x)`

Return the Gamma function at  $x$ .

在 3.2 版被加入。

`math.lgamma(x)`

Return the natural logarithm of the absolute value of the Gamma function at  $x$ .

在 3.2 版被加入。

## 9.2.10 常數

`math.pi`

The mathematical constant  $\pi = 3.141592\dots$ , to available precision.

`math.e`

The mathematical constant  $e = 2.718281\dots$ , to available precision.

`math.tau`

The mathematical constant  $\tau = 6.283185\dots$ , to available precision. Tau is a circle constant equal to  $2\pi$ , the ratio of a circle's circumference to its radius. To learn more about Tau, check out Vi Hart's video [Pi is \(still\) Wrong](#), and start celebrating [Tau day](#) by eating twice as much pie!

在 3.6 版被加入。

`math.inf`

A floating-point positive infinity. (For negative infinity, use `-math.inf`.) Equivalent to the output of `float('inf')`.

在 3.5 版被加入。

`math.nan`

A floating-point "not a number" (NaN) value. Equivalent to the output of `float('nan')`. Due to the requirements of the [IEEE-754 standard](#), `math.nan` and `float('nan')` are not considered to equal to any other numeric value, including themselves. To check whether a number is a NaN, use the `isnan()` function to test for NaNs instead of `is` or `==`. Example:

```
>>> import math
>>> math.nan == math.nan
False
>>> float('nan') == float('nan')
False
>>> math.isnan(math.nan)
```

(繼續下一頁)

(繼續上一頁)

```
True
>>> math.isnan(float('nan'))
True
```

在 3.5 版被加入。

在 3.11 版的變更: It is now always available.

**CPython 實作細節:** The `math` module consists mostly of thin wrappers around the platform C math library functions. Behavior in exceptional cases follows Annex F of the C99 standard where appropriate. The current implementation will raise `ValueError` for invalid operations like `sqrt(-1.0)` or `log(0.0)` (where C99 Annex F recommends signaling invalid operation or divide-by-zero), and `OverflowError` for results that overflow (for example, `exp(1000.0)`). A NaN will not be returned from any of the functions above unless one or more of the input arguments was a NaN; in that case, most functions will return a NaN, but (again following C99 Annex F) there are some exceptions to this rule, for example `pow(float('nan'), 0.0)` or `hypot(float('nan'), float('inf'))`.

Note that Python makes no effort to distinguish signaling NaNs from quiet NaNs, and behavior for signaling NaNs remains unspecified. Typical behavior is to treat all NaNs as though they were quiet.

#### `cmath` 模組

Complex number versions of many of these functions.

## 9.3 `cmath` --- F 數的數學函式

本模組提供一些適用於F數的數學函式。本模組中的函式接受整數、浮點數或F數作F引數。它們也接受任何具有 `__complex__()` 或 `__float__()` 方法的 Python 物件：這些方法分F用於將物件轉FF數或浮點數，然後再將函式應用於轉F後的結果。

### 備F

對於涉及分枝切割 (branch cut) 的函式，我們面臨的問題是F定如何定義在切割本身上的這些函式。遵循 Kahan 的論文“Branch cuts for complex elementary functions”，以及 C99 的附F G 和後來的 C 標準，我們使用零符號來區分分枝切割的兩側：對於沿著（一部分）實數軸的分枝切割，我們查看F部的符號，而對於沿F軸的分枝切割，我們則查看實部的符號。

例如 `cmath.sqrt()` 函式具有一條沿負實軸的分枝切割。引數 `complex(-2.0, -0.0)` 被視F位於分枝切割下方處理，因此給出的結果在負F軸上：

```
>>> cmath.sqrt(complex(-2.0, -0.0))
-1.4142135623730951j
```

但是引數 `complex(-2.0, 0.0)` 會被當成位於分枝切割上方處理：

```
>>> cmath.sqrt(complex(-2.0, 0.0))
1.4142135623730951j
```

### 9.3.1 轉F到極座標和從極座標做轉F

Python F數 `z` 是用直角坐標或笛卡爾坐標儲存在F部的。它完全是由其 實部 `z.real` 和 F部 `z.imag` 所F定。

極座標提供了另一種表示 $\mathbb{C}$ 數的方法。在極座標中， $\mathbb{C}$ 數  $z$  由 $\mathbb{C}$ 對值 (modulus)  $r$  和相位角 (phase)  $\phi$  定義。 $\mathbb{C}$ 對值  $r$  是從  $z$  到原點的距離，而相位角  $\phi$  是從正  $x$  軸到連接原點到  $z$  的 $\mathbb{C}$ 段的逆時針角度（以弧度 $\mathbb{C}$ 單位）。

以下的函式可用於原始直角座標與極座標之間的相互轉 $\mathbb{C}$ 。

`cmath.phase(x)`

以浮點數的形式回傳  $x$  的相位角（也稱 $\mathbb{C}$   $x$  的引數）。`phase(x)` 等價於 `math.atan2(x.imag, x.real)`。結果將位於  $[-\pi, \pi]$  的範圍 $\mathbb{C}$ ，且此操作的分枝切割將位於負實軸上。結果的符號會與 `x.imag` 的符號相同，即使 `x.imag`  $\mathbb{C}$ 零：

```
>>> phase(complex(-1.0, 0.0))
3.141592653589793
>>> phase(complex(-1.0, -0.0))
-3.141592653589793
```

### 備 $\mathbb{C}$

$\mathbb{C}$ 數  $x$  的 $\mathbb{C}$ 對值可以使用 $\mathbb{C}$ 建的 `abs()` 函式計算。 $\mathbb{C}$ 有單獨的 `cmath` 模組函式適用於此操作。

`cmath.polar(x)`

回傳  $x$  在極座標中的表達方式。回傳一組數對  $(r, \phi)$ ， $r$  是  $x$  的 $\mathbb{C}$ 對值， $\phi$  是  $x$  的相位角。`polar(x)` 相當於 `(abs(x), phase(x))`。

`cmath.rect(r, phi)`

透過極座標  $r$  和  $\phi$  回傳 $\mathbb{C}$ 數  $x$ 。相當於 `complex(r * math.cos(phi), r * math.sin(phi))`。

## 9.3.2 $\mathbb{C}$ 函數和對數函數

`cmath.exp(x)`

回傳  $e$  的  $x$  次方，其中  $e$  是自然對數的底數。

`cmath.log(x[, base])`

回傳  $x$  給定 `base` 的對數。如果未指定 `base`，則傳回  $x$  的自然對數。存在一條分枝切割，從 0 沿負實數軸到  $-\infty$ 。

`cmath.log10(x)`

回傳  $x$  以 10  $\mathbb{C}$ 底的對數。它與 `log()` 具有相同的分枝切割。

`cmath.sqrt(x)`

回傳  $x$  的平方根。它與 `log()` 具有相同的分枝切割。

## 9.3.3 三角函數

`cmath.acos(x)`

回傳  $x$  的反余弦值。存在兩條分枝切割：一條是從 1 沿著實數軸向右延伸到  $\infty$ 。另一條從 -1 沿實數軸向左延伸到  $-\infty$ 。

`cmath.asin(x)`

回傳  $x$  的正弦值。它與 `acos()` 具有相同的分枝切割。

`cmath.atan(x)`

回傳  $x$  的正切值。有兩條分枝切割：一條是從  $1j$  沿著 $\mathbb{C}$ 軸延伸到  $\infty j$ 。另一條從  $-1j$  沿著 $\mathbb{C}$ 軸延伸到  $-\infty j$ 。

`cmath.cos(x)`

回傳  $x$  的余弦值。

`cmath.sin(x)`

回傳  $x$  的正弦值。

`cmath.tan(x)`

回傳  $x$  的正切值。

### 9.3.4 雙曲函數

`cmath.acosh(x)`

回傳  $x$  的反雙曲余弦值。存在一條分枝切割，從 1 沿實數軸向左延伸到  $-\infty$ 。

`cmath.asinh(x)`

回傳  $x$  的反雙曲正弦值。存在兩條分枝切割：一條是從  $1j$  沿著  $\mathbb{F}$  軸延伸到  $\infty j$ 。另一條從  $-1j$  沿著  $\mathbb{F}$  軸延伸到  $-\infty j$ 。

`cmath.atanh(x)`

回傳  $x$  的反雙曲正切值。存在兩條分枝切割：一條是從 1 沿著實數軸延伸到  $\infty$ 。另一條從  $-1$  沿著實數軸延伸到  $-\infty$ 。

`cmath.cosh(x)`

回傳  $x$  的反雙曲余弦值。

`cmath.sinh(x)`

回傳  $x$  的反雙曲正弦值。

`cmath.tanh(x)`

回傳  $x$  的反雙曲正切值。

### 9.3.5 分類函式

`cmath.isfinite(x)`

如果  $x$  的實部和  $\mathbb{F}$  部都是有限的，則回傳 True，否則回傳 False。

在 3.2 版被加入。

`cmath.isinf(x)`

如果  $x$  的實部或  $\mathbb{F}$  部是無窮大，則回傳 True，否則回傳 False。

`cmath.isnan(x)`

如果  $x$  的實部或  $\mathbb{F}$  部  $\mathbb{F}$  NaN，則回傳 True，否則回傳 False。

`cmath.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0)`

如果  $a$  和  $b$  的值相互接近，則回傳 True，否則回傳 False。

兩數是否足  $\mathbb{F}$  接近取  $\mathbb{F}$  於給定的  $\mathbb{F}$  對及相對容許偏差 (tolerance)。如果  $\mathbb{F}$  有錯誤發生，結果將  $\mathbb{F}$ ：  
 $\text{abs}(a-b) \leq \max(\text{rel\_tol} * \max(\text{abs}(a), \text{abs}(b)), \text{abs\_tol})$ 。

*rel\_tol*  $\mathbb{F}$  相對容許偏差 ——  $a$  與  $b$  兩數差的最大容許值，與  $a$  及  $b$  兩數的  $\mathbb{F}$  對值中較大者相關。例如欲設置 5% 的容許偏差，則傳入 *rel\_tol*=0.05。其預設值  $\mathbb{F}$  1e-09，該值可確保兩數於大約 9 個十進數位  $\mathbb{F}$  相同。*rel\_tol* 須不  $\mathbb{F}$  負且小於 1.0。

*abs\_tol* is the absolute tolerance; it defaults to 0.0 and it must be nonnegative. When comparing  $x$  to 0.0, `isclose(x, 0)` is computed as  $\text{abs}(x) \leq \text{rel\_tol} * \text{abs}(x)$ , which is False for any  $x$  and *rel\_tol* less than 1.0. So add an appropriate positive *abs\_tol* argument to the call.

定義於 IEEE 754 浮點標準中的特殊值 NaN、*inf* 和 *-inf* 會根據該標準處理。更明確地  $\mathbb{F}$ ，NaN 不會與包含自身在  $\mathbb{F}$  的任何數字足  $\mathbb{F}$  接近，而 *inf* 及 *-inf* 皆只與自身接近。

在 3.5 版被加入。

↩ 也參考

PEP 485 — 用於測試近似相等的函式

### 9.3.6 常數

`cmath.pi`

數學常數  $\pi$ ，作一個浮點數。

`cmath.e`

數學常數  $e$ ，作一個浮點數。

`cmath.tau`

數學常數  $\tau$ ，作一個浮點數。

在 3.6 版被加入。

`cmath.inf`

正無窮大的浮點數。相當於 `float('inf')`。

在 3.6 版被加入。

`cmath.infj`

實部零和部正無窮的數。相當於 `complex(0.0, float('inf'))`。

在 3.6 版被加入。

`cmath.nan`

浮點「非數字」(NaN) 值。相當於 `float('nan')`。

在 3.6 版被加入。

`cmath.nanj`

實部零和部 NaN 的數。相當於 `complex(0.0, float('nan'))`。

在 3.6 版被加入。

請注意，函式的選擇與模組 `math` 的類似，但不完全相同。擁有兩個模組的原因是有些用對數不感興趣，甚至根本就不知道它們是什麼。他們寧願讓 `math.sqrt(-1)` 引發異常，也不願它回傳數。另請注意，`cmath` 中所定義的函式始終都會回傳數，即使答案可以表示實數（在這種情況下，數的部零）。

關於分枝切割的釋：它們是沿著給定的不連續函式的曲。它們是許多變函數的必要特徵。假設你需要使用變函數進行計算，你將會了解分枝切割的概念。請參幾乎所有關於變函數的（不是太初級的）書籍以獲得發。對於如何正確地基於數值目的選擇分枝切割的相關訊息，以下容應該是一個很好的參考：

Kahan, W: Branch cuts for complex elementary functions; or, Much ado about nothing's sign bit. In Iserles, A., and Powell, M. (eds.), The state of the art in numerical analysis. Clarendon Press (1987) pp165--211.

## 9.4 decimal --- 十進位固定點和浮點運算

原始碼：Lib/decimal.py

The `decimal` module provides support for fast correctly rounded decimal floating-point arithmetic. It offers several advantages over the `float` datatype:

- Decimal “is based on a floating-point model which was designed with people in mind, and necessarily has a paramount guiding principle -- computers must provide an arithmetic that works in the same way as the arithmetic that people learn at school.” -- excerpt from the decimal arithmetic specification.
- Decimal numbers can be represented exactly. In contrast, numbers like 1.1 and 2.2 do not have exact representations in binary floating point. End users typically would not expect  $1.1 + 2.2$  to display as 3.3000000000000003 as it does with binary floating point.
- The exactness carries over into arithmetic. In decimal floating point,  $0.1 + 0.1 + 0.1 - 0.3$  is exactly equal to zero. In binary floating point, the result is  $5.5511151231257827e-017$ . While near to zero, the differences prevent reliable equality testing and differences can accumulate. For this reason, decimal is preferred in accounting applications which have strict equality invariants.
- The decimal module incorporates a notion of significant places so that  $1.30 + 1.20$  is 2.50. The trailing zero is kept to indicate significance. This is the customary presentation for monetary applications. For multiplication, the “schoolbook” approach uses all the figures in the multiplicands. For instance,  $1.3 * 1.2$  gives 1.56 while  $1.30 * 1.20$  gives 1.5600.
- Unlike hardware based binary floating point, the decimal module has a user alterable precision (defaulting to 28 places) which can be as large as needed for a given problem:

```
>>> from decimal import *
>>> getcontext().prec = 6
>>> Decimal(1) / Decimal(7)
Decimal('0.142857')
>>> getcontext().prec = 28
>>> Decimal(1) / Decimal(7)
Decimal('0.1428571428571428571428571428571429')
```

- Both binary and decimal floating point are implemented in terms of published standards. While the built-in float type exposes only a modest portion of its capabilities, the decimal module exposes all required parts of the standard. When needed, the programmer has full control over rounding and signal handling. This includes an option to enforce exact arithmetic by using exceptions to block any inexact operations.
- The decimal module was designed to support “without prejudice, both exact unrounded decimal arithmetic (sometimes called fixed-point arithmetic) and rounded floating-point arithmetic.” -- excerpt from the decimal arithmetic specification.

The module design is centered around three concepts: the decimal number, the context for arithmetic, and signals.

A decimal number is immutable. It has a sign, coefficient digits, and an exponent. To preserve significance, the coefficient digits do not truncate trailing zeros. Decimals also include special values such as `Infinity`, `-Infinity`, and `NaN`. The standard also differentiates `-0` from `+0`.

The context for arithmetic is an environment specifying precision, rounding rules, limits on exponents, flags indicating the results of operations, and trap enablers which determine whether signals are treated as exceptions. Rounding options include `ROUND_CEILING`, `ROUND_DOWN`, `ROUND_FLOOR`, `ROUND_HALF_DOWN`, `ROUND_HALF_EVEN`, `ROUND_HALF_UP`, `ROUND_UP`, and `ROUND_05UP`.

Signals are groups of exceptional conditions arising during the course of computation. Depending on the needs of the application, signals may be ignored, considered as informational, or treated as exceptions. The signals in the decimal module are: `Clamped`, `InvalidOperation`, `DivisionByZero`, `Inexact`, `Rounded`, `Subnormal`, `Overflow`, `Underflow` and `FloatOperation`.

For each signal there is a flag and a trap enabler. When a signal is encountered, its flag is set to one, then, if the trap enabler is set to one, an exception is raised. Flags are sticky, so the user needs to reset them before monitoring a calculation.

### 9.4.1 Quick-start Tutorial

The usual start to using decimals is importing the module, viewing the current context with `getcontext()` and, if necessary, setting new values for precision, rounding, or enabled traps:

```
>>> from decimal import *
>>> getcontext()
Context(prec=28, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
        capitals=1, clamp=0, flags=[], traps=[Overflow, DivisionByZero,
        InvalidOperation])

>>> getcontext().prec = 7          # Set a new precision
```

Decimal instances can be constructed from integers, strings, floats, or tuples. Construction from an integer or a float performs an exact conversion of the value of that integer or float. Decimal numbers include special values such as NaN which stands for "Not a number", positive and negative Infinity, and -0:

```
>>> getcontext().prec = 28
>>> Decimal(10)
Decimal('10')
>>> Decimal('3.14')
Decimal('3.14')
>>> Decimal(3.14)
Decimal('3.140000000000000124344978758017532527446746826171875')
>>> Decimal((0, (3, 1, 4), -2))
Decimal('3.14')
>>> Decimal(str(2.0 ** 0.5))
Decimal('1.4142135623730951')
>>> Decimal(2) ** Decimal('0.5')
Decimal('1.414213562373095048801688724')
>>> Decimal('NaN')
Decimal('NaN')
>>> Decimal('-Infinity')
Decimal('-Infinity')
```

If the `FloatOperation` signal is trapped, accidental mixing of decimals and floats in constructors or ordering comparisons raises an exception:

```
>>> c = getcontext()
>>> c.traps[FloatOperation] = True
>>> Decimal(3.14)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') < 3.7
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.FloatOperation: [<class 'decimal.FloatOperation'>]
>>> Decimal('3.5') == 3.5
True
```

在 3.3 版被加入。

The significance of a new Decimal is determined solely by the number of digits input. Context precision and rounding only come into play during arithmetic operations.

```
>>> getcontext().prec = 6
>>> Decimal('3.0')
Decimal('3.0')
>>> Decimal('3.1415926535')
Decimal('3.1415926535')
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85987')
```

(繼續下一頁)

(繼續上一頁)

```
>>> getcontext().rounding = ROUND_UP
>>> Decimal('3.1415926535') + Decimal('2.7182818285')
Decimal('5.85988')
```

If the internal limits of the C version are exceeded, constructing a decimal raises *InvalidOperation*:

```
>>> Decimal("1e999999999999999999")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.InvalidOperation: [<class 'decimal.InvalidOperation'>]
```

在 3.3 版的變更.

Decimals interact well with much of the rest of Python. Here is a small decimal floating-point flying circus:

```
>>> data = list(map(Decimal, '1.34 1.87 3.45 2.35 1.00 0.03 9.25'.split()))
>>> max(data)
Decimal('9.25')
>>> min(data)
Decimal('0.03')
>>> sorted(data)
[Decimal('0.03'), Decimal('1.00'), Decimal('1.34'), Decimal('1.87'),
 Decimal('2.35'), Decimal('3.45'), Decimal('9.25')]
>>> sum(data)
Decimal('19.29')
>>> a,b,c = data[:3]
>>> str(a)
'1.34'
>>> float(a)
1.34
>>> round(a, 1)
Decimal('1.3')
>>> int(a)
1
>>> a * 5
Decimal('6.70')
>>> a * b
Decimal('2.5058')
>>> c % a
Decimal('0.77')
```

And some mathematical functions are also available to Decimal:

```
>>> getcontext().prec = 28
>>> Decimal(2).sqrt()
Decimal('1.414213562373095048801688724')
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal('10').ln()
Decimal('2.302585092994045684017991455')
>>> Decimal('10').log10()
Decimal('1')
```

The *quantize()* method rounds a number to a fixed exponent. This method is useful for monetary applications that often round results to a fixed number of places:

```
>>> Decimal('7.325').quantize(Decimal('.01'), rounding=ROUND_DOWN)
Decimal('7.32')
>>> Decimal('7.325').quantize(Decimal('1.'), rounding=ROUND_UP)
Decimal('8')
```

As shown above, the *getcontext()* function accesses the current context and allows the settings to be changed.

This approach meets the needs of most applications.

For more advanced work, it may be useful to create alternate contexts using the `Context()` constructor. To make an alternate active, use the `setcontext()` function.

In accordance with the standard, the `decimal` module provides two ready to use standard contexts, `BasicContext` and `ExtendedContext`. The former is especially useful for debugging because many of the traps are enabled:

```
>>> myothercontext = Context(prec=60, rounding=ROUND_HALF_DOWN)
>>> setcontext(myothercontext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857142857142857142857')

>>> ExtendedContext
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
       capitals=1, clamp=0, flags=[], traps=[])
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(7)
Decimal('0.142857143')
>>> Decimal(42) / Decimal(0)
Decimal('Infinity')

>>> setcontext(BasicContext)
>>> Decimal(42) / Decimal(0)
Traceback (most recent call last):
  File "<pysHELL#143>", line 1, in -toplevel-
    Decimal(42) / Decimal(0)
DivisionByZero: x / 0
```

Contexts also have signal flags for monitoring exceptional conditions encountered during computations. The flags remain set until explicitly cleared, so it is best to clear the flags before each set of monitored computations by using the `clear_flags()` method.

```
>>> setcontext(ExtendedContext)
>>> getcontext().clear_flags()
>>> Decimal(355) / Decimal(113)
Decimal('3.14159292')
>>> getcontext()
Context(prec=9, rounding=ROUND_HALF_EVEN, Emin=-999999, Emax=999999,
       capitals=1, clamp=0, flags=[Inexact, Rounded], traps=[])
```

The `flags` entry shows that the rational approximation to pi was rounded (digits beyond the context precision were thrown away) and that the result is inexact (some of the discarded digits were non-zero).

Individual traps are set using the dictionary in the `traps` attribute of a context:

```
>>> setcontext(ExtendedContext)
>>> Decimal(1) / Decimal(0)
Decimal('Infinity')
>>> getcontext().traps[DivisionByZero] = 1
>>> Decimal(1) / Decimal(0)
Traceback (most recent call last):
  File "<pysHELL#112>", line 1, in -toplevel-
    Decimal(1) / Decimal(0)
DivisionByZero: x / 0
```

Most programs adjust the current context only once, at the beginning of the program. And, in many applications, data is converted to `Decimal` with a single cast inside a loop. With context set and decimals created, the bulk of the program manipulates the data no differently than with other Python numeric types.

## 9.4.2 Decimal objects

**class** `decimal.Decimal` (*value*=0', *context*=None)

Construct a new *Decimal* object based from *value*.

*value* can be an integer, string, tuple, *float*, or another *Decimal* object. If no *value* is given, returns `Decimal('0')`. If *value* is a string, it should conform to the decimal numeric string syntax after leading and trailing whitespace characters, as well as underscores throughout, are removed:

```
sign          ::= '+' | '-'
digit         ::= '0' | '1' | '2' | '3' | '4' | '5' | '6' | '7' | '8' | '9'
indicator     ::= 'e' | 'E'
digits        ::= digit [digit]...
decimal-part  ::= digits '.' [digits] | ['.' ] digits
exponent-part ::= indicator [sign] digits
infinity      ::= 'Infinity' | 'Inf'
nan           ::= 'NaN' [digits] | 'sNaN' [digits]
numeric-value ::= decimal-part [exponent-part] | infinity
numeric-string ::= [sign] numeric-value | [sign] nan
```

Other Unicode decimal digits are also permitted where *digit* appears above. These include decimal digits from various other alphabets (for example, Arabic-Indic and Devanāgarī digits) along with the fullwidth digits `'\uff10'` through `'\uff19'`.

If *value* is a *tuple*, it should have three components, a sign (0 for positive or 1 for negative), a *tuple* of digits, and an integer exponent. For example, `Decimal((0, (1, 4, 1, 4), -3))` returns `Decimal('1.414')`.

If *value* is a *float*, the binary floating-point value is losslessly converted to its exact decimal equivalent. This conversion can often require 53 or more digits of precision. For example, `Decimal(float('1.1'))` converts to `Decimal('1.1000000000000000088817841970012523233890533447265625')`.

The *context* precision does not affect how many digits are stored. That is determined exclusively by the number of digits in *value*. For example, `Decimal('3.00000')` records all five zeros even if the context precision is only three.

The purpose of the *context* argument is determining what to do if *value* is a malformed string. If the context traps *InvalidOperation*, an exception is raised; otherwise, the constructor returns a new *Decimal* with the value of NaN.

Once constructed, *Decimal* objects are immutable.

在 3.2 版的變更: The argument to the constructor is now permitted to be a *float* instance.

在 3.3 版的變更: *float* arguments raise an exception if the *FloatOperation* trap is set. By default the trap is off.

在 3.6 版的變更: Underscores are allowed for grouping, as with integral and floating-point literals in code.

Decimal floating-point objects share many properties with the other built-in numeric types such as *float* and *int*. All of the usual math operations and special methods apply. Likewise, decimal objects can be copied, pickled, printed, used as dictionary keys, used as set elements, compared, sorted, and coerced to another type (such as *float* or *int*).

There are some small differences between arithmetic on *Decimal* objects and arithmetic on integers and floats. When the remainder operator `%` is applied to *Decimal* objects, the sign of the result is the sign of the *dividend* rather than the sign of the divisor:

```
>>> (-7) % 4
1
>>> Decimal(-7) % Decimal(4)
Decimal('-3')
```

The integer division operator `//` behaves analogously, returning the integer part of the true quotient (truncating towards zero) rather than its floor, so as to preserve the usual identity  $x == (x // y) * y + x \% y$ :

```
>>> -7 // 4
-2
>>> Decimal(-7) // Decimal(4)
Decimal('-1')
```

The `%` and `//` operators implement the `remainder` and `divide-integer` operations (respectively) as described in the specification.

Decimal objects cannot generally be combined with floats or instances of `fractions.Fraction` in arithmetic operations: an attempt to add a `Decimal` to a `float`, for example, will raise a `TypeError`. However, it is possible to use Python's comparison operators to compare a `Decimal` instance `x` with another number `y`. This avoids confusing results when doing equality comparisons between numbers of different types.

在 3.2 版的變更: Mixed-type comparisons between `Decimal` instances and other numeric types are now fully supported.

In addition to the standard numeric properties, decimal floating-point objects also have a number of specialized methods:

#### `adjusted()`

Return the adjusted exponent after shifting out the coefficient's rightmost digits until only the lead digit remains: `Decimal('321e+5').adjusted()` returns seven. Used for determining the position of the most significant digit with respect to the decimal point.

#### `as_integer_ratio()`

Return a pair `(n, d)` of integers that represent the given `Decimal` instance as a fraction, in lowest terms and with a positive denominator:

```
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```

The conversion is exact. Raise `OverflowError` on infinities and `ValueError` on NaNs.

在 3.6 版被加入.

#### `as_tuple()`

Return a *named tuple* representation of the number: `DecimalTuple(sign, digits, exponent)`.

#### `canonical()`

Return the canonical encoding of the argument. Currently, the encoding of a `Decimal` instance is always canonical, so this operation returns its argument unchanged.

#### `compare(other, context=None)`

Compare the values of two `Decimal` instances. `compare()` returns a `Decimal` instance, and if either operand is a NaN then the result is a NaN:

```
a or b is a NaN ==> Decimal('NaN')
a < b           ==> Decimal('-1')
a == b         ==> Decimal('0')
a > b          ==> Decimal('1')
```

#### `compare_signal(other, context=None)`

This operation is identical to the `compare()` method, except that all NaNs signal. That is, if neither operand is a signaling NaN then any quiet NaN operand is treated as though it were a signaling NaN.

#### `compare_total(other, context=None)`

Compare two operands using their abstract representation rather than their numerical value. Similar to the `compare()` method, but the result gives a total ordering on `Decimal` instances. Two `Decimal` instances with the same numeric value but different representations compare unequal in this ordering:

```
>>> Decimal('12.0').compare_total(Decimal('12'))
Decimal('-1')
```

Quiet and signaling NaNs are also included in the total ordering. The result of this function is `Decimal('0')` if both operands have the same representation, `Decimal('-1')` if the first operand is lower in the total order than the second, and `Decimal('1')` if the first operand is higher in the total order than the second operand. See the specification for details of the total order.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

**compare\_total\_mag**(*other*, *context=None*)

Compare two operands using their abstract representation rather than their value as in `compare_total()`, but ignoring the sign of each operand. `x.compare_total_mag(y)` is equivalent to `x.copy_abs().compare_total(y.copy_abs())`.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

**conjugate**()

Just returns self, this method is only to comply with the Decimal Specification.

**copy\_abs**()

Return the absolute value of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

**copy\_negate**()

Return the negation of the argument. This operation is unaffected by the context and is quiet: no flags are changed and no rounding is performed.

**copy\_sign**(*other*, *context=None*)

Return a copy of the first operand with the sign set to be the same as the sign of the second operand. For example:

```
>>> Decimal('2.3').copy_sign(Decimal('-1.5'))
Decimal('-2.3')
```

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

**exp**(*context=None*)

Return the value of the (natural) exponential function  $e^{**x}$  at the given number. The result is correctly rounded using the `ROUND_HALF_EVEN` rounding mode.

```
>>> Decimal(1).exp()
Decimal('2.718281828459045235360287471')
>>> Decimal(321).exp()
Decimal('2.561702493119680037517373933E+139')
```

**classmethod from\_float**(*f*)

Alternative constructor that only accepts instances of `float` or `int`.

Note `Decimal.from_float(0.1)` is not the same as `Decimal('0.1')`. Since 0.1 is not exactly representable in binary floating point, the value is stored as the nearest representable value which is  $0 \times 1.9999999999999999 \text{ap-4}$ . That equivalent value in decimal is 0.1000000000000000055511151231257827021181583404541015625.

From Python 3.2 onwards, a `Decimal` instance can also be constructed directly from a `float`.

```

>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')
>>> Decimal.from_float(float('nan'))
Decimal('NaN')
>>> Decimal.from_float(float('inf'))
Decimal('Infinity')
>>> Decimal.from_float(float('-inf'))
Decimal('-Infinity')

```

在 3.1 版被加入。

**fma** (*other, third, context=None*)

Fused multiply-add. Return  $\text{self} * \text{other} + \text{third}$  with no rounding of the intermediate product  $\text{self} * \text{other}$ .

```

>>> Decimal(2).fma(3, 5)
Decimal('11')

```

**is\_canonical** ()

Return *True* if the argument is canonical and *False* otherwise. Currently, a *Decimal* instance is always canonical, so this operation always returns *True*.

**is\_finite** ()

Return *True* if the argument is a finite number, and *False* if the argument is an infinity or a NaN.

**is\_infinite** ()

Return *True* if the argument is either positive or negative infinity and *False* otherwise.

**is\_nan** ()

Return *True* if the argument is a (quiet or signaling) NaN and *False* otherwise.

**is\_normal** (*context=None*)

Return *True* if the argument is a *normal* finite number. Return *False* if the argument is zero, subnormal, infinite or a NaN.

**is\_qnan** ()

Return *True* if the argument is a quiet NaN, and *False* otherwise.

**is\_signed** ()

Return *True* if the argument has a negative sign and *False* otherwise. Note that zeros and NaNs can both carry signs.

**is\_snan** ()

Return *True* if the argument is a signaling NaN and *False* otherwise.

**is\_subnormal** (*context=None*)

Return *True* if the argument is subnormal, and *False* otherwise.

**is\_zero** ()

Return *True* if the argument is a (positive or negative) zero and *False* otherwise.

**ln** (*context=None*)

Return the natural (base *e*) logarithm of the operand. The result is correctly rounded using the *ROUND\_HALF\_EVEN* rounding mode.

**log10** (*context=None*)

Return the base ten logarithm of the operand. The result is correctly rounded using the *ROUND\_HALF\_EVEN* rounding mode.

**logb** (*context=None*)

For a nonzero number, return the adjusted exponent of its operand as a *Decimal* instance. If the operand is a zero then *Decimal('-Infinity')* is returned and the *DivisionByZero* flag is raised. If the operand is an infinity then *Decimal('Infinity')* is returned.

**logical\_and** (*other*, *context=None*)

*logical\_and()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `and` of the two operands.

**logical\_invert** (*context=None*)

*logical\_invert()* is a logical operation. The result is the digit-wise inversion of the operand.

**logical\_or** (*other*, *context=None*)

*logical\_or()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise `or` of the two operands.

**logical\_xor** (*other*, *context=None*)

*logical\_xor()* is a logical operation which takes two *logical operands* (see *Logical operands*). The result is the digit-wise exclusive or of the two operands.

**max** (*other*, *context=None*)

Like `max(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

**max\_mag** (*other*, *context=None*)

Similar to the *max()* method, but the comparison is done using the absolute values of the operands.

**min** (*other*, *context=None*)

Like `min(self, other)` except that the context rounding rule is applied before returning and that NaN values are either signaled or ignored (depending on the context and whether they are signaling or quiet).

**min\_mag** (*other*, *context=None*)

Similar to the *min()* method, but the comparison is done using the absolute values of the operands.

**next\_minus** (*context=None*)

Return the largest number representable in the given context (or in the current thread's context if no context is given) that is smaller than the given operand.

**next\_plus** (*context=None*)

Return the smallest number representable in the given context (or in the current thread's context if no context is given) that is larger than the given operand.

**next\_toward** (*other*, *context=None*)

If the two operands are unequal, return the number closest to the first operand in the direction of the second operand. If both operands are numerically equal, return a copy of the first operand with the sign set to be the same as the sign of the second operand.

**normalize** (*context=None*)

Used for producing canonical values of an equivalence class within either the current context or the specified context.

This has the same semantics as the unary plus operation, except that if the final result is finite it is reduced to its simplest form, with all trailing zeros removed and its sign preserved. That is, while the coefficient is non-zero and a multiple of ten the coefficient is divided by ten and the exponent is incremented by 1. Otherwise (the coefficient is zero) the exponent is set to 0. In all cases the sign is unchanged.

For example, `Decimal('32.100')` and `Decimal('0.321000e+2')` both normalize to the equivalent value `Decimal('32.1')`.

Note that rounding is applied *before* reducing to simplest form.

In the latest versions of the specification, this operation is also known as `reduce`.

**number\_class** (*context=None*)

Return a string describing the *class* of the operand. The returned value is one of the following ten strings.

- `"-Infinity"`, indicating that the operand is negative infinity.
- `"-Normal"`, indicating that the operand is a negative normal number.

- "-Subnormal", indicating that the operand is negative and subnormal.
- "-Zero", indicating that the operand is a negative zero.
- "+Zero", indicating that the operand is a positive zero.
- "+Subnormal", indicating that the operand is positive and subnormal.
- "+Normal", indicating that the operand is a positive normal number.
- "+Infinity", indicating that the operand is positive infinity.
- "NaN", indicating that the operand is a quiet NaN (Not a Number).
- "sNaN", indicating that the operand is a signaling NaN.

**quantize** (*exp*, *rounding=None*, *context=None*)

Return a value equal to the first operand after rounding and having the exponent of the second operand.

```
>>> Decimal('1.41421356').quantize(Decimal('1.000'))
Decimal('1.414')
```

Unlike other operations, if the length of the coefficient after the quantize operation would be greater than precision, then an *InvalidOperation* is signaled. This guarantees that, unless there is an error condition, the quantized exponent is always equal to that of the right-hand operand.

Also unlike other operations, quantize never signals Underflow, even if the result is subnormal and inexact.

If the exponent of the second operand is larger than that of the first then rounding may be necessary. In this case, the rounding mode is determined by the *rounding* argument if given, else by the given *context* argument; if neither argument is given the rounding mode of the current thread's context is used.

An error is returned whenever the resulting exponent is greater than *E<sub>max</sub>* or less than *E<sub>tiny</sub>*().

**radix** ()

Return `Decimal(10)`, the radix (base) in which the *Decimal* class does all its arithmetic. Included for compatibility with the specification.

**remainder\_near** (*other*, *context=None*)

Return the remainder from dividing *self* by *other*. This differs from `self % other` in that the sign of the remainder is chosen so as to minimize its absolute value. More precisely, the return value is `self - n * other` where *n* is the integer nearest to the exact value of `self / other`, and if two integers are equally near then the even one is chosen.

If the result is zero then its sign will be the sign of *self*.

```
>>> Decimal(18).remainder_near(Decimal(10))
Decimal('-2')
>>> Decimal(25).remainder_near(Decimal(10))
Decimal('5')
>>> Decimal(35).remainder_near(Decimal(10))
Decimal('-5')
```

**rotate** (*other*, *context=None*)

Return the result of rotating the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to rotate. If the second operand is positive then rotation is to the left; otherwise rotation is to the right. The coefficient of the first operand is padded on the left with zeros to length precision if necessary. The sign and exponent of the first operand are unchanged.

**same\_quantum** (*other*, *context=None*)

Test whether *self* and *other* have the same exponent or whether both are NaN.

This operation is unaffected by context and is quiet: no flags are changed and no rounding is performed. As an exception, the C version may raise `InvalidOperation` if the second operand cannot be converted exactly.

**scaleb** (*other*, *context=None*)

Return the first operand with exponent adjusted by the second. Equivalently, return the first operand multiplied by  $10^{**other}$ . The second operand must be an integer.

**shift** (*other*, *context=None*)

Return the result of shifting the digits of the first operand by an amount specified by the second operand. The second operand must be an integer in the range `-precision` through `precision`. The absolute value of the second operand gives the number of places to shift. If the second operand is positive then the shift is to the left; otherwise the shift is to the right. Digits shifted into the coefficient are zeros. The sign and exponent of the first operand are unchanged.

**sqrt** (*context=None*)

Return the square root of the argument to full precision.

**to\_eng\_string** (*context=None*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

For example, this converts `Decimal('123E+1')` to `Decimal('1.23E+3')`.

**to\_integral** (*rounding=None*, *context=None*)

Identical to the `to_integral_value()` method. The `to_integral` name has been kept for compatibility with older versions.

**to\_integral\_exact** (*rounding=None*, *context=None*)

Round to the nearest integer, signaling *Inexact* or *Rounded* as appropriate if rounding occurs. The rounding mode is determined by the `rounding` parameter if given, else by the given `context`. If neither parameter is given then the rounding mode of the current context is used.

**to\_integral\_value** (*rounding=None*, *context=None*)

Round to the nearest integer without signaling *Inexact* or *Rounded*. If given, applies *rounding*; otherwise, uses the rounding method in either the supplied *context* or the current context.

Decimal numbers can be rounded using the `round()` function:

**round(number)**

**round(number, ndigits)**

If *ndigits* is not given or `None`, returns the nearest *int* to *number*, rounding ties to even, and ignoring the rounding mode of the *Decimal* context. Raises *OverflowError* if *number* is an infinity or *ValueError* if it is a (quiet or signaling) NaN.

If *ndigits* is an *int*, the context's rounding mode is respected and a *Decimal* representing *number* rounded to the nearest multiple of `Decimal('1E-ndigits')` is returned; in this case, `round(number, ndigits)` is equivalent to `self.quantize(Decimal('1E-ndigits'))`. Returns `Decimal('NaN')` if *number* is a quiet NaN. Raises *InvalidOperation* if *number* is an infinity, a signaling NaN, or if the length of the coefficient after the quantize operation would be greater than the current context's precision. In other words, for the non-corner cases:

- if *ndigits* is positive, return *number* rounded to *ndigits* decimal places;
- if *ndigits* is zero, return *number* rounded to the nearest integer;
- if *ndigits* is negative, return *number* rounded to the nearest multiple of  $10^{**abs(ndigits)}$ .

For example:

```

>>> from decimal import Decimal, getcontext, ROUND_DOWN
>>> getcontext().rounding = ROUND_DOWN
>>> round(Decimal('3.75'))      # context rounding ignored
4
>>> round(Decimal('3.5'))      # round-ties-to-even
4
>>> round(Decimal('3.75'), 0)  # uses the context rounding
Decimal('3')
>>> round(Decimal('3.75'), 1)
Decimal('3.7')
>>> round(Decimal('3.75'), -1)
Decimal('0E+1')

```

## Logical operands

The `logical_and()`, `logical_invert()`, `logical_or()`, and `logical_xor()` methods expect their arguments to be *logical operands*. A *logical operand* is a `Decimal` instance whose exponent and sign are both zero, and whose digits are all either 0 or 1.

## 9.4.3 Context objects

Contexts are environments for arithmetic operations. They govern precision, set rules for rounding, determine which signals are treated as exceptions, and limit the range for exponents.

Each thread has its own current context which is accessed or changed using the `getcontext()` and `setcontext()` functions:

`decimal.getcontext()`

Return the current context for the active thread.

`decimal.setcontext(c)`

Set the current context for the active thread to `c`.

You can also use the `with` statement and the `localcontext()` function to temporarily change the active context.

`decimal.localcontext(ctx=None, **kwargs)`

Return a context manager that will set the current context for the active thread to a copy of `ctx` on entry to the `with`-statement and restore the previous context when exiting the `with`-statement. If no context is specified, a copy of the current context is used. The `kwargs` argument is used to set the attributes of the new context.

For example, the following code sets the current decimal precision to 42 places, performs a calculation, and then automatically restores the previous context:

```

from decimal import localcontext

with localcontext() as ctx:
    ctx.prec = 42  # Perform a high precision calculation
    s = calculate_something()
s = +s  # Round the final result back to the default precision

```

Using keyword arguments, the code would be the following:

```

from decimal import localcontext

with localcontext(prec=42) as ctx:
    s = calculate_something()
s = +s

```

Raises `TypeError` if `kwargs` supplies an attribute that `Context` doesn't support. Raises either `TypeError` or `ValueError` if `kwargs` supplies an invalid value for an attribute.

在 3.11 版的變更: `localcontext()` now supports setting context attributes through the use of keyword arguments.

New contexts can also be created using the `Context` constructor described below. In addition, the module provides three pre-made contexts:

#### `decimal.BasicContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_UP`. All flags are cleared. All traps are enabled (treated as exceptions) except `Inexact`, `Rounded`, and `Subnormal`.

Because many of the traps are enabled, this context is useful for debugging.

#### `decimal.ExtendedContext`

This is a standard context defined by the General Decimal Arithmetic Specification. Precision is set to nine. Rounding is set to `ROUND_HALF_EVEN`. All flags are cleared. No traps are enabled (so that exceptions are not raised during computations).

Because the traps are disabled, this context is useful for applications that prefer to have result value of `NaN` or `Infinity` instead of raising exceptions. This allows an application to complete a run in the presence of conditions that would otherwise halt the program.

#### `decimal.DefaultContext`

This context is used by the `Context` constructor as a prototype for new contexts. Changing a field (such as precision) has the effect of changing the default for new contexts created by the `Context` constructor.

This context is most useful in multi-threaded environments. Changing one of the fields before threads are started has the effect of setting system-wide defaults. Changing the fields after threads have started is not recommended as it would require thread synchronization to prevent race conditions.

In single threaded environments, it is preferable to not use this context at all. Instead, simply create contexts explicitly as described below.

The default values are `Context.prec=28`, `Context.rounding=ROUND_HALF_EVEN`, and enabled traps for `Overflow`, `InvalidOperation`, and `DivisionByZero`.

In addition to the three supplied contexts, new contexts can be created with the `Context` constructor.

```
class decimal.Context (prec=None, rounding=None, Emin=None, Emax=None, capitals=None, clamp=None,
                       flags=None, traps=None)
```

Creates a new context. If a field is not specified or is `None`, the default values are copied from the `DefaultContext`. If the `flags` field is not specified or is `None`, all flags are cleared.

`prec` is an integer in the range `[1, MAX_PREC]` that sets the precision for arithmetic operations in the context.

The `rounding` option is one of the constants listed in the section [Rounding Modes](#).

The `traps` and `flags` fields list any signals to be set. Generally, new contexts should only set traps and leave the flags clear.

The `Emin` and `Emax` fields are integers specifying the outer limits allowable for exponents. `Emin` must be in the range `[MIN_EMIN, 0]`, `Emax` in the range `[0, MAX_EMAX]`.

The `capitals` field is either 0 or 1 (the default). If set to 1, exponents are printed with a capital E; otherwise, a lowercase e is used: `Decimal('6.02e+23')`.

The `clamp` field is either 0 (the default) or 1. If set to 1, the exponent `e` of a `Decimal` instance representable in this context is strictly limited to the range `Emin - prec + 1 <= e <= Emax - prec + 1`. If `clamp` is 0 then a weaker condition holds: the adjusted exponent of the `Decimal` instance is at most `Emax`. When `clamp` is 1, a large normal number will, where possible, have its exponent reduced and a corresponding number of zeros added to its coefficient, in order to fit the exponent constraints; this preserves the value of the number but loses information about significant trailing zeros. For example:

```
>>> Context(prec=6, Emax=999, clamp=1).create_decimal('1.23e999')
Decimal('1.23000E+999')
```

A `clamp` value of 1 allows compatibility with the fixed-width decimal interchange formats specified in IEEE 754.

The `Context` class defines several general purpose methods as well as a large number of methods for doing arithmetic directly in a given context. In addition, for each of the `Decimal` methods described above (with the exception of the `adjusted()` and `as_tuple()` methods) there is a corresponding `Context` method. For example, for a `Context` instance `C` and `Decimal` instance `x`, `C.exp(x)` is equivalent to `x.exp(context=C)`. Each `Context` method accepts a Python integer (an instance of `int`) anywhere that a `Decimal` instance is accepted.

**clear\_flags()**

Resets all of the flags to 0.

**clear\_traps()**

Resets all of the traps to 0.

在 3.3 版被加入。

**copy()**

Return a duplicate of the context.

**copy\_decimal(num)**

Return a copy of the `Decimal` instance `num`.

**create\_decimal(num)**

Creates a new `Decimal` instance from `num` but using `self` as context. Unlike the `Decimal` constructor, the context precision, rounding method, flags, and traps are applied to the conversion.

This is useful because constants are often given to a greater precision than is needed by the application. Another benefit is that rounding immediately eliminates unintended effects from digits beyond the current precision. In the following example, using unrounded inputs means that adding zero to a sum can change the result:

```
>>> getcontext().prec = 3
>>> Decimal('3.4445') + Decimal('1.0023')
Decimal('4.45')
>>> Decimal('3.4445') + Decimal(0) + Decimal('1.0023')
Decimal('4.44')
```

This method implements the to-number operation of the IBM specification. If the argument is a string, no leading or trailing whitespace or underscores are permitted.

**create\_decimal\_from\_float(f)**

Creates a new `Decimal` instance from a float `f` but rounding using `self` as the context. Unlike the `Decimal.from_float()` class method, the context precision, rounding method, flags, and traps are applied to the conversion.

```
>>> context = Context(prec=5, rounding=ROUND_DOWN)
>>> context.create_decimal_from_float(math.pi)
Decimal('3.1415')
>>> context = Context(prec=5, traps=[Inexact])
>>> context.create_decimal_from_float(math.pi)
Traceback (most recent call last):
...
decimal.Inexact: None
```

在 3.1 版被加入。

**Etiny()**

Returns a value equal to  $E_{\min} - \text{prec} + 1$  which is the minimum exponent value for subnormal results. When underflow occurs, the exponent is set to `Etiny`.

**Etop()**

Returns a value equal to  $E_{\max} - \text{prec} + 1$ .

The usual approach to working with decimals is to create *Decimal* instances and then apply arithmetic operations which take place within the current context for the active thread. An alternative approach is to use context methods for calculating within a specific context. The methods are similar to those for the *Decimal* class and are only briefly recounted here.

**abs**(*x*)

Returns the absolute value of *x*.

**add**(*x*, *y*)

Return the sum of *x* and *y*.

**canonical**(*x*)

Returns the same Decimal object *x*.

**compare**(*x*, *y*)

Compares *x* and *y* numerically.

**compare\_signal**(*x*, *y*)

Compares the values of the two operands numerically.

**compare\_total**(*x*, *y*)

Compares two operands using their abstract representation.

**compare\_total\_mag**(*x*, *y*)

Compares two operands using their abstract representation, ignoring sign.

**copy\_abs**(*x*)

Returns a copy of *x* with the sign set to 0.

**copy\_negate**(*x*)

Returns a copy of *x* with the sign inverted.

**copy\_sign**(*x*, *y*)

Copies the sign from *y* to *x*.

**divide**(*x*, *y*)

Return *x* divided by *y*.

**divide\_int**(*x*, *y*)

Return *x* divided by *y*, truncated to an integer.

**divmod**(*x*, *y*)

Divides two numbers and returns the integer part of the result.

**exp**(*x*)

Returns  $e^{**} x$ .

**fma**(*x*, *y*, *z*)

Returns *x* multiplied by *y*, plus *z*.

**is\_canonical**(*x*)

Returns `True` if *x* is canonical; otherwise returns `False`.

**is\_finite**(*x*)

Returns `True` if *x* is finite; otherwise returns `False`.

**is\_infinite**(*x*)

Returns `True` if *x* is infinite; otherwise returns `False`.

**is\_nan**(*x*)

Returns `True` if *x* is a qNaN or sNaN; otherwise returns `False`.

**is\_normal** (*x*)  
Returns `True` if *x* is a normal number; otherwise returns `False`.

**is\_qnan** (*x*)  
Returns `True` if *x* is a quiet NaN; otherwise returns `False`.

**is\_signed** (*x*)  
Returns `True` if *x* is negative; otherwise returns `False`.

**is\_snan** (*x*)  
Returns `True` if *x* is a signaling NaN; otherwise returns `False`.

**is\_subnormal** (*x*)  
Returns `True` if *x* is subnormal; otherwise returns `False`.

**is\_zero** (*x*)  
Returns `True` if *x* is a zero; otherwise returns `False`.

**ln** (*x*)  
Returns the natural (base e) logarithm of *x*.

**log10** (*x*)  
Returns the base 10 logarithm of *x*.

**logb** (*x*)  
Returns the exponent of the magnitude of the operand's MSD.

**logical\_and** (*x*, *y*)  
Applies the logical operation *and* between each operand's digits.

**logical\_invert** (*x*)  
Invert all the digits in *x*.

**logical\_or** (*x*, *y*)  
Applies the logical operation *or* between each operand's digits.

**logical\_xor** (*x*, *y*)  
Applies the logical operation *xor* between each operand's digits.

**max** (*x*, *y*)  
Compares two values numerically and returns the maximum.

**max\_mag** (*x*, *y*)  
Compares the values numerically with their sign ignored.

**min** (*x*, *y*)  
Compares two values numerically and returns the minimum.

**min\_mag** (*x*, *y*)  
Compares the values numerically with their sign ignored.

**minus** (*x*)  
Minus corresponds to the unary prefix minus operator in Python.

**multiply** (*x*, *y*)  
Return the product of *x* and *y*.

**next\_minus** (*x*)  
Returns the largest representable number smaller than *x*.

**next\_plus** (*x*)  
Returns the smallest representable number larger than *x*.

**next\_toward** (*x*, *y*)

Returns the number closest to *x*, in direction towards *y*.

**normalize** (*x*)

Reduces *x* to its simplest form.

**number\_class** (*x*)

Returns an indication of the class of *x*.

**plus** (*x*)

Plus corresponds to the unary prefix plus operator in Python. This operation applies the context precision and rounding, so it is *not* an identity operation.

**power** (*x*, *y*, *modulo=None*)

Return *x* to the power of *y*, reduced modulo *modulo* if given.

With two arguments, compute  $x^{**}y$ . If *x* is negative then *y* must be integral. The result will be inexact unless *y* is integral and the result is finite and can be expressed exactly in 'precision' digits. The rounding mode of the context is used. Results are always correctly rounded in the Python version.

`Decimal(0) ** Decimal(0)` results in `InvalidOperation`, and if `InvalidOperation` is not trapped, then results in `Decimal('NaN')`.

在 3.3 版的變更: The C module computes `power()` in terms of the correctly rounded `exp()` and `ln()` functions. The result is well-defined but only "almost always correctly rounded".

With three arguments, compute  $(x^{**}y) \% modulo$ . For the three argument form, the following restrictions on the arguments hold:

- all three arguments must be integral
- *y* must be nonnegative
- at least one of *x* or *y* must be nonzero
- *modulo* must be nonzero and have at most 'precision' digits

The value resulting from `Context.power(x, y, modulo)` is equal to the value that would be obtained by computing  $(x^{**}y) \% modulo$  with unbounded precision, but is computed more efficiently. The exponent of the result is zero, regardless of the exponents of *x*, *y* and *modulo*. The result is always exact.

**quantize** (*x*, *y*)

Returns a value equal to *x* (rounded), having the exponent of *y*.

**radix** ()

Just returns 10, as this is Decimal, :)

**remainder** (*x*, *y*)

Returns the remainder from integer division.

The sign of the result, if non-zero, is the same as that of the original dividend.

**remainder\_near** (*x*, *y*)

Returns  $x - y * n$ , where *n* is the integer nearest the exact value of  $x / y$  (if the result is 0 then its sign will be the sign of *x*).

**rotate** (*x*, *y*)

Returns a rotated copy of *x*, *y* times.

**same\_quantum** (*x*, *y*)

Returns `True` if the two operands have the same exponent.

**scaleb** (*x*, *y*)

Returns the first operand after adding the second value its exp.

**shift** (*x*, *y*)Returns a shifted copy of *x*, *y* times.**sqrt** (*x*)

Square root of a non-negative number to context precision.

**subtract** (*x*, *y*)Return the difference between *x* and *y*.**to\_eng\_string** (*x*)

Convert to a string, using engineering notation if an exponent is needed.

Engineering notation has an exponent which is a multiple of 3. This can leave up to 3 digits to the left of the decimal place and may require the addition of either one or two trailing zeros.

**to\_integral\_exact** (*x*)

Rounds to an integer.

**to\_sci\_string** (*x*)

Converts a number to a string using scientific notation.

### 9.4.4 常數

The constants in this section are only relevant for the C module. They are also included in the pure Python version for compatibility.

	32 位元	64 位元
<code>decimal.MAX_PREC</code>	425000000	999999999999999999
<code>decimal.MAX_EMAX</code>	425000000	999999999999999999
<code>decimal.MIN_EMIN</code>	-425000000	-999999999999999999
<code>decimal.MIN_ETINY</code>	-849999999	-1999999999999999997

`decimal.HAVE_THREADS`The value is `True`. Deprecated, because Python now always has threads.

在 3.9 版之後被 用。

`decimal.HAVE_CONTEXTVAR`

The default value is `True`. If Python is configured using the `--without-decimal-contextvar` option, the C version uses a thread-local rather than a coroutine-local context and the value is `False`. This is slightly faster in some nested context scenarios.

在 3.8.3 版被加入。

### 9.4.5 Rounding modes

`decimal.ROUND_CEILING`

Round towards Infinity.

`decimal.ROUND_DOWN`

Round towards zero.

`decimal.ROUND_FLOOR`

Round towards  $-\infty$ .

`decimal.ROUND_HALF_DOWN`

Round to nearest with ties going towards zero.

`decimal.ROUND_HALF_EVEN`

Round to nearest with ties going to nearest even integer.

`decimal.ROUND_HALF_UP`

Round to nearest with ties going away from zero.

`decimal.ROUND_UP`

Round away from zero.

`decimal.ROUND_05UP`

Round away from zero if last digit after rounding towards zero would have been 0 or 5; otherwise round towards zero.

## 9.4.6 Signals

Signals represent conditions that arise during computation. Each corresponds to one context flag and one context trap enabler.

The context flag is set whenever the condition is encountered. After the computation, flags may be checked for informational purposes (for instance, to determine whether a computation was exact). After checking the flags, be sure to clear all flags before starting the next computation.

If the context's trap enabler is set for the signal, then the condition causes a Python exception to be raised. For example, if the `DivisionByZero` trap is set, then a `DivisionByZero` exception is raised upon encountering the condition.

**class** `decimal.Clamped`

Altered an exponent to fit representation constraints.

Typically, clamping occurs when an exponent falls outside the context's `Emin` and `Emax` limits. If possible, the exponent is reduced to fit by adding zeros to the coefficient.

**class** `decimal.DecimalException`

Base class for other signals and a subclass of `ArithmeticError`.

**class** `decimal.DivisionByZero`

Signals the division of a non-infinite number by zero.

Can occur with division, modulo division, or when raising a number to a negative power. If this signal is not trapped, returns `Infinity` or `-Infinity` with the sign determined by the inputs to the calculation.

**class** `decimal.Inexact`

Indicates that rounding occurred and the result is not exact.

Signals when non-zero digits were discarded during rounding. The rounded result is returned. The signal flag or trap is used to detect when results are inexact.

**class** `decimal.InvalidOperation`

An invalid operation was performed.

Indicates that an operation was requested that does not make sense. If not trapped, returns `NaN`. Possible causes include:

```
Infinity - Infinity
0 * Infinity
Infinity / Infinity
x % 0
```

(繼續下一頁)

```

Infinity % x
sqrt(-x) and x > 0
0 ** 0
x ** (non-integer)
x ** Infinity

```

**class decimal.Overflow**

Numerical overflow.

Indicates the exponent is larger than `Context.Emax` after rounding has occurred. If not trapped, the result depends on the rounding mode, either pulling inward to the largest representable finite number or rounding outward to `Infinity`. In either case, *Inexact* and *Rounded* are also signaled.

**class decimal.Rounded**

Rounding occurred though possibly no information was lost.

Signaled whenever rounding discards digits; even if those digits are zero (such as rounding 5.00 to 5.0). If not trapped, returns the result unchanged. This signal is used to detect loss of significant digits.

**class decimal.Subnormal**

Exponent was lower than `Emin` prior to rounding.

Occurs when an operation result is subnormal (the exponent is too small). If not trapped, returns the result unchanged.

**class decimal.Underflow**

Numerical underflow with result rounded to zero.

Occurs when a subnormal result is pushed to zero by rounding. *Inexact* and *Subnormal* are also signaled.

**class decimal.FloatOperation**

Enable stricter semantics for mixing floats and Decimals.

If the signal is not trapped (default), mixing floats and Decimals is permitted in the *Decimal* constructor, *create\_decimal()* and all comparison operators. Both conversion and comparisons are exact. Any occurrence of a mixed operation is silently recorded by setting *FloatOperation* in the context flags. Explicit conversions with *from\_float()* or *create\_decimal\_from\_float()* do not set the flag.

Otherwise (the signal is trapped), only equality comparisons and explicit conversions are silent. All other mixed operations raise *FloatOperation*.

The following table summarizes the hierarchy of signals:

```

exceptions.ArithmeticError(exceptions.Exception)
  DecimalException
    Clamped
    DivisionByZero(DecimalException, exceptions.ZeroDivisionError)
    Inexact
      Overflow(Inexact, Rounded)
      Underflow(Inexact, Rounded, Subnormal)
    InvalidOperation
    Rounded
    Subnormal
    FloatOperation(DecimalException, exceptions.TypeError)

```

## 9.4.7 Floating-Point Notes

### Mitigating round-off error with increased precision

The use of decimal floating point eliminates decimal representation error (making it possible to represent 0.1 exactly); however, some operations can still incur round-off error when non-zero digits exceed the fixed precision.

The effects of round-off error can be amplified by the addition or subtraction of nearly offsetting quantities resulting in loss of significance. Knuth provides two instructive examples where rounded floating-point arithmetic with insufficient precision causes the breakdown of the associative and distributive properties of addition:

```
# Examples from Seminumerical Algorithms, Section 4.2.2.
>>> from decimal import Decimal, getcontext
>>> getcontext().prec = 8

>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('10')

>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.01')
>>> u * (v+w)
Decimal('0.0060000')
```

The `decimal` module makes it possible to restore the identities by expanding the precision sufficiently to avoid loss of significance:

```
>>> getcontext().prec = 20
>>> u, v, w = Decimal(11111113), Decimal(-11111111), Decimal('7.51111111')
>>> (u + v) + w
Decimal('9.51111111')
>>> u + (v + w)
Decimal('9.51111111')
>>>
>>> u, v, w = Decimal(20000), Decimal(-6), Decimal('6.0000003')
>>> (u*v) + (u*w)
Decimal('0.0060000')
>>> u * (v+w)
Decimal('0.0060000')
```

## 特殊值

The number system for the `decimal` module provides special values including `NaN`, `sNaN`, `-Infinity`, `Infinity`, and two zeros, `+0` and `-0`.

Infinities can be constructed directly with: `Decimal('Infinity')`. Also, they can arise from dividing by zero when the `DivisionByZero` signal is not trapped. Likewise, when the `Overflow` signal is not trapped, infinity can result from rounding beyond the limits of the largest representable number.

The infinities are signed (affine) and can be used in arithmetic operations where they get treated as very large, indeterminate numbers. For instance, adding a constant to infinity gives another infinite result.

Some operations are indeterminate and return `NaN`, or if the `InvalidOperation` signal is trapped, raise an exception. For example, `0/0` returns `NaN` which means "not a number". This variety of `NaN` is quiet and, once created, will flow through other computations always resulting in another `NaN`. This behavior can be useful for a series of computations that occasionally have missing inputs --- it allows the calculation to proceed while flagging specific results as invalid.

A variant is `sNaN` which signals rather than remaining quiet after every operation. This is a useful return value when an invalid result needs to interrupt a calculation for special handling.

The behavior of Python's comparison operators can be a little surprising where a `NaN` is involved. A test for equality where one of the operands is a quiet or signaling `NaN` always returns `False` (even when doing `Decimal('NaN')==Decimal('NaN')`), while a test for inequality always returns `True`. An attempt to compare two `Decimals` using any of the `<`, `<=`, `>` or `>=` operators will raise the `InvalidOperation` signal if either operand is a `NaN`, and return `False` if this signal is not trapped. Note that the General Decimal Arithmetic specification does not specify the behavior of direct comparisons; these rules for comparisons involving a `NaN` were taken from

the IEEE 854 standard (see Table 3 in section 5.7). To ensure strict standards-compliance, use the `compare()` and `compare_signal()` methods instead.

The signed zeros can result from calculations that underflow. They keep the sign that would have resulted if the calculation had been carried out to greater precision. Since their magnitude is zero, both positive and negative zeros are treated as equal and their sign is informational.

In addition to the two signed zeros which are distinct yet equal, there are various representations of zero with differing precisions yet equivalent in value. This takes a bit of getting used to. For an eye accustomed to normalized floating-point representations, it is not immediately obvious that the following calculation returns a value equal to zero:

```
>>> 1 / Decimal('Infinity')
Decimal('0E-1000026')
```

## 9.4.8 Working with threads

The `getcontext()` function accesses a different `Context` object for each thread. Having separate thread contexts means that threads may make changes (such as `getcontext().prec=10`) without interfering with other threads.

Likewise, the `setcontext()` function automatically assigns its target to the current thread.

If `setcontext()` has not been called before `getcontext()`, then `getcontext()` will automatically create a new context for use in the current thread.

The new context is copied from a prototype context called `DefaultContext`. To control the defaults so that each thread will use the same values throughout the application, directly modify the `DefaultContext` object. This should be done *before* any threads are started so that there won't be a race condition between threads calling `getcontext()`. For example:

```
# Set applicationwide defaults for all threads about to be launched
DefaultContext.prec = 12
DefaultContext.rounding = ROUND_DOWN
DefaultContext.traps = ExtendedContext.traps.copy()
DefaultContext.traps[InvalidOperation] = 1
setcontext(DefaultContext)

# Afterwards, the threads can be started
t1.start()
t2.start()
t3.start()
. . .
```

## 9.4.9 Recipes

Here are a few recipes that serve as utility functions and that demonstrate ways to work with the `Decimal` class:

```
def moneyfmt(value, places=2, curr='', sep=',', dp='.',
             pos='', neg='-', trailneg=''):
    """Convert Decimal to a money formatted string.

    places:  required number of places after the decimal point
    curr:    optional currency symbol before the sign (may be blank)
    sep:    optional grouping separator (comma, period, space, or blank)
    dp:     decimal point indicator (comma or period)
             only specify as blank when places is zero
    pos:    optional sign for positive numbers: '+', space or blank
    neg:    optional sign for negative numbers: '-', '(', space or blank
    trailneg: optional trailing minus indicator: '-', ')', space or blank

    >>> d = Decimal('-1234567.8901')
    >>> moneyfmt(d, curr='$')
    '-$1,234,567.89'
```

(繼續下一頁)

(繼續上一頁)

```

>>> moneyfmt(d, places=0, sep='.', dp='', neg='', trailneg='-')
'1.234.568-'
>>> moneyfmt(d, curr='$', neg='(', trailneg=')')
'($1,234,567.89)'
>>> moneyfmt(Decimal(123456789), sep=' ')
'123 456 789.00'
>>> moneyfmt(Decimal('-0.02'), neg='<', trailneg='>')
'<0.02>'

"""
q = Decimal(10) ** -places      # 2 places --> '0.01'
sign, digits, exp = value.quantize(q).as_tuple()
result = []
digits = list(map(str, digits))
build, next = result.append, digits.pop
if sign:
    build(trailneg)
for i in range(places):
    build(next() if digits else '0')
if places:
    build(dp)
if not digits:
    build('0')
i = 0
while digits:
    build(next())
    i += 1
    if i == 3 and digits:
        i = 0
        build(sep)
build(curr)
build(neg if sign else pos)
return ''.join(reversed(result))

def pi():
    """Compute Pi to the current precision.

    >>> print(pi())
    3.141592653589793238462643383

    """
    getcontext().prec += 2 # extra digits for intermediate steps
    three = Decimal(3)    # substitute "three=3.0" for regular floats
    lasts, t, s, n, na, d, da = 0, three, 3, 1, 0, 0, 24
    while s != lasts:
        lasts = s
        n, na = n+na, na+8
        d, da = d+da, da+32
        t = (t * n) / d
        s += t
    getcontext().prec -= 2
    return +s          # unary plus applies the new precision

def exp(x):
    """Return e raised to the power of x. Result type matches input type.

```

### 9.4.10 Decimal FAQ

Q. It is cumbersome to type `decimal.Decimal('1234.5')`. Is there a way to minimize typing when using the interactive interpreter?

A. Some users abbreviate the constructor to just a single letter:

```

>>> D = decimal.Decimal
>>> D('1.23') + D('3.45')
Decimal('4.68')

```

Q. In a fixed-point application with two decimal places, some inputs have many places and need to be rounded. Others are not supposed to have excess digits and need to be validated. What methods should be used?

A. The `quantize()` method rounds to a fixed number of decimal places. If the `Inexact` trap is set, it is also useful for validation:

```

>>> TWOPLACES = Decimal(10) ** -2      # same as Decimal('0.01')

```

```

>>> # Round to two places
>>> Decimal('3.214').quantize(TWOPLACES)
Decimal('3.21')

```

```

>>> # Validate that a number does not exceed two places
>>> Decimal('3.21').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Decimal('3.21')

```

```

>>> Decimal('3.214').quantize(TWOPLACES, context=Context(traps=[Inexact]))
Traceback (most recent call last):
...
Inexact: None

```

Q. Once I have valid two place inputs, how do I maintain that invariant throughout an application?

A. Some operations like addition, subtraction, and multiplication by an integer will automatically preserve fixed point. Others operations, like division and non-integer multiplication, will change the number of decimal places and need to be followed-up with a `quantize()` step:

```

>>> a = Decimal('102.72')      # Initial fixed-point values
>>> b = Decimal('3.17')
>>> a + b                      # Addition preserves fixed-point
Decimal('105.89')
>>> a - b
Decimal('99.55')
>>> a * 42                     # So does integer multiplication
Decimal('4314.24')
>>> (a * b).quantize(TWOPLACES) # Must quantize non-integer multiplication
Decimal('325.62')
>>> (b / a).quantize(TWOPLACES) # And quantize division
Decimal('0.03')

```

In developing fixed-point applications, it is convenient to define functions to handle the `quantize()` step:

```
>>> def mul(x, y, fp=TWOPLACES):
...     return (x * y).quantize(fp)
...
>>> def div(x, y, fp=TWOPLACES):
...     return (x / y).quantize(fp)
```

```
>>> mul(a, b)                                     # Automatically preserve fixed-point
Decimal('325.62')
>>> div(b, a)
Decimal('0.03')
```

Q. There are many ways to express the same value. The numbers 200, 200.000, 2E2, and .02E+4 all have the same value at various precisions. Is there a way to transform them to a single recognizable canonical value?

A. The `normalize()` method maps all equivalent values to a single representative:

```
>>> values = map(Decimal, '200 200.000 2E2 .02E+4'.split())
>>> [v.normalize() for v in values]
[Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2'), Decimal('2E+2')]
```

Q. When does rounding occur in a computation?

A. It occurs *after* the computation. The philosophy of the decimal specification is that numbers are considered exact and are created independent of the current context. They can even have greater precision than current context. Computations process with those exact inputs and then rounding (or other context operations) is applied to the *result* of the computation:

```
>>> getcontext().prec = 5
>>> pi = Decimal('3.1415926535') # More than 5 digits
>>> pi                               # All digits are retained
Decimal('3.1415926535')
>>> pi + 0                             # Rounded after an addition
Decimal('3.1416')
>>> pi - Decimal('0.00005')           # Subtract unrounded numbers, then round
Decimal('3.1415')
>>> pi + 0 - Decimal('0.00005').     # Intermediate values are rounded
Decimal('3.1416')
```

Q. Some decimal values always print with exponential notation. Is there a way to get a non-exponential representation?

A. For some values, exponential notation is the only way to express the number of significant places in the coefficient. For example, expressing 5.0E+3 as 5000 keeps the value constant but cannot show the original's two-place significance.

If an application does not care about tracking significance, it is easy to remove the exponent and trailing zeroes, losing significance, but keeping the value unchanged:

```
>>> def remove_exponent(d):
...     return d.quantize(Decimal(1)) if d == d.to_integral() else d.normalize()
```

```
>>> remove_exponent(Decimal('5E+3'))
Decimal('5000')
```

Q. Is there a way to convert a regular float to a `Decimal`?

A. Yes, any binary floating-point number can be exactly expressed as a `Decimal` though an exact conversion may take more precision than intuition would suggest:

```
>>> Decimal(math.pi)
Decimal('3.141592653589793115997963468544185161590576171875')
```

Q. Within a complex calculation, how can I make sure that I haven't gotten a spurious result because of insufficient precision or rounding anomalies.

A. The decimal module makes it easy to test results. A best practice is to re-run calculations using greater precision and with various rounding modes. Widely differing results indicate insufficient precision, rounding mode issues, ill-conditioned inputs, or a numerically unstable algorithm.

Q. I noticed that context precision is applied to the results of operations but not to the inputs. Is there anything to watch out for when mixing values of different precisions?

A. Yes. The principle is that all values are considered to be exact and so is the arithmetic on those values. Only the results are rounded. The advantage for inputs is that "what you type is what you get". A disadvantage is that the results can look odd if you forget that the inputs haven't been rounded:

```
>>> getcontext().prec = 3
>>> Decimal('3.104') + Decimal('2.104')
Decimal('5.21')
>>> Decimal('3.104') + Decimal('0.000') + Decimal('2.104')
Decimal('5.20')
```

The solution is either to increase precision or to force rounding of inputs using the unary plus operation:

```
>>> getcontext().prec = 3
>>> +Decimal('1.23456789')      # unary plus triggers rounding
Decimal('1.23')
```

Alternatively, inputs can be rounded upon creation using the `Context.create_decimal()` method:

```
>>> Context(prec=5, rounding=ROUND_DOWN).create_decimal('1.2345678')
Decimal('1.2345')
```

Q. Is the CPython implementation fast for large numbers?

A. Yes. In the CPython and PyPy3 implementations, the C/CFFI versions of the decimal module integrate the high speed `libmpdec` library for arbitrary precision correctly rounded decimal floating-point arithmetic<sup>1</sup>. `libmpdec` uses [Karatsuba multiplication](#) for medium-sized numbers and the [Number Theoretic Transform](#) for very large numbers.

The context must be adapted for exact arbitrary precision arithmetic. `Emin` and `Emax` should always be set to the maximum values, `clamp` should always be 0 (the default). Setting `prec` requires some care.

The easiest approach for trying out bignum arithmetic is to use the maximum value for `prec` as well<sup>2</sup>:

```
>>> setcontext(Context(prec=MAX_PREC, Emax=MAX_EMAX, Emin=MIN_EMIN))
>>> x = Decimal(2) ** 256
>>> x / 128
Decimal('904625697166532776746648320380374280103671755200316906558262375061821325312')
```

For inexact results, `MAX_PREC` is far too large on 64-bit platforms and the available memory will be insufficient:

```
>>> Decimal(1) / 3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
MemoryError
```

On systems with overallocation (e.g. Linux), a more sophisticated approach is to adjust `prec` to the amount of available RAM. Suppose that you have 8GB of RAM and expect 10 simultaneous operands using a maximum of 500MB each:

```
>>> import sys
>>>
>>> # Maximum number of digits for a single operand using 500MB in 8-byte words
>>> # with 19 digits per word (4-byte and 9 digits for the 32-bit build):
```

(繼續下一頁)

<sup>1</sup>

在 3.3 版被加入。

<sup>2</sup>

在 3.9 版的變更: This approach now works for all exact results except for non-integer powers.

(繼續上一頁)

```

>>> maxdigits = 19 * ((500 * 1024**2) // 8)
>>>
>>> # Check that this works:
>>> c = Context(prec=maxdigits, Emax=MAX_EMAX, Emin=MIN_EMIN)
>>> c.traps[Inexact] = True
>>> setcontext(c)
>>>
>>> # Fill the available precision with nines:
>>> x = Decimal(0).logical_invert() * 9
>>> sys.getsizeof(x)
524288112
>>> x + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
decimal.Inexact: [<class 'decimal.Inexact'>]

```

In general (and especially on systems without overallocation), it is recommended to estimate even tighter bounds and set the *Inexact* trap if all calculations are expected to be exact.

## 9.5 fractions --- 有理數

原始碼: Lib/fractions.py

The *fractions* module provides support for rational number arithmetic.

A *Fraction* instance can be constructed from a pair of integers, from another rational number, or from a string.

```

class fractions.Fraction( numerator=0, denominator=1)
class fractions.Fraction( other_fraction)
class fractions.Fraction( float)
class fractions.Fraction( decimal)
class fractions.Fraction( string)

```

The first version requires that *numerator* and *denominator* are instances of *numbers.Rational* and returns a new *Fraction* instance with value *numerator*/*denominator*. If *denominator* is 0, it raises a *ZeroDivisionError*. The second version requires that *other\_fraction* is an instance of *numbers.Rational* and returns a *Fraction* instance with the same value. The next two versions accept either a *float* or a *decimal.Decimal* instance, and return a *Fraction* instance with exactly the same value. Note that due to the usual issues with binary floating point (see *tut-fp-issues*), the argument to *Fraction(1.1)* is not exactly equal to 11/10, and so *Fraction(1.1)* does *not* return *Fraction(11, 10)* as one might expect. (But see the documentation for the *limit\_denominator()* method below.) The last version of the constructor expects a string or unicode instance. The usual form for this instance is:

```
[sign] numerator ['/' denominator]
```

where the optional *sign* may be either '+' or '-' and *numerator* and *denominator* (if present) are strings of decimal digits (underscores may be used to delimit digits as with integral literals in code). In addition, any string that represents a finite value and is accepted by the *float* constructor is also accepted by the *Fraction* constructor. In either form the input string may also have leading and/or trailing whitespace. Here are some examples:

```

>>> from fractions import Fraction
>>> Fraction(16, -10)
Fraction(-8, 5)
>>> Fraction(123)
Fraction(123, 1)
>>> Fraction()

```

(繼續下一頁)

(繼續上一頁)

```

Fraction(0, 1)
>>> Fraction('3/7')
Fraction(3, 7)
>>> Fraction(' -3/7 ')
Fraction(-3, 7)
>>> Fraction('1.414213 \t\n')
Fraction(1414213, 1000000)
>>> Fraction('-.125')
Fraction(-1, 8)
>>> Fraction('7e-6')
Fraction(7, 1000000)
>>> Fraction(2.25)
Fraction(9, 4)
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
>>> from decimal import Decimal
>>> Fraction(Decimal('1.1'))
Fraction(11, 10)

```

The *Fraction* class inherits from the abstract base class *numbers.Rational*, and implements all of the methods and operations from that class. *Fraction* instances are *hashable*, and should be treated as immutable. In addition, *Fraction* has the following properties and methods:

在 3.2 版的變更: The *Fraction* constructor now accepts *float* and *decimal.Decimal* instances.

在 3.9 版的變更: The *math.gcd()* function is now used to normalize the *numerator* and *denominator*. *math.gcd()* always returns an *int* type. Previously, the GCD type depended on *numerator* and *denominator*.

在 3.11 版的變更: Underscores are now permitted when creating a *Fraction* instance from a string, following **PEP 515** rules.

在 3.11 版的變更: *Fraction* implements `__int__` now to satisfy *typing*. Supports *Int* instance checks.

在 3.12 版的變更: Space is allowed around the slash for string inputs: `Fraction('2 / 3')`.

在 3.12 版的變更: *Fraction* instances now support float-style formatting, with presentation types "e", "E", "f", "F", "g", "G" and "%".

在 3.13 版的變更: Formatting of *Fraction* instances without a presentation type now supports fill, alignment, sign handling, minimum width and grouping.

#### **numerator**

Numerator of the Fraction in lowest term.

#### **denominator**

Denominator of the Fraction in lowest term.

#### **as\_integer\_ratio()**

Return a tuple of two integers, whose ratio is equal to the original Fraction. The ratio is in lowest terms and has a positive denominator.

在 3.8 版被加入.

#### **is\_integer()**

Return `True` if the Fraction is an integer.

在 3.12 版被加入.

#### **classmethod from\_float(*flt*)**

Alternative constructor which only accepts instances of *float* or *numbers.Integral*. Beware that `Fraction.from_float(0.3)` is not the same value as `Fraction(3, 10)`.

**i 備F**

From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *float*.

**classmethod** `from_decimal(dec)`

Alternative constructor which only accepts instances of *decimal.Decimal* or *numbers.Integral*.

**i 備F**

From Python 3.2 onwards, you can also construct a *Fraction* instance directly from a *decimal.Decimal* instance.

**limit\_denominator(*max\_denominator=1000000*)**

Finds and returns the closest *Fraction* to *self* that has denominator at most *max\_denominator*. This method is useful for finding rational approximations to a given floating-point number:

```
>>> from fractions import Fraction
>>> Fraction('3.1415926535897932').limit_denominator(1000)
Fraction(355, 113)
```

or for recovering a rational number that's represented as a float:

```
>>> from math import pi, cos
>>> Fraction(cos(pi/3))
Fraction(4503599627370497, 9007199254740992)
>>> Fraction(cos(pi/3)).limit_denominator()
Fraction(1, 2)
>>> Fraction(1.1).limit_denominator()
Fraction(11, 10)
```

**\_\_floor\_\_()**

Returns the greatest *int*  $\leq$  *self*. This method can also be accessed through the *math.floor()* function:

```
>>> from math import floor
>>> floor(Fraction(355, 113))
3
```

**\_\_ceil\_\_()**

Returns the least *int*  $\geq$  *self*. This method can also be accessed through the *math.ceil()* function.

**\_\_round\_\_()**

**\_\_round\_\_(*ndigits*)**

The first version returns the nearest *int* to *self*, rounding half to even. The second version rounds *self* to the nearest multiple of *Fraction(1, 10\*\*ndigits)* (logically, if *ndigits* is negative), again rounding half toward even. This method can also be accessed through the *round()* function.

**\_\_format\_\_(*format\_spec, /*)**

Provides support for formatting of *Fraction* instances via the *str.format()* method, the *format()* built-in function, or Formatted string literals.

If the *format\_spec* format specification string does not end with one of the presentation types 'e', 'E', 'f', 'F', 'g', 'G' or '%' then formatting follows the general rules for fill, alignment, sign handling, minimum width, and grouping as described in the *format specification mini-language*. The "alternate form" flag '#' is supported: if present, it forces the output string to always include an explicit denominator, even when the value being formatted is an exact integer. The zero-fill flag '0' is not supported.

**警告**

本章所提及的擬隨機數生成器不應該使用於安全目的。有關安全性或加密用途，請參考 `secrets module`。

**也參考**

M. Matsumoto and T. Nishimura, "Mersenne Twister: A 623-dimensionally equidistributed uniform pseudo-random number generator", ACM Transactions on Modeling and Computer Simulation Vol. 8, No. 1, January pp.3--30 1998.

進位互補乘法 (Complementary-Multiply-with-Carry) 用法，可作隨機數生成器的一個可相容替代方案，具有較長的週期和相對簡單的更新操作。

**備註**

The global random number generator and instances of `Random` are thread-safe. However, in the free-threaded build, concurrent calls to the global generator or to the same instance of `Random` may encounter contention and poor performance. Consider using separate instances of `Random` per thread instead.

## 9.6.1 簿記函式 (bookkeeping functions)

`random.seed(a=None, version=2)`

初始化隨機數生成器。

如果 `a` 被省略或 `None`，則使用當前系統時間。如果隨機來源由作業系統提供，則使用它們而不是系統時間（有關可用性的詳細資訊，請參考 `os.urandom()` 函式）。

如果 `a` 是 `int`（整數），則直接使用它。

如使用版本 2（預設值），`str`、`bytes` 或 `bytearray` 物件將轉為 `int`，使用其所有位元。

若使用版本 1（復現於舊版本 Python 中生成隨機序列而提供），`str` 和 `bytes` 的演算法會生成範圍更窄的種子 (seed)。

在 3.2 版的變更：移至版本 2 方案，該方案使用字串種子中的所有位元。

在 3.11 版的變更：`seed` 必須是以下型之一：`None`、`int`、`float`、`str`、`bytes`、`bytearray`。

`random.getstate()`

回傳一個物件，捕獲生成器的當前內部狀態。此物件可以傳遞給 `setstate()` 以恢復狀態。

`random.setstate(state)`

`state` 應該要從之前對 `getstate()` 的呼叫中獲得，且以 `setstate()` 將生成器的內部狀態恢復到呼叫 `getstate()` 時的狀態。

## 9.6.2 回傳位元組的函式

`random.randbytes(n)`

生成 `n` 個隨機位元組。

此方法不應使用於生成安全性權杖 (Token)。請改用 `secrets.token_bytes()`。

在 3.9 版被加入。

### 9.6.3 回傳整數的函式

`random.randrange(stop)`

`random.randrange(start, stop[, step])`

傳回從 `range(start, stop, step)` 中隨機選擇的元素。

這大致相當於 `choice(range(start, stop, step))`，但支援任意大的範圍，且針對常見情形進行了最佳化。

位置引數模式與 `range()` 函式相符。

不應使用關鍵字引數，因為它們可能會以意想不到的方式被直譯。例如 `randrange(start=100)` 會被直譯成 `randrange(0, 100, 1)`。

在 3.2 版的變更：`randrange()` 在生成均勻分佈的值方面更複雜。以前，它使用像 `int(random()*n)` 這樣的樣式，這可能會生成稍微不均勻的分佈。

在 3.12 版的變更：已經不再支援非整數類型到等效整數的自動轉換。像是 `randrange(10.0)` 和 `randrange(Fraction(10, 1))` 的呼叫將會引發 `TypeError`。

`random.randint(a, b)`

回傳一個隨機整數  $N$ ，使得  $a \leq N \leq b$ 。是 `randrange(a, b+1)` 的別名。

`random.getrandbits(k)`

回傳一個具有  $k$  個隨機位元的非負 Python 整數。此方法會隨 Mersenne Twister 生成器一起提供，一些其他的生成器也可能將其作為 API 的可選部分。如果可用，`getrandbits()` 使 `randrange()` 能處理任意大的範圍。

在 3.9 版的變更：此方法現在接受  $k$  為零。

### 9.6.4 回傳序列的函式

`random.choice(seq)`

從非空序列 `seq` 回傳一個隨機元素。如果 `seq` 為空，則引發 `IndexError`。

`random.choices(population, weights=None, *, cum_weights=None, k=1)`

回傳從 `population` 中重置取樣出的一個大小為  $k$  的元素 list。如果 `population` 為空，則引發 `IndexError`。

如果指定了 `weights` 序列，則根據相對權重進行選擇。另外，如果給定 `cum_weights` 序列，則根據累積權重進行選擇（可能使用 `itertools.accumulate()` 計算）。例如，相對權重 `[10, 5, 30, 5]` 等同於累積權重 `[10, 15, 45, 50]`。在內部，相對權重在進行選擇之前會轉換為累積權重，因此提供累積權重可以節省工作。

如果既未指定 `weights` 也未指定 `cum_weights`，則以相等的機率進行選擇。如果提供了加權序列，則該序列的長度必須與 `population` 序列的長度相同。它是一個 `TypeError` 來指定 `weights` 和 `cum_weights`。

`weights` 或 `cum_weights` 可以使用任何與 `random()` 所回傳的 `float` 值（包括整數、float 和分數，但不包括小數）交互操作（interoperates）的數值類型。權重假定非負數和有限的。如果所有權重均為零，則引發 `ValueError`。

對於給定的種子，具有相等權重的 `choices()` 函式通常會生成與重復呼叫 `choice()` 不同的序列。`choices()` 使用的演算法使用浮點運算來實現內部一致性和速度。`choice()` 使用的演算法預設為整數運算和重復選擇，以避免舍入誤差生成的小偏差。

在 3.6 版被加入。

在 3.9 版的變更：如果所有權重均為零，則引發 `ValueError`。

`random.shuffle(x)`

將序列 `x` 原地 (in place) 隨機打亂位置。

要打亂一個不可變的序列，回傳一個新的被打亂的 list（串列），請使用 `sample(x, k=len(x))`。

請注意，即使對於較小的 `len(x)`，`x` 的置換總數也會快速成長到大於大多數隨機數生成器的週期。這意味著長序列的大多數置換永遠無法生成。例如，長度為 2080 的序列是 Mersenne Twister 隨機數生成器週期可以容納的最大序列。

在 3.11 版的變更: 移除可選參數 `random`。

`random.sample(population, k, *, counts=None)`

回傳從母體序列中選擇出的一個包含獨特元素、長度  $k$  的 list。用於不重置的隨機取樣。

回傳包含母體元素的新清單，同時保持原始母體不變。生成的清單按選擇順序排列，因此所有子切片也會是有效的隨機樣本。這允許抽獲者（樣本）分大和第二名獲者（子切片）。

母體成員不必是 `hashable` 或唯一的。如果母體包含重項，則每次出現都是樣本中可能出現的一個選擇。

可以一次指定一個重元素，也可以使用可選的僅關鍵字 `counts` 參數指定重元素。例如 `sample(['red', 'blue'], counts=[4, 2], k=5)` 等同於 `sample(['red', 'red', 'red', 'red', 'blue', 'blue'], k=5)`。

若要從整數範圍中選擇範例，請使用 `range()` 物件作引數。這對於從大型母體中取樣特別快速且節省空間：`sample(range(10000000), k=60)`。

如果樣本大小大於母體大小，`ValueError` 會被引發。

在 3.9 版的變更: 新增 `counts` 參數。

在 3.11 版的變更: `population` 必須是一個序列。不再支援將 `set` 自動轉 list。

## 9.6.5 離散分布

以下函式生離散分。

`random.binomialvariate(n=1, p=0.5)`

二項分 (Binomial distribution)。回傳  $n$  個獨立試驗的成功次數，每個試驗的成功機率  $p$ ：

數學上等價於：

```
sum(random() < p for i in range(n))
```

試驗次數  $n$  應非負整數。成功的機率  $p$  應在  $0.0 \leq p \leq 1.0$  之間。結果是  $0 \leq x \leq n$  範圍的整數。

在 3.12 版被加入。

## 9.6.6 實數分布

以下函式生特定的實數分。函式參數以分方程中的對應變數命名，如常見的數學實踐所示；這些方程式中的大多數都可以在任意統計文本中找到。

`random.random()`

回傳範圍  $0.0 \leq x < 1.0$  中的下一個隨機浮點數

`random.uniform(a, b)`

回傳一個隨機浮點數  $N$ ，當  $a \leq b$  時確保  $a \leq N \leq b$ 、 $b < a$  時確保  $b \leq N \leq a$ 。

終點值  $b$  可能包含在範圍，也可能不包含在範圍，取於運算式  $a + (b-a) * \text{random}()$  中的浮點舍入。

`random.triangular(low, high, mode)`

回傳一個隨機浮點數  $N$ ，使得  $low \leq N \leq high$ ，在這些邊界之間具有指定的 `mode`。`low` 和 `high` 邊界預設零和一。`mode` 引數預設邊界之間的中點，從而給出對稱分。

`random.betavariate(alpha, beta)`

Beta (貝它) 分布。參數的條件  $\alpha > 0$  和  $\beta > 0$ 。回傳值的範圍介於 0 和 1 之間。

`random.expovariate(lambd=1.0)`

指數分。`lambd` 除以所需的平均數。它應該不零。(該參數將被稱“`lambda`”，但這是 Python 中的保留字) 如果 `lambd` 正，則回傳值的範圍從 0 到正無窮大；如果 `lambd` 負，則回傳值的範圍從負無窮大到 0。

在 3.12 版的變更: 新增 `lambda` 的預設值。

`random.gammavariate(alpha, beta)`

Gamma (伽瑪) 分佈。 (不是 Gamma 函式!)。形狀 (shape) 和比例 (scale) 參數 `alpha` 和 `beta` 必須具有正值。(根據呼叫習慣不同, 部分來源會將 `beta` 定義為比例的倒數)。

Probability distribution function (機率密度函式) 是:

$$\text{pdf}(x) = \frac{x^{(\alpha - 1)} * \text{math.exp}(-x / \text{beta})}{\text{math.gamma}(\alpha) * \text{beta} ** \alpha}$$

`random.gauss(mu=0.0, sigma=1.0)`

常態分佈, 也稱高斯分佈。`mu` 是平均數, `sigma` 是標準差。這比下面定義的 `normalvariate()` 函式快一點。

多執行緒須注意: 當兩個執行緒同時呼叫此函式時, 它們可能會收到相同的傳回值。這可以透過三種方式避免。1) 讓每個執行緒使用隨機數生成器的不同實例。2) 在所有呼叫周圍加鎖。3) 使用較慢但執行緒安全的 `normalvariate()` 函式代替。

在 3.11 版的變更: `mu` 和 `sigma` 現在有預設引數。

`random.lognormvariate(mu, sigma)`

對數常態分佈。如果你取此分佈的自然對數, 你將獲得一個具有平均數 `mu` 和標準差 `sigma` 的常態分佈。`mu` 可以任何值, 且 `sigma` 必須大於零。

`random.normalvariate(mu=0.0, sigma=1.0)`

常態分佈。`mu` 是平均數, `sigma` 是標準差。

在 3.11 版的變更: `mu` 和 `sigma` 現在有預設引數。

`random.vonmisesvariate(mu, kappa)`

`mu` 是平均角度, 以 0 到  $2\pi$  之間的弧度表示, `kappa` 是濃度參數, 必須大於或等於零。如果 `kappa` 等於零, 則此分佈在 0 到  $2\pi$  的範圍內將小均的隨機角度。

`random.paretovariate(alpha)`

Pareto distribution (柏拉圖分佈)。`alpha` 是形狀參數。

`random.weibullvariate(alpha, beta)`

Weibull distribution (韋伯分佈)。`alpha` 是比例參數, `beta` 是形狀參數。

## 9.6.7 替代生成器

`class random.Random([seed])`

實現 `random` 模組使用的預設隨機數生成器的 class。

在 3.11 版的變更: 過去 `seed` 可以是任何可雜物件, 但現在必須是以下類型之一: `None`、`int`、`float`、`str`、`bytes`、`bytearray`。

如果 `Random` 的子類希望使用不同的基礎生成器, 則應該覆寫以下方法:

`seed(a=None, version=2)`

在子類中覆寫此方法以自訂 `Random` 實例的 `seed()` 行。

`getstate()`

在子類中覆寫此方法以自訂 `Random` 實例的 `getstate()` 行。

`setstate(state)`

在子類中覆寫此方法以自訂 `Random` 實例的 `setstate()` 行。

`random()`

在子類中覆寫此方法以自訂 `Random` 實例的 `random()` 行。

或者, 自訂生成器子類還可以提供以下方法:

`getrandbits(k)`

在子類中覆寫此方法以自訂 `Random` 實例的 `getrandbits()` 行。

`class random.SystemRandom([seed])`

使用 `os.urandom()` 函式從作業系統提供的來源生隨機數的 Class。非在所有系統上都可用。不依賴於軟體狀態，且序列不可復現。因此 `seed()` 方法有效果且被忽略。如果呼叫 `getstate()` 和 `setstate()` 方法會引發 `NotImplementedError`。

## 9.6.8 關於 Reproducibility (復現性) 的注意事項

有時，能重現隨機數生成器給出的序列很有用。只要多執行緒未運行，透過重使用種子值，同一序列就應該可以被復現。

大多數隨機 module 的演算法和 `seed` 設定函式在 Python 版本中可能會發生變化，但可以保證兩個方面不會改變：

- 如果增加了新的 `seed` 設定函式，則將提供向後相容的播種器 (seeder)。
- 當相容的播種器被賦予相同的種子時，生成器的 `random()` 方法將持續生成相同的序列。

## 9.6.9 范例

基礎範例：

```
>>> random() # Random float: 0.0 <= x < 1.0
0.37444887175646646

>>> uniform(2.5, 10.0) # Random float: 2.5 <= x <= 10.0
3.1800146073117523

>>> expovariate(1 / 5) # Interval between arrivals averaging 5 seconds
5.148957571865031

>>> randrange(10) # Integer from 0 to 9 inclusive
7

>>> randrange(0, 101, 2) # Even integer from 0 to 100 inclusive
26

>>> choice(['win', 'lose', 'draw']) # Single random element from a sequence
'draw'

>>> deck = 'ace two three four'.split()
>>> shuffle(deck) # Shuffle a list
>>> deck
['four', 'two', 'ace', 'three']

>>> sample([10, 20, 30, 40, 50], k=4) # Four samples without replacement
[40, 10, 50, 30]
```

模擬：

```
>>> # Six roulette wheel spins (weighted sampling with replacement)
>>> choices(['red', 'black', 'green'], [18, 18, 2], k=6)
['red', 'green', 'black', 'black', 'red', 'black']

>>> # Deal 20 cards without replacement from a deck
>>> # of 52 playing cards, and determine the proportion of cards
>>> # with a ten-value: ten, jack, queen, or king.
>>> deal = sample(['tens', 'low cards'], counts=[16, 36], k=20)
>>> deal.count('tens') / 20
0.15
```

(繼續下一頁)

(繼續上一頁)

```
>>> # Estimate the probability of getting 5 or more heads from 7 spins
>>> # of a biased coin that settles on heads 60% of the time.
>>> sum(binomialvariate(n=7, p=0.6) >= 5 for i in range(10_000)) / 10_000
0.4169

>>> # Probability of the median of 5 samples being in middle two quartiles
>>> def trial():
...     return 2_500 <= sorted(choices(range(10_000), k=5))[2] < 7_500
...
>>> sum(trial() for i in range(10_000)) / 10_000
0.7958
```

統計 bootstrapping (自助法) 的範例, 使用有重置的重新取樣來估計樣本平均數的信賴區間:

```
# https://www.thoughtco.com/example-of-bootstrapping-3126155
from statistics import fmean as mean
from random import choices

data = [41, 50, 29, 37, 81, 30, 73, 63, 20, 35, 68, 22, 60, 31, 95]
means = sorted(mean(choices(data, k=len(data))) for i in range(100))
print(f'The sample mean of {mean(data):.1f} has a 90% confidence '
      f'interval from {means[5]:.1f} to {means[94]:.1f}')
```

重新取樣排列測試的範例, 來確定觀察到的藥物與安慰劑之間差值的統計學意義或 p 值:

```
# Example from "Statistics is Easy" by Dennis Shasha and Manda Wilson
from statistics import fmean as mean
from random import shuffle

drug = [54, 73, 53, 70, 73, 68, 52, 65, 65]
placebo = [54, 51, 58, 44, 55, 52, 42, 47, 58, 46]
observed_diff = mean(drug) - mean(placebo)

n = 10_000
count = 0
combined = drug + placebo
for i in range(n):
    shuffle(combined)
    new_diff = mean(combined[:len(drug)]) - mean(combined[len(drug):])
    count += (new_diff >= observed_diff)

print(f'{n} label reshufflings produced only {count} instances with a difference')
print(f'at least as extreme as the observed difference of {observed_diff:.1f}.')
print(f'The one-sided p-value of {count / n:.4f} leads us to reject the null')
print(f'hypothesis that there is no difference between the drug and the placebo.')
```

模擬多伺服器列 (queue) 的到達時間與服務交付:

```
from heapq import heapify, heapreplace
from random import expovariate, gauss
from statistics import mean, quantiles

average_arrival_interval = 5.6
average_service_time = 15.0
stdev_service_time = 3.5
num_servers = 3

waits = []
arrival_time = 0.0
servers = [0.0] * num_servers # time when each server becomes available
```

(繼續下一頁)

(繼續上一頁)

```

heapify(servers)
for i in range(1_000_000):
    arrival_time += expovariate(1.0 / average_arrival_interval)
    next_server_available = servers[0]
    wait = max(0.0, next_server_available - arrival_time)
    waits.append(wait)
    service_duration = max(0.0, gauss(average_service_time, stdev_service_time))
    service_completed = arrival_time + wait + service_duration
    heapreplace(servers, service_completed)

print(f'Mean wait: {mean(waits):.1f}   Max wait: {max(waits):.1f}')
print('Quartiles:', [round(q, 1) for q in quantiles(waits)])

```

### 也參考

[Statistics for Hackers](#) 是由 Jake Vanderplas 作的教學影片，僅使用幾個基本概念（包括模擬、取樣、洗牌、交叉驗證）進行統計分析。

[Economics Simulation](#) 是由 Peter Norvig 對市場進行的模擬，顯示了該模組提供的許多工具和分（高斯、均、樣本、beta 變數、選擇，三角形、隨機數）的有效使用。

機率的具體介紹（使用 Python） Peter Norvig 的教學課程，涵蓋了機率理論的基礎知識與如何模擬以及使用 Python 執行數據分析。

## 9.6.10 使用方案

這些使用方案展示了如何有效地從 `itertools` 模組的組合代器 (combinatoric iterators) 中進行隨機選擇：

```

def random_product(*args, repeat=1):
    "Random selection from itertools.product(*args, **kwargs)"
    pools = [tuple(pool) for pool in args] * repeat
    return tuple(map(random.choice, pools))

def random_permutation(iterable, r=None):
    "Random selection from itertools.permutations(iterable, r)"
    pool = tuple(iterable)
    r = len(pool) if r is None else r
    return tuple(random.sample(pool, r))

def random_combination(iterable, r):
    "Random selection from itertools.combinations(iterable, r)"
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.sample(range(n), r))
    return tuple(pool[i] for i in indices)

def random_combination_with_replacement(iterable, r):
    "Choose r elements with replacement. Order the result to match the iterable."
    # Result will be in set(itertools.combinations_with_replacement(iterable, r)).
    pool = tuple(iterable)
    n = len(pool)
    indices = sorted(random.choices(range(n), k=r))
    return tuple(pool[i] for i in indices)

```

預設的 `random()` 回傳  $0.0 \leq x < 1.0$  範圍的  $2^{-53}$  的倍數。所有數字都是均分的，且可以完全表示 Python float。但是，該間隔中的許多其他可表示的 float 不是可能的選擇。例如 `0.05954861408025609` 不是  $2^{-53}$  的整數倍。

以下範例用不同的方法。間隔中的所有 float 都是可能的選擇。尾數來自  $2^{52} \leq \text{尾數} < 2^{53}$  範圍的整數均分。指數來自幾何分，其中小於  $-53$  的指數的出現頻率是下一個較大指數的一半。

```

from random import Random
from math import ldexp

class FullRandom(Random):

    def random(self):
        mantissa = 0x10_0000_0000_0000 | self.getrandbits(52)
        exponent = -53
        x = 0
        while not x:
            x = self.getrandbits(32)
            exponent += x.bit_length() - 32
        return ldexp(mantissa, exponent)

```

Class 中的所有實數分 都將使用新方法：

```

>>> fr = FullRandom()
>>> fr.random()
0.05954861408025609
>>> fr.expovariate(0.25)
8.87925541791544

```

該範例在概念上等效於一種演算法，該演算法從  $0.0 \leq x < 1.0$  範圍內  $2^{-1074}$  的所有倍數中進行選擇。這些數字都是均分 的，但大多數必須向下舍入到最接近的可表示的 Python float。 $(2^{-1074}$  是最小 正的非正規化 float，等於 `math.ulp(0.0)`)

### 也參考

生 隨機浮點值 Allen B. Downey 的一篇論文描述了 生比通常由 `random()` 生的 float 更 fine-grained (細粒的) 的方法。

## 9.6.11 Command-line usage

在 3.13 版被加入。

The `random` module can be executed from the command line.

```
python -m random [-h] [-c CHOICE [CHOICE ...] | -i N | -f N] [input ...]
```

The following options are accepted:

**-h, --help**

Show the help message and exit.

**-c CHOICE [CHOICE ...]**

**--choice CHOICE [CHOICE ...]**

Print a random choice, using `choice()`.

**-i <N>**

**--integer <N>**

Print a random integer between 1 and N inclusive, using `randint()`.

**-f <N>**

**--float <N>**

Print a random floating-point number between 0 and N inclusive, using `uniform()`.

If no options are given, the output depends on the input:

- String or multiple: same as `--choice`.
- Integer: same as `--integer`.

- Float: same as `--float`.

## 9.6.12 Command-line example

Here are some examples of the `random` command-line interface:

```
$ # Choose one at random
$ python -m random egg bacon sausage spam "Lobster Thermidor aux crevettes with a Mornay_
↪sauce"
Lobster Thermidor aux crevettes with a Mornay sauce

$ # Random integer
$ python -m random 6
6

$ # Random floating-point number
$ python -m random 1.8
1.7080016272295635

$ # With explicit arguments
$ python -m random --choice egg bacon sausage spam "Lobster Thermidor aux crevettes with a_
↪Mornay sauce"
egg

$ python -m random --integer 6
3

$ python -m random --float 1.8
1.5666339105010318

$ python -m random --integer 6
5

$ python -m random --float 6
3.1942323316565915
```

## 9.7 statistics --- 數學統計函式

在 3.4 版被加入。

原始碼: [Lib/statistics.py](#)

這個模組提供計算數值 (Real-valued) 資料的數學統計函式。

這個模組非旨在與 `NumPy`、`SciPy` 等第三方函式庫，或者像 `Minitab`、`SAS` 和 `Matlab` 等專門設計給專業統計學家的高階統計軟體互相競。此模組的目標在於繪圖和科學計算。

除非特明，這些函數支援 `int`、`float`、`Decimal` 以及 `Fraction`。目前不支援其他型 (無論是否數值型)。含有混合型資料的集合亦是尚未定義，且取於該型的實作。若你的輸入資料含有混合型，你可以考慮使用 `map()` 來確保結果是一致的，例如：`map(float, input_data)`。

有些資料集使用 `NaN` (非數) 來表示缺漏的資料。由於 `NaN` 具有特殊的比較語義，在排序資料或是統計出現次數的統計函數中，會引發意料之外或是未定義的行。受影響的函數包含 `median()`、`median_low()`、`median_high()`、`median_grouped()`、`mode()`、`multimode()` 以及 `quantiles()`。在呼叫這些函數之前，應該先移除 `NaN` 值：

```
>>> from statistics import median
>>> from math import isnan
>>> from itertools import filterfalse
```

(繼續下一頁)

(繼續上一頁)

```

>>> data = [20.7, float('NaN'), 19.2, 18.3, float('NaN'), 14.4]
>>> sorted(data) # This has surprising behavior
[20.7, nan, 14.4, 18.3, 19.2, nan]
>>> median(data) # This result is unexpected
16.35

>>> sum(map(isnan, data)) # Number of missing values
2
>>> clean = list(filterfalse(isnan, data)) # Strip NaN values
>>> clean
[20.7, 19.2, 18.3, 14.4]
>>> sorted(clean) # Sorting now works as expected
[14.4, 18.3, 19.2, 20.7]
>>> median(clean) # This result is now well defined
18.75

```

### 9.7.1 平均值與中央位置量數

這些函式計算來自一個母體或樣本的平均值或代表值。

<code>mean()</code>	資料的算術平均數 (平均值)。
<code>fmean()</code>	快速浮點數算數平均數, 可調整權重。
<code>geometric_mean()</code>	資料的幾何平均數。
<code>harmonic_mean()</code>	資料的調和平均數。
<code>kde()</code>	Estimate the probability density distribution of the data.
<code>kde_random()</code>	Random sampling from the PDF generated by <code>kde()</code> .
<code>median()</code>	資料的中位數 (中間值)。
<code>median_low()</code>	資料中較小的中位數。
<code>median_high()</code>	資料中較大的中位數。
<code>median_grouped()</code>	分組資料的中位數 (第 50 百分位數)。
<code>mode()</code>	離散 (discrete) 或名目 (nomial) 資料中的 最頻數 (出現次數最多次的值), 只回傳一個。
<code>multimode()</code>	離散或名目資料中的 最頻數 (出現次數最多次的值) 組成的 list。
<code>quantiles()</code>	將資料分成數個具有相等機率的區間, 即分位數 (quantile)。

### 9.7.2 離度 (spread) 的測量

這些函式計算母體或樣本偏離平均值的程度。

<code>pstdev()</code>	資料的母體標準差。
<code>pvariance()</code>	資料的母體變異數。
<code>stdev()</code>	資料的樣本標準差。
<code>variance()</code>	資料的樣本變異數。

### 9.7.3 兩個輸入之間的關聯統計

這些函式計算兩個輸入之間的關聯統計數據。

<code>covariance()</code>	兩變數的樣本共變異數。
<code>correlation()</code>	Pearson 與 Spearman 相關係數 (correlation coefficient)。
<code>linear_regression()</code>	簡單線性回歸的斜率和截距。

## 9.7.4 函式細節

☞：這些函式☞不要求輸入的資料必須排序過。☞了☞讀方便，大部份的範例仍已排序過。

`statistics.mean(data)`

回傳 *data* 的樣本算數平均數，輸入可☞一個 `sequence` 或者 `iterable`。

算數平均數☞資料總和除以資料點的數目。他通常被稱☞「平均值」，☞管它只是☞多不同的數學平均值之一。它是衡量資料集中位置的一種指標。

若 *data* ☞空，則會引發 `StatisticsError`。

使用範例：

```
>>> mean([1, 2, 3, 4, 4])
2.8
>>> mean([-1.0, 2.5, 3.25, 5.75])
2.625

>>> from fractions import Fraction as F
>>> mean([F(3, 7), F(1, 21), F(5, 3), F(1, 3)])
Fraction(13, 21)

>>> from decimal import Decimal as D
>>> mean([D("0.5"), D("0.75"), D("0.625"), D("0.375")])
Decimal('0.5625')
```

### ☞

平均值☞烈受到離群值 (outliers) 的影響，且不一定能當作這些資料點的典型範例。若要使用更穩健但效率較低的集中趨勢 (central tendency) 度量，請參考 `median()`。

樣本平均數提供了對真實母體平均數的不偏估計 (unbiased estimate)，所以從所有可能的樣本中取平均值時，`mean(sample)` 會收斂至整個母體的真实平均值。若 *data* ☞整個母體而非單一樣本，則 `mean(data)` 等同於計算真实的母體平均數  $\mu$ 。

`statistics.fmean(data, weights=None)`

將 *data* 轉☞☞浮點數☞計算其算數平均數。

這個函式運算比 `mean()` 更快，☞且它總是回傳一個 `float`。*data* 可以是一個 `sequence` 或者 `iterable`。如果輸入的資料☞空，則引發 `StatisticsError`。

```
>>> fmean([3.5, 4.0, 5.25])
4.25
```

支援選擇性的加權。例如，一位教授以 20% 的比重計算小考分數，20% 的比重計算作業分數，30% 的比重計算期中考試分數，以及 30% 的比重計算期末考試分數：

```
>>> grades = [85, 92, 83, 91]
>>> weights = [0.20, 0.20, 0.30, 0.30]
>>> fmean(grades, weights)
87.6
```

如果有提供 *weights*，它必須與 *data* 長度相同，否則將引發 `ValueError`。

在 3.8 版被加入。

在 3.11 版的變更：新增 *weights* 的支援。

`statistics.geometric_mean(data)`

將 *data* 轉☞☞浮點數☞計算其幾何平均數。

幾何平均數使用數值的乘積（與之對照，算數平均數使用的是數值的和）來表示 *data* 的集中趨勢或典型值。

若輸入的資料集空、包含零、包含負值，則引發 `StatisticsError`。 *data* 可 sequence 或者 iterable。

目前有特了精確結果而特多下什工夫。（然而，未來或許會有。）

```
>>> round(geometric_mean([54, 24, 36]), 1)
36.0
```

在 3.8 版被加入。

`statistics.harmonic_mean(data, weights=None)`

回傳 *data* 的調和平均數。 *data* 可實數 (real-valued) sequence 或者 iterable。如果省略 *weights* 或者 *weights* 是 `None`，則假設各權重相等。

調和平均數是資料的倒數 (reciprocal) 經過 `mean()` 運算過後的倒數。例如，三個數 *a*、*b* 與 *c* 的調和平均數等於  $3 / (1/a + 1/b + 1/c)$ 。若其中一個值零，結果將零。

調和平均數是一種平均數，是衡量資料中心位置的一種方法。它通常用於計算比率 (ratio) 或率 (rate) 的平均，例如速率 (speed)。

假設一輛汽車以時速 40 公里的速率行駛 10 公里，然後再以時速 60 公里的速率行駛 10 公里，求汽車的平均速率？

```
>>> harmonic_mean([40, 60])
48.0
```

假設一輛汽車以時速 40 公里的速率行駛 5 公里，然後在交通順暢時，加速到時速 60 公里，以此速度行駛剩下的 30 公里。求汽車的平均速率？

```
>>> harmonic_mean([40, 60], weights=[5, 30])
56.0
```

若 *data* 空、含有任何小於零的元素、或者加權總和不正數，則引發 `StatisticsError`。

目前的演算法設計，若在輸入當中遇到零，則會提前退出。這意味著後續的輸入未進行有效性檢查。（這種行在未來可能會改變。）

在 3.6 版被加入。

在 3.10 版的變更：新增 *weights* 的支援。

`statistics.kde(data, h, kernel='normal', *, cumulative=False)`

**Kernel Density Estimation (KDE):** Create a continuous probability density function or cumulative distribution function from discrete samples.

The basic idea is to smooth the data using a kernel function. to help draw inferences about a population from a sample.

The degree of smoothing is controlled by the scaling parameter *h* which is called the bandwidth. Smaller values emphasize local features while larger values give smoother results.

The kernel determines the relative weights of the sample data points. Generally, the choice of kernel shape does not matter as much as the more influential bandwidth smoothing parameter.

Kernels that give some weight to every sample point include *normal* (*gauss*), *logistic*, and *sigmoid*.

Kernels that only give weight to sample points within the bandwidth include *rectangular* (*uniform*), *triangular*, *parabolic* (*epanechnikov*), *quartic* (*biweight*), *triweight*, and *cosine*.

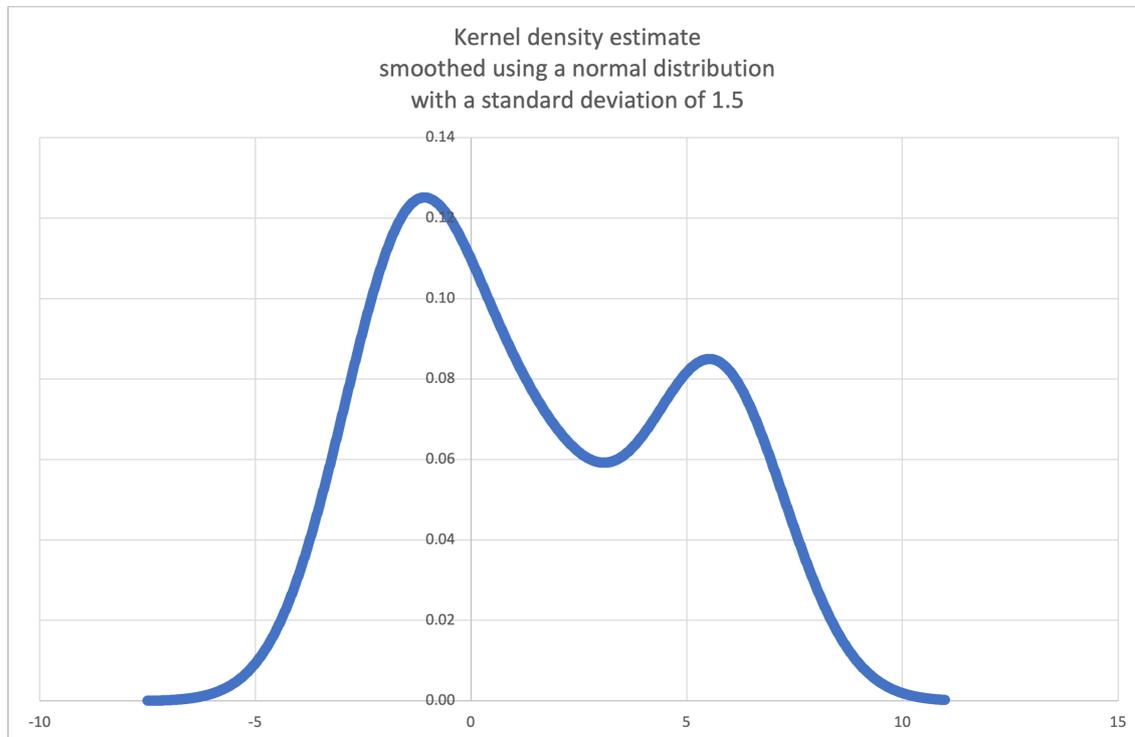

If *cumulative* is true, will return a cumulative distribution function.

A `StatisticsError` will be raised if the *data* sequence is empty.

Wikipedia has an example where we can use `kde()` to generate and plot a probability density function estimated from a small sample:

```
>>> sample = [-2.1, -1.3, -0.4, 1.9, 5.1, 6.2]
>>> f_hat = kde(sample, h=1.5)
>>> xarr = [i/100 for i in range(-750, 1100)]
>>> yarr = [f_hat(x) for x in xarr]
```

xarr 和 yarr 中的點可用於繪 PDF 圖：

在 3.13 版被加入。

`statistics.kde_random(data, h, kernel='normal', *, seed=None)`

Return a function that makes a random selection from the estimated probability density function produced by `kde(data, h, kernel)`.

Providing a *seed* allows reproducible selections. In the future, the values may change slightly as more accurate kernel inverse CDF estimates are implemented. The seed may be an integer, float, str, or bytes.

A *StatisticsError* will be raised if the *data* sequence is empty.

Continuing the example for `kde()`, we can use `kde_random()` to generate new random selections from an estimated probability density function:

```
>>> data = [-2.1, -1.3, -0.4, 1.9, 5.1, 6.2]
>>> rand = kde_random(data, h=1.5, seed=8675309)
>>> new_selections = [rand() for i in range(10)]
>>> [round(x, 1) for x in new_selections]
[0.7, 6.2, 1.2, 6.9, 7.0, 1.8, 2.5, -0.5, -1.8, 5.6]
```

在 3.13 版被加入。

`statistics.median(data)`

使用常見的「中間兩數取平均」方法回傳數值資料的中位數（中間值）。若 *data* 空，則會引發 *StatisticsError*。*data* 可一個 *sequence* 或者 *iterable*。

中位數是一種穩健的衡量資料中心位置的方法，較不易被離群值影響。當資料點數量奇數時，會回傳中間的資料點：

```
>>> median([1, 3, 5])
3
```

當資料點數量為偶數時，中位數透過中間兩個值的平均數來插值計算：

```
>>> median([1, 3, 5, 7])
4.0
```

若你的資料為離散資料，且你不介意中位數可能非真實的資料點，那這函式適合你。

若你的資料為順序 (ordinal) 資料 (支援排序操作) 但非數值型 (不支援加法)，可以考慮改用 `median_low()` 或是 `median_high()` 代替。

`statistics.median_low(data)`

回傳數值型資料的低中位數 (low median)。若 `data` 為空，則引發 `StatisticsError`。`data` 可為 `sequence` 或者 `iterable`。

低中位數一定會在原本的資料集當中。當資料點數量為奇數時，回傳中間值。當數量為偶數時，回傳兩個中間值當中較小的值。

```
>>> median_low([1, 3, 5])
3
>>> median_low([1, 3, 5, 7])
3
```

當你的資料為離散資料，且你希望中位數是實際的資料點而不是插值時，可以用低中位數。

`statistics.median_high(data)`

回傳數值型資料的高中位數 (high median)。若 `data` 為空，則引發 `StatisticsError`。`data` 可為 `sequence` 或者 `iterable`。

高中位數一定會在原本的資料集當中。當資料點數量為奇數時，回傳中間值。當數量為偶數時，回傳兩個中間值當中較大的值。

```
>>> median_high([1, 3, 5])
3
>>> median_high([1, 3, 5, 7])
5
```

當你的資料為離散資料，且你希望中位數是實際的資料點而不是插值時，可以用高中位數。

`statistics.median_grouped(data, interval=1.0)`

Estimates the median for numeric data that has been [grouped or binned](#) around the midpoints of consecutive, fixed-width intervals.

The `data` can be any iterable of numeric data with each value being exactly the midpoint of a bin. At least one value must be present.

The `interval` is the width of each bin.

For example, demographic information may have been summarized into consecutive ten-year age groups with each group being represented by the 5-year midpoints of the intervals:

```
>>> from collections import Counter
>>> demographics = Counter({
...     25: 172, # 20 to 30 years old
...     35: 484, # 30 to 40 years old
...     45: 387, # 40 to 50 years old
...     55: 22, # 50 to 60 years old
...     65: 6, # 60 to 70 years old
... })
... 
```

The 50th percentile (median) is the 536th person out of the 1071 member cohort. That person is in the 30 to 40 year old age group.

The regular `median()` function would assume that everyone in the tricenarian age group was exactly 35 years old. A more tenable assumption is that the 484 members of that age group are evenly distributed between 30 and 40. For that, we use `median_grouped()`:

```
>>> data = list(demographics.elements())
>>> median(data)
35
>>> round(median_grouped(data, interval=10), 1)
37.5
```

The caller is responsible for making sure the data points are separated by exact multiples of *interval*. This is essential for getting a correct result. The function does not check this precondition.

Inputs may be any numeric type that can be coerced to a float during the interpolation step.

`statistics.mode(data)`

回傳離散或名目 *data* 中出現次數最多次的值，只回傳一個。☐數（如果存在）是最典型的值，☐用來衡量資料的中心位置。

若有多個出現次數相同的☐數，則回傳在 *data* 中最先出現的☐數。如果希望回傳其中最小或最大的☐數，可以使用 `min(multimode(data))` 或 `max(multimode(data))`。如果輸入的 *data* ☐空，則會引發 `StatisticsError`。

`mode` 假定☐離散資料，☐回傳單一的值。這也是一般學校教授的标准☐數定義：

```
>>> mode([1, 1, 2, 3, 3, 3, 3, 4])
3
```

☐數特☐之處在於它是此套件中唯一也適用於名目（非數值型）資料的統計量：

```
>>> mode(["red", "blue", "blue", "red", "green", "red", "red"])
'red'
```

Only hashable inputs are supported. To handle type `set`, consider casting to `frozenset`. To handle type `list`, consider casting to `tuple`. For mixed or nested inputs, consider using this slower quadratic algorithm that only depends on equality tests: `max(data, key=data.count)`.

在 3.8 版的變更：現在，遇到資料中有多個☐數時，會回傳第一個遇到的☐數。在以前，當找到大於一個☐數時，會引發 `StatisticsError`。

`statistics.multimode(data)`

回傳一個 `list`，其組成☐ *data* 中出現次數最多次的值，☐按照它們在 *data* 中首次出現的順序排列。如果有多個☐數，將會回傳所有結果。若 *data* ☐空，則回傳空的 `list`：

```
>>> multimode('aabbbbccddddeeffffgg')
['b', 'd', 'f']
>>> multimode('')
[]
```

在 3.8 版被加入。

`statistics.pstdev(data, mu=None)`

回傳母體標準差（即母體變☐數的平方根）。有關引數以及其他細節，請參見 `pvariance()`。

```
>>> pstdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
0.986893273527251
```

`statistics.pvariance(data, mu=None)`

回傳 *data* 的母體變☐數。*data* 可☐非空實數 `sequence` 或者 `iterable`。變☐數，或者以平均數☐中心的二階動差，用於衡量資料的變☐性（離度或分散程度）。變☐數大表示資料分散，變☐數小表示資料集中在平均數附近。

若有傳入選擇性的第二個引數  $\mu$ ，該引數應該要是  $data$  的母體平均值 (population mean)。它也可以用於計算非以平均值中心的第二動差。如果沒有傳入此引數或者引數 `None` (預設值)，則自動計算資料的算數平均數。

使用此函式來計算整個母體的變數。如果要從樣本估算變數，`variance()` 通常是較好的選擇。若  $data$  空，則引發 `StatisticsError`。

範例：

```
>>> data = [0.0, 0.25, 0.25, 1.25, 1.5, 1.75, 2.75, 3.25]
>>> pvariance(data)
1.25
```

如果已經計算出資料的平均值，你可以將其作選擇性的第二個引數  $\mu$  傳遞以避免重新計算：

```
>>> mu = mean(data)
>>> pvariance(data, mu)
1.25
```

支援小數 (decimal) 與分數 (fraction)：

```
>>> from decimal import Decimal as D
>>> pvariance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('24.815')

>>> from fractions import Fraction as F
>>> pvariance([F(1, 4), F(5, 4), F(1, 2)])
Fraction(13, 72)
```

#### 備註

當在整個母體上呼叫此函式時，會回傳母體變數  $\sigma^2$ 。當在樣本上呼叫此函式時，會回傳有偏差的樣本變數  $s^2$ ，也就是具有  $N$  個自由度的變數。

若你以某種方式知道真正的母體平均數  $\mu$ ，你可以將一個已知的母體平均數作第二個引數提供給此函式，用以計算樣本的變數。只要資料點是母體的隨機樣本，結果將是母體變數的不偏估計。

`statistics.stdev(data, xbar=None)`

回傳樣本標準差 (即樣本變數的平方根)。有關引數以及其他細節，請參見 `variance()`。

```
>>> stdev([1.5, 2.5, 2.5, 2.75, 3.25, 4.75])
1.0810874155219827
```

`statistics.variance(data, xbar=None)`

回傳  $data$  的樣本變數。 $data$  兩個值以上的實數 iterable。變數，或者以平均數中心的二階動差，用於衡量資料的變性 (離度或分散程度)。變數大表示資料分散，變數小表示資料集中在平均數附近。

若有傳入選擇性的第二個引數  $xbar$ ，它應該是  $data$  的樣本平均值 (sample mean)。如果沒有傳入或者 `None` (預設值)，則自動計算資料的平均值。

當你的資料是來自母體的樣本時，請使用此函式。若要從整個母體計算變數，請參見 `pvariance()`。

若  $data$  少於兩個值，則引發 `StatisticsError`。

範例：

```
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> variance(data)
1.3720238095238095
```

如果已經計算出資料的樣本平均值，你可以將其作選擇性的第二個引數  $mu$  傳遞以避免重新計算：

```
>>> m = mean(data)
>>> variance(data, m)
1.3720238095238095
```

此函式不會驗證你傳入的  $xbar$  是否實際的平均數。傳入任意的  $xbar$  會導致無效或不可能的結果。支援小數 (decimal) 與分數 (fraction)：

```
>>> from decimal import Decimal as D
>>> variance([D("27.5"), D("30.25"), D("30.25"), D("34.5"), D("41.75")])
Decimal('31.01875')

>>> from fractions import Fraction as F
>>> variance([F(1, 6), F(1, 2), F(5, 3)])
Fraction(67, 108)
```

### 備

這是經過 Bessel 校正 (Bessel's correction) 後的樣本變數  $s^2$ ，又稱自由度  $N-1$  的變數。只要資料點具有代表性 (例如：獨立且具有相同分布)，結果應該會是對真實母體變數的不偏估計。

若你剛好知道真正的母體平均數  $\mu$ ，你應該將其作  $mu$  參數傳入 `pvariance()` 函式來計算樣本變數。

`statistics.quantiles(data, *, n=4, method='exclusive')`

將  $data$  分成  $n$  個具有相等機率的連續區間。回傳一個包含  $n - 1$  個用於切分各區間的分隔點的 list。

將  $n$  設 4 以表示四分位數 (quartile) (預設值)。將  $n$  設置 100 表示百分位數 (percentile)，這將給出 99 個分隔點將  $data$  分成 100 個大小相等的組。如果  $n$  不是至少 1，則引發 `StatisticsError`。

The  $data$  can be any iterable containing sample data. For meaningful results, the number of data points in  $data$  should be larger than  $n$ . Raises `StatisticsError` if there is not at least one data point.

分隔點是從兩個最近的資料點性插值計算出來的。舉例來，如果分隔點落在兩個樣本值 100 與 112 之間的距離三分之一處，則分隔點的值將 104。

計算分位數的  $method$  可以根據  $data$  是否包含或排除來自母體的最小與最大可能的值而改變。

預設的  $method$  是 "exclusive"，用於從可能找到比樣本更極端的值的母體中抽樣的樣本資料。對於  $m$  個已排序的資料點，計算出低於  $i$ -th 的部分  $i / (m + 1)$ 。給定九個樣本資料，此方法將對資料排序且計算下列百分位數：10%、20%、30%、40%、50%、60%、70%、80%、90%。

若將  $method$  設 "inclusive"，則用於描述母體或者已知包含母體中最極端值的樣本資料。在  $data$  中的最小值被視第 0 百分位數，最大值第 100 百分位數。對於  $m$  個已排序的資料點，計算出低於  $i$ -th 的部分  $(i - 1) / (m - 1)$ 。給定十一個樣本資料，此方法將對資料排序且計算下列百分位數：0%、10%、20%、30%、40%、50%、60%、70%、80%、90%、100%。

```
# Decile cut points for empirically sampled data
>>> data = [105, 129, 87, 86, 111, 111, 89, 81, 108, 92, 110,
...         100, 75, 105, 103, 109, 76, 119, 99, 91, 103, 129,
...         106, 101, 84, 111, 74, 87, 86, 103, 103, 106, 86,
...         111, 75, 87, 102, 121, 111, 88, 89, 101, 106, 95,
...         103, 107, 101, 81, 109, 104]
>>> [round(q, 1) for q in quantiles(data, n=10)]
[81.0, 86.2, 89.0, 99.4, 102.5, 103.6, 106.0, 109.8, 111.0]
```

在 3.8 版被加入。

在 3.13 版的變更: No longer raises an exception for an input with only a single data point. This allows quantile estimates to be built up one sample point at a time becoming gradually more refined with each new data point.

`statistics.covariance(x, y, /)`

回傳兩輸入  $x$  與  $y$  的樣本共變數 (sample covariance)。共變數是衡量兩輸入的聯合變性 (joint variability) 的指標。

兩輸入必須具有相同長度 (至少兩個)，否則會引發 `StatisticsError`。

範例：

```
>>> x = [1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> y = [1, 2, 3, 1, 2, 3, 1, 2, 3]
>>> covariance(x, y)
0.75
>>> z = [9, 8, 7, 6, 5, 4, 3, 2, 1]
>>> covariance(x, z)
-7.5
>>> covariance(z, x)
-7.5
```

在 3.10 版被加入。

`statistics.correlation(x, y, /, *, method='linear')`

回傳兩輸入的 Pearson 相關數 (Pearson's correlation coefficient)。Pearson 相關數  $r$  的值介於  $-1$  與  $+1$  之間。它衡量性關的度與方向。

如果 `method` 是 "ranked"，則計算兩輸入的 Spearman 等級相關數 (Spearman's rank correlation coefficient)。資料將被取代等級。平手的情況則取平均，令相同的值排名也相同。所得數衡量單調關 (monotonic relationship) 的度。

Spearman 相關數適用於順序型資料，或者不符合 Pearson 相關數要求的性比例關的連續型 (continuous) 資料。

兩輸入必須具有相同長度 (至少兩個)，且不須常數，否則會引發 `StatisticsError`。

以 Kepler 行星運動定律例：

```
>>> # Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune
>>> orbital_period = [88, 225, 365, 687, 4331, 10_756, 30_687, 60_190] # days
>>> dist_from_sun = [58, 108, 150, 228, 778, 1_400, 2_900, 4_500] # million km

>>> # Show that a perfect monotonic relationship exists
>>> correlation(orbital_period, dist_from_sun, method='ranked')
1.0

>>> # Observe that a linear relationship is imperfect
>>> round(correlation(orbital_period, dist_from_sun), 4)
0.9882

>>> # Demonstrate Kepler's third law: There is a linear correlation
>>> # between the square of the orbital period and the cube of the
>>> # distance from the sun.
>>> period_squared = [p * p for p in orbital_period]
>>> dist_cubed = [d * d * d for d in dist_from_sun]
>>> round(correlation(period_squared, dist_cubed), 4)
1.0
```

在 3.10 版被加入。

在 3.12 版的變更: 新增了對 Spearman 等級相關數的支援。

`statistics.linear_regression(x, y, /, *, proportional=False)`

回傳使用普通最小平方法 (ordinary least square) 估計出的簡單性歸 (simple linear regression) 參數中的斜率 (slope) 與截距 (intercept)。簡單性歸描述自變數 (independent variable)  $x$  與應變數 (dependent variable)  $y$  之間的關，用以下的性函式表示：

$$y = \text{slope} * x + \text{intercept} + \text{noise}$$

其中 `slope` 和 `intercept` 是被估計的迴歸參數，而 `noise` 表示由迴歸未解釋的資料變異性（它等於應變數的預測值與實際值之差）。

兩輸入必須具有相同長度（至少兩個），且自變數  $x$  不得為常數，否則會引發 `StatisticsError`。

舉例來說，我們可以使用 `Monty Python` 系列電影的上映日期來預測至 2019 年為止，假設他們保持固定的製作速度，應該會產生的 `Monty Python` 電影的累計數量。

```
>>> year = [1971, 1975, 1979, 1982, 1983]
>>> films_total = [1, 2, 3, 4, 5]
>>> slope, intercept = linear_regression(year, films_total)
>>> round(slope * 2019 + intercept)
16
```

若將 `proportional` 設為 `True`，則假設自變數  $x$  與應變數  $y$  是直接成比例的，資料座落在通過原點的一直線上。由於 `intercept` 始終為 0.0，因此函式可簡化如下：

$$y = \text{slope} * x + \text{noise}$$

繼續 `correlation()` 中的範例，我們看看基於主要行星的模型可以如何很好地預測矮行星的軌道距離：

```
>>> model = linear_regression(period_squared, dist_cubed, proportional=True)
>>> slope = model.slope

>>> # Dwarf planets: Pluto, Eris, Makemake, Haumea, Ceres
>>> orbital_periods = [90_560, 204_199, 111_845, 103_410, 1_680] # days
>>> predicted_dist = [math.cbrt(slope * (p * p)) for p in orbital_periods]
>>> list(map(round, predicted_dist))
[5912, 10166, 6806, 6459, 414]

>>> [5_906, 10_152, 6_796, 6_450, 414] # actual distance in million km
[5906, 10152, 6796, 6450, 414]
```

在 3.10 版被加入。

在 3.11 版的變更：新增 `proportional` 的支援。

## 9.7.5 例外

定義了一個單一的例外：

**exception** `statistics.StatisticsError`

`ValueError` 的子類，用於和統計相關的例外。

## 9.7.6 NormalDist 物件

`NormalDist` 是一種用於建立與操作隨機變數 (random variable) 的常態分布的工具。它是一個將量測資料的平均數與標準差視為單一實體的類。

常態分布源自於中央極限定理 (Central Limit Theorem)，在統計學中有著廣泛的應用。

**class** `statistics.NormalDist (mu=0.0, sigma=1.0)`

此方法會回傳一個新 `NormalDist` 物件，其中 `mu` 代表算數平均數而 `sigma` 代表標準差。

若 `sigma` 為負值，則引發 `StatisticsError`。

**mean**

常態分布中的算數平均數唯讀屬性。

**median**

常態分布中的中位數唯讀屬性。

**mode**

常態分布中的`mode`唯讀屬性。

**stdev**

常態分布中的標準差唯讀屬性。

**variance**

常態分布中的變異數唯讀屬性。

**classmethod from\_samples (data)**

利用 `fmean()` 與 `stdev()` 函式，估計 `data` 的 `mu` 與 `sigma` 參數，建立一個常態分布的實例。

`data` 可以是任何 `iterable`，`data` 應包含可以轉換為 `float` 的值。若 `data` 有包含至少兩個以上的元素，則引發 `StatisticsError`，因至少需要一個點來估計中央值且至少需要兩個點來估計分散情形。

**samples (n, \*, seed=None)**

給定平均值與標準差，生成 `n` 個隨機樣本。回傳一個由 `float` 組成的 `list`。

若有給定 `seed`，則會建立一個以此為基礎的亂數生成器實例。這對於建立可重現的結果很有幫助，即使在多執行緒情境下也是如此。

在 3.13 版的變更。

Switched to a faster algorithm. To reproduce samples from previous versions, use `random.seed()` and `random.gauss()`.

**pdf (x)**

利用機率密度函數 (probability density function, pdf) 計算隨機變數 `X` 接近給定值 `x` 的相對概度 (relative likelihood)。數學上，它是比率  $P(x \leq X < x+dx) / dx$  在 `dx` 趨近於零時的極限值。

相對概度是樣本出現在狹窄範圍的機率，除以該範圍的寬度 (故稱「密度」) 計算而得。由於概度是相對於其它點，故其值可大於 1.0。

**cdf (x)**

利用累積分布函式 (cumulative distribution function, cdf) 計算隨機變數 `X` 小於或等於 `x` 的機率。數學上，它記  $P(X \leq x)$ 。

**inv\_cdf (p)**

計算反累計分布函式 (inverse cumulative distribution function)，也稱分位數函式 (quantile function) 或者百分率點 (percent-point) 函式。數學上記  $x : P(X \leq x) = p$ 。

找出一個值 `x`，使得隨機變數 `X` 小於或等於該值的機率等於給定的機率 `p`。

**overlap (other)**

衡量兩常態分布之間的一致性。回傳一個介於 0.0 與 1.0 之間的值，表示兩機率密度函式的重疊區域。

**quantiles (n=4)**

將常態分布分割成 `n` 個具有相等機率的連續區間。回傳一個 `list`，包含 `(n-1)` 個切割區間的分隔點。

將 `n` 設定為 4 表示四分位數 (預設值)。將 `n` 設定為 10 表示十分位數。將 `n` 設定為 100 表示百分位數，這會生成 99 個分隔點，將常態分布切割成大小相等的群組。

**zscore (x)**

計算標準分數 (Standard Score)，用以描述在常態分布中，`x` 高出或低於平均數幾個標準差： $(x - \text{mean}) / \text{stdev}$ 。

在 3.9 版被加入。

`NormalDist` 的實例支援對常數的加法、乘法、乘法與除法。這些操作用於平移與縮放。例如：

```
>>> temperature_february = NormalDist(5, 2.5)           # Celsius
>>> temperature_february * (9/5) + 32                 # Fahrenheit
NormalDist(mu=41.0, sigma=4.5)
```

不支援將常數除以 `NormalDist` 的實例，因結果將不符合常態分布。

由於常態分布源自於自變數的加法效應 (additive effects)，因此可以將兩個獨立的常態分布隨機變數相加與相，且表示 `NormalDist` 的實例。例如：

```
>>> birth_weights = NormalDist.from_samples([2.5, 3.1, 2.1, 2.4, 2.7, 3.5])
>>> drug_effects = NormalDist(0.4, 0.15)
>>> combined = birth_weights + drug_effects
>>> round(combined.mean, 1)
3.1
>>> round(combined.stdev, 1)
0.5
```

在 3.8 版被加入。

## 9.7.7 范例與錦囊妙計

### 經典機率問題

`NormalDist` 可以輕易地解經典的機率問題。

例如，給定 SAT 測驗的歷史資料，顯示成績平均 1060、標準差 195 的常態分布。我們要求出分數在 1100 與 1200 之間（四舍五入至最接近的整數）的學生的百分比：

```
>>> sat = NormalDist(1060, 195)
>>> fraction = sat.cdf(1200 + 0.5) - sat.cdf(1100 - 0.5)
>>> round(fraction * 100.0, 1)
18.4
```

找出 SAT 分數的四分位數以及十分位數：

```
>>> list(map(round, sat.quantiles()))
[928, 1060, 1192]
>>> list(map(round, sat.quantiles(n=10)))
[810, 896, 958, 1011, 1060, 1109, 1162, 1224, 1310]
```

### 用於模擬的蒙地卡羅 (Monte Carlo) 輸入

欲估計一個不易透過解析方法求解的模型的分佈，`NormalDist` 可以生輸入樣本以進行蒙地卡羅模擬：

```
>>> def model(x, y, z):
...     return (3*x + 7*x*y - 5*y) / (11 * z)
...
>>> n = 100_000
>>> X = NormalDist(10, 2.5).samples(n, seed=3652260728)
>>> Y = NormalDist(15, 1.75).samples(n, seed=4582495471)
>>> Z = NormalDist(50, 1.25).samples(n, seed=6582483453)
>>> quantiles(map(model, X, Y, Z))
[1.4591308524824727, 1.8035946855390597, 2.175091447274739]
```

### 近似二項分布

當樣本數量大，且試驗成功的機率接近 50%，可以使用常態分布來近似二項分布 (Binomial distributions)。

例如，一場有 750 位參加者的開源研討會中，有兩間可容納 500 人的會議室。一場是關於 Python 的講座，另一場則是關於 Ruby 的。在過去的會議中，有 65% 的參加者傾向參與 Python 講座。假設參與者的偏好有改變，那 Python 會議室未超過自身容量限制的機率是？

```
>>> n = 750                # Sample size
>>> p = 0.65               # Preference for Python
>>> q = 1.0 - p           # Preference for Ruby
>>> k = 500                # Room capacity
```

(繼續下一頁)

(繼續上一頁)

```

>>> # Approximation using the cumulative normal distribution
>>> from math import sqrt
>>> round(NormalDist(mu=n*p, sigma=sqrt(n*p*q)).cdf(k + 0.5), 4)
0.8402

>>> # Exact solution using the cumulative binomial distribution
>>> from math import comb, fsum
>>> round(fsum(comb(n, r) * p**r * q**(n-r) for r in range(k+1)), 4)
0.8402

>>> # Approximation using a simulation
>>> from random import seed, binomialvariate
>>> seed(8675309)
>>> mean(binomialvariate(n, p) <= k for i in range(10_000))
0.8406

```

### 單純貝氏分類器 (Naive bayesian classifier)

常態分布常在機器學習問題中出現。

維基百科有個 [Naive Bayesian Classifier](#) 的優良範例。課題 從身高、體重與鞋子尺寸等符合常態分布的特徵量測值中判斷一個人的性 。

給定一組包含八個人的量測值的訓練資料集。假設這些量測值服從常態分布，我們可以利用 `NormalDist` 來總結資料：

```

>>> height_male = NormalDist.from_samples([6, 5.92, 5.58, 5.92])
>>> height_female = NormalDist.from_samples([5, 5.5, 5.42, 5.75])
>>> weight_male = NormalDist.from_samples([180, 190, 170, 165])
>>> weight_female = NormalDist.from_samples([100, 150, 130, 150])
>>> foot_size_male = NormalDist.from_samples([12, 11, 12, 10])
>>> foot_size_female = NormalDist.from_samples([6, 8, 7, 9])

```

接著，我們遇到一個新的人，他的特徵量測值已知，但性 未知：

```

>>> ht = 6.0      # height
>>> wt = 130     # weight
>>> fs = 8       # foot size

```

從可能 男性或女性的 50% 先驗機率 (prior probability) 開端，我們將後驗機率 (posterior probability) 計算 先驗機率乘以給定性 下，各特徵量測值的概度乘積：

```

>>> prior_male = 0.5
>>> prior_female = 0.5
>>> posterior_male = (prior_male * height_male.pdf(ht) *
...                  weight_male.pdf(wt) * foot_size_male.pdf(fs))

>>> posterior_female = (prior_female * height_female.pdf(ht) *
...                    weight_female.pdf(wt) * foot_size_female.pdf(fs))

```

最終的預測結果將取 於最大的後驗機率。這被稱 最大後驗機率 (maximum a posteriori) 或者 MAP：

```

>>> 'male' if posterior_male > posterior_female else 'female'
'female'

```

The modules described in this chapter provide functions and classes that support a functional programming style, and general operations on callables.

本章包含下列的模組：

## 10.1 `itertools` --- 建立無限生成高效率之迭代器的函式

這個模組實作了許多迭代器 (*iterator*) 構建塊 (building block)，其靈感來自 APL、Haskell 和 SML 的結構。每個構建塊都以適合 Python 的形式來重新設計。

這個模組標準化了快速且高效率利用記憶體的核心工具集，這些工具本身或組合使用都很有用。它們共同構成了一個「迭代器代數 (iterator algebra)」，使得在純 Python 中簡潔且高效地建構專用工具成可能。

例如，SML 提供了一個造表工具：`tabulate(f)`，它生成一個序列  $f(0), f(1), \dots$ 。在 Python 中，可以透過結合 `map()` 和 `count()` 組成 `map(f, count())` 以達到同樣的效果。

無限迭代器：

迭代器	引數	結果	範例
<code>count()</code>	[start[, step]]	start, start+step, start+2*step, ...	<code>count(10)</code> → 10 11 12 13 14 ...
<code>cycle()</code>	p	p0, p1, ... p <sub>last</sub> , p0, p1, ...	<code>cycle('ABCD')</code> → A B C D A B C D ...
<code>repeat()</code>	elem [,n]	elem, elem, elem, ... 重無限次或 n 次	<code>repeat(10, 3)</code> → 10 10 10

在最短輸入序列 (shortest input sequence) 處終止的迭代器：

代器	引數	結果	範例
<code>accumulate()</code>	<code>p [,func]</code>	<code>p0, p0+p1, p0+p1+p2, ...</code>	<code>accumulate([1,2,3,4,5])</code> → 1 3 6 10 15
<code>batched()</code>	<code>p, n</code>	<code>(p0, p1, ..., p_n-1), ...</code>	<code>batched('ABCDEFGH', n=3)</code> → ABC DEF G
<code>chain()</code>	<code>p, q, ...</code>	<code>p0, p1, ... plast, q0, q1, ...</code>	<code>chain('ABC', 'DEF')</code> → A B C D E F
<code>chain.from_iterable()</code>	可代物件	<code>p0, p1, ... plast, q0, q1, ...</code>	<code>chain.from_iterable(['ABC', 'DEF'])</code> → A B C D E F
<code>compress()</code>	<code>data, selectors</code>	<code>(d[0] if s[0]), (d[1] if s[1]), ...</code>	<code>compress('ABCDEF', [1,0,1,0,1,1])</code> → A C E F
<code>dropwhile()</code>	<code>predicate, seq</code>	<code>seq[n], seq[n+1],</code> 當 <code>predicate</code> 失敗時開始	<code>dropwhile(lambda x: x&lt;5, [1,4,6,3,8])</code> → 6 3 8
<code>filterfalse()</code>	<code>predicate, seq</code>	當 <code>predicate(elem)</code> 失敗時 <code>seq</code> 的元素	<code>filterfalse(lambda x: x&lt;5, [1,4,6,3,8])</code> → 6 8
<code>groupby()</code>	<code>iterable[, key]</code>	根據 <code>key(v)</code> 的值分組的子代器	<code>groupby(['A','B','DEF'], len)</code> → (1, A B) (3, DEF)
<code>islice()</code>	<code>seq, [start,] stop [, step]</code>	<code>seq[start:stop:step]</code> 的元素	<code>islice('ABCDEFGH', 2, None)</code> → C D E F G
<code>pairwise()</code>	可代物件	<code>(p[0], p[1]), (p[1], p[2])</code>	<code>pairwise('ABCDEFGH')</code> → AB BC CD DE EF FG
<code>starmap()</code>	<code>func, seq</code>	<code>func(*seq[0]), func(*seq[1]), ...</code>	<code>starmap(pow, [(2,5), (3,2), (10,3)])</code> → 32 9 1000
<code>takewhile()</code>	<code>predicate, seq</code>	<code>seq[0], seq[1],</code> 直到 <code>predicate</code> 失敗	<code>takewhile(lambda x: x&lt;5, [1,4,6,3,8])</code> → 1 4
<code>tee()</code>	<code>it, n</code>	<code>it1, it2, ... itn,</code> 將一個代器分成 <code>n</code> 個	
<code>zip_longest()</code>	<code>p, q, ...</code>	<code>(p[0], q[0]), (p[1], q[1]), ...</code>	<code>zip_longest('ABCD', 'xy', fillvalue='-')</code> → Ax By C- D-

組合代器:

代器	引數	結果
<code>product()</code>	<code>p, q, ... [repeat=1]</code>	笛卡爾乘積 (cartesian product), 相當於巢狀的 <code>for</code> 圈
<code>permutations()</code>	<code>p[, r]</code>	長度 <code>r</code> 的元組, 所有可能的定序, 無重元素
<code>combinations()</code>	<code>p, r</code>	長度 <code>r</code> 的元組, 按照排序過後的定序, 無重元素
<code>combinations_with_replacement()</code>	<code>p, r</code>	長度 <code>r</code> 的元組, 按照排序過後的定序, 有重元素

範例	結果
<code>product('ABCD', repeat=2)</code>	AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD
<code>permutations('ABCD', 2)</code>	AB AC AD BA BC BD CA CB CD DA DB DC
<code>combinations('ABCD', 2)</code>	AB AC AD BC BD CD
<code>combinations_with_replacement('ABCD', 2)</code>	AA AB AC AD BB BC BD CC CD DD

### 10.1.1 itertools 函式

以下的函式都會建構回傳代器。一些函式提供無限長度的串流 (stream)，因此應僅由截斷串流的函式或圈來存取它們。

`itertools.accumulate(iterable[, function, *, initial=None])`

建立一個回傳累積和的代器，或其他二進位函式的累積結果。

`function` 預設加法。`function` 應接受兩個引數，即累積總和和來自 `iterable` 的值。

如果提供了 `initial` 值，則累積將從該值開始，且輸出的元素數將比輸入的可代物件多一個。

大致等價於：

```
def accumulate(iterable, function=operator.add, *, initial=None):
    'Return running totals'
    # accumulate([1,2,3,4,5]) → 1 3 6 10 15
    # accumulate([1,2,3,4,5], initial=100) → 100 101 103 106 110 115
    # accumulate([1,2,3,4,5], operator.mul) → 1 2 6 24 120

    iterator = iter(iterable)
    total = initial
    if initial is None:
        try:
            total = next(iterator)
        except StopIteration:
            return

    yield total
    for element in iterator:
        total = function(total, element)
        yield total
```

`function` 引數可以被設定 `min()` 以得到連續的最小值，設定 `max()` 以得到連續的最大值，或者設定 `operator.mul()` 以得到連續的乘積。也可以透過累積利息和付款來建立攤銷表 (Amortization tables)：

```
>>> data = [3, 4, 6, 2, 1, 9, 0, 7, 5, 8]
>>> list(accumulate(data, max))           # running maximum
[3, 4, 6, 6, 6, 9, 9, 9, 9, 9]
>>> list(accumulate(data, operator.mul)) # running product
[3, 12, 72, 144, 144, 1296, 0, 0, 0, 0]

# Amortize a 5% loan of 1000 with 10 annual payments of 90
>>> update = lambda balance, payment: round(balance * 1.05) - payment
>>> list(accumulate(repeat(90, 10), update, initial=1_000))
[1000, 960, 918, 874, 828, 779, 728, 674, 618, 559, 497]
```

可參見 `functools.reduce()`，其是個類似的函式，但僅回傳最終的累積值。

在 3.2 版被加入。

在 3.3 版的變更：新增可選的 `function` 參數。

在 3.8 版的變更：新增可選的 `initial` 參數。

`itertools.batched(iterable, n, *, strict=False)`

將來自 `iterable` 的資料分批長度 `n` 的元組。最後一個批次可能比 `n` 短。

If `strict` is true, will raise a `ValueError` if the final batch is shorter than `n`.

對輸入的可代物件進行圈，將資料累積到大小 `n` 的元組中。輸入是惰性地被消耗 (consumed lazily) 的，會剛好足填充一批的資料。一旦批次填滿或輸入的可代物件耗盡，就會 yield 出結果：

```
>>> flattened_data = ['roses', 'red', 'violets', 'blue', 'sugar', 'sweet']
>>> unflattened = list(batched(flattened_data, 2))
>>> unflattened
[('roses', 'red'), ('violets', 'blue'), ('sugar', 'sweet')]
```

大致等價於：

```
def batched(iterable, n, *, strict=False):
    # batched('ABCDEFGG', 3) → ABC DEF G
    if n < 1:
        raise ValueError('n must be at least one')
    iterator = iter(iterable)
    while batch := tuple(islice(iterator, n)):
        if strict and len(batch) != n:
            raise ValueError('batched(): incomplete batch')
        yield batch
```

在 3.12 版被加入。

在 3.13 版的變更：新增 *strict* 選項。

`itertools.chain(*iterables)`

建立一個迭代器，從第一個可迭代物件回傳元素直到其耗盡，然後繼續處理下一個可迭代物件，直到所有可迭代物件都耗盡。這將多個資料來源結合為單一個迭代器。大致等價於：

```
def chain(*iterables):
    # chain('ABC', 'DEF') → A B C D E F
    for iterable in iterables:
        yield from iterable
```

`classmethod chain.from_iterable(iterable)`

`chain()` 的另一個建構函式。從單個可迭代的引數中得到鏈接的輸入，該引數是惰性計算的。大致等價於：

```
def from_iterable(iterables):
    # chain.from_iterable(['ABC', 'DEF']) → A B C D E F
    for iterable in iterables:
        yield from iterable
```

`itertools.combinations(iterable, r)`

從輸入 *iterable* 中回傳長度 *r* 的元素的子序列。

輸出是 `product()` 的子序列，僅保留作 *iterable* 子序列的條目。輸出的長度由 `math.comb()` 給定，當  $0 \leq r \leq n$  時，長度為  $n! / r! / (n - r)!$ ，當  $r > n$  時為零。

根據輸入值 *iterable* 的順序，組合的元組會按照字典順序輸出。如果輸入的 *iterable* 已經排序，則輸出的元組也將按排序的順序生成。

元素是根據它們的位置（而非值）來確定其唯一性。如果輸入的元素都是獨特的，則每個組合將不會有重複的值。

大致等價於：

```
def combinations(iterable, r):
    # combinations('ABCD', 2) → AB AC AD BC BD CD
    # combinations(range(4), 3) → 012 013 023 123

    pool = tuple(iterable)
    n = len(pool)
    if r > n:
        return
    indices = list(range(r))
```

(繼續下一頁)

(繼續上一頁)

```

yield tuple(pool[i] for i in indices)
while True:
    for i in reversed(range(r)):
        if indices[i] != i + n - r:
            break
    else:
        return
    indices[i] += 1
    for j in range(i+1, r):
        indices[j] = indices[j-1] + 1
    yield tuple(pool[i] for i in indices)

```

`itertools.combinations_with_replacement` (*iterable*, *r*)

回傳來自輸入 *iterable* 的長度 *r* 的子序列，且允許個元素重多次。

其輸出是一個 `product()` 的子序列，僅保留作 *iterable* 子序列（可能有重元素）的條目。當  $n > 0$  時，回傳的子序列數量  $(n + r - 1)! / r! / (n - 1)!$ 。

根據輸入值 *iterable* 的順序，組合的元組會按照字典順序輸出。如果輸入的 *iterable* 已經排序，則輸出的元組也將按排序的順序生。

元素是根據它們的位置（而非值）來定其唯一性。如果輸入的元素都是獨特的，生成的組合也將是獨特的。

大致等價於：

```

def combinations_with_replacement(iterable, r):
    # combinations_with_replacement('ABC', 2) -> AA AB AC BB BC CC

    pool = tuple(iterable)
    n = len(pool)
    if not n and r:
        return
    indices = [0] * r

    yield tuple(pool[i] for i in indices)
    while True:
        for i in reversed(range(r)):
            if indices[i] != n - 1:
                break
        else:
            return
        indices[i:] = [indices[i] + 1] * (r - i)
        yield tuple(pool[i] for i in indices)

```

在 3.1 版被加入。

`itertools.compress` (*data*, *selectors*)

建立一個代器，回傳 *data* 中對應 *selectors* 的元素 `true` 的元素。當 *data* 或 *selectors* 可代物件耗盡時停止。大致等價於：

```

def compress(data, selectors):
    # compress('ABCDEF', [1,0,1,0,1,1]) -> A C E F
    return (datum for datum, selector in zip(data, selectors) if selector)

```

在 3.1 版被加入。

`itertools.count` (*start=0*, *step=1*)

建立一個代器，回傳從 *start* 開始的等差的值。可以與 `map()` 一起使用來生連續的資料點，或與 `zip()` 一起使用來增加序列號。大致等價於：

```
def count(start=0, step=1):
    # count(10) → 10 11 12 13 14 ...
    # count(2.5, 0.5) → 2.5 3.0 3.5 ...
    n = start
    while True:
        yield n
        n += step
```

當用浮點數計數時，將上述程式碼替換乘法有時可以獲得更好的精確度，例如：`(start + step * i for i in count())`。

在 3.1 版的變更：新增 `step` 引數允許非整數引數。

`itertools.cycle(iterable)`

建立一個代器，回傳 `iterable` 中的元素保存每個元素的副本。當可代物件耗盡時，從保存的副本中回傳元素。會無限次的重。大致等價於：

```
def cycle(iterable):
    # cycle('ABCD') → A B C D A B C D A B C D ...

    saved = []
    for element in iterable:
        yield element
        saved.append(element)

    while saved:
        for element in saved:
            yield element
```

此 `itertool` 可能需要大量的輔助儲存空間（取於可代物件的長度）。

`itertools.dropwhile(predicate, iterable)`

建立一個代器，在 `predicate` 為 `true` 時略過 `iterable` 中的元素，之後回傳每個元素。大致等價於：

```
def dropwhile(predicate, iterable):
    # dropwhile(lambda x: x<5, [1,4,6,3,8]) → 6 3 8

    iterator = iter(iterable)
    for x in iterator:
        if not predicate(x):
            yield x
            break

    for x in iterator:
        yield x
```

注意，在 `predicate` 首次變為 `False` 之前，這不會產生任何輸出，所以此 `itertool` 可能會有較長的啟動時間。

`itertools.filterfalse(predicate, iterable)`

建立一個代器，過濾 `iterable` 中的元素，僅回傳 `predicate` 為 `False` 值的元素。如果 `predicate` 是 `None`，則回傳 `False` 的項目。大致等價於：

```
def filterfalse(predicate, iterable):
    # filterfalse(lambda x: x<5, [1,4,6,3,8]) → 6 8

    if predicate is None:
        predicate = bool

    for x in iterable:
        if not predicate(x):
            yield x
```

`itertools.groupby(iterable, key=None)`

建立一個迭代器，回傳 `iterable` 中連續的鍵和群組。`key` 是一個每個元素計算鍵值的函式。如果其未指定或 `None`，則 `key` 預設一個識性函式 (identity function)，回傳未被更改的元素。一般來，可代物件需要已經用相同的鍵函式進行排序。

`groupby()` 的操作類似於 Unix 中的 `uniq` 過濾器。每當鍵函式的值發生變化時，它會生一個 `break` 或新的群組（這就是什通常需要使用相同的鍵函式對資料進行排序）。這種行不同於 SQL 的 `GROUP BY`，其無論輸入順序如何都會聚合相同的元素。

回傳的群組本身是一個與 `groupby()` 共享底層可代物件的迭代器。由於來源是共享的，當 `groupby()` 物件前進時，前一個群組將不再可見。因此，如果之後需要該資料，應將其儲存串列：

```
groups = []
uniquekeys = []
data = sorted(data, key=keyfunc)
for k, g in groupby(data, keyfunc):
    groups.append(list(g))      # Store group iterator as a list
    uniquekeys.append(k)
```

`groupby()` 大致等價於：

```
def groupby(iterable, key=None):
    # [k for k, g in groupby('AAAABBBCCDAABBB')] → A B C D A B
    # [list(g) for k, g in groupby('AAAABBBCCD')] → AAAA BBB CC D

    keyfunc = (lambda x: x) if key is None else key
    iterator = iter(iterable)
    exhausted = False

    def _grouper(target_key):
        nonlocal curr_value, curr_key, exhausted
        yield curr_value
        for curr_value in iterator:
            curr_key = keyfunc(curr_value)
            if curr_key != target_key:
                return
            yield curr_value
        exhausted = True

    try:
        curr_value = next(iterator)
    except StopIteration:
        return
    curr_key = keyfunc(curr_value)

    while not exhausted:
        target_key = curr_key
        curr_group = _grouper(target_key)
        yield curr_key, curr_group
        if curr_key == target_key:
            for _ in curr_group:
                pass
```

`itertools.islice(iterable, stop)`

`itertools.islice(iterable, start, stop[, step])`

建立一個迭代器，回傳從 `iterable` 中選取的元素。其作用類似於序列切片 (sequence slicing)，但不支援負數的 `start`、`stop` 或 `step` 的值。

如果 `start` 零或 `None`，則從零開始代。否則在達到 `start` 之前，會跳過 `iterable` 中的元素。

如果 `stop` `None`，則代將繼續前進直到輸入耗盡。如果指定了 `stop`，則在達到指定位置時停止。

如果 `step` 為 `None`，則步長 (`step`) 預設為 1。元素會連續回傳，除非將 `step` 設定大於一，這會導致一些項目被跳過。

大致等價於：

```
def islice(iterable, *args):
    # islice('ABCDEFGH', 2) → A B
    # islice('ABCDEFGH', 2, 4) → C D
    # islice('ABCDEFGH', 2, None) → C D E F G
    # islice('ABCDEFGH', 0, None, 2) → A C E G

    s = slice(*args)
    start = 0 if s.start is None else s.start
    stop = s.stop
    step = 1 if s.step is None else s.step
    if start < 0 or (stop is not None and stop < 0) or step <= 0:
        raise ValueError

    indices = count() if stop is None else range(max(start, stop))
    next_i = start
    for i, element in zip(indices, iterable):
        if i == next_i:
            yield element
            next_i += step
```

If the input is an iterator, then fully consuming the `islice` advances the input iterator by `max(start, stop)` steps regardless of the `step` value.

`itertools.pairwise(iterable)`

回傳從輸入的 `iterable` 中提取的連續重疊對。

輸出代器中的 2 元組數量將比輸入少一個。如果輸入的可代物件中的值少於兩個，則輸出將空值。

大致等價於：

```
def pairwise(iterable):
    # pairwise('ABCDEFGH') → AB BC CD DE EF FG

    iterator = iter(iterable)
    a = next(iterator, None)

    for b in iterator:
        yield a, b
        a = b
```

在 3.10 版被加入。

`itertools.permutations(iterable, r=None)`

回傳 `iterable` 中連續且長度為 `r` 的元素排列。

如果未指定 `r` 或其值為 `None`，則 `r` 預設為 `iterable` 的長度，生成所有可能的完整長度的排列。

輸出是 `product()` 的子序列，其中重疊元素的條目已被濾除。輸出的長度由 `math.perm()` 給定，當  $0 \leq r \leq n$  時，長度為  $n! / (n - r)!$ ，當  $r > n$  時為零。

根據輸入值 `iterable` 的順序，排列的元組會按照字典順序輸出。如果輸入的 `iterable` 已排序，則輸出的元組也將按排序的順序生成。

元素是根據它們的位置（而非值）來固定其唯一性。如果輸入的元素都是獨特的，則排列中將不會有重疊的值。

大致等價於：

```

def permutations(iterable, r=None):
    # permutations('ABCD', 2) → AB AC AD BA BC BD CA CB CD DA DB DC
    # permutations(range(3)) → 012 021 102 120 201 210

    pool = tuple(iterable)
    n = len(pool)
    r = n if r is None else r
    if r > n:
        return

    indices = list(range(n))
    cycles = list(range(n, n-r, -1))
    yield tuple(pool[i] for i in indices[:r])

    while n:
        for i in reversed(range(r)):
            cycles[i] -= 1
            if cycles[i] == 0:
                indices[i:] = indices[i+1:] + indices[i:i+1]
                cycles[i] = n - i
            else:
                j = cycles[i]
                indices[i], indices[-j] = indices[-j], indices[i]
                yield tuple(pool[i] for i in indices[:r])
                break
        else:
            return

```

`itertools.product(*iterables, repeat=1)`

Cartesian product of the input iterables.

大致等價於生成器運算式中的巢狀 `for` 圈。例如，`product(A, B)` 的回傳結果與 `((x, y) for x in A for y in B)` 相同。

巢狀圈的循環類似於里程表，最右邊的元素在每次迭代時前進。這種模式會建立字典順序，因此如果輸入的 `iterables` 已排序，則輸出的乘積元組也將按排序的順序生成。

要計算可迭代物件自身的乘積，可以使用可選的 `repeat` 關鍵字引數來指定重復次數。例如，`product(A, repeat=4)` 與 `product(A, A, A, A)` 相同。

此函式大致等價於以下的程式碼，不同之處在於真正的實作不會在記憶體中建立中間結果：

```

def product(*iterables, repeat=1):
    # product('ABCD', 'xy') → Ax Ay Bx By Cx Cy Dx Dy
    # product(range(2), repeat=3) → 000 001 010 011 100 101 110 111

    if repeat < 0:
        raise ValueError('repeat argument cannot be negative')
    pools = [tuple(pool) for pool in iterables] * repeat

    result = [[]]
    for pool in pools:
        result = [x+[y] for x in result for y in pool]

    for prod in result:
        yield tuple(prod)

```

在 `product()` 執行之前，它會完全消耗輸入的 `iterables`，將值的池 (pools of values) 保存在記憶體中以生成乘積。因此，它僅對有限的輸入有用。

`itertools.repeat(object[, times])`

建立一個迭代器，反覆回傳 `object`。除非指定了 `times` 引數，否則會執行無限次。

大致等價於：

```
def repeat(object, times=None):
    # repeat(10, 3) → 10 10 10
    if times is None:
        while True:
            yield object
    else:
        for i in range(times):
            yield object
```

`repeat` 的常見用途是 `map` 或 `zip` 提供定值的串流：

```
>>> list(map(pow, range(10), repeat(2)))
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

`itertools.starmap` (*function, iterable*)

建立一個 `map` 代器，使用從 *iterable* 獲取的引數計算 *function*。當引數參數已經被「預先壓縮 (pre-zipped)」成元組時，使用此方法代替 `map()`。

`map()` 和 `starmap()` 之間的區別類似於 `function(a,b)` 和 `function(*c)` 之間的區別。大致等價於：

```
def starmap(function, iterable):
    # starmap(pow, [(2,5), (3,2), (10,3)]) → 32 9 1000
    for args in iterable:
        yield function(*args)
```

`itertools.takewhile` (*predicate, iterable*)

建立一個 `map` 代器，只在 *predicate* 為 `true` 時回傳 *iterable* 中的元素。大致等價於：

```
def takewhile(predicate, iterable):
    # takewhile(lambda x: x<5, [1,4,6,3,8]) → 1 4
    for x in iterable:
        if not predicate(x):
            break
        yield x
```

注意，第一個不符合條件判斷的元素將從輸入 `map` 代器中被消耗，且無法再存取它。如果應用程式希望在 `takewhile` 耗盡後進一步消耗輸入 `map` 代器，這可能會是個問題。了解這個問題，可以考慮使用 `more-itertools` 中的 `before_and_after()` 作替代。

`itertools.tee` (*iterable, n=2*)

從一個 *iterable* 中回傳 *n* 個獨立的 `map` 代器。

大致等價於：

```
def tee(iterable, n=2):
    if n < 0:
        raise ValueError
    if n == 0:
        return ()
    iterator = _tee(iterable)
    result = [iterator]
    for _ in range(n - 1):
        result.append(_tee(iterator))
    return tuple(result)

class _tee:
    def __init__(self, iterable):
        it = iter(iterable)
        if isinstance(it, _tee):
```

(繼續下一頁)

(繼續上一頁)

```

        self.iterator = it.iterator
        self.link = it.link
    else:
        self.iterator = it
        self.link = [None, None]

    def __iter__(self):
        return self

    def __next__(self):
        link = self.link
        if link[1] is None:
            link[0] = next(self.iterator)
            link[1] = [None, None]
        value, self.link = link
        return value

```

When the input *iterable* is already a tee iterator object, all members of the return tuple are constructed as if they had been produced by the upstream *tee()* call. This "flattening step" allows nested *tee()* calls to share the same underlying data chain and to have a single update step rather than a chain of calls.

The flattening property makes tee iterators efficiently peekable:

```

def lookahead(tee_iterator):
    "Return the next value without moving the input forward"
    [forked_iterator] = tee(tee_iterator, 1)
    return next(forked_iterator)

```

```

>>> iterator = iter('abcdef')
>>> [iterator] = tee(iterator, 1)    # Make the input peekable
>>> next(iterator)                  # Move the iterator forward
'a'
>>> lookahead(iterator)             # Check next value
'b'
>>> next(iterator)                  # Continue moving forward
'b'

```

*tee()* 代器不是執行緒安全 (threadsafe) 的。當同時使用由同一個 *tee()* 呼叫所回傳的 *tee()* 代器時，即使原始的 *iterable* 是執行緒安全的，也可能引發 *RuntimeError*。

此 *itertools* 可能需要大量的輔助儲存空間 (取決於需要儲存多少臨時資料)。通常如果一個 *tee()* 代器在另一個 *tee()* 代器開始之前使用了大部分或全部的資料，使用 *list()* 會比 *tee()* 更快。

*itertools.zip\_longest* (\*iterables, fillvalue=None)

建立一個 *tee()* 代器，聚合來自每個 *iterables* 中的元素。

如果 *iterables* 的長度不一，則使用 *fillvalue* 填充缺少的值。如果未指定，*fillvalue* 會預設 *None*。

*tee()* 代將持續直到最長的可 *tee()* 代物件耗盡為止。

大致等價於：

```

def zip_longest(*iterables, fillvalue=None):
    # zip_longest('ABCD', 'xy', fillvalue='-') → Ax By C- D-

    iterators = list(map(iter, iterables))
    num_active = len(iterators)
    if not num_active:
        return

    while True:
        values = []

```

(繼續下一頁)

```

for i, iterator in enumerate(iterators):
    try:
        value = next(iterator)
    except StopIteration:
        num_active -= 1
        if not num_active:
            return
        iterators[i] = repeat(fillvalue)
        value = fillvalue
    values.append(value)
yield tuple(values)

```

如果其中一個 iterables 可能是無限的，那應該用可以限制呼叫次數的方法來包裝 `zip_longest()` 函式（例如 `islice()` 或 `takewhile()`）。

### 10.1.2 Itertools 應用技巧

此段落展示了使用現有的 `itertools` 作構建塊來建立擴展工具集的應用技巧。

`itertools` 應用技巧的主要目的是教學。這些應用技巧展示了對單個工具進行思考的各種方式——例如，`chain.from_iterable` 與攤平 (flattening) 的概念相關。這些應用技巧還提供了組合使用工具的想法——例如，`starmap()` 和 `repeat()` 如何一起工作。另外還展示了將 `itertools` 與 `operator` 和 `collections` 模組一同使用以及與自建 `itertools`（如 `map()`、`filter()`、`reversed()` 和 `enumerate()`）一同使用的模式。

應用技巧的次要目的是作 `itertools` 的孵化器。`accumulate()`、`compress()` 和 `pairwise()` `itertools` 最初都是作應用技巧出現的。目前，`sliding_window()`、`iter_index()` 和 `sieve()` 的應用技巧正在被測試，以確定它們是否有價值被收到自建的 `itertools` 中。

幾乎所有這些應用技巧以及許多其他應用技巧都可以從 Python Package Index 上的 `more-itertools` 專案中安裝：

```
python -m pip install more-itertools
```

許多應用技巧提供了與底層工具集相同的高性能。透過一次處理一個元素而不是將整個可代物件一次性引入記憶體，能保持優的記憶體性能。以函式風格 (functional style) 將工具連接在一起，能將程式碼的數量維持在較少的情。透過優先使用「向量化 (vectorized)」的構建塊而不是使用會造成直譯器負擔的 `for` 圈和生成器，則能保持高速度。

```

from collections import Counter, deque

    return prod(map(comb, accumulate(counts), counts))

```

## 10.2 functools --- 可呼叫物件上的高階函式與操作

原始碼: Lib/functools.py

`functools` 模組用於高階函式：作用於或回傳其他函式的函式。一般來，任何可呼叫物件都可以被視用於此模組的函式。

`functools` 模組定義了以下函式：

`@functools.cache` (*user\_function*)

簡單的輕量級無結函式快取 (Simple lightweight unbounded function cache)。有時稱之 “memoize” (記憶化)。

和 `lru_cache` (`maxsize=None`) 回傳相同的值，函式引數建立一個字典查找的薄包裝器。因它永遠不需要舊值，所以這比有大小限制的 `lru_cache()` 更小、更快。

舉例來：

```

@cache
def factorial(n):
    return n * factorial(n-1) if n else 1

>>> factorial(10)      # no previously cached result, makes 11 recursive calls
3628800
>>> factorial(5)      # just looks up cached value result
120
>>> factorial(12)     # makes two new recursive calls, the other 10 are cached
479001600

```

該快取是執行緒安全的 (threadsafe)，因此包裝的函式可以在多個執行緒中使用。這意味著底層資料結構在更新期間將保持連貫 (coherent)。

如果另一個執行緒在初始呼叫完成快取之前進行額外的呼叫，則包裝的函式可能會被多次呼叫。

在 3.9 版被加入。

`@functools.cached_property(func)`

將類的一個方法轉成屬性 (property)，其值會計算一次，然後在實例的生命週期快取普通屬性。類似 `property()`，但增加了快取機制。對於除使用該裝飾器的屬性外實質上幾乎是不可變 (immutable) 的實例，針對其所需要繁重計算會很有用。

範例：

```
class DataSet:

    def __init__(self, sequence_of_numbers):
        self._data = tuple(sequence_of_numbers)

    @cached_property
    def stdev(self):
        return statistics.stdev(self._data)
```

`cached_property()` 的機制與 `property()` 有所不同。除非定義了 setter，否則常規屬性會阻止屬性的寫入。相反地，`cached_property` 則允許寫入。

`cached_property` 裝飾器僅在查找時且僅在同名屬性不存在時運行。當它運行時，`cached_property` 會寫入同名的屬性。後續屬性讀取和寫入優先於 `cached_property` 方法，且它的工作方式與普通屬性類似。

可以透過刪除屬性來清除快取的值，這使得 `cached_property` 方法可以再次運行。

`cached_property` 無法防止多執行緒使用中可能出現的競態條件 (race condition)。getter 函式可以在同一個實例上運行多次，最後一次運行會設定快取的值。所以快取的屬性最好是等 (idempotent)，或者在一個實例上運行多次不會有害，就不會有問題。如果同步是必要的，請在裝飾的 getter 函式部或在快取的屬性存取周圍實作必要的鎖。

請注意，此裝飾器會干擾 PEP 412 金鑰共用字典的操作。這意味著實例字典可能比平常用更多的空間。

此外，此裝飾器要求每個實例上的 `__dict__` 屬性是可變對映 (mutable mapping)。這意味著它不適用於某些型別，例如元類 (metaclass) (因型別實例上的 `__dict__` 屬性是類命名空間的唯讀代理)，以及那些指定 `__slots__` 而不包含 `__dict__` 的型別 (有定義的插槽之一 (因此此種類別根本不提供 `__dict__` 屬性))。

如果可變對映不可用或需要金鑰共享以節省空間，則也可以透過在 `lru_cache()` 之上堆疊 `property()` 來實作類似於 `cached_property()` 的效果。請參閱 `faq-cache-method-calls` 以了解有關這與 `cached_property()` 間不同之處的更多詳細資訊。

在 3.8 版被加入。

在 3.12 版的變更：在 Python 3.12 之前，`cached_property` 包含一個未以文件記的鎖，以確保在多執行緒使用中能保證 getter 函式對於每個實例只會執行一次。然而，鎖是針對每個屬性，而不是針對每個實例，這可能會導致無法被接受的嚴重鎖 (lock contention)。在 Python 3.12+ 中，此鎖已被刪除。

`functools.cmp_to_key(func)`

將舊式比較函式轉成鍵函式，能與接受鍵函式的工具一起使用 (例如 `sorted()`、`min()`、`max()`、`heapq.nlargest()`、`heapq.nsmallest()`、`itertools.groupby()`)。此函式主要作轉工具，用於從有支援使用比較函式的 Python 2 轉成的程式。

比較函式是任何能接受兩個引數、對它們進行比較，回傳負數 (小於)、零 (相等) 或正數 (大於) 的可呼叫物件。鍵函式是接受一個引數回傳另一個用作排序鍵之值的可呼叫物件。

範例：

```
sorted(iterable, key=cmp_to_key(locale.strcoll)) # locale-aware sort order
```

有關排序範例和簡短的排序教學，請參閱 `sortinghowto`。

在 3.2 版被加入。

`@functools.lru_cache(user_function)`

```
@functools.lru_cache(maxsize=128, typed=False)
```

以記憶化可呼叫物件來包裝函式的裝飾器，最多可省去 *maxsize* 個最近的呼叫。當使用相同引數定期呼叫繁重的或 I/O 密集的函式時，它可以節省時間。

該快取是執行緒安全的 (threadsafe)，因此包裝的函式可以在多個執行緒中使用。這意味著底層資料結構在執行更新期間將保持連貫 (coherent)。

如果另一個執行緒在初始呼叫完成快取之前進行額外的呼叫，則包裝的函式可能會被多次呼叫。

由於字典用於快取結果，因此函式的位置引數和關鍵字引數必須是可雜的。

不同的引數模式可以被認為是具有不同快取條目的不同呼叫。例如，`f(a=1, b=2)` 和 `f(b=2, a=1)` 的關鍵字引數順序不同，且可能有兩個不同的快取條目。

如果指定了 *user\_function*，則它必須是個可呼叫物件。這使得 *lru\_cache* 裝飾器能直接應用於使用者函式，將 *maxsize* 保留其預設值 128：

```
@lru_cache
def count_vowels(sentence):
    return sum(sentence.count(vowel) for vowel in 'AEIOUaeiou')
```

如果 *maxsize* 設定 `None`，則 LRU 功能將被停用，且快取可以無限制地成長。

如果 *typed* 設定 `true`，不同型的函式引數將會被單獨快取起來。如果 *typed* `false`，則實作通常會將它們視等效呼叫，且僅快取單一結果。(某些型，例如 *str* 和 *int* 可能會被單獨快取起來，即使 *typed* `false`。)

請注意，型特性 (type specificity) 僅適用於函式的直接引數而不是其內容。純量 (scalar) 引數 `Decimal(42)` 和 `Fraction(42)` 被視為具有不同結果的不同呼叫。相反地，元組引數 `('answer', Decimal(42))` 和 `('answer', Fraction(42))` 被視為等效。

包裝的函式使用一個 `cache_parameters()` 函式來進行偵測，該函式回傳一個新的 *dict* 以顯示 *maxsize* 和 *typed* 的值。這僅能顯示資訊，改變其值不會有任何效果。

為了輔助測量快取的有效性調整 *maxsize* 參數，包裝的函式使用了一個 `cache_info()` 函式來做檢測，該函式會回傳一個附名元組來顯示 *hits*、*misses*、*maxsize* 和 *currsz*。

裝飾器還提供了一個 `cache_clear()` 函式來清除或使快取失效。

原本的底層函式可以透過 `__wrapped__` 屬性存取。這對於要自我檢查 (introspection)、繞過快取或使用不同的快取重新包裝函式時非常有用。

快取會保留對引數和回傳值的參照，直到快取過時 (age out) 或快取被清除止。

如果方法被快取起來，則 `self` 實例引數將包含在快取中。請參 [faq-cache-method-calls](#)

當最近的呼叫是即將發生之呼叫的最佳預測因子時 (例如新聞伺服器上最受歡迎的文章往往每天都會發生變化)，LRU (least recently used) 快取能發揮最好的效果。快取的大小限制可確保快取不會在長時間運行的行程 (例如 Web 伺服器) 上無限制地成長。

一般來，僅當你想要重用先前計算的值時才應使用 LRU 快取。因此，快取具有 side-effects 的函式、需要在每次呼叫時建立不同可變物件的函式 (例如生成器和非同步函式) 或不純函式 (impure function，例如 `time()` 或 `random()`) 是有意義的。

態網頁內容的 LRU 快取範例：

```
@lru_cache(maxsize=32)
def get_pep(num):
    'Retrieve text of a Python Enhancement Proposal'
    resource = f'https://peps.python.org/pep-{num:04d}'
    try:
        with urllib.request.urlopen(resource) as s:
            return s.read()
    except urllib.error.HTTPError:
        return 'Not Found'

>>> for n in 8, 290, 308, 320, 8, 218, 320, 279, 289, 320, 9991:
```

(繼續下一頁)

(繼續上一頁)

```
...     pep = get_pep(n)
...     print(n, len(pep))

>>> get_pep.cache_info()
CacheInfo(hits=3, misses=8, maxsize=32, currsize=8)
```

使用快取來實作動態規劃 (dynamic programming) 技法以有效率地計算費波那契數 (Fibonacci numbers) 的範例：

```
@lru_cache(maxsize=None)
def fib(n):
    if n < 2:
        return n
    return fib(n-1) + fib(n-2)

>>> [fib(n) for n in range(16)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610]

>>> fib.cache_info()
CacheInfo(hits=28, misses=16, maxsize=None, currsize=16)
```

在 3.2 版被加入。

在 3.3 版的變更：新增 *typed* 選項。

在 3.8 版的變更：新增 *user\_function* 選項。

在 3.9 版的變更：新增 `cache_parameters()` 函式。

#### @functools.total\_ordering

給定一個定義一個或多個 rich comparison 排序方法的類，該類裝飾器會提供其余部分。這簡化了指定所有可能的 rich comparison 操作所涉及的工作：

類必須定義 `__lt__()`、`__le__()`、`__gt__()` 或 `__ge__()` 其中之一。此外，該類應該提供 `__eq__()` 方法。

舉例來：

```
@total_ordering
class Student:
    def _is_valid_operand(self, other):
        return (hasattr(other, "lastname") and
                hasattr(other, "firstname"))
    def __eq__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) ==
                (other.lastname.lower(), other.firstname.lower()))
    def __lt__(self, other):
        if not self._is_valid_operand(other):
            return NotImplemented
        return ((self.lastname.lower(), self.firstname.lower()) <
                (other.lastname.lower(), other.firstname.lower()))
```

#### 備

雖然此裝飾器可以輕鬆建立能好好運作的完全有序型 (totally ordered types)，但它的確以衍生比較方法的執行速度較慢和堆 (stack trace) 較雜做其代價。如果效能基準測試顯示這是給定應用程式的效能瓶頸，那實作全部六種 rich comparison 方法通常能輕鬆地提升速度。

**備**

此裝飾器不會嘗試覆寫類或其超類 (*superclass*) 中宣告的方法。這意味著如果超類定義了比較運算子，`total_ordering` 將不會再次實作它，即使原始方法是抽象的。

在 3.2 版被加入。

在 3.4 版的變更: 現在支援從底層對於未識型型的比較函式回傳 `NotImplemented`。

`functools.partial(func, /, *args, **keywords)`

回傳一個新的 *partial* 物件，它在被呼叫時的行類似於使用位置引數 *args* 和關鍵字引數 *keywords* 呼叫的 *func*。如果向呼叫提供更多引數，它們將被附加到 *args*。如果提供了額外的關鍵字引數，它們會擴充覆寫 *keywords*。大致相當於：

```
def partial(func, /, *args, **keywords):
    def newfunc(*fargs, **fkeywords):
        newkeywords = {**keywords, **fkeywords}
        return func(*args, *fargs, **newkeywords)
    newfunc.func = func
    newfunc.args = args
    newfunc.keywords = keywords
    return newfunc
```

`partial()` 用於部分函式應用程序，它「凍結」函式引數和/或關鍵字的某些部分，從而生成具有簡化簽名的新物件。例如，`partial()` 可用來建立可呼叫函式，其行類似於 `int()` 函式，其中 *base* 引數預設 2：

```
>>> from functools import partial
>>> basetwo = partial(int, base=2)
>>> basetwo.__doc__ = 'Convert base 2 string to an int.'
>>> basetwo('10010')
18
```

`class functools.partialmethod(func, /, *args, **keywords)`

回傳一個新的 *partialmethod* 描述器 (descriptor)，其行類似於 *partial*，只不過它被設計用於方法定義而不能直接呼叫。

*func* 必須是一個 *descriptor* 或可呼叫物件 (兩者兼具的物件，就像普通函式一樣，會被當作描述器處理)。

當 *func* 是描述器時 (例如普通的 Python 函式、`classmethod()`、`staticmethod()`、`abstractmethod()` 或 *partialmethod* 的另一個實例)，對 `__get__` 的呼叫將被委任 (delegated) 給底層描述器，且一個適當的 *partial* 物件會被作結果回傳。

當 *func* 是非描述器可呼叫物件 (non-descriptor callable) 時，會動態建立適當的結方法 (bound method)。當被作方法使用時，其行類似於普通的 Python 函式：*self* 引數將作第一個位置引數插入，甚至會在提供給 *partialmethod* 建構函式的 *args* 和 *keywords* 的前面。

範例：

```
>>> class Cell:
...     def __init__(self):
...         self._alive = False
...     @property
...     def alive(self):
...         return self._alive
...     def set_state(self, state):
...         self._alive = bool(state)
...     set_alive = partialmethod(set_state, True)
...     set_dead = partialmethod(set_state, False)
... 
```

(繼續下一頁)

```

>>> c = Cell()
>>> c.alive
False
>>> c.set_alive()
>>> c.alive
True

```

在 3.4 版被加入。

`functools.reduce` (*function, iterable, [initial, ]*)

從左到右，將兩個引數的 *function* 累加運用到 *iterable* 的項目上，從而將可迭代物件減少單一值。例如，`reduce(lambda x, y: x+y, [1, 2, 3, 4, 5])` 會計算出 `((((1+2)+3)+4)+5)`。左邊的引數 *x* 是累積值，右邊的引數 *y* 是來自 *iterable* 的更新值。如果可選的 *initial* 存在，則在計算中會將其放置在可迭代物件的項目之前，在可迭代物件空時作預設值。如果未給定 *initial* 且 *iterable* 僅包含一個項目，則回傳第一個項目。

大致相當於：

```

initial_missing = object()

def reduce(function, iterable, initial=initial_missing, /):
    it = iter(iterable)
    if initial is initial_missing:
        value = next(it)
    else:
        value = initial
    for element in it:
        value = function(value, element)
    return value

```

請參閱 `itertools.accumulate()` 以了解生成 (yield) 所有中間值 (intermediate value) 的迭代器。

`@functools singledispatch`

將函式轉為單一調度泛型函式。

若要定義泛型函式，請使用 `@singledispatch` 裝飾器對其裝飾。請注意，使用 `@singledispatch` 定義函式時，分派調度 (dispatch) 是發生在第一個引數的型別上：

```

>>> from functools import singledispatch
>>> @singledispatch
... def fun(arg, verbose=False):
...     if verbose:
...         print("Let me just say,", end=" ")
...     print(arg)

```

若要為函式新增過載實作，請使用泛型函式的 `register()` 屬性，該屬性可用作裝飾器。對於以型別來解釋的函式，裝飾器將自動推斷第一個引數的型別：

```

>>> @fun.register
... def _(arg: int, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> @fun.register
... def _(arg: list, verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)

```

也可以使用 `types.UnionType` 和 `typing.Union`：

```

>>> @fun.register
... def _(arg: int | float, verbose=False):
...     if verbose:
...         print("Strength in numbers, eh?", end=" ")
...     print(arg)
...
>>> from typing import Union
>>> @fun.register
... def _(arg: Union[list, set], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
...

```

對於不使用型釋的程式碼，可以將適當的型引數明確傳遞給裝飾器本身：

```

>>> @fun.register(complex)
... def _(arg, verbose=False):
...     if verbose:
...         print("Better than complicated.", end=" ")
...     print(arg.real, arg.imag)
...

```

For code that dispatches on a collections type (e.g., `list`), but wants to typehint the items of the collection (e.g., `list[int]`), the dispatch type should be passed explicitly to the decorator itself with the typehint going into the function definition:

```

>>> @fun.register(list)
... def _(arg: list[int], verbose=False):
...     if verbose:
...         print("Enumerate this:")
...     for i, elem in enumerate(arg):
...         print(i, elem)
...

```

### 備

At runtime the function will dispatch on an instance of a list regardless of the type contained within the list i.e. `[1, 2, 3]` will be dispatched the same as `["foo", "bar", "baz"]`. The annotation provided in this example is for static type checkers only and has no runtime impact.

若要用在 `lambdas` 和預先存在的函式，`register()` 屬性也能以函式形式使用：

```

>>> def nothing(arg, verbose=False):
...     print("Nothing.")
...
>>> fun.register(type(None), nothing)

```

`register()` 屬性回傳未加裝飾器的函式。這讓使得裝飾器堆疊 (decorator stacking)、*pickling* 以及每個變體獨立建立單元測試成可能：

```

>>> @fun.register(float)
... @fun.register(Decimal)
... def fun_num(arg, verbose=False):
...     if verbose:
...         print("Half of your number:", end=" ")
...     print(arg / 2)
...
>>> fun_num is fun
False

```

呼叫時，泛型函式會分派第一個引數的型：

```
>>> fun("Hello, world.")
Hello, world.
>>> fun("test.", verbose=True)
Let me just say, test.
>>> fun(42, verbose=True)
Strength in numbers, eh? 42
>>> fun(['spam', 'spam', 'eggs', 'spam'], verbose=True)
Enumerate this:
0 spam
1 spam
2 eggs
3 spam
>>> fun(None)
Nothing.
>>> fun(1.23)
0.615
```

如果`fun`有`fun`特定型`fun`實作，則使用其方法解析順序 (method resolution order) 來尋找更通用的實作。用 `@singledispatch` 裝飾的原始函式是`fun`基底`object`型`fun`的，這意味著如果`fun`有找到更好的實作就會使用它。

如果一個實作有被`fun`到一個抽象基底類`fun`，則基底類`fun`的`fun`擬子類`fun`將被分派到該實作：

```
>>> from collections.abc import Mapping
>>> @fun.register
... def _(arg: Mapping, verbose=False):
...     if verbose:
...         print("Keys & Values")
...     for key, value in arg.items():
...         print(key, "=>", value)
...
>>> fun({"a": "b"})
a => b
```

若要檢查泛型函式將`fun`給定型`fun`選擇哪種實作，請使用 `dispatch()` 屬性：

```
>>> fun.dispatch(float)
<function fun_num at 0x1035a2840>
>>> fun.dispatch(dict) # note: default implementation
<function fun at 0x103fe0000>
```

若要存取所有已`fun`的實作，請使用唯讀 `registry` 屬性：

```
>>> fun.registry.keys()
dict_keys([<class 'NoneType'>, <class 'int'>, <class 'object'>,
          <class 'decimal.Decimal'>, <class 'list'>,
          <class 'float'>])
>>> fun.registry[float]
<function fun_num at 0x1035a2840>
>>> fun.registry[object]
<function fun at 0x103fe0000>
```

在 3.4 版被加入。

在 3.7 版的變更: `register()` 屬性現在支援使用型`fun`釋。

在 3.11 版的變更: `register()` 屬性現在支援以`types.UnionType` 和`typing.Union` 作`fun`型`fun`釋。

**class** `functools.singledispatchmethod(func)`

將方法轉`fun`單一調度泛型函式。

若要定義泛型方法，請使用 `@singledispatchmethod` 裝飾器對其裝飾。請注意，使用 `@singledispatchmethod` 定義函式時，分派調度是發生在第一個非 `self` 或非 `cls` 引數的型`fun`上：

```
class Negator:
    @singledispatchmethod
    def neg(self, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    def _(self, arg: int):
        return -arg

    @neg.register
    def _(self, arg: bool):
        return not arg
```

`@singledispatchmethod` 支援與其他裝飾器巢狀使用 (nesting)，例如 `@classmethod`。請注意，`@singledispatchmethod` 必須是最外面的裝飾器。以下範例是 `Negator` 類，其 `neg` 方法結到該類，而不是該類的實例：

```
class Negator:
    @singledispatchmethod
    @classmethod
    def neg(cls, arg):
        raise NotImplementedError("Cannot negate a")

    @neg.register
    @classmethod
    def _(cls, arg: int):
        return -arg

    @neg.register
    @classmethod
    def _(cls, arg: bool):
        return not arg
```

相同的模式可用於其他類似的裝飾器：`@staticmethod`、`@abstractmethod` 等。

在 3.8 版被加入。

`functools.update_wrapper(wrapper, wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

更新 `wrapper` 函式，使其看起來像 `wrapped` 函式。可選引數是元組，用於指定原始函式的哪些屬性直接賦值給包裝函式上的匹配屬性，以及包裝函式的哪些屬性使用原始函式中的對應屬性進行更新。這些引數的預設值是模組層級的常數 `WRAPPER_ASSIGNMENTS`（它賦值給包裝函式的 `__module__`、`__name__`、`__qualname__`、`__annotations__`、`__type_params__` 和 `__doc__` 文件字串 (docstring)）和 `WRAPPER_UPDATES`（更新包裝器函式的 `__dict__`，即實例字典）。

為了允許出於自省 (introspection) 和其他目的所對原始函式的存取（例如繞過快取裝飾器，如 `lru_cache()`），此函式會自動向包裝器新增 `__wrapped__` 屬性，該包裝器參照被包裝的函式。

此函式的主要用途是在 `decorator` 函式中，它包裝函式回傳包裝器。如果包裝器函式未更新，則回傳函式的元資料 (metadata) 將反映包裝器定義而非原始函式定義，這通常不太會有幫助。

`update_wrapper()` 可以與函式以外的可呼叫物件一起使用。被包裝的物件中缺少的 `assigned` 或 `updated` 中指定的任何屬性都將被忽略（即此函式不會嘗試在包裝器函式上設定它們）。如果包裝函式本身缺少 `updated` 中指定的任何屬性，仍然會引發 `AttributeError`。

在 3.2 版的變更：現在會自動新增 `__wrapped__` 屬性。現在預設會 `__annotations__` 屬性。缺少的屬性不再觸發 `AttributeError`。

在 3.4 版的變更：`__wrapped__` 屬性現在都會參照包裝函式，即便函式有定義 `__wrapped__` 屬性。（參見 [bpo-17482](#)）

在 3.12 版的變更：現在預設會 `__type_params__` 屬性。

`@functools.wraps(wrapped, assigned=WRAPPER_ASSIGNMENTS, updated=WRAPPER_UPDATES)`

這是一個方便的函式，用於在定義包裝器函式時呼叫 `update_wrapper()` 作函式裝飾器。它相當於 `partial(update_wrapper, wrapped=wrapped, assigned=assigned, updated=updated)`。例如：

```
>>> from functools import wraps
>>> def my_decorator(f):
...     @wraps(f)
...     def wrapper(*args, **kwds):
...         print('Calling decorated function')
...         return f(*args, **kwds)
...     return wrapper
...
>>> @my_decorator
... def example():
...     """Docstring"""
...     print('Called example function')
...
>>> example()
Calling decorated function
Called example function
>>> example.__name__
'example'
>>> example.__doc__
'Docstring'
```

如果不使用這個裝飾器工廠 (decorator factory)，範例函式的名稱將會是 'wrapper'，且原始 `example()` 的文件字串將會遺失。

## 10.2.1 partial 物件

`partial` 物件是由 `partial()` 所建立的可呼叫物件。它們有三個唯讀屬性：

`partial.func`

一個可呼叫的物件或函式。對 `partial` 物件的呼叫將被轉送到帶有新引數和關鍵字的 `func`。

`partial.args`

最左邊的位置引數將會被加入到提供給 `partial` 物件呼叫的位置引數的前面。

`partial.keywords`

呼叫 `partial` 物件時將提供的關鍵字引數。

`partial` 物件與函式物件類似，因它們是可呼叫的、可弱參照的 (weak referencable) 且可以具有屬性。有一些重要的區別，例如，`__name__` 和 `function.__doc__` 屬性不會自動建立。此外，類中定義的 `partial` 物件的行類似於態方法，且在實例屬性查找期間不會轉態方法。

## 10.3 operator --- 標準運算子替代函式

原始碼：Lib/operator.py

`operator` module (模組) 提供了一套與 Python 原生運算子對應的高效率函式。例如，`operator.add(x, y)` 與表示式 `x+y` 相同。許多函式名與特殊方法名相同，只是有雙底。為了向後相容，許多包含雙底的函式被保留了下來，但為了易於表達，建議使用有雙底的函式。

函式種類有物件的比較運算、邏輯運算、數學運算以及序列運算。

物件比較函式適用於所有物件，函式根據它們對應的 rich comparison 運算子命名：

`operator.lt(a, b)`

`operator.le(a, b)`

```
operator.eq(a, b)
operator.ne(a, b)
operator.ge(a, b)
operator.gt(a, b)
operator.lt(a, b)
operator.le(a, b)
operator.__eq__(a, b)
operator.__ne__(a, b)
operator.__ge__(a, b)
operator.__gt__(a, b)
```

在  $a$  和  $b$  之間進行“rich comparison”。具體來，`lt(a, b)` 與  $a < b$  相同，`le(a, b)` 與  $a \leq b$  相同，`eq(a, b)` 與  $a == b$  相同，`ne(a, b)` 與  $a != b$  相同，`gt(a, b)` 與  $a > b$  相同，`ge(a, b)` 與  $a \geq b$  相同。注意這些函式可以回傳任何值，無論它是否可當作 `boolean`（布林）值。關於 rich comparison 的更多資訊請參考 `comparisons`。

邏輯運算通常也適用於所有物件，且支援真值檢測、識性測試和 `boolean` 運算：

```
operator.not_(obj)
operator.__not__(obj)
```

回傳 `not obj` 的結果。（請注意物件實例有 `__not__()` method（方法）；只有直譯器核心定義此操作。結果會受 `__bool__()` 和 `__len__()` method 影響。）

```
operator.truth(obj)
```

如果 `obj` 真值則回傳 `True`，否則回傳 `False`。這等價於使用 `bool` 建構器。

```
operator.is_(a, b)
```

回傳 `a is b`。測試物件識性。

```
operator.is_not(a, b)
```

回傳 `a is not b`。測試物件識性。

數學和位元運算的種類是最多的：

```
operator.abs(obj)
operator.__abs__(obj)
```

回傳 `obj` 的對值。

```
operator.add(a, b)
operator.__add__(a, b)
```

對於數字  $a$  和  $b$ ，回傳  $a + b$ 。

```
operator.and_(a, b)
operator.__and__(a, b)
```

回傳  $x$  和  $y$  位元運算與 `(and)` 的結果。

```
operator.floordiv(a, b)
operator.__floordiv__(a, b)
```

回傳  $a // b$ 。

```
operator.index(a)
operator.__index__(a)
```

回傳  $a$  轉整數的結果。等價於 `a.__index__()`。

在 3.10 版的變更：結果總是 `int` 型。在過去的版本中，結果可能 `int` 子類的實例。

```
operator.inv(obj)
operator.invert(obj)
operator.__inv__(obj)
```

`operator.__invert__(obj)`

回傳數字 *obj* 按位元取反 (inverse) 的結果。這等價於  $\sim obj$ 。

`operator.lshift(a, b)`

`operator.__lshift__(a, b)`

回傳 *a* 左移 *b* 位的結果。

`operator.mod(a, b)`

`operator.__mod__(a, b)`

回傳  $a \% b$ 。

`operator.mul(a, b)`

`operator.__mul__(a, b)`

對於數字 *a* 和 *b*，回傳  $a * b$ 。

`operator.matmul(a, b)`

`operator.__matmul__(a, b)`

回傳  $a @ b$ 。

在 3.5 版被加入。

`operator.neg(obj)`

`operator.__neg__(obj)`

回傳 *obj* 取負值的結果 ( $-obj$ )。

`operator.or_(a, b)`

`operator.__or__(a, b)`

回傳 *a* 和 *b* 按位元或 (or) 的結果。

`operator.pos(obj)`

`operator.__pos__(obj)`

回傳 *obj* 取正的結果 ( $+obj$ )。

`operator.pow(a, b)`

`operator.__pow__(a, b)`

對於數字 *a* 和 *b*，回傳  $a ** b$ 。

`operator.rshift(a, b)`

`operator.__rshift__(a, b)`

回傳 *a* 右移 *b* 位的結果。

`operator.sub(a, b)`

`operator.__sub__(a, b)`

回傳  $a - b$ 。

`operator.truediv(a, b)`

`operator.__truediv__(a, b)`

回傳  $a / b$ ，例如  $2/3$  將等於 .66 而不是 0。這也被稱「真」除法。

`operator.xor(a, b)`

`operator.__xor__(a, b)`

回傳 *a* 和 *b* 按位元或 (exclusive or) 的結果。

適用於序列的操作（其中一些也適用於對映 (mapping)），包括：

`operator.concat(a, b)`

`operator.__concat__(a, b)`

對於序列 *a* 和 *b*，回傳  $a + b$ 。

`operator.contains(a, b)`

`operator.__contains__(a, b)`

回傳 `b in a` 檢測的結果。請注意運算元是反序的。

`operator.countOf(a, b)`

回傳 `b` 在 `a` 中的出現次數。

`operator.delitem(a, b)`

`operator.__delitem__(a, b)`

移除 `a` 中索引 `b` 的值。

`operatorgetitem(a, b)`

`operator.__getitem__(a, b)`

回傳 `a` 中索引 `b` 的值。

`operator.indexOf(a, b)`

回傳 `b` 在 `a` 中首次出現所在的索引。

`operator.setitem(a, b, c)`

`operator.__setitem__(a, b, c)`

將 `a` 中索引 `b` 的值設 `c`。

`operator.length_hint(obj, default=0)`

回傳物件 `obj` 的估計長度。首先嘗試回傳其實際長度，再使用 `object.__length_hint__()` 得出估計值，最後才是回傳預設值。

在 3.4 版被加入。

The following operation works with callables:

`operator.call(obj, /, *args, **kwargs)`

`operator.__call__(obj, /, *args, **kwargs)`

Return `obj(*args, **kwargs)`.

在 3.11 版被加入。

`operator` module 還定義了一些用於常規屬性和條目查詢的工具。這些工具適合用來編寫快速欄位提取器以作 `map()`、`sorted()`、`itertools.groupby()` 或其他需要函式引數的函式之引數。

`operator.attrgetter(attr)`

`operator.attrgetter(*attrs)`

回傳一個可從運算元中獲取 `attr` 的可呼叫 (callable) 物件。如果請求了一個以上的屬性，則回傳一個包含屬性的 `tuple` (元組)。屬性名稱還可包含點號。例如：

- 在 `f = attrgetter('name')` 之後，呼叫 `f(b)` 將回傳 `b.name`。
- 在 `f = attrgetter('name', 'date')` 之後，呼叫 `f(b)` 將回傳 `(b.name, b.date)`。
- 在 `f = attrgetter('name.first', 'name.last')` 之後，呼叫 `f(b)` 將回傳 `(b.name.first, b.name.last)`。

等價於：

```
def attrgetter(*items):
    if any(not isinstance(item, str) for item in items):
        raise TypeError('attribute name must be a string')
    if len(items) == 1:
        attr = items[0]
        def g(obj):
            return resolve_attr(obj, attr)
    else:
        def g(obj):
            return tuple(resolve_attr(obj, attr) for attr in items)
    return g
```

(繼續下一頁)

(繼續上一頁)

```
def resolve_attr(obj, attr):
    for name in attr.split("."):
        obj = getattr(obj, name)
    return obj
```

operator.itemgetter(*item*)operator.itemgetter(\**items*)

回傳一個使用運算元的 `__getitem__()` 方法從運算元中獲取 *item* 的可呼叫物件。如果指定了多個條目，則回傳一個查詢值的 `tuple`。例如：

- 在 `f = itemgetter(2)` 之後，呼叫 `f(r)` 將回傳 `r[2]`。
- 在 `g = itemgetter(2, 5, 3)` 之後，呼叫 `g(r)` 將回傳 `(r[2], r[5], r[3])`。

等價於：

```
def itemgetter(*items):
    if len(items) == 1:
        item = items[0]
        def g(obj):
            return obj[item]
    else:
        def g(obj):
            return tuple(obj[item] for item in items)
    return g
```

傳入的條目可以運算元的 `__getitem__()` 所接受的任何型。dictionary (字典) 接受任意可雜的值。list、tuple 和字串接受索引或切片：

```
>>> itemgetter(1)('ABCDEFG')
'B'
>>> itemgetter(1, 3, 5)('ABCDEFG')
('B', 'D', 'F')
>>> itemgetter(slice(2, None))('ABCDEFG')
'CDEFG'
>>> soldier = dict(rank='captain', name='dotterbart')
>>> itemgetter('rank')(soldier)
'captain'
```

使用 `itemgetter()` 從 tuple 中提取特定欄位的例子：

```
>>> inventory = [('apple', 3), ('banana', 2), ('pear', 5), ('orange', 1)]
>>> getcount = itemgetter(1)
>>> list(map(getcount, inventory))
[3, 2, 5, 1]
>>> sorted(inventory, key=getcount)
 [('orange', 1), ('banana', 2), ('apple', 3), ('pear', 5)]
```

operator.methodcaller(*name*, /, \**args*, \*\**kwargs*)

回傳一個在運算元上呼叫 *name* method 的可呼叫物件。如果給定額外的引數和/或關鍵字引數，它們也將被傳給該 method。例如：

- 在 `f = methodcaller('name')` 之後，呼叫 `f(b)` 將回傳 `b.name()`。
- 在 `f = methodcaller('name', 'foo', bar=1)` 之後，呼叫 `f(b)` 將回傳 `b.name('foo', bar=1)`。

等價於：

```
def methodcaller(name, /, *args, **kwargs):
    def caller(obj):
```

(繼續下一頁)

(繼續上一頁)

```

return getattr(obj, name)(*args, **kwargs)
return caller

```

### 10.3.1 運算子與函式間的對映

以下表格表示了抽象運算是如何對應於 Python 語法中的運算子和 `operator` module 中的函式。

運算	語法	函式
加法	<code>a + b</code>	<code>add(a, b)</code>
字串串接	<code>seq1 + seq2</code>	<code>concat(seq1, seq2)</code>
包含性檢測	<code>obj in seq</code>	<code>contains(seq, obj)</code>
除法	<code>a / b</code>	<code>truediv(a, b)</code>
除法	<code>a // b</code>	<code>floordiv(a, b)</code>
按位元與 (And)	<code>a &amp; b</code>	<code>and_(a, b)</code>
按位元互斥或 (Exclusive Or)	<code>a ^ b</code>	<code>xor(a, b)</code>
按位元取反 (Inversion)	<code>~ a</code>	<code>invert(a)</code>
按位元或 (Or)	<code>a   b</code>	<code>or_(a, b)</code>
取冪	<code>a ** b</code>	<code>pow(a, b)</code>
識別性	<code>a is b</code>	<code>is_(a, b)</code>
識別性	<code>a is not b</code>	<code>is_not(a, b)</code>
索引賦值	<code>obj[k] = v</code>	<code>setitem(obj, k, v)</code>
索引刪除	<code>del obj[k]</code>	<code>delitem(obj, k)</code>
索引取值	<code>obj[k]</code>	<code>getitem(obj, k)</code>
左移	<code>a &lt;&lt; b</code>	<code>lshift(a, b)</code>
模除 (Modulo)	<code>a % b</code>	<code>mod(a, b)</code>
乘法	<code>a * b</code>	<code>mul(a, b)</code>
矩陣乘法	<code>a @ b</code>	<code>matmul(a, b)</code>
反相 (算術)	<code>- a</code>	<code>neg(a)</code>
反相 (邏輯)	<code>not a</code>	<code>not_(a)</code>
正數	<code>+ a</code>	<code>pos(a)</code>
右移	<code>a &gt;&gt; b</code>	<code>rshift(a, b)</code>
切片賦值	<code>seq[i:j] = values</code>	<code>setitem(seq, slice(i, j), values)</code>
切片刪除	<code>del seq[i:j]</code>	<code>delitem(seq, slice(i, j))</code>
切片取值	<code>seq[i:j]</code>	<code>getitem(seq, slice(i, j))</code>
字串格式化	<code>s % obj</code>	<code>mod(s, obj)</code>
減法	<code>a - b</code>	<code>sub(a, b)</code>
真值檢測	<code>obj</code>	<code>truth(obj)</code>
比較大小	<code>a &lt; b</code>	<code>lt(a, b)</code>
比較大小	<code>a &lt;= b</code>	<code>le(a, b)</code>
相等性	<code>a == b</code>	<code>eq(a, b)</code>
不等性	<code>a != b</code>	<code>ne(a, b)</code>
比較大小	<code>a &gt;= b</code>	<code>ge(a, b)</code>
比較大小	<code>a &gt; b</code>	<code>gt(a, b)</code>

### 10.3.2 原地 (in-place) 運算子

許多運算都有「原地」版本。以下列出的是提供對原地運算子（與一般語法相比）更底層存取的函式，例如 `statement x += y` 相當於 `x = operator.iadd(x, y)`。一種方式來講就是 `z = operator.iadd(x, y)` 等價於組合陳述式 `z = x; z += y`。

在這些例子中，請注意當呼叫一個原地方法時，運算和賦值是分成兩個步驟來執行的。下面列出的原地函式只執行第一步，即呼叫原地方法，第二步賦值則不加處理。

對於不可變 (immutable) 的目標例如字串、數字和 tuple，更新的值會被計算，但不會被再被賦值給輸入變數：

```
>>> a = 'hello'
>>> iadd(a, ' world')
'hello world'
>>> a
'hello'
```

對於可變 (mutable) 的目標例如 list 和 dictionary, 原地方法將執行更新, 因此不需要後續賦值操作:

```
>>> s = ['h', 'e', 'l', 'l', 'o']
>>> iadd(s, [' ', 'w', 'o', 'r', 'l', 'd'])
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
>>> s
['h', 'e', 'l', 'l', 'o', ' ', 'w', 'o', 'r', 'l', 'd']
```

`operator.iadd(a, b)`

`operator.__iadd__(a, b)`

`a = iadd(a, b)` 等價於 `a += b`。

`operator.iand(a, b)`

`operator.__iand__(a, b)`

`a = iand(a, b)` 等價於 `a &= b`。

`operator.iconcat(a, b)`

`operator.__iconcat__(a, b)`

`a = iconcat(a, b)` 等價於 `a += b`, 其中 `a` 和 `b` 是序列。

`operator.ifloordiv(a, b)`

`operator.__ifloordiv__(a, b)`

`a = ifloordiv(a, b)` 等價於 `a //= b`。

`operator.ilshift(a, b)`

`operator.__ilshift__(a, b)`

`a = ilshift(a, b)` 等價於 `a <<= b`。

`operator.imod(a, b)`

`operator.__imod__(a, b)`

`a = imod(a, b)` 等價於 `a %= b`。

`operator.imul(a, b)`

`operator.__imul__(a, b)`

`a = imul(a, b)` 等價於 `a *= b`。

`operator.imatmul(a, b)`

`operator.__imatmul__(a, b)`

`a = imatmul(a, b)` 等價於 `a @= b`。

在 3.5 版被加入。

`operator.ior(a, b)`

`operator.__ior__(a, b)`

`a = ior(a, b)` 等價於 `a |= b`。

`operator.ipow(a, b)`

`operator.__ipow__(a, b)`

`a = ipow(a, b)` 等價於 `a **= b`。

`operator.irshift(a, b)`

---

`operator.__irshift__(a, b)`  
    `a = irshift(a, b)` 等價於 `a >>= b`。

`operator.isub(a, b)`  
`operator.__isub__(a, b)`  
    `a = isub(a, b)` 等價於 `a -= b`。

`operator.itruediv(a, b)`  
`operator.__itruediv__(a, b)`  
    `a = itrueidiv(a, b)` 等價於 `a /= b`。

`operator.ixor(a, b)`  
`operator.__ixor__(a, b)`  
    `a = ixor(a, b)` 等價於 `a ^= b`。

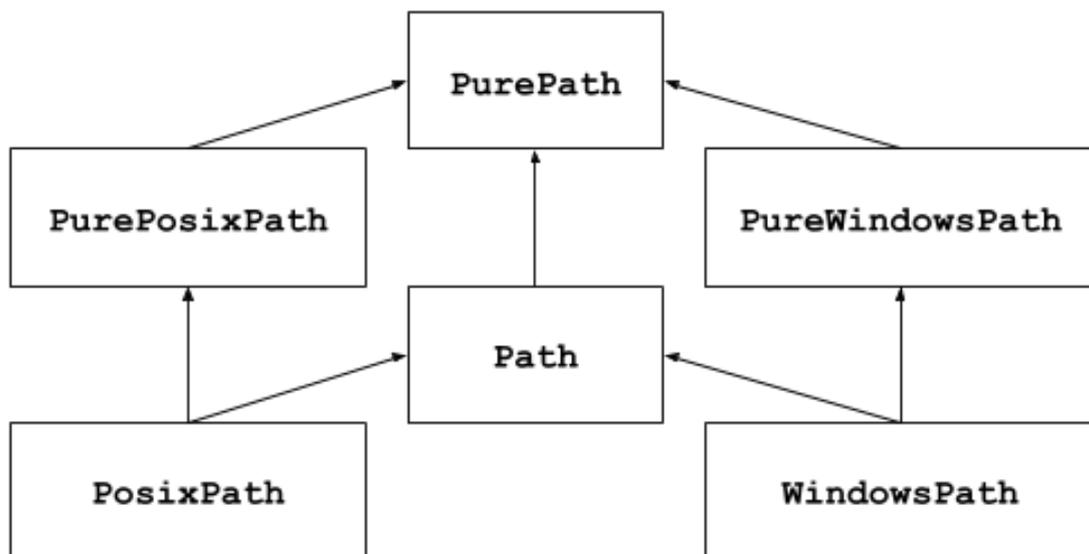

本章中描述的 module (模組) 用於處理硬碟檔案和目錄。例如，有一些 module 用於讀取檔案的屬性、以可移植 (portable) 方式操作路徑以及建立暫存檔。本章中的完整 module 清單是：

## 11.1 pathlib --- 物件導向檔案系統路徑

在 3.4 版被加入。

原始碼：[Lib/pathlib/](#)

此模組提供代表檔案系統路徑的類別，能適用不同作業系統的語意。路徑類別分成兩種，一種是純路徑 (*pure paths*)，提供只有 I/O 的單純計算操作，另一種是實體路徑 (*concrete paths*)，繼承自純路徑但也提供 IO 操作。

如果你之前從未使用過此模組或不確定哪個類適合你的任務，那你需要的最有可能是 `Path`。它針對程式執行所在的平台實例化一個實體路徑。

純路徑在某些特殊情境下是有用的，例如：

1. 如果你想在 Unix 機器上處理 Windows 路徑（或反過來），你無法在 Unix 上實例化 `WindowsPath`，但你可以實例化 `PureWindowsPath`。
2. 你想確保你的程式在操作路徑的時候不會真的存取到 OS。在這個情況下，實例化其中一種純路徑類可能是有用的，因為它們不會有任何存取 OS 的操作。

### 也參考

**PEP 428**: `pathlib` 模組 -- 物件導向檔案系統路徑。

### 也參考

針對字串上的底層路徑操作，你也可以使用 `os.path` 模組。

## 11.1.1 基本用法

匯入主要類：

```
>>> from pathlib import Path
```

列出子目：

```
>>> p = Path('.')
>>> [x for x in p.iterdir() if x.is_dir()]
[PosixPath('.hg'), PosixPath('docs'), PosixPath('dist'),
 PosixPath('__pycache__'), PosixPath('build')]
```

在當前目樹下列出 Python 原始碼檔案：

```
>>> list(p.glob('**/*.py'))
[PosixPath('test_pathlib.py'), PosixPath('setup.py'),
 PosixPath('pathlib.py'), PosixPath('docs/conf.py'),
 PosixPath('build/lib/pathlib.py')]
```

覽目樹部：

```
>>> p = Path('/etc')
>>> q = p / 'init.d' / 'reboot'
>>> q
PosixPath('/etc/init.d/reboot')
>>> q.resolve()
PosixPath('/etc/rc.d/init.d/halt')
```

查詢路徑屬性：

```
>>> q.exists()
True
>>> q.is_dir()
False
```

開檔案：

```
>>> with q.open() as f: f.readline()
...
'#!/bin/bash\n'
```

## 11.1.2 例外

### exception `pathlib.UnsupportedOperation`

繼承自 `NotImplementedError` 的例外，當在路徑物件上呼叫不支援的操作時會被引發。

在 3.13 版被加入。

## 11.1.3 純路徑

純路徑物件提供處理路徑的操作，實際上不會存取檔案系統。有三種方式可以存取這些類，我們也稱之類 (flavours):

### class `pathlib.PurePath` (\**pathsegments*)

一個通用的類，表示系統的路徑類型（實例化時會建立一個 `PurePosixPath` 或 `PureWindowsPath`）:

```
>>> PurePath('setup.py')           # 執行在 Unix 機器上
PurePosixPath('setup.py')
```

*pathsegments* 中的每個元素可以是以下的其中一種：一個表示路徑片段的字串，或一個物件，它實作了 `os.PathLike` 介面且其中的 `__fspath__()` 方法會回傳字串，就像是另一個路徑物件：

```
>>> PurePath('foo', 'some/path', 'bar')
PurePosixPath('foo/some/path/bar')
>>> PurePath(Path('foo'), Path('bar'))
PurePosixPath('foo/bar')
```

當有給 *pathsegments* 的時候，會假設是目前的目錄：

```
>>> PurePath()
PurePosixPath('.')
```

如果一個片段是絕對路徑，則所有之前的片段會被忽略（類似 `os.path.join()`）:

```
>>> PurePath('/etc', '/usr', 'lib64')
PurePosixPath('/usr/lib64')
>>> PureWindowsPath('c:/Windows', 'd:bar')
PureWindowsPath('d:bar')
```

在 Windows 系統上，當遇到具有根目錄的相對路徑片段（例如 `r'\foo'`）時，磁碟機 (drive) 部分不會被重置：

```
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

不必要的斜和單點會被省略，但雙點 (`'..'`) 和前置的雙斜 (`'//'`) 不會被省略，因為這樣會因為各種原因改變路徑的意義（例如符號連結 (symbolic links)、UNC 路徑）:

```
>>> PurePath('foo//bar')
PurePosixPath('foo/bar')
>>> PurePath('//foo/bar')
PurePosixPath('//foo/bar')
>>> PurePath('foo./bar')
PurePosixPath('foo/bar')
>>> PurePath('foo../bar')
PurePosixPath('foo../bar')
```

（一個使得 `PurePosixPath('foo../bar')` 等同於 `PurePosixPath('bar')` 的單純方法，但如果 `foo` 是指到另一個目錄的符號連結，就會是錯誤的。）

純路徑物件實作了 `os.PathLike` 介面，使得它們可以在任何接受該介面的地方使用。

在 3.6 版的變更: 新增了對於 `os.PathLike` 介面的支援。

`class pathlib.PurePosixPath(*pathsegments)`

`PurePath` 的一個子類，該路徑類型表示非 Windows 檔案系統的路徑：

```
>>> PurePosixPath('/etc/hosts')
PurePosixPath('/etc/hosts')
```

`pathsegments` 的指定方式與 `PurePath` 類似。

`class pathlib.PureWindowsPath(*pathsegments)`

`PurePath` 的一個子類，該路徑類型表示 Windows 檔案系統的路徑，包括 UNC paths：

```
>>> PureWindowsPath('c:/', 'Users', 'Ximénez')
PureWindowsPath('c:/Users/Ximénez')
>>> PureWindowsPath('//server/share/file')
PureWindowsPath('//server/share/file')
```

`pathsegments` 的指定方式與 `PurePath` 類似。

不論你使用的是什麼系統，你都可以實例化這些類，因為它們不提供任何涉及系統呼叫的操作。

## 通用屬性

路徑物件是不可變 (immutable) 且可雜 (hashable) 的。相同類型的路徑物件可以被比較和排序。這些屬性遵守該類型的大小寫語意規則：

```
>>> PurePosixPath('foo') == PurePosixPath('FOO')
False
>>> PureWindowsPath('foo') == PureWindowsPath('FOO')
True
>>> PureWindowsPath('FOO') in { PureWindowsPath('foo') }
True
>>> PureWindowsPath('C:') < PureWindowsPath('d:')
True
```

不同類型的路徑物件在比較時視不相等且無法被排序：

```
>>> PureWindowsPath('foo') == PurePosixPath('foo')
False
>>> PureWindowsPath('foo') < PurePosixPath('foo')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: '<' not supported between instances of 'PureWindowsPath' and 'PurePosixPath'
```

## 運算子

斜運算子 (slash operator) 用於建立子路徑，就像是 `os.path.join()` 函式一樣。如果引數是對路徑，則忽略前一個路徑。在 Windows 系統上，當引數是具有根目錄的相對路徑 (例如，`r'\foo'`)，磁碟機部分不會被重置：

```
>>> p = PurePath('/etc')
>>> p
PurePosixPath('/etc')
>>> p / 'init.d' / 'apache2'
PurePosixPath('/etc/init.d/apache2')
>>> q = PurePath('bin')
>>> '/usr' / q
PurePosixPath('/usr/bin')
>>> p / '/an_absolute_path'
PurePosixPath('/an_absolute_path')
>>> PureWindowsPath('c:/Windows', '/Program Files')
PureWindowsPath('c:/Program Files')
```

路徑物件可以被用在任何可以接受實作 `os.PathLike` 的物件的地方：

```
>>> import os
>>> p = PurePath('/etc')
>>> os.fspath(p)
'/etc'
```

路徑的字串表示是原始的檔案系統路徑本身（以原生的形式，例如在 Windows 下是反斜`\`），你可以將其傳入任何將檔案路徑當作字串傳入的函式：

```
>>> p = PurePath('/etc')
>>> str(p)
'/etc'
>>> p = PureWindowsPath('c:/Program Files')
>>> str(p)
'c:\\Program Files'
```

類似地，對路徑呼叫 `bytes` 會得到原始檔案系統路徑的 `bytes` 物件，就像使用 `os.fsencode()` 編碼過的一樣：

```
>>> bytes(p)
b'/etc'
```

### 備

只建議在 Unix 下呼叫 `bytes`。在 Windows `\`，`unicode` 形式是檔案系統路徑的權威表示方式。

## 對個組成的存取

可以使用下列屬性來存取路徑的個「組成」(parts, components)：

### `PurePath.parts`

一個可存取路徑的各組成的元組：

```
>>> p = PurePath('/usr/bin/python3')
>>> p.parts
('/', 'usr', 'bin', 'python3')

>>> p = PureWindowsPath('c:/Program Files/PSF')
>>> p.parts
('c:\\', 'Program Files', 'PSF')
```

(特注意磁碟機跟本地根目是如何被重新組合成一個單一組成)

## 方法與屬性

純路徑提供以下方法與屬性：

### `PurePath.parser`

用於底層路徑剖析和結合的 `os.path` 模組的實作：可能是 `posixpath` 或 `ntpath`。

在 3.13 版被加入。

### `PurePath.drive`

若存在則一個表示磁碟機字母 (drive letter) 或磁碟機名稱 (drive name) 的字串：

```
>>> PureWindowsPath('c:/Program Files/').drive
'c:'
>>> PureWindowsPath('/Program Files/').drive
''
```

(繼續下一頁)

(繼續上一頁)

```
>>> PurePosixPath('/etc').drive
''
```

UNC shares 也被視磁碟機：

```
>>> PureWindowsPath('//host/share/foo.txt').drive
'\\\\host\\share'
```

#### PurePath.root

若存在則一個表示（本地或全域）根目的字串：

```
>>> PureWindowsPath('c:/Program Files/').root
'\\'
>>> PureWindowsPath('c:Program Files/').root
''
>>> PurePosixPath('/etc').root
 '/'
```

UNC shares 都會有一個根目：

```
>>> PureWindowsPath('//host/share').root
'\\'
```

如果路徑以超過兩個連續的斜開頭，`PurePosixPath` 會合它們：

```
>>> PurePosixPath('//etc').root
'/'
>>> PurePosixPath('///etc').root
 '/'
>>> PurePosixPath('////etc').root
 '/'
```

#### 備

此行符合 *The Open Group Base Specifications Issue 6*，章節 4.11 路徑名稱解析：

「以兩個連續斜開頭的路徑名態可以根據實作定義的方式來解讀，管如此，開頭超過兩個斜應該視單一斜。」

#### PurePath.anchor

磁碟機與根目的結合：

```
>>> PureWindowsPath('c:/Program Files/').anchor
'c:\\'
>>> PureWindowsPath('c:Program Files/').anchor
'c:'
>>> PurePosixPath('/etc').anchor
 '/'
>>> PureWindowsPath('//host/share').anchor
'\\\\host\\share\\'
```

#### PurePath.parents

一個不可變的序列，路徑邏輯上的祖先 (logical ancestors) 提供存取：

```
>>> p = PureWindowsPath('c:/foo/bar/setup.py')
>>> p.parents[0]
PureWindowsPath('c:/foo/bar')
>>> p.parents[1]
```

(繼續下一頁)

(繼續上一頁)

```
PureWindowsPath('c:/foo')
>>> p.parents[2]
PureWindowsPath('c:/')
```

在 3.10 版的變更: 父序列現在支援 *slices* 及負的索引值。

#### PurePath.parent

邏輯上的父路徑:

```
>>> p = PurePosixPath('/a/b/c/d')
>>> p.parent
PurePosixPath('/a/b/c')
```

你不能越過一個 anchor 或空路徑:

```
>>> p = PurePosixPath('/')
>>> p.parent
PurePosixPath('/')
>>> p = PurePosixPath('.')
>>> p.parent
PurePosixPath('.')
```

#### 備

這是一個純粹字句上的 (lexical) 運算, 因此會有以下行:

```
>>> p = PurePosixPath('foo/..')
>>> p.parent
PurePosixPath('foo')
```

如果你想要沿任意的檔案系統路徑往上走, 建議要先呼叫 `Path.resolve()` 來解析符號連結 (symlink) 及去除其中的 ”..”。

#### PurePath.name

最後的路徑組成 (final path component) 的字串表示, 不包含任何磁碟機或根目:

```
>>> PurePosixPath('my/library/setup.py').name
'setup.py'
```

UNC 磁碟機名稱有算在:

```
>>> PureWindowsPath('//some/share/setup.py').name
'setup.py'
>>> PureWindowsPath('//some/share').name
''
```

#### PurePath.suffix

以點分隔路徑的最後一個部分 (如存在):

```
>>> PurePosixPath('my/library/setup.py').suffix
'.py'
>>> PurePosixPath('my/library.tar.gz').suffix
'.gz'
>>> PurePosixPath('my/library').suffix
''
```

這通常被稱檔案副檔名。

**PurePath.suffixes**

一個路徑後綴 (suffix) 的串列，通常被稱爲檔案副檔名：

```
>>> PurePosixPath('my/library.tar.gar').suffixes
['.tar', '.gar']
>>> PurePosixPath('my/library.tar.gz').suffixes
['.tar', '.gz']
>>> PurePosixPath('my/library').suffixes
[]
```

**PurePath.stem**

最後的路徑組成，不包括後綴：

```
>>> PurePosixPath('my/library.tar.gz').stem
'library.tar'
>>> PurePosixPath('my/library.tar').stem
'library'
>>> PurePosixPath('my/library').stem
'library'
```

**PurePath.as\_posix()**

回傳一個使用正斜 (/) 的路徑的字串表示：

```
>>> p = PureWindowsPath('c:\\windows')
>>> str(p)
'c:\\windows'
>>> p.as_posix()
'c:/windows'
```

**PurePath.is\_absolute()**

回傳一個路徑是否是絕對路徑。一個路徑被視爲絕對路徑的條件是它同時有根目及（如果該系統類型允許的話）磁碟機：

```
>>> PurePosixPath('/a/b').is_absolute()
True
>>> PurePosixPath('a/b').is_absolute()
False

>>> PureWindowsPath('c:/a/b').is_absolute()
True
>>> PureWindowsPath('/a/b').is_absolute()
False
>>> PureWindowsPath('c:').is_absolute()
False
>>> PureWindowsPath('//some/share').is_absolute()
True
```

**PurePath.is\_relative\_to(other)**

回傳此路徑是否爲 *other* 路徑的相對路徑。

```
>>> p = PurePath('/etc/passwd')
>>> p.is_relative_to('/etc')
True
>>> p.is_relative_to('/usr')
False
```

該方法是基於字串的；它既不存取檔案系統，也不特別處理“..”片段。以下程式碼是等效的：

```
>>> u = PurePath('/usr')
>>> u == p or u in p.parents
False
```

在 3.9 版被加入。

Deprecated since version 3.12, will be removed in version 3.14: 額外引數的傳入已用；如果有的話，它們會與 *other* 連接在一起。

`PurePath.is_reserved()`

對 `PureWindowsPath` 來，當路徑在 Windows 下被視保留的話會回傳 `True`，否則回傳 `False`。對 `PurePosixPath` 來，總是回傳 `False`。

在 3.13 版的變更: Windows 路徑名稱中包含冒號或結尾點或空格會被視保留。UNC 路徑可能被視保留。

Deprecated since version 3.13, will be removed in version 3.15: 此方法已被用；請使用 `os.path.isreserved()` 來檢測 Windows 上的保留路徑。

`PurePath.joinpath(*pathsegments)`

呼叫此方法會依序結合每個所給定的 *pathsegments* 到路徑上：

```
>>> PurePosixPath('/etc').joinpath('passwd')
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath(PurePosixPath('passwd'))
PurePosixPath('/etc/passwd')
>>> PurePosixPath('/etc').joinpath('init.d', 'apache2')
PurePosixPath('/etc/init.d/apache2')
>>> PureWindowsPath('c:').joinpath('/Program Files')
PureWindowsPath('c:/Program Files')
```

`PurePath.full_match(pattern, *, case_sensitive=None)`

將路徑與 `glob` 形式的模式 (`glob-style pattern`) 做比對。如果比對成功則回傳 `True`，否則回傳 `False`，例如：

```
>>> PurePath('a/b.py').full_match('a/*.py')
True
>>> PurePath('a/b.py').full_match('*.py')
False
>>> PurePath('/a/b/c.py').full_match('/a/**')
True
>>> PurePath('/a/b/c.py').full_match('**/*.py')
True
```

### 也參考

模式語言 (*pattern language*) 文件。

像其它方法一樣，是否區分大小寫會遵循平台的預設行：

```
>>> PurePosixPath('b.py').full_match('*.PY')
False
>>> PureWindowsPath('b.py').full_match('*.PY')
True
```

將 `case_sensitive` 設定成 `True` 或 `False` 會覆蓋這個行。

在 3.13 版被加入。

`PurePath.match(pattern, *, case_sensitive=None)`

將路徑與非遞 `glob` 形式的模式 (`glob-style pattern`) 做比對。如果比對成功則回傳 `True`，否則回傳 `False`。

此方法類似於 `full_match()`，但不允許空白模式 (會引發 `ValueError`)、不支援遞萬用字元 `"**"` (它會像非遞的 `"*"` 一樣)，且如果提供相對模式，則會從右邊進行比對：

```
>>> PurePath('a/b.py').match('*.py')
True
>>> PurePath('/a/b/c.py').match('b/*.py')
True
>>> PurePath('/a/b/c.py').match('a/*.py')
False
```

在 3.12 版的變更: *pattern* 參數接受類路徑物件。

在 3.12 版的變更: 新增 *case\_sensitive* 參數。

`PurePath.relative_to(other, walk_up=False)`

計算這個路徑相對於 *other* 所表示路徑的版本。如果做不到會引發 `ValueError`:

```
>>> p = PurePosixPath('/etc/passwd')
>>> p.relative_to('/')
PurePosixPath('etc/passwd')
>>> p.relative_to('/etc')
PurePosixPath('passwd')
>>> p.relative_to('/usr')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not in the subpath of '/usr' OR one path is relative and
↳the other is absolute.
```

當 *walk\_up* 是 `False` (預設值), 路徑必須以 *other* 開始。當此引數是 `True`, 可能會加入 `..` 以組成相對路徑。在其他情況下, 例如路徑參考到不同的磁碟機, 則會引發 `ValueError`:

```
>>> p.relative_to('/usr', walk_up=True)
PurePosixPath('../etc/passwd')
>>> p.relative_to('foo', walk_up=True)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 941, in relative_to
    raise ValueError(error_message.format(str(self), str(formatted)))
ValueError: '/etc/passwd' is not on the same drive as 'foo' OR one path is relative and
↳the other is absolute.
```

### 警告

這個函式是 `PurePath` 的一部分且可以在字串上運作。它不會檢查或存取實際的檔案架構。這會影響到 *walk\_up* 選項, 因為它假設路徑中有符號連結; 如果需要解析符號連結的話可以先呼叫 `resolve()`。

在 3.12 版的變更: 加入 *walk\_up* 參數 (舊的行和 `walk_up=False` 相同)。

Deprecated since version 3.12, will be removed in version 3.14: 額外位置引數的傳入已用; 如果有的話, 它們會與 *other* 連接在一起。

`PurePath.with_name(name)`

回傳一個修改 *name* 後的新路徑。如果原始路徑有名稱則引發 `ValueError`:

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_name('setup.py')
PureWindowsPath('c:/Downloads/setup.py')
>>> p = PureWindowsPath('c:/')
>>> p.with_name('setup.py')
Traceback (most recent call last):
```

(繼續下一頁)

(繼續上一頁)

```
File "<stdin>", line 1, in <module>
File "/home/antoine/cpython/default/Lib/pathlib.py", line 751, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

`PurePath.with_stem(stem)`

回傳一個修改 *stem* 後的新路徑。如果原始路徑有名稱則引發 `ValueError`：

```
>>> p = PureWindowsPath('c:/Downloads/draft.txt')
>>> p.with_stem('final')
PureWindowsPath('c:/Downloads/final.txt')
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_stem('lib')
PureWindowsPath('c:/Downloads/lib.gz')
>>> p = PureWindowsPath('c:/')
>>> p.with_stem('')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 861, in with_stem
    return self.with_name(stem + self.suffix)
  File "/home/antoine/cpython/default/Lib/pathlib.py", line 851, in with_name
    raise ValueError("%r has an empty name" % (self,))
ValueError: PureWindowsPath('c:/') has an empty name
```

在 3.9 版被加入。

`PurePath.with_suffix(suffix)`

回傳一個修改 *suffix* 後的新路徑。如果原始路徑有後綴，新的 *suffix* 會附加在後面。如果 *suffix* 是一個空字串，原來的後綴會被移除：

```
>>> p = PureWindowsPath('c:/Downloads/pathlib.tar.gz')
>>> p.with_suffix('.bz2')
PureWindowsPath('c:/Downloads/pathlib.tar.bz2')
>>> p = PureWindowsPath('README')
>>> p.with_suffix('.txt')
PureWindowsPath('README.txt')
>>> p = PureWindowsPath('README.txt')
>>> p.with_suffix('')
PureWindowsPath('README')
```

`PurePath.with_segments(*pathsegments)`

透過結合給定的 *pathsegments* 建立一個相同型的新路徑物件，當一個衍生路徑被建立的時候會呼叫這個方法，例如從 `parent` 和 `relative_to()` 建立衍生路徑。子類可以覆寫此方法來傳遞資訊給衍生路徑，例如：

```
from pathlib import PurePosixPath

class MyPath(PurePosixPath):
    def __init__(self, *pathsegments, session_id):
        super().__init__(*pathsegments)
        self.session_id = session_id

    def with_segments(self, *pathsegments):
        return type(self)(*pathsegments, session_id=self.session_id)

etc = MyPath('/etc', session_id=42)
hosts = etc / 'hosts'
print(hosts.session_id) # 42
```

在 3.12 版被加入。

### 11.1.4 實體路徑

實體路徑是純路徑類 `Path` 的子類。除了後者本來就有提供的操作，它們也提供方法可以對路徑物件做系統呼叫。有三種方式可以實例化實體路徑：

**class** `pathlib.Path` (*\*pathsegments*)

`PurePath` 的子類，此類表示系統的路徑類型的實體路徑（實例化時會建立一個 `PosixPath` 或 `WindowsPath`）：

```
>>> Path('setup.py')
PosixPath('setup.py')
```

*pathsegments* 的指定方式與 `PurePath` 類似。

**class** `pathlib.PosixPath` (*\*pathsegments*)

`Path` 和 `PurePosixPath` 的子類，此類表示實體非 Windows 檔案系統路徑：

```
>>> PosixPath('/etc/hosts')
PosixPath('/etc/hosts')
```

*pathsegments* 的指定方式與 `PurePath` 類似。

在 3.13 版的變更：在 Windows 上會引發 `UnsupportedOperation`。在先前版本中，則是引發 `NotImplementedError`。

**class** `pathlib.WindowsPath` (*\*pathsegments*)

`Path` 和 `PureWindowsPath` 的子類，此類表示實體 Windows 檔案系統路徑：

```
>>> WindowsPath('c:', 'Users', 'Ximénez')
WindowsPath('c:/Users/Ximénez')
```

*pathsegments* 的指定方式與 `PurePath` 類似。

在 3.13 版的變更：在非 Windows 平台上會引發 `UnsupportedOperation`。在先前版本中，則是引發 `NotImplementedError`。

你只能實例化對應你的系統的類類型（允許在不相容的路徑類型上做系統呼叫可能在你的應用程式導致漏洞或故障）：

```
>>> import os
>>> os.name
'posix'
>>> Path('setup.py')
PosixPath('setup.py')
>>> PosixPath('setup.py')
PosixPath('setup.py')
>>> WindowsPath('setup.py')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "pathlib.py", line 798, in __new__
    % (cls.__name__,))
UnsupportedOperation: cannot instantiate 'WindowsPath' on your system
```

有些實體路徑方法會在系統呼叫失敗（例如因路徑不存在）時引發 `OSError`。

#### 剖析和生 URI

實體路徑物件可以從符合 **RFC 8089** 中的 'file' URI 建立，也可以以該形式來表示。

#### 備

檔案 URI 在跨不同檔案系統編碼的機器上是無法移植的。

**classmethod** `Path.from_uri(uri)`

從剖析'file' URI 回傳新的路徑物件。例如：

```
>>> p = Path.from_uri('file:///etc/hosts')
PosixPath('/etc/hosts')
```

在 Windows 上，從 URI 可以剖析 DOS 裝置和 UNC 路徑：

```
>>> p = Path.from_uri('file:///c:/windows')
WindowsPath('c:/windows')
>>> p = Path.from_uri('file://server/share')
WindowsPath('//server/share')
```

支援多種變形：

```
>>> p = Path.from_uri('file:///server/share')
WindowsPath('//server/share')
>>> p = Path.from_uri('file:///server/share')
WindowsPath('//server/share')
>>> p = Path.from_uri('file:c:/windows')
WindowsPath('c:/windows')
>>> p = Path.from_uri('file:/c|/windows')
WindowsPath('c:/windows')
```

如果 URI 不是 file: 開頭，或是剖析後的路徑不是絕對路徑，則會引發 `ValueError`。

在 3.13 版被加入。

`Path.as_uri()`

以'file' URI 來表示路徑。如果路徑不是絕對的則會引發 `ValueError`。

```
>>> p = PosixPath('/etc/passwd')
>>> p.as_uri()
'file:///etc/passwd'
>>> p = WindowsPath('c:/Windows')
>>> p.as_uri()
'file:///c:/Windows'
```

因歷史上的原因，此方法也可以從 `PurePath` 物件上使用。然而，它使用 `os.fsencode()` 而讓它完全不純粹。

## 擴展和解析路徑

**classmethod** `Path.home()`

回傳一個代表使用者家目錄的新的路徑物件（像以 `~` 構成的 `os.path.expanduser()` 的回傳一樣）。如果無法解析家目錄，會引發 `RuntimeError`。

```
>>> Path.home()
PosixPath('/home/antoine')
```

在 3.5 版被加入。

`Path.expanduser()`

回傳一個展開 `~` 和 `~user` 構成的新路徑，像 `os.path.expanduser()` 回傳的一樣。如果無法解析家目錄，會引發 `RuntimeError`。

```
>>> p = PosixPath('~/.films/Monty Python')
>>> p.expanduser()
PosixPath('/home/eric/.films/Monty Python')
```

在 3.5 版被加入。

**classmethod** `Path.cwd()`

回傳一個代表目前目錄的新的路徑物件（像 `os.getcwd()` 回傳的一樣）：

```
>>> Path.cwd()
PosixPath('/home/antoine/pathlib')
```

**Path.absolute()**

將路徑轉對路徑，不進行標準化或解析符號連結。回傳一個新的路徑物件：

```
>>> p = Path('tests')
>>> p
PosixPath('tests')
>>> p.absolute()
PosixPath('/home/antoine/pathlib/tests')
```

**Path.resolve(strict=False)**

將路徑轉對路徑，解析所有符號連結。回傳一個新的路徑物件：

```
>>> p = Path()
>>> p
PosixPath('.')
>>> p.resolve()
PosixPath('/home/antoine/pathlib')
```

同時也會消除“..”的路徑組成（只有此方法這樣做）：

```
>>> p = Path('docs/../setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
```

如果路徑不存在或遇到符號連結圈，且 `strict` 為 `True`，則引發 `OSError`。如果 `strict` 為 `False`，則將盡可能解析該路徑，並將任何剩余部分追加到路徑中，而不檢查其是否存在。

在 3.6 版的變更：新增 `strict` 參數（在 3.6 版本之前的行是嚴格的）。

在 3.13 版的變更：在嚴格模式下，符號連結圈會像其他錯誤一樣來處理：`OSError` 會被引發，而在非嚴格模式下，不會引發任何例外。在先前版本中，不管 `strict` 的值是什麼，都會引發 `RuntimeError`。

**Path.readlink()**

回傳符號連結指向的路徑（如 `os.readlink()` 的回傳值）：

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.readlink()
PosixPath('setup.py')
```

在 3.9 版被加入。

在 3.13 版的變更：如果 `os.readlink()` 不可用，會引發 `UnsupportedOperation`。在先前版本中，則是引發 `NotImplementedError`。

## 查詢檔案類型和狀態

在 3.8 版的變更：`exists()`、`is_dir()`、`is_file()`、`is_mount()`、`is_symlink()`、`is_block_device()`、`is_char_device()`、`is_fifo()`、`is_socket()` 遇到路徑包含 OS 層無法表示的字元時現在會回傳 `False` 而不是引發例外。

**Path.stat(\*, follow\_symlinks=True)**

回傳一個包含該路徑資訊的 `os.stat_result` 物件，像 `os.stat()` 一樣。每次呼叫此方法都會重新查詢結果。

此方法通常會跟隨 (follow) 符號連結；想要取得符號連結的資訊，可以加上引數 `follow_symlinks=False` 或使用 `lstat()`。

```
>>> p = Path('setup.py')
>>> p.stat().st_size
956
>>> p.stat().st_mtime
1327883547.852554
```

在 3.10 版的變更: 新增 `follow_symlinks` 參數。

`Path.lstat()`

類似 `Path.stat()`，但如果該路徑指向一個符號連結，則回傳符號連結的資訊而不是其指向的目標。

`Path.exists(*, follow_symlinks=True)`

如果路徑指向存在的檔案或目錄則回傳 `True`。

此方法通常會跟隨符號連結；如果想檢查符號連結是否存在，可以加上引數 `follow_symlinks=False`。

```
>>> Path('.').exists()
True
>>> Path('setup.py').exists()
True
>>> Path('/etc').exists()
True
>>> Path('nonexistentfile').exists()
False
```

在 3.12 版的變更: 新增 `follow_symlinks` 參數。

`Path.is_file(*, follow_symlinks=True)`

如果該路徑指向一個普通檔案則回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

此方法通常會跟隨符號連結；如果想將符號連結除外，可以加上引數 `follow_symlinks=False`。

在 3.13 版的變更: 新增 `follow_symlinks` 參數。

`Path.is_dir(*, follow_symlinks=True)`

如果該路徑指向一個目錄則回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

此方法通常會跟隨符號連結；如果想將對目錄的符號連結除外，可以加上引數 `follow_symlinks=False`。

在 3.13 版的變更: 新增 `follow_symlinks` 參數。

`Path.is_symlink()`

如果該路徑指向一個符號連結則回傳 `True`，否則回傳 `False`。

如果該路徑不存在也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.is_junction()`

如果該路徑指向一個連接點 (junction) 則回傳 `True`，對其他類型的檔案則回傳 `False`。目前只有 Windows 支援連接點。

在 3.12 版被加入。

`Path.is_mount()`

如果路徑是一個 *mount point*（一個檔案系統載不同檔案系統的存取點）則回傳 `True`。在 POSIX 上，此函式檢查 `path` 的父路徑 `path/..` 是否和 `path` 在不同的裝置上，或者 `path/..` 和 `path` 是否指向相同裝置的相同 i-node —— 這對於所有 Unix 和 POSIX 變體來應該會偵測出載點。在 Windows

上，一個載點被視一個根磁碟機字母（例如 `c:\`）、一個 UNC share（例如 `\\server\share`）或是載的檔案系統目。

在 3.7 版被加入。

在 3.12 版的變更：加入對 Windows 的支援。

`Path.is_socket()`

如果該路徑指向一個 Unix socket（或者是一個指向 Unix socket 的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.is_fifo()`

如果該路徑指向一個 FIFO（或者是一個指向 FIFO 的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.is_block_device()`

如果該路徑指向一個區塊裝置 (block device)（或者是一個指向區塊裝置的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.is_char_device()`

如果該路徑指向一個字元裝置 (character device)（或者是一個指向字元裝置的符號連結）則會回傳 `True`，如果指向其他類型的檔案則回傳 `False`。

如果路徑不存在或者是一個斷掉的符號連結則也會回傳 `False`；其他錯誤（例如權限錯誤）則會傳遞出來。

`Path.samefile(other_path)`

回傳此路徑是否指向與 `other_path` 相同的檔案，`other_path` 可以是路徑 (Path) 物件或字串。其語義類似於 `os.path.samefile()` 和 `os.path.samestat()`。

若任何一個檔案因某些原因無法存取，則引發 `OSError`。

```
>>> p = Path('spam')
>>> q = Path('eggs')
>>> p.samefile(q)
False
>>> p.samefile('spam')
True
```

在 3.5 版被加入。

## 讀取和寫入檔案

`Path.open(mode='r', buffering=-1, encoding=None, errors=None, newline=None)`

開該路徑指向的檔案，像建的 `open()` 函式做的一樣：

```
>>> p = Path('setup.py')
>>> with p.open() as f:
...     f.readline()
...
'#!/usr/bin/env python3\n'
```

`Path.read_text(encoding=None, errors=None, newline=None)`

將路徑指向的檔案的解碼內容以字串形式回傳：

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

該檔案被打開且隨後關閉。可選參數的含義與 `open()` 中的相同。

在 3.5 版被加入。

在 3.13 版的變更: 新增 `newline` 參數。

`Path.read_bytes()`

將路徑指向的檔案的二進位內容以一個位元組物件回傳:

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

在 3.5 版被加入。

`Path.write_text(data, encoding=None, errors=None, newline=None)`

以文字模式開路徑指向的檔案，將 `data` 寫到檔案，關閉檔案:::

```
>>> p = Path('my_text_file')
>>> p.write_text('Text file contents')
18
>>> p.read_text()
'Text file contents'
```

一個名稱相同的已存在檔案會被覆寫。可選參數和 `open()` 的參數有相同意義。

在 3.5 版被加入。

在 3.10 版的變更: 新增 `newline` 參數。

`Path.write_bytes(data)`

以位元組模式開路徑指向的檔案，將 `data` 寫到檔案，關閉檔案:::

```
>>> p = Path('my_binary_file')
>>> p.write_bytes(b'Binary file contents')
20
>>> p.read_bytes()
b'Binary file contents'
```

一個名稱相同的已存在檔案會被覆寫。

在 3.5 版被加入。

## 讀取目錄

`Path.iterdir()`

當該路徑指向一個目錄，會 yield 目錄面的路徑物件:

```
>>> p = Path('docs')
>>> for child in p.iterdir(): child
...
PosixPath('docs/conf.py')
PosixPath('docs/_templates')
PosixPath('docs/make.bat')
PosixPath('docs/index.rst')
```

(繼續下一頁)

```
PosixPath('docs/_build')
PosixPath('docs/_static')
PosixPath('docs/Makefile')
```

子路徑會以任意順序被 `yield`，且不會包含特殊項目 `'.'` 和 `'..'`。如果一個檔案在建立這個代器之後加到該目或從目除，這個檔案的路徑物件是否會被包含是有明定的。

如果路徑不是目或無法存取，則會引發 `OSError`。

`Path.glob` (*pattern*, \*, *case\_sensitive=None*, *recurse\_symlinks=False*)

在該路徑表示的目，以 `glob` 方式比對所給定的相對 *pattern*，`yield` 所有比對到的檔案（任意類型）：

```
>>> sorted(Path('.').glob('*.py'))
[PosixPath('pathlib.py'), PosixPath('setup.py'), PosixPath('test_pathlib.py')]
>>> sorted(Path('.').glob('*/*.py'))
[PosixPath('docs/conf.py')]
>>> sorted(Path('.').glob('**/*.py'))
[PosixPath('build/lib/pathlib.py'),
 PosixPath('docs/conf.py'),
 PosixPath('pathlib.py'),
 PosixPath('setup.py'),
 PosixPath('test_pathlib.py')]
```

### 也參考

模式語言 (*pattern language*) 文件。

預設情況下，或者當 *case\_sensitive* 僅限關鍵字引數被設定 `None` 的時候，此方法會使用平台特定的大小寫規則來比對路徑；通常在 `POSIX` 上會區分大小寫，而在 `Windows` 上不區分大小寫。將 *case\_sensitive* 設成 `True` 或 `False` 會覆寫這個行。

預設情況下，或者當 *recurse\_symlinks* 僅限關鍵字引數被設定 `False` 的時候，此方法會跟隨符號連結，除非在擴展 `**` 萬用字元時。將 *recurse\_symlinks* 設成 `True` 以總是跟隨符號連結。

引發一個附帶引數 *self*、*pattern* 的稽核事件 `pathlib.Path.glob`。

在 3.12 版的變更: 新增 *case\_sensitive* 參數。

在 3.13 版的變更: 新增 *recurse\_symlinks* 參數。

在 3.13 版的變更: *pattern* 參數接受類路徑物件。

在 3.13 版的變更: 從掃描檔案系統引發的任何 `OSError` 例外都會被抑制。在先前版本中，在許多情況下這種例外都會被抑制，但不是所有情況。

`Path.rglob` (*pattern*, \*, *case\_sensitive=None*, *recurse\_symlinks=False*)

遞地 `glob` 給定的相對 *pattern*。這相當於在給定的相對 *pattern* 前面加上 `**/"` 呼叫 `Path.glob()`。

### 也參考

模式語言 (*pattern language*) 和 `Path.glob()` 文件。

引發一個附帶引數 *self*、*pattern* 的稽核事件 `pathlib.Path.rglob`。

在 3.12 版的變更: 新增 *case\_sensitive* 參數。

在 3.13 版的變更: 新增 *recurse\_symlinks* 參數。

在 3.13 版的變更: *pattern* 參數接受類路徑物件。

`Path.walk(top_down=True, on_error=None, follow_symlinks=False)`

透過由上而下或由下而上地走訪目錄樹的檔案名稱。

對每個以 `self` 為根且在目錄樹的目錄 (包含 `self` 但不包含 `'.'` 和 `'..'`)，此方法會 `yield` 一個 `(dirpath, dirnames, filenames)` 的三元素元組。

`dirpath` 是一個目前走訪到的目錄的 `Path`，`dirnames` 是一個 `dirpath` 的子目錄名稱的字串串列 (不包含 `'.'` 和 `'..'`)，而 `filenames` 是一個 `dirpath` 非目錄檔案名稱的字串串列。要取得在 `dirpath` 檔案或目錄的完整路徑 (以 `self` 開頭)，可以使用 `dirpath / name`。會根據檔案系統來決定串列是否有排序。

如果可選引數 `top_down` 是 `true` (預設值)，一個目錄的三元素元組會在其任何子目錄的三元素元組之前生成 (目錄是由上而下走訪)。如果 `top_down` 是 `false`，一個目錄的三元素元組會在其所有子目錄的三元素元組之後生成 (目錄是由下而上走訪)。不論 `top_down` 的值是什麼，子目錄的串列會在走訪該目錄及其子目錄的三元素元組之前取得。

當 `top_down` 是 `true`，呼叫者可以原地 (in-place) 修改 `dirnames` 串列 (例如使用 `del` 或切片賦值 (slice assignment))，且 `Path.walk()` 只會遞進名稱依然留在 `dirnames` 的子目錄。這可以用來修剪搜尋，或者增加特定順序的訪問，或者甚至在繼續 `Path.walk()` 之前，用來告訴 `Path.walk()` 關於呼叫者建立或重新命名的目錄。當 `top_down` 是 `false` 的時候，修改 `dirnames` 對 `Path.walk()` 的行有影響，因為 `dirnames` 的目錄已經在 `dirnames` `yield` 給呼叫者之前被生成。

預設來自 `os.scandir()` 的錯誤會被忽略。如果指定了可選引數 `on_error` (它應該要是一個可呼叫物件)，它會被以一個 `OSError` 實例引數來呼叫。這個可呼叫物件可以處理錯誤以繼續走訪，或者再次引發錯誤來停止走訪。注意，檔案名稱可以從例外物件的 `filename` 屬性來取得。

預設 `Path.walk()` 不會跟隨符號連結，而是會把它們加到 `filenames` 串列。將 `follow_symlinks` 設定 `true` 會解析符號連結，將它們根據其指向的目標放在適當的 `dirnames` 和 `filenames`，而因此訪問到符號連結指向的目錄 (在有支援符號連結的地方)。

#### 備註

需要注意的是如果符號連結指向一個其本身的父目錄，則將 `follow_symlinks` 設定 `true` 會導致無窮的遞進。 `Path.walk()` 不會紀錄其已經訪問過的目錄。

#### 備註

`Path.walk()` 假設其走訪的目錄在執行過程中不會被修改。舉例來說，如果在 `dirnames` 的目錄已經被一個符號連結取代，且 `follow_symlinks` 是 `false`，`Path.walk()` 依然會試著往下進入它。為了防止這樣的行，可以從 `dirnames` 適當地移除目錄。

#### 備註

如果 `follow_symlinks` 是 `false`，和 `os.walk()` 行不同的是 `Path.walk()` 會將指向目錄的符號連結放在 `filenames` 串列。

這個範例會顯示在每個目錄所有檔案使用的位元組數量，同時忽略 `__pycache__` 目錄：

```
from pathlib import Path
for root, dirs, files in Path("cpython/Lib/concurrent").walk(on_error=print):
    print(
        root,
        "consumes",
        sum((root / file).stat().st_size for file in files),
        "bytes in",
        len(files),
        "non-directory files"
```

(繼續下一頁)

(繼續上一頁)

```
)
if '__pycache__' in dirs:
    dirs.remove('__pycache__')
```

下一個範例是 `shutil.rmtree()` 的一個簡單的實作方式。由下而上走訪目錄是必要的，因 `rmdir()` 不允許在目錄空之前刪除它：

```
# 刪除可從 "top" 目錄到達的所有東西。
# 注意：這是危險的！例如，如果 top == Path('/'),
# 它可能會刪除你所有的檔案。
for root, dirs, files in top.walk(top_down=False):
    for name in files:
        (root / name).unlink()
    for name in dirs:
        (root / name).rmdir()
```

在 3.12 版被加入。

## 建立檔案和目錄

`Path.touch(mode=0o666, exist_ok=True)`

根據給定路徑來建立一個檔案。如果 `mode` 有給定，它會與行程的 `umask` 值結合，以確定檔案模式和存取旗標。當檔案已經存在時，若 `exist_ok` 為 `true` 則函式不會失敗（其變更時間會被更新當下時間），否則會引發 `FileExistsError`。

### 也參考

`open()`、`write_text()` 和 `write_bytes()` 方法通常用於建立檔案。

`Path.mkdir(mode=0o777, parents=False, exist_ok=False)`

在給定路徑下建立一個新的目錄。如果有給 `mode` 則會結合行程 (process) 的 `umask` 值來設定檔案模式與存取旗標 (access flag)。如果路徑已經存在，會引發 `FileExistsError`。

如果 `parents` 是 `true`，則任何缺少的父路徑都會依需要被建立；它們不考慮 `mode` 而會以預設的權限來建立（模仿 POSIX 的 `mkdir -p` 指令）。

如果 `parents` 是 `false`（預設值），缺少的父路徑會引發 `FileNotFoundError`。

如果 `exist_ok` 是 `false`（預設值），則當目標目錄已經存在的話會引發 `FileExistsError`。

如果 `exist_ok` 是 `true`，只有當最後的路徑組成不是一個已存在的非目錄檔案，`FileExistsError` 例外會被忽略（與 POSIX 的 `mkdir -p` 指令行相同）。

在 3.5 版的變更：新增 `exist_ok` 參數。

`Path.symlink_to(target, target_is_directory=False)`

使這個路徑成一個指向 `target` 的符號連結。

在 Windows 上，符號連結代表一個檔案或目錄，且不會隨著目標 (`target`) 動態改變。如果目標存在，則符號連結的類型會被建立來符合其目標。否則如果 `target_is_directory` 是 `true`，該符號連結會被建立成目錄，如果不是則建立成檔案（預設值）。在非 Windows 平台上，`target_is_directory` 會被忽略。

```
>>> p = Path('mylink')
>>> p.symlink_to('setup.py')
>>> p.resolve()
PosixPath('/home/antoine/pathlib/setup.py')
>>> p.stat().st_size
956
>>> p.lstat().st_size
8
```

**備註**

引數的順序 (`link`, `target`) 和 `os.symlink()` 相反。

在 3.13 版的變更: 如果 `os.symlink()` 不可用, 會引發 `UnsupportedOperation`。在先前版本中, 則是引發 `NotImplementedError`。

`Path.hardlink_to(target)`

使這個路徑成與 `target` 相同檔案的一個硬連結 (hard link)。

**備註**

引數的順序 (`link`, `target`) 和 `os.link()` 相反。

在 3.10 版被加入。

在 3.13 版的變更: 如果 `os.link()` 不可用, 會引發 `UnsupportedOperation`。在先前版本中, 則是引發 `NotImplementedError`。

**重新命名和刪除**

`Path.rename(target)`

將此檔案或目錄重新命名給定的 `target`, 回傳一個新的 `Path` 實例指向該 `target`。在 Unix 系統上, 若 `target` 存在且一個檔案, 若使用者有權限, 則會在不顯示訊息的情況下進行取代。在 Windows 系統上, 若 `target` 存在, 則會引發 `FileExistsError` 錯誤。 `target` 可以是字串或另一個路徑物件:

```
>>> p = Path('foo')
>>> p.open('w').write('some text')
9
>>> target = Path('bar')
>>> p.rename(target)
PosixPath('bar')
>>> target.open().read()
'some text'
```

目標路徑可以是絕對路徑或相對路徑。相對路徑會相對於當前的工作目錄進行解釋, 而不是相對於 `Path` 物件所在的目錄。

此功能是使用 `os.rename()` 實現的, 提供相同的保證。

在 3.8 版的變更: 新增了回傳值, 回傳新的 `Path` 實例。

`Path.replace(target)`

將此檔案或目錄重新命名給定的 `target`, 回傳一個指向 `target` 的新 `Path` 實例。如果 `target` 指向一個現有的檔案或空目錄, 它將被無條件地取代。

目標路徑可以是絕對路徑或相對路徑。相對路徑會相對於當前的工作目錄進行解釋, 而不是相對於 `Path` 物件所在的目錄。

在 3.8 版的變更: 新增了回傳值, 回傳新的 `Path` 實例。

`Path.unlink(missing_ok=False)`

移除這個檔案或符號連結。如果路徑指向目錄, 請改用 `Path.rmdir()`。

如果 `missing_ok` 是 `false` (預設值), `FileNotFoundError` 會在路徑不存在時被引發。

如果 `missing_ok` 是 `true`, `FileNotFoundError` 例外會被忽略 (行與 POSIX `rm -f` 指令相同)。

在 3.8 版的變更: 新增 `missing_ok` 參數。

`Path.rmdir()`

移除此目錄。該目錄必須空。

## 權限和所有權

`Path.owner(*, follow_symlinks=True)`

回傳擁有該檔案的用字元名稱。如果在系統資料庫中找不到該檔案的使用者識字元 (UID)，則會引發 `KeyError`。

此方法通常會跟隨符號連結；如果想取得符號連結的擁有者，可以加上引數 `follow_symlinks=False`。

在 3.13 版的變更: 如果 `pwd` 模組不可用，會引發 `UnsupportedOperation`。在先前版本中，則是引發 `NotImplementedError`。

在 3.13 版的變更: 新增 `follow_symlinks` 參數。

`Path.group(*, follow_symlinks=True)`

回傳擁有該檔案的群組名稱。如果在系統資料庫中找不到檔案的群組識字元 (GID) 會引發 `KeyError`。

此方法通常會跟隨符號連結；如果想取得符號連結的群組，可以加上引數 `follow_symlinks=False`。

在 3.13 版的變更: 如果 `grp` 模組不可用，會引發 `UnsupportedOperation`。在先前版本中，則是引發 `NotImplementedError`。

在 3.13 版的變更: 新增 `follow_symlinks` 參數。

`Path.chmod(mode, *, follow_symlinks=True)`

修改檔案模式 (file mode) 與權限，像 `os.chmod()` 一樣。

此方法通常會跟隨符號連結。一些 Unix 類型支援修改符號連結本身的權限；在這些平台上你可以加上引數 `follow_symlinks=False` 或使用 `lchmod()`。

```

>>> p = Path('setup.py')
>>> p.stat().st_mode
33277
>>> p.chmod(0o444)
>>> p.stat().st_mode
33060

```

在 3.10 版的變更: 新增 `follow_symlinks` 參數。

`Path.lchmod(mode)`

類似 `Path.chmod()`，但如果該路徑指向一個符號連結，則符號連結的模式 (mode) 會被改變而不是其指向的目標。

### 11.1.5 模式語言 (pattern language)

以下的萬用字元在 `full_match()`、`glob()` 和 `rglob()` 的模式中被支援：

**\*\* (整個片段)**

匹配任何數量的檔案或目錄片段，包括零個。

**\* (整個片段)**

匹配一個檔案或目錄的片段。

**\* (片段的一部分)**

匹配任意數量的非分隔字元，包括零個。

**?**

匹配一個非分隔字元。

**[seq]**

匹配一個在 `seq` 中的字元。

**[!seq]**

匹配一個不在 `seq` 中的字元。

對於文本 (literal) 匹配，可以用方括號包裝元字元 (meta-characters)。例如，"[?]" 會匹配字元 "?"。

"\*\*" 萬用字元讓它可以做遞迴 glob。例如：

模式	意涵
"**/*"	至少有一個片段的路徑。
"**/*.py"	最後一個片段以 ".py" 結尾的任何路徑。
"assets/**"	任何以 "assets/" 開頭的路徑。
"assets/**/*"	任何以 "assets/" 開頭的路徑，不包括 "assets/" 本身。

### 備註

Glob 使用 \*\* 萬用字元會訪問目錄樹中的每個目錄。對於大型的目錄樹，搜尋可能需要花費很長的時間。

在 3.13 版的變更: Glob 使用結尾 \*\* 的模式會同時回傳檔案和目錄。在先前版本中，只會回傳目錄。

在 `Path.glob()` 和 `rglob()` 中，可以在模式後面加上斜杠以只匹配目錄。

在 3.11 版的變更: Glob 使用以路徑名稱組成的分隔符號 (`sep` 或 `altsep`) 作結尾的模式則只會回傳目錄。

## 11.1.6 與 glob 模組的比較

`Path.glob()` 和 `Path.rglob()` 接受的模式和生成的結果與 `glob` 模組略有不同：

1. `pathlib` 中以點開頭的檔案不特殊。這和將 `include_hidden=True` 傳遞給 `glob.glob()` 相同。
2. \*\* 模式組成在 `pathlib` 中總是遞迴的。這與將 `recursive=True` 傳遞給 `glob.glob()` 相同。
3. 在 `pathlib` 中，\*\* 模式組成預設不跟隨符號連結。這在 `glob.glob()` 中可有等效的行，但你可以將 `recurse_symlinks=True` 傳遞給 `Path.glob()` 以獲得相容的行。
4. 與所有 `PurePath` 和 `Path` 物件一樣，從 `Path.glob()` 和 `Path.rglob()` 回傳的值不包含結尾斜杠。
5. `pathlib` 的 `path.glob()` 和 `path.rglob()` 回傳的值包含了 `path` 作前綴，而 `glob.glob(root_dir=path)` 的結果則不會如此。
6. `pathlib` 的 `path.glob()` 和 `path.rglob()` 回傳的值可能包含 `path` 本身，例如當使用 "\*\*" 做 glob 的時候，然而 `glob.glob(root_dir=path)` 的結果則永遠不會包含一個對應到 `path` 的空字串。

## 11.1.7 與 os 和 os.path 模組的比較

`pathlib` 使用 `PurePath` 和 `Path` 物件來實作路徑操作，因此它被稱是物件導向的。另一方面，`os` 和 `os.path` 模組提供能與底層 `str` 和 `bytes` 物件互動的函式，這是一種更程序式的方法。有些使用者認為物件導向的風格更易讀。

`os` 和 `os.path` 中的許多函式支援 `bytes` 路徑和相對路徑的目錄描述器 (*paths relative to directory descriptors*)。這些功能在 `pathlib` 中不可用。

Python 的 `str` 和 `bytes` 型別，以及 `os` 和 `os.path` 模組的一些部分，是用 C 寫的且非常快速。`pathlib` 是用純 Python 寫的且通常比較慢，但很少會慢到足以產生影響。

`pathlib` 的路徑正規化略比 `os.path` 更武斷和一致。例如，儘管 `os.path.abspath()` 會從路徑中移除 "." 片段，如果包含符號連結的話這可能會改變其意義，而 `Path.absolute()` 則會保留這些片段以增加安全性。

`pathlib` 的路徑正規化可能會使它不適合某些應用程式：

1. `pathlib` 將 `Path("my_folder/")` 正規化到 `Path("my_folder")`，這會在提供給各種操作系統 API 和命令列工具時改變路徑的意義。具體來說，缺少結尾分隔符號可能會允許該路徑被解析為檔案或目錄，而不只是目錄。

2. `pathlib` 將 `Path("./my_program")` 正規化爲 `Path("my_program")`，這會在作執行檔搜尋路徑使用時改變路徑的意義，例如在 `shell` 或在衍生 (`spawn`) 子行程時。具體來講，在路徑中缺少分隔符號可能會使其限制在 `PATH` 中尋找，而不是當前目錄。

因此這些差別，`pathlib` 不是 `os.path` 的直接替代品。

## 對應工具

以下是一張表格，對應許多 `os` 函式及其相符於 `PurePath/Path` 的項目。

<code>os</code> 和 <code>os.path</code>	<code>pathlib</code>
<code>os.path.dirname()</code>	<code>PurePath.parent</code>
<code>os.path.basename()</code>	<code>PurePath.name</code>
<code>os.path.splitext()</code>	<code>PurePath.stem</code> 和 <code>PurePath.suffix</code>
<code>os.path.join()</code>	<code>PurePath.joinpath()</code>
<code>os.path.isabs()</code>	<code>PurePath.is_absolute()</code>
<code>os.path.relpath()</code>	<code>PurePath.relative_to()</code> <sup>1</sup>
<code>os.path.expanduser()</code>	<code>Path.expanduser()</code> <sup>2</sup>
<code>os.path.realpath()</code>	<code>Path.resolve()</code>
<code>os.path.abspath()</code>	<code>Path.absolute()</code> <sup>3</sup>
<code>os.path.exists()</code>	<code>Path.exists()</code>
<code>os.path.isfile()</code>	<code>Path.is_file()</code>
<code>os.path.isdir()</code>	<code>Path.is_dir()</code>
<code>os.path.islink()</code>	<code>Path.is_symlink()</code>
<code>os.path.isjunction()</code>	<code>Path.is_junction()</code>
<code>os.path.ismount()</code>	<code>Path.is_mount()</code>
<code>os.path.samefile()</code>	<code>Path.samefile()</code>
<code>os.getcwd()</code>	<code>Path.cwd()</code>
<code>os.stat()</code>	<code>Path.stat()</code>
<code>os.lstat()</code>	<code>Path.lstat()</code>
<code>os.listdir()</code>	<code>Path.iterdir()</code>
<code>os.walk()</code>	<code>Path.walk()</code> <sup>4</sup>
<code>os.mkdir()</code> 、 <code>os.makedirs()</code>	<code>Path.mkdir()</code>
<code>os.link()</code>	<code>Path.hardlink_to()</code>
<code>os.symlink()</code>	<code>Path.symlink_to()</code>
<code>os.readlink()</code>	<code>Path.readlink()</code>
<code>os.rename()</code>	<code>Path.rename()</code>
<code>os.replace()</code>	<code>Path.replace()</code>
<code>os.remove()</code> 、 <code>os.unlink()</code>	<code>Path.unlink()</code>
<code>os.rmdir()</code>	<code>Path.rmdir()</code>
<code>os.chmod()</code>	<code>Path.chmod()</code>
<code>os.lchmod()</code>	<code>Path.lchmod()</code>

## 11.2 `os.path` --- 常見的路徑名操作

原始碼： `Lib/genericpath.py`、`Lib/posixpath.py` (用於 POSIX 系統) 和 `Lib/ntpath.py` (用於 Windows)。

該模組實現了一些有用的路徑名操作函式。若要讀取或寫入檔案，請參閱 `open()` 函式，要存取檔案系統，請參閱 `os` 模組。路徑參數可以以字串、位元組或任何依照 `os.PathLike` 協議實作的物件傳遞。

<sup>1</sup> `os.path.relpath()` 會呼叫 `abspath()` 來將路徑變成絕對路徑並移除“..”部分，而 `PurePath.relative_to()` 是一個文本上的操作，當它輸入的錨點不同時（例如一個是絕對路徑，另一個則是相對路徑）會引發 `ValueError`。

<sup>2</sup> `os.path.expanduser()` 會在無法解析家目錄時回傳原始路徑，而 `Path.expanduser()` 則會引發 `RuntimeError`。

<sup>3</sup> `os.path.abspath()` 將“..”組成移除而不解析符號連結，這可能會改變路徑的意義，而 `Path.absolute()` 則會保留路徑中任何“..”組成。

<sup>4</sup> 當分類路徑成 `dirnames` 和 `filenames` 時 `os.walk()` 總是跟隨符號連結，而 `Path.walk()` 在 `follow_symlinks` 爲 `false` (預設值) 時，會將所有符號連結都分類爲 `filenames`。

與 Unix shell 不同，Python 不會自動進行路徑展開 (path expansions)。當應用程式需要進行類似 shell 的路徑展開時，可以明確地呼叫 `expanduser()` 和 `expandvars()` 等函式。(另請參閱 `glob` 模組。)

### 也參考

`pathlib` 模組提供了高階的路徑物件。

### 備註

所有這些函式都只接受位元組或字串物件作參數。如果回傳的是路徑或檔案名稱，結果將是相同型的物件。

### 備註

由於不同的作業系統具有不同的路徑命名慣例，在標準函式庫中的路徑模組有數個版本可供使用，而 `os.path` 模組都會是運行 Python 之作業系統所適用本地路徑。然而，如果你想要操作始終以某個不同於本機格式表示的路徑，你也可以引入使用對應的模組。它們都具有相同的介面：

- `posixpath` 用於 UNIX 形式的路徑
- `ntpath` 用於 Windows 的路徑

在 3.8 版的變更：對於包含有作業系統層級無法表示之字元或位元組的路徑，`exists()`、`lexists()`、`isdir()`、`isfile()`、`islink()` 和 `ismount()` 函式現在會回傳 `False`，而不是引發例外。

`os.path.abspath(path)`

回傳經正規化的對路徑名 `path`。在大多數平台上，這等效於按照以下方式呼叫 `normpath()` 函式：`normpath(join(os.getcwd(), path))`。

在 3.6 版的變更：接受一個 `path-like object`。

`os.path.basename(path)`

回傳路徑名 `path` 的基底名稱。這是將 `path` 傳遞給函式 `split()` 後回傳結果中的第二個元素。請注意，此函式的結果與 Unix 的 `basename` 程式不同；對於 `'/foo/bar/'`，`basename` 回傳 `'bar'`，而 `basename()` 函式回傳空字串 `('')`。

在 3.6 版的變更：接受一個 `path-like object`。

`os.path.commonpath(paths)`

Return the longest common sub-path of each pathname in the iterable `paths`. Raise `ValueError` if `paths` contain both absolute and relative pathnames, if `paths` are on different drives, or if `paths` is empty. Unlike `commonprefix()`, this returns a valid path.

在 3.5 版被加入。

在 3.6 版的變更：接受一個類路徑物件的序列。

在 3.13 版的變更：Any iterable can now be passed, rather than just sequences.

`os.path.commonprefix(list)`

回傳 `list` 中所有路徑的最長路徑前綴（逐字元比較）。如果 `list` 空，則回傳空字串 `('')`。

### 備註

由於此函式是逐字元比較，因此可能會回傳無效的路徑。若要獲得有效的路徑，請參考 `commonpath()` 函式。

```
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib'])
'/usr/l'

>>> os.path.commonpath(['/usr/lib', '/usr/local/lib'])
'/usr'
```

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.dirname(path)`

回傳路徑名 *path* 的目錄名稱。這是將 *path* 傳遞給函式 `split()` 後回傳之成對結果中的第一個元素。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.exists(path)`

如果 *path* 是一個存在的路徑或一個開頭的檔案描述器則回傳 `True`。對於已損壞的符號連結則回傳 `False`。在某些平台上，即使 *path* 實際存在，如果未被授予執行 `os.stat()` 的權限，此函式仍可能回傳 `False`。

在 3.3 版的變更: 現在 *path* 可以是一個整數: 如果它是一個開頭的檔案描述器，則回傳 `True`; 否則回傳 `False`。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.lexists(path)`

如果 *path* 是一個存在的路徑則回傳 `True`，對已損壞的符號連結也是。在缺乏 `os.lstat()` 的平台上，與 `exists()` 函式等效。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.expanduser(path)`

在 Unix 和 Windows 上，將引數中以 `~` 或 `~user` 開頭的部分替換該 *user* 的家目錄。

在 Unix 上，如果環境變數 `HOME` 有被設置，則將初始的 `~` 替換該變數的值; 否則將使用 `pwd` 在密碼目錄中查找當前使用者的家目錄。對於初始的 `~user`，直接在密碼目錄中查找該使用者的家目錄。

在 Windows 上，如果 `USERPROFILE` 有被設置，則使用該變數的值; 否則將結合 `HOMEPATH` 和 `HOMEDRIVE`。對於初始的 `~user`，會檢查當前使用者的家目錄的最後一個目錄元件是否與 `USERNAME` 相符，如果相符則替換它。

如果展開失敗或路徑不以波浪符號 (`tilde`) 開頭，則回傳原始路徑，不做任何變更。

在 3.6 版的變更: 接受一個 *path-like object*。

在 3.8 版的變更: 在 Windows 上不再使用 `HOME` 變數。

`os.path.expandvars(path)`

回傳已展開環境變數的引數。形如 `$name` 或 `${name}` 的子字串會被替換環境變數 *name* 的值。無效的變數名稱和對不存在變數的引用保持不變。

在 Windows 上，除了支援 `$name` 和 `${name}` 形式的展開外，還支援 `%name%` 形式的展開。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.getatime(path)`

回傳 *path* 的最後存取時間。回傳值是一個浮點數，表示自紀元 (參見 `time` 模組) 以來的秒數。如果檔案不存在或無法存取，則引發 `OSError`。

`os.path.getmtime(path)`

回傳 *path* 的最後修改時間。回傳值是一個浮點數，表示自紀元 (參見 `time` 模組) 以來的秒數。如果檔案不存在或無法存取，則引發 `OSError`。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.getctime(path)`

回傳系統的 `ctime`。在某些系統（如 Unix）上，這是最後一次元數據（metadata）更改的時間，在其他系統（如 Windows）上則是 `path` 的建立時間。回傳值是一個浮點數，表示自紀元（參見 `time` 模組）以來的秒數。如果檔案不存在或無法存取，則引發 `OSError`。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.getsize(path)`

回傳 `path` 的大小（以位元組單位）。如果檔案不存在或無法存取，則引發 `OSError`。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.isabs(path)`

Return `True` if `path` is an absolute pathname. On Unix, that means it begins with a slash, on Windows that it begins with two (back)slashes, or a drive letter, colon, and (back)slash together.

在 3.6 版的變更: 接受一個 `path-like object`。

在 3.13 版的變更: On Windows, returns `False` if the given path starts with exactly one (back)slash.

`os.path.isfile(path)`

如果 `path` 是一個已存在的常規檔案，則回傳 `True`。這將跟隨符號連結，因此同一個路徑可以同時回傳 `islink()` 和 `isfile()` 的結果為真。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.isdir(path)`

如果 `path` 是一個已存在的目錄，則回傳 `True`。這將跟隨符號連結，因此同一個路徑可以同時回傳 `islink()` 和 `isfile()` 的結果為真。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.isjunction(path)`

如果 `path` 是指向已存在的目錄條目且是聯接點（junction），則回傳 `True`。如果目前平台不支援聯接點，則始終返回 `False`。

在 3.12 版被加入。

`os.path.islink(path)`

如果 `path` 是指向已存在的目錄項目且是符號連結，則回傳 `True`。如果 Python 執行時不支援符號連結，則始終回傳 `False`。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.ismount(path)`

如果路徑名 `path` 是一個載點（mount point），則回傳 `True`：即在檔案系統中載了不同的檔案系統。在 POSIX 系統上，該函式檢查 `path` 的父目錄 `path/..` 是否位於不同的設備上，或者 `path/..` 和 `path` 是否指向同一設備上的相同 i-node --- 這應該能檢測出所有 Unix 和 POSIX 變體的載點。但無法可靠地檢測出相同檔案系統上的綁定載點（bind mount）。在 Windows 上，以驅動機字樣開頭的根目錄和 UNC 共享路徑始終是載點，對於任何其他路徑，會呼叫 `GetVolumePathName` 函式來檢查它是否與輸入路徑不同。

在 3.4 版的變更: 新增在 Windows 上檢測非根目錄載點的支援。

在 3.6 版的變更: 接受一個 `path-like object`。

`os.path.isdevdrive(path)`

如果路徑名 `path` 位於 Windows Dev 驅動機上，則回傳 `True`。Dev 驅動機針對開發人員場景進行了優化，提供更快的讀寫檔案性能。建議將其用於原始程式碼、臨時建置目錄、封包快取和其他 I/O 密集型操作。

可能會對無效的路徑引發錯誤，例如，有可識別的驅動機的路徑，但在不支援 Dev 磁碟機的平台返回 `False`。請參閱 Windows 文件以了解有關 Dev 驅動機的資訊。

在 3.12 版被加入。

在 3.13 版的變更: The function is now available on all platforms, and will always return `False` on those that have no support for Dev Drives

`os.path.isreserved(path)`

Return `True` if *path* is a reserved pathname on the current system.

On Windows, reserved filenames include those that end with a space or dot; those that contain colons (i.e. file streams such as "name:stream"), wildcard characters (i.e. '\*?<>'), pipe, or ASCII control characters; as well as DOS device names such as "NUL", "CON", "CONIN\$", "CONOUT\$", "AUX", "PRN", "COM1", and "LPT1".

#### 備

This function approximates rules for reserved paths on most Windows systems. These rules change over time in various Windows releases. This function may be updated in future Python releases as changes to the rules become broadly available.

適用: Windows.

在 3.13 版被加入.

`os.path.join(path, *paths)`

聰明地連接一個或多個路徑段。回傳值是 *path* 和 *\*paths* 的所有成員的串聯，每個非空部分後面都有一個目 分隔符號，除了最後一個部分。句話，如果最後一個部分空或以分隔符號結尾，結果只會以分隔符號結尾。如果一個段是 對路徑（在 Windows 上需要驅動機和根），則忽略所有之前的段，從 對路徑段繼續連接。

在 Windows 上，當遇到根路徑段（例如，`r'\foo'`）時，驅動機不會被重置。如果一個段位於不同的驅動機上，或者是 對路徑，則將忽略所有之前的段 重置驅動機。請注意，由於每個驅動機都有當前目，`os.path.join("c:", "foo")` 表示相對於驅動機 C: 的當前目 的路徑（即 `c:foo`），而不是 `c:\foo`。

在 3.6 版的變更: *path* 和 *paths* 接受 *path-like object* 作 參數。

`os.path.normcase(path)`

將路徑名的大小寫規範化。在 Windows 上，將路徑名中的所有字元轉 小寫，將正斜 轉 反斜。在其他作業系統上，回傳原始路徑。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.normpath(path)`

通過合 多余的分隔符號和上層引用來標準化路徑名，使得 `A//B`、`A/B/`、`A/./B` 和 `A/foo/../B` 都變成 `A/B`。這種字串操作可能會改變包含符號連結的路徑的含義。在 Windows 上，它將正斜 轉 反斜。要標準化大小寫，請使用 `normcase()`。

#### 備

在 POSIX 系統中，根據 IEEE Std 1003.1 2013 版; 4.13 Pathname Resolution 標準，如果一個路徑名恰好以兩個斜 開頭，則在前導字元後的第一個部分可能會以由實作品自行定義的方式解釋，雖然多於兩個前導字元應該被視 單個字元。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.realpath(path, *, strict=False)`

Return the canonical path of the specified filename, eliminating any symbolic links encountered in the path (if they are supported by the operating system). On Windows, this function will also resolve MS-DOS (also called 8.3) style names such as `C:\\PROGRA~1` to `C:\\Program Files`.

If a path doesn't exist or a symlink loop is encountered, and *strict* is `True`, `OSError` is raised. If *strict* is `False` these errors are ignored, and so the result might be missing or otherwise inaccessible.

**備**

此函式模擬作業系統使路徑成規範的過程，Windows 和 UNIX 之間在鏈接和後續路徑部份交互方式方面略有不同。

作業系統的 API 會根據需要自動使路徑正則，因此通常不需要呼叫此函式。

在 3.6 版的變更: 接受一個 *path-like object*。

在 3.8 版的變更: 在 Windows 上，現在會解析符號連結和連接點。

在 3.10 版的變更: 新增 *strict* 參數。

`os.path.realpath(path, start=os.curdir)`

從當前目錄或可選的 *start* 目錄回傳到 *path* 的相對檔案路徑。這是一個路徑計算：不會訪問檔案系統來確認 *path* 或 *start* 的存在或屬性。在 Windows 上，當 *path* 和 *start* 在不同的驅動機上時，會引發 *ValueError*。

*start* 的預設值 `os.curdir`。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.samefile(path1, path2)`

如果兩個路徑名引數指向同一個檔案或目錄，則回傳 `True`。這是通過設備編號和 i-node 編號來確定的，如果對任一路徑名的 `os.stat()` 呼叫失敗，則會引發異常。

在 3.2 版的變更: 新增對 Windows 的支援。

在 3.4 版的變更: 現在在 Windows 上使用與其他所有平台相同的實作方式。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.sameopenfile(fp1, fp2)`

如果文件描述符 *fp1* 和 *fp2* 指向同一個檔案，則回傳 `True`。

在 3.2 版的變更: 新增對 Windows 的支援。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.samestat(stat1, stat2)`

如果 *stat* 值組 *stat1* 和 *stat2* 指向同一個檔案，則回傳 `True`。這些結構可能由 `os.fstat()`、`os.lstat()` 或 `os.stat()` 回傳。此函式使用 `samefile()` 和 `sameopenfile()` 實現了底層比較。

在 3.4 版的變更: 新增對 Windows 的支援。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.split(path)`

將路徑名 *path* 拆分 (head, tail) 一對，其中 *tail* 是最後一個路徑名部份，*head* 是在它之前的所有部分。*tail* 部分不會包含斜線；如果 *path* 以斜線結尾，則 *tail* 將空。如果 *path* 中有斜線，則 *head* 將空。如果 *path* 空，則 *head* 和 *tail* 都空。除非 *head* 是根目錄 (僅有一個或多個斜線)，否則從 *head* 中除尾部的斜線。在所有情況下，`join(head, tail)` 回傳指向與 *path* 相同位置的路徑 (但字串可能不同)。還可以參考函式 `dirname()` 和 `basename()`。

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.splitdrive(path)`

將路徑名 *path* 拆分 (drive, tail) 一對，其中 *drive* 是載點或空字串。在不使用驅動機規範的系統上，*drive* 將始終空字串。在所有情況下，`drive + tail` 將與 *path* 相同。

在 Windows 上，將路徑名拆分成驅動機或 UNC 共享點以及相對路徑。

如果路徑包含驅動機字母，則 *drive* 將包含從頭到冒號 (包括冒號) 的所有內容：

```
>>> splitdrive("c:/dir")
("c:", "/dir")
```

如果路徑包含 UNC 路徑，則驅動機將包含主機名和共享名：

```
>>> splitdrive("//host/computer/dir")
("//host/computer", "/dir")
```

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.splitroot(path)`

將路徑名 *path* 拆分一個 3 項值組 (*drive*, *root*, *tail*)，其中 *drive* 是設備名稱或載點，*root* 是驅動機後的分隔符字串，*tail* 是在根後的所有內容。這些項目中的任何一個都可能是空字串。在所有情況下，*drive* + *root* + *tail* 將與 *path* 相同。

在 POSIX 系統上，*drive* 始終空。 *root* 可能空 (如果 *path* 是相對路徑)，一個斜 (如果 *path* 是對路徑)，或者兩個斜 (根據 IEEE Std 1003.1-2017; 4.13 Pathname Resolution 的實作定義)。例如：

```
>>> splitroot('/home/sam')
('/', '/', 'home/sam')
>>> splitroot('//home/sam')
('/', '//', 'home/sam')
>>> splitroot('///home/sam')
('/', '/', '//home/sam')
```

在 Windows 上，*drive* 可能空、驅動機名稱、UNC 共享或設備名稱。 *root* 可能空，斜或反斜。例如：

```
>>> splitroot('C:/Users/Sam')
('C:', '/', 'Users/Sam')
>>> splitroot('//Server/Share/Users/Sam')
('//Server/Share', '/', 'Users/Sam')
```

在 3.12 版被加入。

`os.path.splitext(path)`

將路徑名 *path* 拆分一對 (*root*, *ext*)，使得 *root* + *ext* == *path*，且副檔名 *ext* 空或以點開頭且最多包含一個點 (period)。

如果路徑不包含副檔名，則 *ext* 將空：

```
>>> splitext('bar')
('bar', '')
```

如果路徑包含副檔名，則 *ext* 將設置該副檔名，包括前導的點。請注意，前面的點將被忽略：

```
>>> splitext('foo.bar.exe')
('foo.bar', '.exe')
>>> splitext('/foo/bar.exe')
('/foo/bar', '.exe')
```

路徑的最後一個部份的前導點被認是根的一部分：

```
>>> splitext('.cshrc')
('.cshrc', '')
>>> splitext('/foo/...jpg')
('/foo/...jpg', '')
```

在 3.6 版的變更: 接受一個 *path-like object*。

`os.path.supports_unicode_filenames`

如果可以使用任意的 Unicode 字串作檔案名 (在檔案系統所施加的限制範圍內)，則回傳 `True`。

## 11.3 stat --- 直譯 stat () 的結果

原始碼: Lib/stat.py

The `stat` module defines constants and functions for interpreting the results of `os.stat()`, `os.fstat()` and `os.lstat()` (if they exist). For complete details about the `stat()`, `fstat()` and `lstat()` calls, consult the documentation for your system.

在 3.4 版的變更: The `stat` module is backed by a C implementation.

The `stat` module defines the following functions to test for specific file types:

`stat.S_ISDIR(mode)`

Return non-zero if the mode is from a directory.

`stat.S_ISCHR(mode)`

Return non-zero if the mode is from a character special device file.

`stat.S_ISBLK(mode)`

Return non-zero if the mode is from a block special device file.

`stat.S_ISREG(mode)`

Return non-zero if the mode is from a regular file.

`stat.S_ISFIFO(mode)`

Return non-zero if the mode is from a FIFO (named pipe).

`stat.S_ISLNK(mode)`

Return non-zero if the mode is from a symbolic link.

`stat.S_ISSOCK(mode)`

Return non-zero if the mode is from a socket.

`stat.S_ISDOOR(mode)`

Return non-zero if the mode is from a door.

在 3.4 版被加入.

`stat.S_ISPORT(mode)`

Return non-zero if the mode is from an event port.

在 3.4 版被加入.

`stat.S_ISWHT(mode)`

Return non-zero if the mode is from a whiteout.

在 3.4 版被加入.

Two additional functions are defined for more general manipulation of the file's mode:

`stat.S_IMODE(mode)`

Return the portion of the file's mode that can be set by `os.chmod()`---that is, the file's permission bits, plus the sticky bit, set-group-id, and set-user-id bits (on systems that support them).

`stat.S_IFMT(mode)`

Return the portion of the file's mode that describes the file type (used by the `S_IS*()` functions above).

Normally, you would use the `os.path.is*()` functions for testing the type of a file; the functions here are useful when you are doing multiple tests of the same file and wish to avoid the overhead of the `stat()` system call for each test. These are also useful when checking for information about a file that isn't handled by `os.path`, like the tests for block and character devices.

範例:

```

import os, sys
from stat import *

def walktree(top, callback):
    '''recursively descend the directory tree rooted at top,
       calling the callback function for each regular file'''

    for f in os.listdir(top):
        pathname = os.path.join(top, f)
        mode = os.lstat(pathname).st_mode
        if S_ISDIR(mode):
            # It's a directory, recurse into it
            walktree(pathname, callback)
        elif S_ISREG(mode):
            # It's a file, call the callback function
            callback(pathname)
        else:
            # Unknown file type, print a message
            print('Skipping %s' % pathname)

def visitfile(file):
    print('visiting', file)

if __name__ == '__main__':
    walktree(sys.argv[1], visitfile)

```

An additional utility function is provided to convert a file's mode in a human readable string:

`stat.filemode(mode)`

Convert a file's mode to a string of the form `'-rwxrwxrwx'`.

在 3.3 版被加入.

在 3.4 版的變更: The function supports `S_IFDOOR`, `S_IFPORT` and `S_IFWHT`.

All the variables below are simply symbolic indexes into the 10-tuple returned by `os.stat()`, `os.fstat()` or `os.lstat()`.

`stat.ST_MODE`

Inode protection mode.

`stat.ST_INO`

Inode number.

`stat.ST_DEV`

Device inode resides on.

`stat.ST_NLINK`

Number of links to the inode.

`stat.ST_UID`

User id of the owner.

`stat.ST_GID`

Group id of the owner.

`stat.ST_SIZE`

Size in bytes of a plain file; amount of data waiting on some special files.

`stat.ST_ATIME`

Time of last access.

`stat.ST_MTIME`

Time of last modification.

`stat.ST_CTIME`

The "ctime" as reported by the operating system. On some systems (like Unix) is the time of the last metadata change, and, on others (like Windows), is the creation time (see platform documentation for details).

The interpretation of "file size" changes according to the file type. For plain files this is the size of the file in bytes. For FIFOs and sockets under most flavors of Unix (including Linux in particular), the "size" is the number of bytes waiting to be read at the time of the call to `os.stat()`, `os.fstat()`, or `os.lstat()`; this can sometimes be useful, especially for polling one of these special files after a non-blocking open. The meaning of the size field for other character and block devices varies more, depending on the implementation of the underlying system call.

The variables below define the flags used in the `ST_MODE` field.

Use of the functions above is more portable than use of the first set of flags:

`stat.S_IFSOCK`

Socket.

`stat.S_IFLNK`

Symbolic link.

`stat.S_IFREG`

Regular file.

`stat.S_IFBLK`

Block device.

`stat.S_IFDIR`

Directory.

`stat.S_IFCHR`

Character device.

`stat.S_IFIFO`

FIFO.

`stat.S_IFDOOR`

Door.

在 3.4 版被加入.

`stat.S_IFPORT`

Event port.

在 3.4 版被加入.

`stat.S_IFWHT`

Whiteout.

在 3.4 版被加入.

備 F

`S_IFDOOR`, `S_IFPORT` or `S_IFWHT` are defined as 0 when the platform does not have support for the file types.

The following flags can also be used in the `mode` argument of `os.chmod()`:

`stat.S_ISUID`

Set UID bit.

`stat.S_ISGID`

Set-group-ID bit. This bit has several special uses. For a directory it indicates that BSD semantics is to be used for that directory: files created there inherit their group ID from the directory, not from the effective group ID of the creating process, and directories created there will also get the `S_ISGID` bit set. For a file that does not

have the group execution bit (*S\_IXGRP*) set, the set-group-ID bit indicates mandatory file/record locking (see also *S\_ENFMT*).

stat.**S\_ISVTX**

Sticky bit. When this bit is set on a directory it means that a file in that directory can be renamed or deleted only by the owner of the file, by the owner of the directory, or by a privileged process.

stat.**S\_IRWXU**

Mask for file owner permissions.

stat.**S\_IRUSR**

Owner has read permission.

stat.**S\_IWUSR**

Owner has write permission.

stat.**S\_IXUSR**

Owner has execute permission.

stat.**S\_IRWXG**

Mask for group permissions.

stat.**S\_IRGRP**

Group has read permission.

stat.**S\_IWGRP**

Group has write permission.

stat.**S\_IXGRP**

Group has execute permission.

stat.**S\_IRWXO**

Mask for permissions for others (not in group).

stat.**S\_IROTH**

Others have read permission.

stat.**S\_IWOTH**

Others have write permission.

stat.**S\_IXOTH**

Others have execute permission.

stat.**S\_ENFMT**

System V file locking enforcement. This flag is shared with *S\_ISGID*: file/record locking is enforced on files that do not have the group execution bit (*S\_IXGRP*) set.

stat.**S\_IREAD**

Unix V7 synonym for *S\_IRUSR*.

stat.**S\_IWRITE**

Unix V7 synonym for *S\_IWUSR*.

stat.**S\_IEXEC**

Unix V7 synonym for *S\_IXUSR*.

The following flags can be used in the *flags* argument of *os.chflags()*:

stat.**UF\_SETTABLE**

All user settable flags.

在 3.13 版被加入.

`stat.UF_NODUMP`  
Do not dump the file.

`stat.UF_IMMUTABLE`  
The file may not be changed.

`stat.UF_APPEND`  
The file may only be appended to.

`stat.UF_OPAQUE`  
The directory is opaque when viewed through a union stack.

`stat.UF_NOUNLINK`  
The file may not be renamed or deleted.

`stat.UF_COMPRESSED`  
The file is stored compressed (macOS 10.6+).

`stat.UF_TRACKED`  
Used for handling document IDs (macOS)  
在 3.13 版被加入.

`stat.UF_DATAVAULT`  
The file needs an entitlement for reading or writing (macOS 10.13+)  
在 3.13 版被加入.

`stat.UF_HIDDEN`  
The file should not be displayed in a GUI (macOS 10.5+).

`stat.SF_SETTABLE`  
All super-user changeable flags  
在 3.13 版被加入.

`stat.SF_SUPPORTED`  
All super-user supported flags  
適用: macOS  
在 3.13 版被加入.

`stat.SF_SYNTHETIC`  
All super-user read-only synthetic flags  
適用: macOS  
在 3.13 版被加入.

`stat.SF_ARCHIVED`  
The file may be archived.

`stat.SF_IMMUTABLE`  
The file may not be changed.

`stat.SF_APPEND`  
The file may only be appended to.

`stat.SF_RESTRICTED`  
The file needs an entitlement to write to (macOS 10.13+)  
在 3.13 版被加入.

`stat.SF_NOUNLINK`  
The file may not be renamed or deleted.

`stat.SF_SNAPSHOT`

The file is a snapshot file.

`stat.SF_FIRMLINK`

The file is a firmlink (macOS 10.15+)

在 3.13 版被加入.

`stat.SF_DATALESS`

The file is a dataless object (macOS 10.15+)

在 3.13 版被加入.

See the \*BSD or macOS systems man page *chflags(2)* for more information.

On Windows, the following file attribute constants are available for use when testing bits in the `st_file_attributes` member returned by `os.stat()`. See the [Windows API documentation](#) for more detail on the meaning of these constants.

`stat.FILE_ATTRIBUTE_ARCHIVE`

`stat.FILE_ATTRIBUTE_COMPRESSED`

`stat.FILE_ATTRIBUTE_DEVICE`

`stat.FILE_ATTRIBUTE_DIRECTORY`

`stat.FILE_ATTRIBUTE_ENCRYPTED`

`stat.FILE_ATTRIBUTE_HIDDEN`

`stat.FILE_ATTRIBUTE_INTEGRITY_STREAM`

`stat.FILE_ATTRIBUTE_NORMAL`

`stat.FILE_ATTRIBUTE_NOT_CONTENT_INDEXED`

`stat.FILE_ATTRIBUTE_NO_SCRUB_DATA`

`stat.FILE_ATTRIBUTE_OFFLINE`

`stat.FILE_ATTRIBUTE_READONLY`

`stat.FILE_ATTRIBUTE_REPARSE_POINT`

`stat.FILE_ATTRIBUTE_SPARSE_FILE`

`stat.FILE_ATTRIBUTE_SYSTEM`

`stat.FILE_ATTRIBUTE_TEMPORARY`

`stat.FILE_ATTRIBUTE_VIRTUAL`

在 3.5 版被加入.

On Windows, the following constants are available for comparing against the `st_reparse_tag` member returned by `os.lstat()`. These are well-known constants, but are not an exhaustive list.

`stat.IO_REPARSE_TAG_SYMLINK`

`stat.IO_REPARSE_TAG_MOUNT_POINT`

`stat.IO_REPARSE_TAG_APPEXECLINK`

在 3.8 版被加入.

## 11.4 filecmp --- 檔案與目 F 比較

原始碼: [Lib/filecmp.py](#)

---

The *filecmp* module defines functions to compare files and directories, with various optional time/correctness trade-offs. For comparing files, see also the *difflib* module.

The *filecmp* module defines the following functions:

`filecmp.cmp(f1, f2, shallow=True)`

Compare the files named *f1* and *f2*, returning `True` if they seem equal, `False` otherwise.

If *shallow* is true and the `os.stat()` signatures (file type, size, and modification time) of both files are identical, the files are taken to be equal.

Otherwise, the files are treated as different if their sizes or contents differ.

Note that no external programs are called from this function, giving it portability and efficiency.

This function uses a cache for past comparisons and the results, with cache entries invalidated if the `os.stat()` information for the file changes. The entire cache may be cleared using `clear_cache()`.

`filecmp.cmpfiles(dir1, dir2, common, shallow=True)`

Compare the files in the two directories *dir1* and *dir2* whose names are given by *common*.

Returns three lists of file names: *match*, *mismatch*, *errors*. *match* contains the list of files that match, *mismatch* contains the names of those that don't, and *errors* lists the names of files which could not be compared. Files are listed in *errors* if they don't exist in one of the directories, the user lacks permission to read them or if the comparison could not be done for some other reason.

The *shallow* parameter has the same meaning and default value as for `filecmp.cmp()`.

For example, `cmpfiles('a', 'b', ['c', 'd/e'])` will compare *a/c* with *b/c* and *a/d/e* with *b/d/e*. 'c' and 'd/e' will each be in one of the three returned lists.

`filecmp.clear_cache()`

Clear the filecmp cache. This may be useful if a file is compared so quickly after it is modified that it is within the mtime resolution of the underlying filesystem.

在 3.4 版被加入。

### 11.4.1 The `dircmp` class

`class filecmp.dircmp(a, b, ignore=None, hide=None, *, shallow=True)`

Construct a new directory comparison object, to compare the directories *a* and *b*. *ignore* is a list of names to ignore, and defaults to `filecmp.DEFAULT_IGNORES`. *hide* is a list of names to hide, and defaults to `[os.curdir, os.pardir]`.

The `dircmp` class compares files by doing *shallow* comparisons as described for `filecmp.cmp()` by default using the *shallow* parameter.

在 3.13 版的變更: Added the *shallow* parameter.

The `dircmp` class provides the following methods:

`report()`

Print (to `sys.stdout`) a comparison between *a* and *b*.

`report_partial_closure()`

Print a comparison between *a* and *b* and common immediate subdirectories.

`report_full_closure()`

Print a comparison between *a* and *b* and common subdirectories (recursively).

The `dircmp` class offers a number of interesting attributes that may be used to get various bits of information about the directory trees being compared.

Note that via `__getattr__()` hooks, all attributes are computed lazily, so there is no speed penalty if only those attributes which are lightweight to compute are used.

`left`

The directory *a*.

**right**

The directory *b*.

**left\_list**

Files and subdirectories in *a*, filtered by *hide* and *ignore*.

**right\_list**

Files and subdirectories in *b*, filtered by *hide* and *ignore*.

**common**

Files and subdirectories in both *a* and *b*.

**left\_only**

Files and subdirectories only in *a*.

**right\_only**

Files and subdirectories only in *b*.

**common\_dirs**

Subdirectories in both *a* and *b*.

**common\_files**

Files in both *a* and *b*.

**common\_funny**

Names in both *a* and *b*, such that the type differs between the directories, or names for which `os.stat()` reports an error.

**same\_files**

Files which are identical in both *a* and *b*, using the class's file comparison operator.

**diff\_files**

Files which are in both *a* and *b*, whose contents differ according to the class's file comparison operator.

**funny\_files**

Files which are in both *a* and *b*, but could not be compared.

**subdirs**

A dictionary mapping names in `common_dirs` to `dircmp` instances (or `MyDirCmp` instances if this instance is of type `MyDirCmp`, a subclass of `dircmp`).

在 3.10 版的變更: Previously entries were always `dircmp` instances. Now entries are the same type as `self`, if `self` is a subclass of `dircmp`.

**filecmp.DEFAULT\_IGNORES**

在 3.4 版被加入。

List of directories ignored by `dircmp` by default.

Here is a simplified example of using the `subdirs` attribute to search recursively through two directories to show common different files:

```
>>> from filecmp import dircmp
>>> def print_diff_files(dcmp):
...     for name in dcmp.diff_files:
...         print("diff_file %s found in %s and %s" % (name, dcmp.left,
...             dcmp.right))
...     for sub_dcmp in dcmp.subdirs.values():
...         print_diff_files(sub_dcmp)
...
>>> dcmp = dircmp('dir1', 'dir2')
>>> print_diff_files(dcmp)
```

## 11.5 tempfile --- 生成臨時檔案和目錄

原始碼: Lib/tempfile.py

該 module (模組) 用於建立臨時檔案和目錄，它可以在所有有支援的平臺上使用。`TemporaryFile`、`NamedTemporaryFile`、`TemporaryDirectory` 和 `SpooledTemporaryFile` 是有自動清除功能的高階介面，可作情境管理器 (context manager) 使用。`mkstemp()` 和 `mkdtemp()` 是低階函式，使用完畢後需手動清理。

所有可被使用者呼叫的函式和建構函式都帶有可以設定臨時檔案和臨時目錄的路徑和名稱的引數。此 module 所使用的檔名一個隨機字元組成的字串，這讓檔案可以更安全地在共享的臨時目錄中被建立。為了維持向後相容性，引數的順序會稍微奇怪，所以為了讓程式更容易被理解，建議使用關鍵字引數。

這個 module 定義了以下可供使用者呼叫的項目：

```
tempfile.TemporaryFile(mode='w+b', buffering=-1, encoding=None, newline=None, suffix=None,
                       prefix=None, dir=None, *, errors=None)
```

回傳一個可當作臨時儲存區域的類檔案物件。建立該檔案使用了與 `mkstemp()` 相同的安全規則。它將在關閉 (包括當物件被垃圾回收 (garbage collect) 時的隱式關閉) 後立即銷毀。在 Unix 下，該檔案所在的目錄可能根本不被建立、或者在建立檔案後立即就被刪除，其他平臺不支援此功能；你的程式不應依賴使用此功能建立的臨時檔案名稱，因為它在檔案系統中的名稱有可能是不可見的。

生成的物件可以作情境管理器使用 (參見範例)。完成情境或銷毀臨時檔案物件後，臨時檔案將從檔案系統中刪除。

`mode` 參數預設為 `'w+b'`，所以建立的檔案不用關閉就可以讀取或寫入。因為用的是二進位制模式，所以無論存的是什麼資料，它在所有平臺上的行都一致。`buffering`、`encoding`、`errors` 和 `newline` 的含義與 `open()` 中的相同。

參數 `dir`、`prefix` 和 `suffix` 的含義和預設值都與它們在 `mkstemp()` 中的相同。

在 POSIX 平臺上，回傳物件是真實的檔案物件。在其他平臺上，它是一個 file-like object，它的 `file` 屬性底層的真实檔案物件。

如果可用且可運作，則使用 `os.O_TMPFILE` 旗標 (僅限於 Linux，需要 3.11 版本以上的核心)。

在不是 Posix 或 Cygwin 的平臺上，`TemporaryFile` 是 `NamedTemporaryFile` 的別名。

引發一個附帶引數 `fullpath` 的 `tempfile.mkstemp` 稽核事件。

在 3.5 版的變更: 如果可用，自此開始使用 `os.O_TMPFILE` 旗標。

在 3.8 版的變更: 新增 `errors` 參數。

```
tempfile.NamedTemporaryFile(mode='w+b', buffering=-1, encoding=None, newline=None, suffix=None,
                             prefix=None, dir=None, delete=True, *, errors=None, delete_on_close=True)
```

此函式的操作與 `TemporaryFile()` 完全相同，但存在以下差別：

- 此函式回傳一個保證在檔案系統中具有可見名稱的檔案。
- 為了管理指定檔案，它使用 `delete` 和 `delete_on_close` 參數擴充 `TemporaryFile()` 來指定是否以及如何自動刪除指定檔案。

回傳的物件始終是一個類檔案物件，其 `file` 屬性是底層的真实檔案物件。這個類檔案物件可以在 `with` 陳述式中使用，就像普通檔案一樣。臨時檔案的名稱可以從回傳的類檔案物件的 `name` 屬性中取得。在 Unix 上則與 `TemporaryFile()` 不同，目錄條目不會在檔案建立後立即被取消鏈接 (unlink)。

如果 `delete` 為 `true` (預設值) 且 `delete_on_close` 為 `true` (預設值)，則檔案在關閉後會立即被刪除。如果 `delete` 為 `true` 且 `delete_on_close` 為 `false`，則僅在情境管理器退出時刪除檔案，或者在類檔案物件完結時刪除檔案。在這種情況下，不總是保證能成功刪除 (請參見 `object.__del__()`)。如果 `delete` 為 `false`，則會忽略 `delete_on_close` 的值。

因此，要在關閉檔案後使用臨時檔案的名稱重新打開檔案，請確保在關閉時不刪除檔案（將 `delete` 參數設定為 `false`），或者如果臨時檔案是以 `with` 陳述式建立，要將 `delete_on_close` 參數設定為 `false`。建議使用後者，因為它有助於在情境管理器退出時自動清理臨時檔案。

在臨時檔案仍處於打開狀態時再次按其名稱打開它，其作用方式如下：

- 在 POSIX 上，檔案始終可以再次打開。
- 在 Windows 上，確保至少滿足以下條件之一：
  - `delete` 為 `false`
  - 額外的 `open` 會共享刪除存取權限（例如，通過使用旗標 `O_TEMPORARY` 來呼叫 `os.open()`）
  - `delete` 為 `true` 但 `delete_on_close` 為 `false`。請注意，在這種情況下不共享刪除存取權限的其他 `open`（例如透過建立的 `open()` 建立）必須在退出情境管理器之前關閉，否則情境管理器上的 `os.unlink()` 呼叫退出將失敗並出現 `PermissionError`。

在 Windows 上，如果 `delete_on_close` 為 `false`，且檔案是在使用者缺乏刪除存取權限的目錄中建立的，則情境管理器退出時的 `os.unlink()` 呼叫將失敗，並引發 `PermissionError`。當 `delete_on_close` 為 `true` 時，不會發生這種情況，因為刪除存取權限是由 `open` 來要求的，如果未授予存取權限則會立即失敗。

（僅）在 POSIX 上，因使用 `SIGKILL` 而被終止的行程無法自動刪除它建立的任何 `NamedTemporaryFiles`。

引發一個附帶引數 `fullpath` 的 `tempfile.mkstemp` 稽核事件。

在 3.8 版的變更：新增 `errors` 參數。

在 3.12 版的變更：新增 `delete_on_close` 參數。

```
class tempfile.SpooledTemporaryFile (max_size=0, mode='w+b', buffering=-1, encoding=None,
                                     newline=None, suffix=None, prefix=None, dir=None, *,
                                     errors=None)
```

此類執行的操作與 `TemporaryFile()` 完全相同，但會將資料排存 (spool) 於在記憶體中，直到檔案大小超過 `max_size`，或檔案的 `fileno()` 方法被呼叫時，此時資料會被寫入磁碟，且之後的操作與 `TemporaryFile()` 相同。

**rollover()**

生成的檔案物件有一個額外的方法 `rollover()`，忽略檔案大小立即將其寫入磁碟。

回傳的物件是 file-like object，它的 `_file` 屬性是 `io.BytesIO` 或 `io.TextIOWrapper` 物件（取決於指定的是二進位制模式還是文字模式）或真實的檔案物件（取決於是否已呼叫 `rollover()`）。file-like object 可以像普通檔案一樣在 `with` 陳述式中使用。

在 3.3 版的變更：現在，檔案的截斷方法 (truncate method) 可接受一個 `size` 引數。

在 3.8 版的變更：新增 `errors` 參數。

在 3.11 版的變更：完全實作 `io.BufferedIOBase` 和 `io.TextIOBase` 抽象基底類（取決於指定的是二進位還是文本 `mode`）。

```
class tempfile.TemporaryDirectory (suffix=None, prefix=None, dir=None, ignore_cleanup_errors=False,
                                     *, delete=True)
```

此類會使用與 `mkdtemp()` 相同安全規則來建立一個臨時目錄。回傳物件可當作情境管理器使用（參見範例）。在完成情境或銷毀臨時目錄物件時，新建立的臨時目錄及其所有內容會從檔案系統中被移除。

**name**

可以從回傳物件的 `name` 屬性中找到的臨時目錄名稱。當回傳的物件用作情境管理器時，這個 `name` 會作為 `with` 陳述句中 `as` 子句的目標（如果有 `as` 的話）。

**cleanup()**

此目錄可透過呼叫 `cleanup()` 方法來顯式地清理。如果 `ignore_cleanup_errors` 為 `true`，則在顯式或隱式清理期間出現的未處理例外（例如在 Windows 上移除開關的檔案而引發的 `PermissionError`）將被忽略，且剩余的可移除條目會「可能」地被刪除。在其他

情下，錯誤將在任何情境清理發生時被引發（`cleanup()` 呼叫、退出情境管理器、物件被作垃圾回收或直譯器關閉等）。

`delete` 參數可以停用在退出情境時對目錄的清理，雖然停用情境管理器在退出情境時所取的操作似乎不常見，但它在除錯期間或當你需要基於其他邏輯的清理行時會非常有用。

引發一個附帶引數 `fullpath` 的 `tempfile.mkdtemp` 稽核事件。

在 3.2 版被加入。

在 3.10 版的變更：新增 `ignore_cleanup_errors` 參數。

在 3.12 版的變更：新增 `delete` 參數。

`tempfile.mkstemp` (`suffix=None, prefix=None, dir=None, text=False`)

盡可能以最安全的方式建立一個臨時檔案。假設所在平臺正確實作了 `os.open()` 的 `os.O_EXCL` 旗標，則建立檔案時不會有 race condition（競條件）的情。該檔案只能由建立者讀寫，如果所在平臺用 permission bit（許可權位元）來表示檔案是否可執行，則有人有執行權。檔案描述器不會被子行程繼承。

與 `TemporaryFile()` 不同，`mkstemp()` 使用者用完臨時檔案後需要自行將其除。

如果 `suffix` 不是 `None` 則檔名將以該後綴結尾，若 `None` 則有後綴。`mkstemp()` 不會在檔名和後綴之間加點（dot），如果需要加一個點號，請將其放在 `suffix` 的開頭。

如果 `prefix` 不是 `None` 則檔名將以該字首開頭，若 `None` 則使用預設前綴。預設前綴是 `gettempprefix()` 或 `gettempprefixb()` 函式的回傳值（自動呼叫合適的函式）。

如果 `dir` 不 `None` 則在指定的目錄建立檔案，若 `None` 則使用預設目錄。預設目錄是從一個相依於平臺的列表中選擇出來的，但是使用者可以設定 `TMPDIR`、`TEMP` 或 `TMP` 環境變數來設定目錄的位置。因此，不能保證生成的臨時檔案路徑是使用者友善的，比如透過 `os.popen()` 將路徑傳遞給外部命令時仍需要加引號（quoting）。

如果 `suffix`、`prefix` 和 `dir` 中的任何一個不是 `None`，就要保證它們資料型相同。如果它們是位元組串，則回傳名稱的型就是位元組串而非字串。如果不想遵循預設行但又想要回傳值是位元組串型，請傳入 `suffix=b''`。

如果指定了 `text` 且真值，檔案會以文字模式開。否則，檔案（預設）以二進位制模式開。

`mkstemp()` 回傳一個 tuple，tuple 中，第一個元素是一個作業系統層級（OS-level）控制代碼，指向一個開的檔案（如同 `os.open()` 的回傳值），第二元素是該檔案的對路徑。

引發一個附帶引數 `fullpath` 的 `tempfile.mkstemp` 稽核事件。

在 3.5 版的變更：現在，`suffix`、`prefix` 和 `dir` 可以以位元組串型按順序提供，以獲得位元組串型的回傳值。在之前只允許使用字串。`suffix` 和 `prefix` 現在可以接受 `None`，且預設 `None` 以使用合適的預設值。

在 3.6 版的變更：`dir` 參數現在可接受一個類路徑物件（*path-like object*）。

`tempfile.mkdtemp` (`suffix=None, prefix=None, dir=None`)

盡可能以最安全的方式建立一個臨時目錄，建立該目錄時不會有 race condition 的情，該目錄只能由建立者讀取、寫入和搜尋。

`mkdtemp()` 的使用者用完臨時目錄後需要自行將其除。

引數 `prefix`、`suffix` 和 `dir` 的含義與它們在 `mkstemp()` 中相同。

`mkdtemp()` 回傳新目錄的對路徑名稱。

引發一個附帶引數 `fullpath` 的 `tempfile.mkdtemp` 稽核事件。

在 3.5 版的變更：現在，`suffix`、`prefix` 和 `dir` 可以以位元組串型按順序提供，以獲得位元組串型的回傳值。在之前只允許使用字串。`suffix` 和 `prefix` 現在可以接受 `None`，且預設 `None` 以使用合適的預設值。

在 3.6 版的變更：`dir` 參數現在可接受一個類路徑物件（*path-like object*）。

在 3.12 版的變更：`mkdtemp()` 現在都會回傳對路徑，即使 `dir` 是相對路徑。

`tempfile.gettempdir()`

回傳儲存臨時檔案的目錄名稱。這設定了此 module 所有函式 *dir* 引數的預設值。

Python 搜尋標準目錄列表來找到呼叫者可以在其中建立檔案的目錄。這個列表是：

1. `TMPDIR` 環境變數指向的目錄。
2. `TEMP` 環境變數指向的目錄。
3. `TMP` 環境變數指向的目錄。
4. 與平臺相關的位置：
  - 在 Windows 上，目錄依次 `C:\TEMP`、`C:\TMP`、`\TEMP` 和 `\TMP`。
  - 在所有其他平臺上，目錄依次 `/tmp`、`/var/tmp` 和 `/usr/tmp`。
5. 不得已時，使用當前工作目錄。

搜尋的結果會被 cache (快取) 起來，請見下面 `tempdir` 的描述。

在 3.10 版的變更：回傳一個字串。在之前的版本中它會回傳任意 `tempdir` 的值而不考慮它的型別，只要它不是 `None`。

`tempfile.gettempdirb()`

與 `gettempdir()` 相同，但回傳值位元組串型別。

在 3.5 版被加入。

`tempfile.gettempprefix()`

回傳用於建立臨時檔案的檔名前綴，它不包含目錄部分。

`tempfile.gettempprefixb()`

與 `gettempprefix()` 相同，但回傳值位元組串型別。

在 3.5 版被加入。

此 module 使用一個全域性變數來儲存由 `gettempdir()` 回傳的臨時檔案使用的目錄路徑。它可被直接設定以覆蓋選擇過程，但不建議這樣做。此 module 中的所有函式都接受一個 *dir* 引數，它可被用於指定目錄。這是個推薦的做法，它不會透過改變全域性 API 行而對其他不預期此行程式造成影響。

`tempfile.tempdir`

當被設 `None` 以外的值時，此變數會此 module 所定義函式的引數 *dir* 定義預設值，包括確定其型別位元組串還是字串。它不可以 *path-like object*。

如果在呼叫除 `gettempprefix()` 外的上述任何函式時 `tempdir` 是 `None` (預設值) 則它會按照 `gettempdir()` 中所描述的演算法來初始化。

### 備

請注意如果你將 `tempdir` 設位元組串值，會有一個麻煩的副作用：`mkstemp()` 和 `mkdtemp()` 的全域性預設回傳型別會在有提供明顯字串型別的 `prefix`、`suffix` 或 `dir` 時被改位元組串。請不要編寫預期此行或依賴於此行的程式。這個奇怪的行是維持與以往實作版本的相容性。

## 11.5.1 范例

以下是 `tempfile` module 的一些常見用法範例：

```
>>> import tempfile

# create a temporary file and write some data to it
>>> fp = tempfile.TemporaryFile()
>>> fp.write(b'Hello world!')
# read data from file
```

(繼續下一頁)

(繼續上一頁)

```

>>> fp.seek(0)
>>> fp.read()
b'Hello world!'
# close the file, it will be removed
>>> fp.close()

# create a temporary file using a context manager
>>> with tempfile.TemporaryFile() as fp:
...     fp.write(b'Hello world!')
...     fp.seek(0)
...     fp.read()
b'Hello world!'
>>>
# file is now closed and removed

# create a temporary file using a context manager
# close the file, use the name to open the file again
>>> with tempfile.NamedTemporaryFile(delete_on_close=False) as fp:
...     fp.write(b'Hello world!')
...     fp.close()
...     # the file is closed, but not removed
...     # open the file again by using its name
...     with open(fp.name, mode='rb') as f:
...         f.read()
b'Hello world!'
>>>
# file is now removed

# create a temporary directory using the context manager
>>> with tempfile.TemporaryDirectory() as tmpdirname:
...     print('created temporary directory', tmpdirname)
>>>
# directory and contents have been removed

```

## 11.5.2 已用的函式和變數

在過去，建立臨時檔案首先使用 `mktemp()` 函式生成一個檔名，然後使用該檔名建立檔案。不幸的是這函式不安全的，因其在呼叫 `mktemp()` 與隨後嘗試建立檔案之間的時間，其他程式可能會使用該名稱建立檔案。解方案是將兩個步驟結合起來，立即建立檔案。這個方案目前被 `mkstemp()` 和上述其他函式所使用。

`tempfile.mktemp(suffix="", prefix='tmp', dir=None)`

在 2.3 版之後被使用: 使用 `mkstemp()` 代替。

回傳一個在呼叫本方法時不存在檔案的對路徑。引數 `prefix`、`suffix` 和 `dir` 與 `mkstemp()` 中所用的類似，除了在於不支援位元組串型的檔名且不支援 `suffix=None` 和 `prefix=None`。

### 警告

使用此功能可能會在程式中引入安全漏洞。當你開始使用本方法回傳的檔案執行任何操作時，可能有人已經捷足先登了。`mktemp()` 的功能可以很輕鬆地用帶有 `delete=False` 參數的 `NamedTemporaryFile()` 代替：

```

>>> f = NamedTemporaryFile(delete=False)
>>> f.name
'/tmp/tmpjtujjt'
>>> f.write(b"Hello World!\n")
13
>>> f.close()
>>> os.unlink(f.name)
>>> os.path.exists(f.name)
False

```

## 11.6 glob --- Unix 風格的路徑名稱模式擴展

原始碼: Lib/glob.py

`glob` 模組根據 Unix shell 使用的規則查找與指定模式匹配的所有路徑名稱，結果以任意順序回傳。有波浪號 (tilde) 擴展，但是 \*、? 和用 [] 表示的字元範圍將被正確匹配。這是透過同時使用 `os.scandir()` 和 `fnmatch.fnmatch()` 函式來完成的，而有實際調用 `subshell`。

請注意，以點 (.) 開頭的檔案只能與同樣以點開頭的模式匹配，這與 `fnmatch.fnmatch()` 或 `pathlib.Path.glob()` 不同。（對於波浪號和 shell 變數擴展，請使用 `os.path.expanduser()` 和 `os.path.expandvars()`。）

對於文本 (literal) 匹配，將元字元 (meta-character) 括在方括號中。例如，'[?]' 會匹配 '?' 字元。

The `glob` module defines the following functions:

`glob.glob(pathname, *, root_dir=None, dir_fd=None, recursive=False, include_hidden=False)`

回傳與 `pathname` 匹配、可能為空的路徑名稱 list，它必須是包含路徑規範的字串。`pathname` 可以是絕對的（如 `/usr/src/Python-1.5/Makefile`）或相對的（如 `../Tools/*/*.gif`），並且可以包含 shell 樣式的通用字元 (wildcard)。已損壞的符號連接也會（如同在 shell）被包含在結果中。結果是否排序取決於檔案系統 (file system)。如果在呼叫此函式期間刪除或新增滿足條件的檔案，則結果不一定會包含該檔案的路徑名稱。

如果 `root_dir` 不是 `None`，它應該是一個指定搜索根目的 `path-like object`。它在呼叫它之前更改當前目的的影響與 `glob()` 相同。如果 `pathname` 是相對的，結果將包含相對於 `root_dir` 的路徑。

此函式可以支援以 `dir_fd` 參數使用相對目描述器的路徑。

如果 `recursive` 為真，模式 `"**"` 將匹配任何檔案、零個或多個目、子目和目的符號連結。如果模式後面有 `os.sep` 或 `os.altsep` 那檔案將不會被匹配。

如果 `include_hidden` 為真，`"**"` 模式將匹配被隱藏的目。

引發一個附帶引數 `pathname`、`recursive` 的稽核事件 `glob.glob`。

引發一個附帶引數 `pathname`、`recursive`、`root_dir`、`dir_fd` 的稽核事件 `glob.glob/2`。

### 備註

在大型目樹中使用 `"**"` 模式可能會消耗過多的時間。

### 備註

This function may return duplicate path names if `pathname` contains multiple `"**"` patterns and `recursive` is true.

在 3.5 版的變更: 支援以 `"**"` 使用遞歸 `glob`。

在 3.10 版的變更: 新增 `root_dir` 與 `dir_fd` 參數。

在 3.11 版的變更: 新增 `include_hidden` 參數。

`glob.iglob(pathname, *, root_dir=None, dir_fd=None, recursive=False, include_hidden=False)`

回傳一個會產生與 `glob()` 相同的值的 `iterator`，而不是同時存儲全部的值。

引發一個附帶引數 `pathname`、`recursive` 的稽核事件 `glob.glob`。

引發一個附帶引數 `pathname`、`recursive`、`root_dir`、`dir_fd` 的稽核事件 `glob.glob/2`。

**備**

This function may return duplicate path names if *pathname* contains multiple "\*" patterns and *recursive* is true.

在 3.5 版的變更: 支援以 "\*" 使用遞 。

在 3.10 版的變更: 新增 *root\_dir* 與 *dir\_fd* 參數。

在 3.11 版的變更: 新增 *include\_hidden* 參數。

`glob.escape(pathname)`

跳 (escape) 所有特殊字元 ('?', '\*', 和 '[')。如果你想匹配其中可能包含特殊字元的任意文本字串, 這將會很有用。驅動器 (drive)/UNC 共享點 (sharepoints) 中的特殊字元不會被跳, 例如在 Windows 上, `escape('///?/c:/Quo vadis?.txt')` 會回傳 `'///?/c:/Quo vadis[?].txt'`。

在 3.4 版被加入。

`glob.translate(pathname, *, recursive=False, include_hidden=False, seps=None)`

Convert the given path specification to a regular expression for use with `re.match()`. The path specification can contain shell-style wildcards.

舉例來:

```
>>> import glob, re
>>>
>>> regex = glob.translate('**/*.txt', recursive=True, include_hidden=True)
>>> regex
'(?s:(?:.+/?)?[^\/*]*\.txt)\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foo/bar/baz.txt')
<re.Match object; span=(0, 15), match='foo/bar/baz.txt'>
```

Path separators and segments are meaningful to this function, unlike `fnmatch.translate()`. By default wildcards do not match path separators, and \* pattern segments match precisely one path segment.

If *recursive* is true, the pattern segment "\*" will match any number of path segments.

If *include\_hidden* is true, wildcards can match path segments that start with a dot (.

A sequence of path separators may be supplied to the *seps* argument. If not given, `os.sep` and `altsep` (if available) are used.

**也參考**

`pathlib.PurePath.full_match()` and `pathlib.Path.glob()` methods, which call this function to implement pattern matching and globbing.

在 3.13 版被加入。

**11.6.1 范例**

例如, 在一個包含以下檔案的目錄: `1.gif`, `2.txt`, `card.gif`, 和一個僅包含 `3.txt` 檔案的子目錄 `sub`, `glob()` 將 生以下結果。請注意路徑的任何前導部分是如何保留的。

```
>>> import glob
>>> glob.glob('./[0-9].*')
['./1.gif', './2.txt']
>>> glob.glob('*.gif')
['1.gif', 'card.gif']
>>> glob.glob('?.gif')
```

(繼續下一頁)

(繼續上一頁)

```
['1.gif']
>>> glob.glob('**/*.txt', recursive=True)
['2.txt', 'sub/3.txt']
>>> glob.glob('./**/', recursive=True)
['./', './sub/']
```

如果目錄包含以 . 開頭的檔案, 則預設情況下不會去匹配到它們。例如, 一個包含 `card.gif` 和 `.card.gif` 的目錄:

```
>>> import glob
>>> glob.glob('*.gif')
['card.gif']
>>> glob.glob('.c*')
['.card.gif']
```

`fnmatch` 模組提供了 shell 風格檔案名 (不是路徑) 的擴展

### 也參考

`pathlib` 模組提供高階路徑物件。

## 11.7 fnmatch --- Unix 檔案名稱模式比對

原始碼: `Lib/fnmatch.py`

This module provides support for Unix shell-style wildcards, which are *not* the same as regular expressions (which are documented in the `re` module). The special characters used in shell-style wildcards are:

Pattern	含義
*	matches everything
?	matches any single character
[seq]	matches any character in <i>seq</i>
[!seq]	matches any character not in <i>seq</i>

For a literal match, wrap the meta-characters in brackets. For example, `'[?]'` matches the character `'?'`.

Note that the filename separator (`'/'` on Unix) is *not* special to this module. See module `glob` for pathname expansion (`glob` uses `filter()` to match pathname segments). Similarly, filenames starting with a period are not special for this module, and are matched by the `*` and `?` patterns.

Unless stated otherwise, "filename string" and "pattern string" either refer to `str` or ISO-8859-1 encoded `bytes` objects. Note that the functions documented below do not allow to mix a `bytes` pattern with a `str` filename, and vice-versa.

Finally, note that `functools.lru_cache()` with a `maxsize` of 32768 is used to cache the (typed) compiled regex patterns in the following functions: `fnmatch()`, `fnmatchcase()`, `filter()`.

`fnmatch.fnmatch(name, pat)`

Test whether the filename string `name` matches the pattern string `pat`, returning `True` or `False`. Both parameters are case-normalized using `os.path.normcase()`. `fnmatchcase()` can be used to perform a case-sensitive comparison, regardless of whether that's standard for the operating system.

This example will print all file names in the current directory with the extension `.txt`:

```
import fnmatch
import os

for file in os.listdir('.'):
    if fnmatch.fnmatch(file, '*.txt'):
        print(file)
```

`fnmatch.fnmatchcase` (*name*, *pat*)

Test whether the filename string *name* matches the pattern string *pat*, returning `True` or `False`; the comparison is case-sensitive and does not apply `os.path.normcase()`.

`fnmatch.filter` (*names*, *pat*)

Construct a list from those elements of the *iterable* of filename strings *names* that match the pattern string *pat*. It is the same as `[n for n in names if fnmatch(n, pat)]`, but implemented more efficiently.

`fnmatch.translate` (*pat*)

Return the shell-style pattern *pat* converted to a regular expression for using with `re.match()`. The pattern is expected to be a *str*.

範例：

```
>>> import fnmatch, re
>>>
>>> regex = fnmatch.translate('*.txt')
>>> regex
'(?s:.*\\.txt)\\Z'
>>> reobj = re.compile(regex)
>>> reobj.match('foobar.txt')
<re.Match object; span=(0, 10), match='foobar.txt'>
```

### `glob` 模組

Unix shell-style path expansion.

## 11.8 linecache --- 隨機存取文字列

原始碼：[Lib/linecache.py](#)

The `linecache` module allows one to get any line from a Python source file, while attempting to optimize internally, using a cache, the common case where many lines are read from a single file. This is used by the `traceback` module to retrieve source lines for inclusion in the formatted traceback.

The `tokenize.open()` function is used to open files. This function uses `tokenize.detect_encoding()` to get the encoding of the file; in the absence of an encoding token, the file encoding defaults to UTF-8.

The `linecache` module defines the following functions:

`linecache.getline` (*filename*, *lineno*, *module\_globals=None*)

Get line *lineno* from file named *filename*. This function will never raise an exception --- it will return `''` on errors (the terminating newline character will be included for lines that are found).

If a file named *filename* is not found, the function first checks for a **PEP 302** `__loader__` in *module\_globals*. If there is such a loader and it defines a `get_source` method, then that determines the source lines (if `get_source()` returns `None`, then `''` is returned). Finally, if *filename* is a relative filename, it is looked up relative to the entries in the module search path, `sys.path`.

`linecache.clearcache()`

Clear the cache. Use this function if you no longer need lines from files previously read using `getline()`.

`linecache.checkcache(filename=None)`

Check the cache for validity. Use this function if files in the cache may have changed on disk, and you require the updated version. If `filename` is omitted, it will check all the entries in the cache.

`linecache.lazycache(filename, module_globals)`

Capture enough detail about a non-file-based module to permit getting its lines later via `getline()` even if `module_globals` is `None` in the later call. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely.

在 3.5 版被加入。

範例：

```
>>> import linecache
>>> linecache.getline(linecache.__file__, 8)
'import sys\n'
```

## 11.9 shutil — 高階檔案操作

原始碼：Lib/shutil.py

The `shutil` module offers a number of high-level operations on files and collections of files. In particular, functions are provided which support file copying and removal. For operations on individual files, see also the `os` module.

### 警告

Even the higher-level file copying functions (`shutil.copy()`, `shutil.copy2()`) cannot copy all file metadata. On POSIX platforms, this means that file owner and group are lost as well as ACLs. On Mac OS, the resource fork and other metadata are not used. This means that resources will be lost and file type and creator codes will not be correct. On Windows, file owners, ACLs and alternate data streams are not copied.

### 11.9.1 Directory and files operations

`shutil.copyfileobj(fsrc, fdst[, length])`

Copy the contents of the *file-like object* `fsrc` to the file-like object `fdst`. The integer `length`, if given, is the buffer size. In particular, a negative `length` value means to copy the data without looping over the source data in chunks; by default the data is read in chunks to avoid uncontrolled memory consumption. Note that if the current file position of the `fsrc` object is not 0, only the contents from the current file position to the end of the file will be copied.

`shutil.copyfile(src, dst, *, follow_symlinks=True)`

Copy the contents (no metadata) of the file named `src` to a file named `dst` and return `dst` in the most efficient way possible. `src` and `dst` are *path-like objects* or path names given as strings.

`dst` must be the complete target file name; look at `copy()` for a copy that accepts a target directory path. If `src` and `dst` specify the same file, `SameFileError` is raised.

The destination location must be writable; otherwise, an `OSError` exception will be raised. If `dst` already exists, it will be replaced. Special files such as character or block devices and pipes cannot be copied with this function.

If `follow_symlinks` is false and `src` is a symbolic link, a new symbolic link will be created instead of copying the file `src` points to.

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copyfile`。

在 3.3 版的變更: `IOError` used to be raised instead of `OSError`. Added `follow_symlinks` argument. Now returns `dst`.

在 3.4 版的變更: Raise `SameFileError` instead of `Error`. Since the former is a subclass of the latter, this change is backward compatible.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

**exception** `shutil.SameFileError`

This exception is raised if source and destination in `copyfile()` are the same file.

在 3.4 版被加入。

`shutil.copymode(src, dst, *, follow_symlinks=True)`

Copy the permission bits from `src` to `dst`. The file contents, owner, and group are unaffected. `src` and `dst` are *path-like objects* or path names given as strings. If `follow_symlinks` is false, and both `src` and `dst` are symbolic links, `copymode()` will attempt to modify the mode of `dst` itself (rather than the file it points to). This functionality is not available on every platform; please see `copystat()` for more information. If `copymode()` cannot modify symbolic links on the local platform, and it is asked to do so, it will do nothing and return.

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copymode`。

在 3.3 版的變更: 新增 `follow_symlinks` 引數。

`shutil.copystat(src, dst, *, follow_symlinks=True)`

Copy the permission bits, last access time, last modification time, and flags from `src` to `dst`. On Linux, `copystat()` also copies the "extended attributes" where possible. The file contents, owner, and group are unaffected. `src` and `dst` are *path-like objects* or path names given as strings.

If `follow_symlinks` is false, and `src` and `dst` both refer to symbolic links, `copystat()` will operate on the symbolic links themselves rather than the files the symbolic links refer to—reading the information from the `src` symbolic link, and writing the information to the `dst` symbolic link.

**備 F**

Not all platforms provide the ability to examine and modify symbolic links. Python itself can tell you what functionality is locally available.

- If `os.chmod` in `os.supports_follow_symlinks` is True, `copystat()` can modify the permission bits of a symbolic link.
- If `os.utime` in `os.supports_follow_symlinks` is True, `copystat()` can modify the last access and modification times of a symbolic link.
- If `os.chflags` in `os.supports_follow_symlinks` is True, `copystat()` can modify the flags of a symbolic link. (`os.chflags` is not available on all platforms.)

On platforms where some or all of this functionality is unavailable, when asked to modify a symbolic link, `copystat()` will copy everything it can. `copystat()` never returns failure.

更多資訊請見 `os.supports_follow_symlinks`。

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copystat`。

在 3.3 版的變更: Added `follow_symlinks` argument and support for Linux extended attributes.

`shutil.copy(src, dst, *, follow_symlinks=True)`

Copies the file `src` to the file or directory `dst`. `src` and `dst` should be *path-like objects* or strings. If `dst` specifies a directory, the file will be copied into `dst` using the base filename from `src`. If `dst` specifies a file that already exists, it will be replaced. Returns the path to the newly created file.

If `follow_symlinks` is false, and `src` is a symbolic link, `dst` will be created as a symbolic link. If `follow_symlinks` is true and `src` is a symbolic link, `dst` will be a copy of the file `src` refers to.

`copy()` copies the file data and the file's permission mode (see `os.chmod()`). Other metadata, like the file's creation and modification times, is not preserved. To preserve all file metadata from the original, use `copy2()` instead.

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copyfile`。

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copymode`。

在 3.3 版的變更: Added `follow_symlinks` argument. Now returns path to the newly created file.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

`shutil.copy2(src, dst, *, follow_symlinks=True)`

Identical to `copy()` except that `copy2()` also attempts to preserve file metadata.

When `follow_symlinks` is false, and `src` is a symbolic link, `copy2()` attempts to copy all metadata from the `src` symbolic link to the newly created `dst` symbolic link. However, this functionality is not available on all platforms. On platforms where some or all of this functionality is unavailable, `copy2()` will preserve all the metadata it can; `copy2()` never raises an exception because it cannot preserve file metadata.

`copy2()` uses `copystat()` to copy the file metadata. Please see `copystat()` for more information about platform support for modifying symbolic link metadata.

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copyfile`。

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copystat`。

在 3.3 版的變更: Added `follow_symlinks` argument, try to copy extended file system attributes too (currently Linux only). Now returns path to the newly created file.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

`shutil.ignore_patterns(*patterns)`

This factory function creates a function that can be used as a callable for `copytree()`'s `ignore` argument, ignoring files and directories that match one of the glob-style `patterns` provided. See the example below.

`shutil.copytree(src, dst, symlinks=False, ignore=None, copy_function=copy2, ignore_dangling_symlinks=False, dirs_exist_ok=False)`

Recursively copy an entire directory tree rooted at `src` to a directory named `dst` and return the destination directory. All intermediate directories needed to contain `dst` will also be created by default.

Permissions and times of directories are copied with `copystat()`, individual files are copied using `copy2()`.

If `symlinks` is true, symbolic links in the source tree are represented as symbolic links in the new tree and the metadata of the original links will be copied as far as the platform allows; if false or omitted, the contents and metadata of the linked files are copied to the new tree.

When `symlinks` is false, if the file pointed to by the symlink doesn't exist, an exception will be added in the list of errors raised in an `Error` exception at the end of the copy process. You can set the optional `ignore_dangling_symlinks` flag to true if you want to silence this exception. Notice that this option has no effect on platforms that don't support `os.symlink()`.

If `ignore` is given, it must be a callable that will receive as its arguments the directory being visited by `copytree()`, and a list of its contents, as returned by `os.listdir()`. Since `copytree()` is called recursively, the `ignore` callable will be called once for each directory that is copied. The callable must return a sequence of directory and file names relative to the current directory (i.e. a subset of the items in its second argument); these names will then be ignored in the copy process. `ignore_patterns()` can be used to create such a callable that ignores names based on glob-style patterns.

If exception(s) occur, an `Error` is raised with a list of reasons.

If `copy_function` is given, it must be a callable that will be used to copy each file. It will be called with the source path and the destination path as arguments. By default, `copy2()` is used, but any function that supports the same signature (like `copy()`) can be used.

If `dirs_exist_ok` is false (the default) and `dst` already exists, a `FileExistsError` is raised. If `dirs_exist_ok` is true, the copying operation will continue if it encounters existing directories, and files within the `dst` tree will be overwritten by corresponding files from the `src` tree.

引發一個附帶引數 `src`、`dst` 的稽核事件 `shutil.copytree`。

在 3.2 版的變更: Added the `copy_function` argument to be able to provide a custom copy function. Added the `ignore_dangling_symlinks` argument to silence dangling symlinks errors when `symlinks` is false.

在 3.3 版的變更: Copy metadata when `symlinks` is false. Now returns `dst`.

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

在 3.8 版的變更: 新增 `dirs_exist_ok` 參數。

`shutil.rmtree(path, ignore_errors=False, onerror=None, *, onexc=None, dir_fd=None)`

Delete an entire directory tree; `path` must point to a directory (but not a symbolic link to a directory). If `ignore_errors` is true, errors resulting from failed removals will be ignored; if false or omitted, such errors are handled by calling a handler specified by `onexc` or `onerror` or, if both are omitted, exceptions are propagated to the caller.

This function can support *paths relative to directory descriptors*.

#### 備 F

On platforms that support the necessary fd-based functions a symlink attack resistant version of `rmtree()` is used by default. On other platforms, the `rmtree()` implementation is susceptible to a symlink attack: given proper timing and circumstances, attackers can manipulate symlinks on the filesystem to delete files they wouldn't be able to access otherwise. Applications can use the `rmtree.avoids_symlink_attacks` function attribute to determine which case applies.

If `onexc` is provided, it must be a callable that accepts three parameters: `function`, `path`, and `excinfo`.

The first parameter, `function`, is the function which raised the exception; it depends on the platform and implementation. The second parameter, `path`, will be the path name passed to `function`. The third parameter, `excinfo`, is the exception that was raised. Exceptions raised by `onexc` will not be caught.

The deprecated `onerror` is similar to `onexc`, except that the third parameter it receives is the tuple returned from `sys.exc_info()`.

引發一個附帶引數 `path`、`dir_fd` 的稽核事件 `shutil.rmtree`。

在 3.3 版的變更: Added a symlink attack resistant version that is used automatically if platform supports fd-based functions.

在 3.8 版的變更: On Windows, will no longer delete the contents of a directory junction before removing the junction.

在 3.11 版的變更: 新增 `dir_fd` 參數。

在 3.12 版的變更: 新增 `onexc` 參數 F F 用 `onerror`。

在 3.13 版的變更: `rmtree()` now ignores `FileNotFoundError` exceptions for all but the top-level path. Exceptions other than `OSError` and subclasses of `OSError` are now always propagated to the caller.

`rmtree.avoids_symlink_attacks`

Indicates whether the current platform and implementation provides a symlink attack resistant version of `rmtree()`. Currently this is only true for platforms supporting fd-based directory access functions.

在 3.3 版被加入。

`shutil.move(src, dst, copy_function=copy2)`

Recursively move a file or directory (`src`) to another location and return the destination.

If *dst* is an existing directory or a symlink to a directory, then *src* is moved inside that directory. The destination path in that directory must not already exist.

If *dst* already exists but is not a directory, it may be overwritten depending on `os.rename()` semantics.

If the destination is on the current filesystem, then `os.rename()` is used. Otherwise, *src* is copied to the destination using *copy\_function* and then removed. In case of symlinks, a new symlink pointing to the target of *src* will be created as the destination and *src* will be removed.

If *copy\_function* is given, it must be a callable that takes two arguments, *src* and the destination, and will be used to copy *src* to the destination if `os.rename()` cannot be used. If the source is a directory, `copytree()` is called, passing it the *copy\_function*. The default *copy\_function* is `copy2()`. Using `copy()` as the *copy\_function* allows the move to succeed when it is not possible to also copy the metadata, at the expense of not copying any of the metadata.

引發一個附帶引數 *src*、*dst* 的稽核事件 `shutil.move`。

在 3.3 版的變更: Added explicit symlink handling for foreign filesystems, thus adapting it to the behavior of GNU's `mv`. Now returns *dst*.

在 3.5 版的變更: 新增 *copy\_function* 關鍵字引數。

在 3.8 版的變更: Platform-specific fast-copy syscalls may be used internally in order to copy the file more efficiently. See *Platform-dependent efficient copy operations* section.

在 3.9 版的變更: Accepts a *path-like object* for both *src* and *dst*.

`shutil.disk_usage(path)`

Return disk usage statistics about the given path as a *named tuple* with the attributes *total*, *used* and *free*, which are the amount of total, used and free space, in bytes. *path* may be a file or a directory.

#### 備 F

On Unix filesystems, *path* must point to a path within a **mounted** filesystem partition. On those platforms, CPython doesn't attempt to retrieve disk usage information from non-mounted filesystems.

在 3.3 版被加入。

在 3.8 版的變更: On Windows, *path* can now be a file or directory.

適用: Unix, Windows.

`shutil.chown(path, user=None, group=None, *, dir_fd=None, follow_symlinks=True)`

Change owner *user* and/or *group* of the given *path*.

*user* can be a system user name or a uid; the same applies to *group*. At least one argument is required.

See also `os.chown()`, the underlying function.

引發一個附帶引數 *path*、*user*、*group* 的稽核事件 `shutil.chown`。

適用: Unix.

在 3.3 版被加入。

在 3.13 版的變更: 新增 *dir\_fd* 和 *follow\_symlinks* 參數。

`shutil.which(cmd, mode=os.F_OK | os.X_OK, path=None)`

Return the path to an executable which would be run if the given *cmd* was called. If no *cmd* would be called, return `None`.

*mode* is a permission mask passed to `os.access()`, by default determining if the file exists and is executable.

*path* is a "PATH string" specifying the directories to look in, delimited by `os.pathsep`. When no *path* is specified, the `PATH` environment variable is read from `os.environ`, falling back to `os.defpath` if it is not set.

On Windows, the current directory is prepended to the *path* if *mode* does not include `os.X_OK`. When the *mode* does include `os.X_OK`, the Windows API `NeedCurrentDirectoryForExePathW` will be consulted to determine if the current directory should be prepended to *path*. To avoid consulting the current working directory for executables: set the environment variable `NoDefaultCurrentDirectoryInExePath`.

Also on Windows, the `PATHEXT` environment variable is used to resolve commands that may not already include an extension. For example, if you call `shutil.which("python")`, `which()` will search `PATHEXT` to know that it should look for `python.exe` within the *path* directories. For example, on Windows:

```
>>> shutil.which("python")
'C:\\Python33\\python.EXE'
```

This is also applied when *cmd* is a path that contains a directory component:

```
>> shutil.which("C:\\Python33\\python")
'C:\\Python33\\python.EXE'
```

在 3.3 版被加入。

在 3.8 版的變更: The *bytes* type is now accepted. If *cmd* type is *bytes*, the result type is also *bytes*.

在 3.12 版的變更: On Windows, the current directory is no longer prepended to the search path if *mode* includes `os.X_OK` and `WinAPI.NeedCurrentDirectoryForExePathW(cmd)` is false, else the current directory is prepended even if it is already in the search path; `PATHEXT` is used now even when *cmd* includes a directory component or ends with an extension that is in `PATHEXT`; and filenames that have no extension can now be found.

#### exception `shutil.Error`

This exception collects exceptions that are raised during a multi-file operation. For `copytree()`, the exception argument is a list of 3-tuples (*srcname*, *dstname*, *exception*).

### Platform-dependent efficient copy operations

Starting from Python 3.8, all functions involving a file copy (`copyfile()`, `copy()`, `copy2()`, `copytree()`, and `move()`) may use platform-specific "fast-copy" syscalls in order to copy the file more efficiently (see [bpo-33671](#)). "fast-copy" means that the copying operation occurs within the kernel, avoiding the use of userspace buffers in Python as in `outfd.write(infd.read())`.

On macOS `fcopyfile` is used to copy the file content (not metadata).

On Linux `os.sendfile()` is used.

On Windows `shutil.copyfile()` uses a bigger default buffer size (1 MiB instead of 64 KiB) and a `memoryview()`-based variant of `shutil.copyfileobj()` is used.

If the fast-copy operation fails and no data was written in the destination file then `shutil` will silently fallback on using less efficient `copyfileobj()` function internally.

在 3.8 版的變更。

### copytree 范例

An example that uses the `ignore_patterns()` helper:

```
from shutil import copytree, ignore_patterns

copytree(source, destination, ignore=ignore_patterns('*.pyc', 'tmp*'))
```

This will copy everything except `.pyc` files and files or directories whose name starts with `tmp`.

Another example that uses the `ignore` argument to add a logging call:

```

from shutil import copytree
import logging

def _logpath(path, names):
    logging.info('Working in %s', path)
    return [] # nothing will be ignored

copytree(source, destination, ignore=_logpath)

```

### rmmtree 范例

This example shows how to remove a directory tree on Windows where some of the files have their read-only bit set. It uses the `onexc` callback to clear the readonly bit and reattempt the remove. Any subsequent failure will propagate.

```

import os, stat
import shutil

def remove_readonly(func, path, _):
    "Clear the readonly bit and reattempt the removal"
    os.chmod(path, stat.S_IWRITE)
    func(path)

shutil.rmtree(directory, onexc=remove_readonly)

```

## 11.9.2 Archiving operations

在 3.2 版被加入。

在 3.5 版的變更: 新增 *xz*tar 格式的支援。

High-level utilities to create and read compressed and archived files are also provided. They rely on the *zipfile* and *tarfile* modules.

```

shutil.make_archive(base_name, format[, root_dir[, base_dir[, verbose[, dry_run[, owner[, group[, logger
]]]]]])

```

Create an archive file (such as zip or tar) and return its name.

*base\_name* is the name of the file to create, including the path, minus any format-specific extension.

*format* is the archive format: one of "zip" (if the *zlib* module is available), "tar", "gztar" (if the *zlib* module is available), "bztar" (if the *bz2* module is available), or "xztar" (if the *lzma* module is available).

*root\_dir* is a directory that will be the root directory of the archive, all paths in the archive will be relative to it; for example, we typically `chdir` into *root\_dir* before creating the archive.

*base\_dir* is the directory where we start archiving from; i.e. *base\_dir* will be the common prefix of all files and directories in the archive. *base\_dir* must be given relative to *root\_dir*. See *Archiving example with base\_dir* for how to use *base\_dir* and *root\_dir* together.

*root\_dir* and *base\_dir* both default to the current directory.

If *dry\_run* is true, no archive is created, but the operations that would be executed are logged to *logger*.

*owner* and *group* are used when creating a tar archive. By default, uses the current owner and group.

*logger* must be an object compatible with **PEP 282**, usually an instance of *logging.Logger*.

The *verbose* argument is unused and deprecated.

引發一個附帶引數 *base\_name*、*format*、*root\_dir*、*base\_dir* 的稽核事件 `shutil.make_archive`。

**備 F**

This function is not thread-safe when custom archivers registered with `register_archive_format()` do not support the `root_dir` argument. In this case it temporarily changes the current working directory of the process to `root_dir` to perform archiving.

在 3.8 版的變更: The modern pax (POSIX.1-2001) format is now used instead of the legacy GNU format for archives created with `format="tar"`.

在 3.10.6 版的變更: This function is now made thread-safe during creation of standard `.zip` and tar archives.

`shutil.get_archive_formats()`

Return a list of supported formats for archiving. Each element of the returned sequence is a tuple `(name, description)`.

By default `shutil` provides these formats:

- `zip`: ZIP file (if the `zlib` module is available).
- `tar`: Uncompressed tar file. Uses POSIX.1-2001 pax format for new archives.
- `gztar`: gzipped tar-file (if the `zlib` module is available).
- `bztar`: bzip2'ed tar-file (if the `bz2` module is available).
- `xztar`: xz'ed tar-file (if the `lzma` module is available).

You can register new formats or provide your own archiver for any existing formats, by using `register_archive_format()`.

`shutil.register_archive_format(name, function[, extra_args[, description]])`

Register an archiver for the format `name`.

`function` is the callable that will be used to unpack archives. The callable will receive the `base_name` of the file to create, followed by the `base_dir` (which defaults to `os.curdir`) to start archiving from. Further arguments are passed as keyword arguments: `owner`, `group`, `dry_run` and `logger` (as passed in `make_archive()`).

If `function` has the custom attribute `function.supports_root_dir` set to `True`, the `root_dir` argument is passed as a keyword argument. Otherwise the current working directory of the process is temporarily changed to `root_dir` before calling `function`. In this case `make_archive()` is not thread-safe.

If given, `extra_args` is a sequence of `(name, value)` pairs that will be used as extra keywords arguments when the archiver callable is used.

`description` is used by `get_archive_formats()` which returns the list of archivers. Defaults to an empty string.

在 3.12 版的變更: Added support for functions supporting the `root_dir` argument.

`shutil.unregister_archive_format(name)`

Remove the archive format `name` from the list of supported formats.

`shutil.unpack_archive(filename[, extract_dir[, format[, filter]])`

Unpack an archive. `filename` is the full path of the archive.

`extract_dir` is the name of the target directory where the archive is unpacked. If not provided, the current working directory is used.

`format` is the archive format: one of "zip", "tar", "gztar", "bztar", or "xztar". Or any other format registered with `register_unpack_format()`. If not provided, `unpack_archive()` will use the archive file name extension and see if an unpacker was registered for that extension. In case none is found, a `ValueError` is raised.

The keyword-only *filter* argument is passed to the underlying unpacking function. For zip files, *filter* is not accepted. For tar files, it is recommended to set it to 'data', unless using features specific to tar and UNIX-like filesystems. (See *Extraction filters* for details.) The 'data' filter will become the default for tar files in Python 3.14.

引發一個附帶引數 `filename`、`extract_dir`、`format` 的稽核事件 `shutil.unpack_archive`。

### 警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of the path specified in the *extract\_dir* argument, e.g. members that have absolute filenames starting with "/" or filenames with two dots "..".

在 3.7 版的變更: Accepts a *path-like object* for *filename* and *extract\_dir*.

在 3.12 版的變更: 新增 *filter* 引數。

`shutil.register_unpack_format(name, extensions, function[, extra_args[, description]])`

Registers an unpack format. *name* is the name of the format and *extensions* is a list of extensions corresponding to the format, like `.zip` for Zip files.

*function* is the callable that will be used to unpack archives. The callable will receive:

- the path of the archive, as a positional argument;
- the directory the archive must be extracted to, as a positional argument;
- possibly a *filter* keyword argument, if it was given to `unpack_archive()`;
- additional keyword arguments, specified by *extra\_args* as a sequence of (name, value) tuples.

*description* can be provided to describe the format, and will be returned by the `get_unpack_formats()` function.

`shutil.unregister_unpack_format(name)`

Unregister an unpack format. *name* is the name of the format.

`shutil.get_unpack_formats()`

Return a list of all registered formats for unpacking. Each element of the returned sequence is a tuple (name, extensions, description).

By default *shutil* provides these formats:

- *zip*: ZIP file (unpacking compressed files works only if the corresponding module is available).
- *tar*: uncompressed tar file.
- *gztar*: gzip'ed tar-file (if the *zlib* module is available).
- *bztar*: bzip2'ed tar-file (if the *bz2* module is available).
- *xztar*: xz'ed tar-file (if the *lzma* module is available).

You can register new formats or provide your own unpacker for any existing formats, by using `register_unpack_format()`.

## Archiving example

In this example, we create a gzip'ed tar-file archive containing all files found in the `.ssh` directory of the user:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> root_dir = os.path.expanduser(os.path.join('~', '.ssh'))
>>> make_archive(archive_name, 'gztar', root_dir)
'/Users/tarek/myarchive.tar.gz'
```

The resulting archive contains:

```
$ tar -tzvf /Users/tarek/myarchive.tar.gz
drwx----- tarek/staff      0 2010-02-01 16:23:40 ./
-rw-r--r-- tarek/staff     609 2008-06-09 13:26:54 ./authorized_keys
-rwxr-xr-x tarek/staff      65 2008-06-09 13:26:54 ./config
-rwx----- tarek/staff     668 2008-06-09 13:26:54 ./id_dsa
-rwxr-xr-x tarek/staff     609 2008-06-09 13:26:54 ./id_dsa.pub
-rw----- tarek/staff    1675 2008-06-09 13:26:54 ./id_rsa
-rw-r--r-- tarek/staff      397 2008-06-09 13:26:54 ./id_rsa.pub
-rw-r--r-- tarek/staff   37192 2010-02-06 18:23:10 ./known_hosts
```

### Archiving example with `base_dir`

In this example, similar to the *one above*, we show how to use `make_archive()`, but this time with the usage of `base_dir`. We now have the following directory structure:

```
$ tree tmp
tmp
├── root
│   └── structure
│       ├── content
│       │   └── please_add.txt
│       └── do_not_add.txt
```

In the final archive, `please_add.txt` should be included, but `do_not_add.txt` should not. Therefore we use the following:

```
>>> from shutil import make_archive
>>> import os
>>> archive_name = os.path.expanduser(os.path.join('~', 'myarchive'))
>>> make_archive(
...     archive_name,
...     'tar',
...     root_dir='tmp/root',
...     base_dir='structure/content',
... )
'/Users/tarek/my_archive.tar'
```

Listing the files in the resulting archive gives us:

```
$ python -m tarfile -l /Users/tarek/myarchive.tar
structure/content/
structure/content/please_add.txt
```

## 11.9.3 Querying the size of the output terminal

`shutil.get_terminal_size(fallback=(columns, lines))`

Get the size of the terminal window.

For each of the two dimensions, the environment variable, `COLUMNS` and `LINES` respectively, is checked. If the variable is defined and the value is a positive integer, it is used.

When `COLUMNS` or `LINES` is not defined, which is the common case, the terminal connected to `sys.__stdout__` is queried by invoking `os.get_terminal_size()`.

If the terminal size cannot be successfully queried, either because the system doesn't support querying, or because we are not connected to a terminal, the value given in `fallback` parameter is used. `fallback` defaults to `(80, 24)` which is the default size used by many terminal emulators.

The value returned is a named tuple of type `os.terminal_size`.

See also: The Single UNIX Specification, Version 2, [Other Environment Variables](#).

在 3.3 版被加入。

在 3.11 版的變更: The fallback values are also used if `os.get_terminal_size()` returns zeroes.

內建函式 `open()`

使用 Python 打開檔案以進行讀寫檔案的標準方法。

---

## 資料持久性 (Data Persistence)

---

The modules described in this chapter support storing Python data in a persistent form on disk. The `pickle` and `marshal` modules can turn many Python data types into a stream of bytes and then recreate the objects from the bytes. The various DBM-related modules support a family of hash-based file formats that store a mapping of strings to other strings.

本章節所描述的模組列表：

### 12.1 `pickle` --- Python 物件序列化

原始碼：[Lib/pickle.py](#)

---

`pickle` 模組實作的是一個在二進位層級上對 Python 物件進行序列化 (serialize) 或去序列化 (de-serialize)。`"Pickling"` 用於專門指摘將一個 Python 物件轉成一個二進位串流的過程，`"unpickling"` 則相反，指的是將一個 (來自 `binary file` 或 `bytes-like object` 的) 二進位串流轉回 Python 物件的過程。Pickling (和 unpickling) 的過程也可能被稱作 "serialization", "marshalling,"<sup>1</sup> 或 "flattening"。不過，為了避免混淆，本文件將統一稱作封裝 (pickling)、拆封 (unpickling)。

#### 警告

`pickle` 模組 \*\* 不安全 \*\*，切記只拆封你信任的資料。

`pickle` 封包是有可能被建立來在拆封的時候 \*\* 執行任意惡意程式碼 \*\* 的。對不要拆封任何你無法信任其來源、或可能被修改過的 `pickle` 封包。

建議你可以使用 `hmac` 模組來簽署這個封包，以確保其未被修改過。

如果你在處理不受信任的資料，其他比較安全的序列化格式 (例如 `json`) 可能會更適合。請參照 [See 和 `json` 的比較](#) 的說明。

---

<sup>1</sup> 不要將此模組與 `marshal` 模組混淆

## 12.1.1 和其他 Python 模組的關

### 和 `marshal` 的比較

Python 有另一個比較原始的序列化模組叫 `marshal`，不過其設計目的是了支援 Python 的預編譯功能 `.pyc` 的運作。總地來，請盡可能地使用 `pickle`，事不要用 `marshal`。

`pickle` 和 `marshal` 有幾個明顯不同的地方：

- `pickle` 會記住哪些物件已經被序列化過了，稍後再次參照到這個物件的時候才不會進行重序列化。`marshal` 有這個功能。  
這對遞物件和物件共用都有影響。遞物件是指包含自我參照的物件。這些情在 `marshal` 模組中不會被處理，若嘗試使用 `marshal` 處理遞物件會導致 Python 直譯器崩潰。物件共用發生在序列化的物件階層中、不同位置對同一物件有多個參照時。`pickle` 只會儲存這個被參照的物件一次，確保所有其他參照指向這個主要的版本。共用的物件會保持共用，這對於可變 (mutable) 物件來非常重要。
- `marshal` 無法序列化使用者自訂的類和的實例。`pickle` 則可以讓使用者儲存還源自訂的類實例，前提是儲存時該類的定義存在於與要被儲存的物件所在的模組中、且可以被引入 (`import`)。
- `marshal` 序列化格式無法保證能在不同版本的 Python 之間移植。因其主要的作用是支援 `.pyc` 檔案的運作，Python 的實作人員會在需要時實作無法前向相容的序列化方式。但只要選擇了相容的 `pickle` 協定，且處理了 Python 2 和 Python 3 之間的資料類型差，`pickle` 序列化協定能保證在不同 Python 版本間的相容性。

### 和 `json` 的比較

`pickle` 協定和 JSON (JavaScript Object Notation) 有一些根本上的不同：

- JSON 以文字形式作序列化的輸出 (輸出 unicode 文字，但大多數又會被編碼 UTF-8)，而 `pickle` 則是以二進位形式作序列化的輸出；
- JSON 是人類可讀的，而 `pickle` 則無法；
- JSON 具有高互通性 (interoperability) 且在 Python 以外的環境也被大量利用，但 `pickle` 只能在 Python 使用。
- 預設狀態下的 JSON 只能紀一小部份的 Python 建型，且無法紀自訂類；但透過 Python 的自省措施，`pickle` 可以紀大多數的 Python 型 (其他比較雜的狀況也可以透過實作 *specific object APIs* 來解)；
- 去序列化不安全的 JSON 不會生任意程式執行的風險，但去序列化不安全的 `pickle` 會。

#### 也參考

`json` module: 是標準函式庫的一部分，可讓使用者進行 JSON 的序列化與去序列化。

## 12.1.2 資料串流格式

`pickle` 使用的資料格式是針對 Python 而設計的。好處是他不會受到外部標準 (像是 JSON，無法紀指標共用) 的限制；不過這也代表其他不是 Python 的程式可能無法重建 `pickle` 封裝的 Python 物件。

以預設設定來，`pickle` 使用相對緊的二進位形式來儲存資料。如果你需要盡可能地縮小檔案大小，你可以壓縮封裝的資料。

`pickletools` 含有工具可分析 `pickle` 所生的資料流。`pickletools` 的原始碼詳細地記載了所有 `pickle` 協定的操作碼 (opcode)。

截至目前止，共有六種不同版本的協定可用於封裝 `pickle`。數字越大版本代表你需要使用越新的 Python 版本來拆封相應的 `pickle` 封裝。

- 版本 0 的協定是最初「人類可讀」的版本，且可以向前支援早期版本的 Python。
- 版本 1 的協定使用舊的二進位格式，一樣能向前支援早期版本的 Python。

- 版本 2 的協定在 Python 2.3 中初次被引入。其可提供更高效率的 *new-style classes* 封裝過程。請參 [PEP 307](#) 以了解版本 2 帶來的改進。
- 版本 3 的協定在 Python 3.0 被新增。現在能支援封裝 *bytes* 的物件且無法被 2.x 版本的 Python 拆封。在 3.0 ~ 3.7 的 Python 預設使用 3 版協定。
- 版本 4 的協定在 Python 3.4 被新增。現在能支援超大物件的封裝、更多種型的物件以及針對部份資料格式的儲存進行最佳化。從 Python 3.8 起，預設使用第 4 版協定。請參 [PEP 3154](#) 以了解第 4 版協定改進的細節。
- 版本 5 的協定在 Python 3.8 被新增。現在能支援帶外資料 (Out-of-band data) 加速帶資料的處理速度。請參 [PEP 574](#) 以了解第 5 版協定改進的細節。

### 備

資料序列化是一個比資料持久化更早出現的概念；雖然 *pickle* 可以讀寫檔案物件，但它不處理命名持久物件的問題，也不處理對持久物件的存取、一個更棘手的問題。*pickle* 模組可以將雜物件轉成位元組串流，也可以將位元組串流轉回具有相同原始部結構的物件。對這些位元組串流最常見的處理方式是將它們寫入檔案中，但也可以將它們透過網路傳送或儲存在一個資料庫中。*shelve* 模組提供了一個簡單的介面來讓使用者在 DBM 風格的資料庫檔案中對物件進行封裝和拆封的操作。

## 12.1.3 模組介面

想要序列化一個物件，你只需要呼叫 `dumps()` 函式。而當你想要去序列化一個資料流時，你只需要呼叫 `loads()` 即可。不過，若你希望能各自對序列化和去序列化的過程中有更多的掌控度，你可以自訂一個 *Pickler* 或 *Unpickler* 物件。

*pickle* 模組提供以下常數：

`pickle.HIGHEST_PROTOCOL`

一個整數，表示可使用的最高協定版本。這個值可作 *protocol* 的數值傳給 `dump()` 和 `dumps()` 函式以及 *Pickler* 建構式。

`pickle.DEFAULT_PROTOCOL`

一個整數，指示用於序列化的預設協定版本。有可能小於 `HIGHEST_PROTOCOL`。目前的預設協定版本 4，是在 Python 3.4 中首次引入的，且與先前版本不相容。

在 3.0 版的變更：預設協定版本 3。

在 3.8 版的變更：預設協定版本 4。

*pickle* 模組提供下列函式來簡化封裝的過程：

`pickle.dump(obj, file, protocol=None, *, fix_imports=True, buffer_callback=None)`

將被封裝成 *pickle* 形式的物件 `obj` 寫入到已開的 *file object* `file`。這等效於 `Pickler(file, protocol).dump(obj)`。

引數 `file`、`protocol`、`fix_imports` 和 `buffer_callback` 的意義與 *Pickler* 建構式中的相同。

在 3.8 版的變更：新增 `buffer_callback` 引數。

`pickle.dumps(obj, protocol=None, *, fix_imports=True, buffer_callback=None)`

將被封裝成 *pickle* 形式的物件 `obj` 以 *bytes* 類回傳，而非寫入進檔案。

引數 `protocol`、`fix_imports` 和 `buffer_callback` 的意義和 *Pickler* 建構式中的相同。

在 3.8 版的變更：新增 `buffer_callback` 引數。

`pickle.load(file, *, fix_imports=True, encoding='ASCII', errors='strict', buffers=None)`

從已開的檔案物件 `file` 中讀取已序列化的物件，傳回其重建後的物件階層。這相當於呼叫 `Unpickler(file).load()`。

模組會自動偵測 pickle 封包所使用的協定版本，所以無須另外指定。超出 pickle 封包表示範圍的位元組將被忽略。

引數 *file*、*fix\_imports*、*encoding*、*errors*、*strict* 和 *buffers* 的意義和 *Unpickler* 建構式中的相同。

在 3.8 版的變更: 新增 *buffer* 引數。

`pickle.loads(data, /, *, fix_imports=True, encoding='ASCII', errors='strict', buffers=None)`

回傳從 *data* 的 pickle 封包重建後的物件階層。*data* 必須是一個 *bytes-like object*。

模組會自動偵測 pickle 封包所使用的協定版本，所以無須另外指定。超出 pickle 封包表示範圍的位元組將被忽略。

引數 *fix\_imports*、*encoding*、*errors*、*strict* 和 *buffers* 的意義與 *Unpickler* 建構式所用的相同。

在 3.8 版的變更: 新增 *buffer* 引數。

*pickle* 模組定義了以下三種例外:

**exception** `pickle.PickleError`

繼承 *Exception* 類。一個在封裝或拆封時遭遇其他例外時通用的基底類。

**exception** `pickle.PicklingError`

當 *Pickler* 遭遇無法封裝物件時會引發的例外。繼承 *PickleError* 類。

請參閱 [哪些物件能或不能被封裝、拆封?](#) 以了解哪些物件是可以被封裝的。

**exception** `pickle.UnpicklingError`

拆封物件時遇到問題 (如資料損或違反安全性原則等) 所引發的意外。繼承自 *PickleError* 類。

拆封的時候還是可能會遭遇其他不在此列的例外 (例如: *AttributeError*、*EOFError*、*ImportError*、或 *IndexError*)，請注意。

引入模組 *pickle* 時會帶來三個類: *Pickler*、*Unpickler* 和 *PickleBuffer*:

**class** `pickle.Pickler(file, protocol=None, *, fix_imports=True, buffer_callback=None)`

接受一個用以寫入 pickle 資料流的二進位檔案。

可選引數 *protocol* 接受整數，用來要求封裝器 (*pickler*) 使用指定的協定；支援從 0 版起到 *HIGHEST\_PROTOCOL* 版的協定。如未指定，則預設 *DEFAULT\_PROTOCOL*。若指定了負數，則視選擇 *HIGHEST\_PROTOCOL*。

引數 *file* 必須支援可寫入單一位元組引數的 *write()* 方法。只要滿足此條件，傳入的物件可以是一個硬碟上二進位檔案、一個 *io.BytesIO* 實例或任何其他滿足這個介面要求的物件。

若 *fix\_imports* 設 *true* 且 *protocol* 版本小於 3，本模組會嘗試將 Python 3 的新模組名稱轉 Python 2 所支援的舊名，以讓 Python 2 能正確地讀取此資料流。

如果 *buffer\_callback* 是 *None* (預設值)，緩衝區的視圖會作 pickle 封裝串流的一部分被序列化進 *file* 中。

如果 *buffer\_callback* 不是 *None*，則它可以被多次呼叫回傳一個緩衝區的視圖。如果回呼函式回傳一個假值 (例如 *None*)，則所給的緩衝區將被視帶外資料；否則，該緩衝區將被視 pickle 串流的帶資料被序列化。

如果 *buffer\_callback* 不是 *None* 且 *protocol* 是 *None* 或小於 5 則會報錯。

在 3.8 版的變更: 新增 *buffer\_callback* 引數。

**dump** (*obj*)

將已封裝 (pickled) 的 *obj* 寫入已在建構式中開的對應檔案。

**persistent\_id** (*obj*)

預設不進行任何動作。這是一種抽象方法，用於讓後續繼承這個類的物件可以覆寫本方法函式。

如果 `persistent_id()` 回傳 `None`，則 `obj` 會照一般的方式進行封裝 (pickling)。若回傳其他值，則 `Pickler` 會將該值作為 `obj` 的永久識碼回傳。此永久識碼的意義應由 `Unpickler.persistent_load()` 定義。請注意 `persistent_id()` 回傳的值本身不能擁有自己的永久識碼。

關於細節與用法範例請見外部物件持久化。

在 3.13 版的變更: 在 C 的 `Pickler` 實作中的增加了這個方法的預設實作。

#### `dispatch_table`

封裝器 (pickler) 物件含有的調度表是一個縮函式 (reduction function) 的表，可以使用 `copyreg.pickle()` 來宣告這類縮函式。它是一個以類鍵、還原函式值的映射表。縮函式應準備接收一個對應類的引數，應遵循與 `__reduce__()` 方法相同的介面。

預設情況下，封裝器 (pickler) 物件不會有 `dispatch_table` 屬性，而是會使用由 `copyreg` 模組管理的全域調度表。不過，若要自訂某個封裝器 (pickler) 物件的序列化行，可以將 `dispatch_table` 屬性設置為類字典物件。另外，如果 `Pickler` 的子類具有 `dispatch_table` 屬性，那麼這個屬性將作為該子類實例的預設調度表。

關於用法範例請見調度表。

在 3.3 版被加入。

#### `reducer_override(obj)`

一個可以在 `Pickler` 子類中被定義的縮函器 (reducer)。這個方法的優先度高於任何其他分派表中的縮函器。他應該要有和 `__reduce__()` 方法相同的函式介面，且可以可選地回傳 `NotImplemented` 以退回 (fallback) 使用分派表中登載的縮函方法來封裝 `obj`。

請查針對型、函式或特定物件定縮函式來參考其他較詳細的範例。

在 3.8 版被加入。

#### `fast`

已啟用。如果設置為 `true`，將啟用快速模式。快速模式會停用備忘 (memo)，因此能透過不產生多余的 PUT 操作碼 (OpCode) 來加速封裝過程。它不應被用於自我參照物件，否則將導致 `Pickler` 陷入無限遞。

使用 `pickletools.optimize()` 以獲得更緊湊的 pickle 輸出。

```
class pickle.Unpickler(file, *, fix_imports=True, encoding='ASCII', errors='strict', buffers=None)
```

這個物件接受一個二進位檔案 `file` 來從中讀取 pickle 資料流。

協定版本號會被自動偵測，所以不需要在這邊手動輸入。

參數 `file` 必須擁有三個方法，分別是接受整數作為引數的 `read()` 方法、接受緩衝區作為引數的 `readinto()` 方法以及不需要引數的 `readline()` 方法，如同在 `io.BufferedIOBase` 的介面一樣。因此，`file` 可以是一個以二進位讀取模式開啟的檔案、一個 `io.BytesIO` 物件、或任何符合此介面的自訂物件。

可選引數 `fix_imports`、`encoding` 和 `errors` 用來控制 Python 2 pickle 資料的相容性支援。如果 `fix_imports` 為 `true`，則 pickle 模組會嘗試將舊的 Python 2 模組名稱映射到 Python 3 中使用的新名稱。`encoding` 和 `errors` 告訴 pickle 模組如何解碼由 Python 2 pickle 封裝的 8 位元字串實例；`encoding` 和 `errors` 預設分別為 'ASCII' 和 'strict'。`encoding` 可以設定為 'bytes' 以將這些 8 位元字串實例讀入位元組物件。而由 Python 2 封裝的 NumPy 陣列、`datetime`、`date` 和 `time` 的實例則必須使用 `encoding='latin1'` 來拆封。

如果 `buffers` 是 `None` (預設值)，那麼去序列化所需的所有資料都必須已經包含在 pickle 串流中。這意味著當初在建立對應的 `Pickler` 時 (或在呼叫 `dump()` 或 `dumps()` 時) `*buffer_callback*` 引數必須為 `None`。

如果 `buffers` 不是 `None`，則其應該是一個可迭代物件，包含數個支援緩衝區的物件，且每當 pickle 串流引用一個帶外緩衝區視圖時將會被照順序消耗。這些緩衝資料當初建立時應已按照順序給定於 `Pickler` 物件中的 `buffer_callback`。

在 3.8 版的變更: 新增 `buffer` 引數。

**load()**

開 先前被傳入建構子的檔案，從中讀取一個被 pickle 封裝的物件，回傳重建完成的物件階層。超過 pickle 表示範圍的位元組會被忽略。

**persistent\_load(pid)**

預設會引發 `UnpicklingError` 例外。

若有定義 `persistent_load()`，則其將回傳符合持久化識碼 `pid` 的物件。如果遭遇了無效的持久化識碼，則會引發 `UnpicklingError`。

關於細節與用法範例請見外部物件持久化。

在 3.13 版的變更: Add the default implementation of this method in the C implementation of Unpickler.

**find\_class(module, name)**

如有需要將引入 `module`，從中回傳名 `name` 的物件，這的 `module` 和 `name` 引數接受的輸入是 `str` 物件。注意，雖然名稱上看起來不像，但 `find_class()` 亦可被用於尋找其他函式。

子類可以覆寫此方法以控制可以載入哪些類型的物件、以及如何載入它們，從而在地降低安全性風險。詳情請參考限制全域物件。

引發一個附帶引數 `module`、`name` 的稽核事件 `pickle.find_class`。

**class pickle.PickleBuffer(buffer)**

一個表示了含有可封裝資料緩衝區的包裝函式 (wrapper function)。 `buffer` 必須是一個提供緩衝區的物件，例如一個類位元組物件或 N 維陣列。

`PickleBuffer` 本身就是一個提供緩衝區的物件，所以是能將其提供給其它「預期收到含有緩衝物件的 API」的，比如 `memoryview`。

`PickleBuffer` 物件僅能由 5 版或以上的 pickle 協定進行封裝。該物件亦能被作帶外資料來進行帶外資料序列化

在 3.8 版被加入。

**raw()**

回傳此緩衝區底層記憶體區域的 `memoryview`。被回傳的物件是一個 (在 C 語言的 formatter 格式中) 以 B (unsigned bytes) 二進位格式儲存、一維且列連續 (C-contiguous) 的 `memoryview`。如果緩衝區既不是列連續 (C-contiguous) 也不是行連續 (Fortran-contiguous) 的，則會引發 `BufferError`。

**release()**

釋放 `PickleBuffer` 物件現正曝光中的緩衝區。

## 12.1.4 哪些物件能或不能被封裝、拆封？

下列型可以被封裝：

- 建常數 (None、True、False、Ellipsis 和 `NotImplemented`)；
- 整數、浮點數和數；
- 字串、位元組物件、位元組陣列；
- 元組 (tuple)、串列 (list)、集合 (set) 和僅含有可封裝物件的字典；
- 在模組最表面的層級就能被存取的函式 (建或自訂的皆可，不過僅限使用 `def` 定義的函式，`lambda` 函式不適用)；
- 在模組最表面的層級就能被存取的類；
- 實例，只要在呼叫了 `__getstate__()` 後其回傳值全都是可封裝物件。(詳情請參 `Pickling` 類實例)。

嘗試封裝無法封裝的物件會引發 `PicklingError` 例外；注意當這種情況發生時，可能已經有未知數量的位元組已被寫入到檔案。嘗試封裝深度遞迴的資料結構可能會導致其超出最大遞迴深度，在這種情況下會引發 `RecursionError` 例外。你可以（小心地）使用 `sys.setrecursionlimit()` 來提高此上限。

請注意，函式（函式及自訂兩者皆是）是依據完整的限定名來封裝，而非依其值。<sup>2</sup> 這意味著封裝時只有函式名稱、所屬的模組和所屬的類名稱會被封裝。函式本身的程式碼及其附帶的任何屬性均不會被封裝。因此，在拆封該物件的環境中，定義此函式的模組必須可被引入，且該模組必須包含具此命名之物件，否則將引發例外。<sup>3</sup>

同樣情況，類是依照其完整限定名稱來進行封裝，因此在進行拆封的環境中會具有同上的限制。類中的程式碼或資料皆不會被封裝，因此在以下範例中，注意到類屬性 `attr` 在拆封的環境中不會被還原：

```
class Foo:
    attr = 'A class attribute'

picklestring = pickle.dumps(Foo)
```

這些限制就是可封裝的函式和類必須被定義在模組頂層的原因。

同樣地，當類實例被封裝時，它所屬類具有的程式碼和資料不會被一起封裝。只有實例資料本身會被封裝。這是有意而為的，因為如此你才可以在類中修正錯誤或新增其他方法，且於此同時仍能載入使用較早期版本的類所建立的物件實例。如果你預計將有長期存在的物件，且該物件將經歷許多版本的更替，你可以在物件中存放一個版本號，以便未來能透過 `__setstate__()` 方法來進行適當的版本轉。

### 12.1.5 Pickling 類實例

在這一章節，我們會講述如何封裝或拆封一個物件實例的相關機制，以方便你進行自訂。

大部分的實例不需要額外的程式碼就已經是可封裝的了。在這樣的預設狀況中，`pickle` 模組透過自省機制來取得類及其實例的屬性。當類實例被拆封時，其 `__init__()` 方法通常 \*不會\* 被呼叫。預設行首先會建立一個未初始化的實例，然後還原紀錄中的屬性。以下程式碼的實作展示了前述行：

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def restore(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

被封裝的目標類可以提供一個或數個下列特殊方法來改變 `pickle` 的預設行：

`object.__getnewargs_ex__()`

在第 2 版協定或更新的版本中，有實作 `__getnewargs_ex__()` 方法的類，可以固定在拆封時要傳遞給 `__new__()` 方法的值。該方法必須回傳一個 `(args, kwargs)` 的組合，其中 `args` 是一個位置引數的元組 (tuple)，`kwargs` 是一個用於建構物件的命名引數字典。這些資訊將在拆封時傳遞給 `__new__()` 方法。

如果目標類的方法 `__new__()` 需要僅限關鍵字的參數時，你應該實作此方法。否則，為了提高相容性，建議你改實作 `__getnewargs__()`。

在 3.6 版的變更：在第 2、3 版的協定中現在改使用 `__getnewargs_ex__()`。

`object.__getnewargs__()`

此方法與 `__getnewargs_ex__()` 的目的一樣，但僅支援位置參數。它必須回傳一個由傳入引數所組成的元組 (tuple) `args`，這些引數會在拆封時傳遞給 `__new__()` 方法。

當有定義 `__getnewargs_ex__()` 的時候便不會呼叫 `__getnewargs__()`。

<sup>2</sup> 這就是為什麼 lambda 函式無法被封裝：所有 lambda 函式共享相同的名稱：<lambda>。

<sup>3</sup> 引發的例外應該是 `ImportError` 或 `AttributeError`，但也可能是其他例外。

在 3.6 版的變更: 在 Python 3.6 之前、版本 2 和版本 3 的協定中，會呼叫 `__getnewargs__()` 而非 `__getnewargs_ex__()`。

`object.__getstate__()`

目標類可以透過覆寫方法 `__getstate__()` 進一步影響其實例被封裝的方式。封裝時，呼叫該方法所回傳的物件將作為該實例的內容被封裝、而非一個預設狀態。以下列出幾種預設狀態：

- 有 `__dict__` 和 `__slots__` 實例的類，其預設狀態是 `None`。
- 有 `__dict__` 實例、但沒有 `__slots__` 實例的類，其預設狀態是 `self.__dict__`。
- 有 `__dict__` 和 `__slots__` 實例的類，其預設狀態是一個含有兩個字典的元組 (tuple)，該字典分別為 `self.__dict__` 本身，和紀錄欄位 (slot) 名稱和值對應關係的字典 (只有含有值的欄位 (slot) 會被紀錄其中)。
- 有 `__dict__` 但有 `__slots__` 實例的類，其預設狀態是一個二元組 (tuple)，元組中的第一個值是 `None`，第二個值則是紀錄欄位 (slot) 名稱和值對應關係的字典 (與前一項提到的字典是同一個)。

在 3.11 版的變更: 在 `object` 類中增加預設的 `__getstate__()` 實作。

`object.__setstate__(state)`

在拆封時，如果類定義了 `__setstate__()`，則會使用拆封後的狀態呼叫它。在這種情況下，紀錄狀態的物件不需要是字典 (dictionary)。否則，封裝時的狀態紀錄必須是一個字典，其紀錄的項目將被賦值給新實例的字典。

#### 備註

如果 `__reduce__()` 在封裝時回傳了 `None` 狀態，則拆封時就不會去呼叫 `__setstate__()`。

參閱紀錄大量狀態的物件以了解 `__getstate__()` 和 `__setstate__()` 的使用方法。

#### 備註

在拆封時，某些方法如 `__getattr__()`、`__getattribute__()` 或 `__setattr__()` 可能會在建立實例時被呼叫。如果這些方法依賴了某些實例內部的不變性，則應實作 `__new__()` 以建立此不變性，因為在拆封實例時不會呼叫 `__init__()`。

如稍後所演示，`pickle` 不直接使用上述方法。這些方法實際上是實作了 `__reduce__()` 特殊方法的拷貝協定 (copy protocol)。拷貝協定提供了統一的介面，以檢索進行封裝及物件時所需的資料。<sup>4</sup>

直接在類中實作 `__reduce__()` 雖然功能大但容易導致出錯。因此，設計類者應盡可能使用高階介面 (例如，`__getnewargs_ex__()`、`__getstate__()` 和 `__setstate__()`)。不過，我們也將展示一些特例狀況，在這些狀況中，使用 `__reduce__()` 可能是唯一的選擇、是更有效率的封裝方法或二者兼備。

`object.__reduce__()`

目前的介面定義如下。`__reduce__()` 方法不接受引數，且應回傳一個字串或一個元組 (元組一般而言是較佳的選擇；所回傳的物件通常稱「縮值」)。

如果回傳的是字串，該字串應被解讀成一個全域變數的名稱。它應是該物件相對其所在模組的本地名稱；`pickle` 模組會在模組命名空間中尋找，以確定該物件所在的模組。這種行通常對於單例物件特別有用。

當回傳一個元組時，其長度必須介於兩至六項元素之間。可選項可以被省略，或者其值可以被設為 `None`。各項物件的語意依序：

- 一個將會被呼叫來建立初始版本物件的可呼叫物件。

<sup>4</sup> `copy` 模組使用此協定進行淺層及深層操作。

- 一個用於傳遞引數給前述物件的元組。如果前述物件不接受引數輸入，則你仍應在這給定一個空元組。
  - 可選項。物件狀態。如前所述，會被傳遞給該物件的 `__setstate__()` 方法。如果該物件有實作此方法，則本值必須是一個字典，且其將會被新增到物件的 `__dict__` 屬性中。
  - 可選項。一個用來提供連續項目的代器（而非序列）。這些項目將個透過 `obj.append(item)` 方法或成批次地透過 `obj.extend(list_of_items)` 方法被附加到物件中。主要用於串列（list）子類，但只要其他類具有相應的 `append` 和 `extend` 方法以及相同的函式簽章（signature）就也可以使用。（是否會調用 `append()` 或 `extend()` 方法將取於所選用的 pickle 協定版本以及要附加的項目數量，因此必須同時支援這兩種方法。）
  - 可選項。一個生成連續鍵值對的代器（不是序列）。這些項目將以 `obj[key] = value` 方式被儲存到物件中。主要用於字典（dictionary）子類，但只要有實現了 `__setitem__()` 的其他類也可以使用。
  - 可選項。一個具有 `(obj, state)` 函式簽章（signature）的可呼叫物件。該物件允許使用者以可編寫的邏輯，而不是物件 `obj` 預設的 `__setstate__()` 態方法去控制特定物件的狀態更新方式。如果這個物件不是 `None`，這個物件的呼叫優先權將優於物件 `obj` 的 `__setstate__()`。
- 在 3.8 版被加入：加入第六個可選項（一個 `(obj, state)` 元組）。

`object.__reduce_ex__` (protocol)

另外，你也可以定義一個 `__reduce_ex__()` 方法。唯一的不同的地方是此方法只接受協定版本（整數）作參數。當有定義本方法時，pickle 會優先調用它而不是 `__reduce__()`。此外，呼叫 `__reduce__()` 時也會自動變成呼叫這個變體版本。此方法主要是為了向後相容的舊的 Python 版本而存在。

## 外部物件持久化

為了方便物件持久化，`pickle` 模組支援對被封裝資料串流以外的物件參照。被參照的物件是透過一個持久化 ID 來參照的，這個 ID 應該要是字母數字字元（alphanumeric）組成的字串（協定 0<sup>5</sup>）或者是任意的物件（任何較新的協定）。

`pickle` 有定義要如何解或分派這個持久化 ID 的問題；故其處理方式有賴使用者自行定義在封裝器（pickler）以及拆封器（unpickler）中。方法的名稱各自在 `persistent_id()` 和 `persistent_load()`。

要封裝具有外部持久化 ID 的物件，封裝器（pickler）必須擁有一個自訂的方法 `persistent_id()`，這個方法將接收一個物件作參數，回傳 `None` 或該物件的持久化 ID。當回傳 `None` 時，封裝器會正常地封裝該物件。當回傳一個持久化 ID 字串時，封裝器會封裝該物件加上一個標記，讓拆封器（unpickler）能識它是一個持久化 ID。

要拆封外部物件，拆封器（unpickler）必須有一個自訂的 `persistent_load()` 方法，該方法應接受一個持久化 ID 物件，回傳相對應的物件。

以下是一個完整的範例，用以說明如何使用持久化 ID 來封裝具外部參照的物件。

```
# 展示如何使用持久化 ID 來封裝外部物件的簡單範例

import pickle
import sqlite3
from collections import namedtuple

# 代表資料庫中紀的一個簡易類
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # 我們派發出一個持久 ID，而不是像一般類實例那樣封裝 MemoRecord。
        if isinstance(obj, MemoRecord):
```

(繼續下一頁)

<sup>5</sup> 協定 0 中限制僅能使用英文字母或數字字元來分配持久化 ID 是因持久化 ID 是由行符號所分隔的。因此，如果持久化 ID 中出現任何形式的行字元，將導致封裝資料變得無法讀取。

(繼續上一頁)

```

    # 我們的持久 ID 就是一個元組，包含一個標和一個鍵，指向資料庫中的特定紀錄。
    return ("MemoRecord", obj.key)
else:
    # 如果 obj 有持久 ID，則回傳 None。這表示 obj 像平常那樣封裝即可。
    return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # 每當遇到持久 ID 時，此方法都會被呼叫。
        # pid 是 DBPickler 所回傳的元組。
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # 從資料庫中抓取所引用的紀錄回傳。
            cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # 如果無法回傳正確的物件，則必須引發錯誤。
            # 否則 unpickler 會誤認 None 是持久 ID 所引用的物件。
            raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
    import pprint

    # 初始化資料庫。
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
        'fight with a zebra',
    )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))

    # 抓取要封裝的紀錄。
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor]
    # 使用我們自訂的 DBPickler 來保存紀錄。
    file = io.BytesIO()
    DBPickler(file).dump(memos)

    print("被封裝的紀錄:")
    pprint.pprint(memos)

    # 更新一筆紀錄 (測試用)。
    cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

    # 從 pickle 資料流中載入紀錄。
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

```

(繼續下一頁)

(繼續上一頁)

```
print("已拆封的紀:")
pprint.pprint(memos)

if __name__ == '__main__':
    main()
```

## 調度表

如果你希望在不干擾其他物件正常封裝的前提下建立一個針對特定物件的封裝器，你可建立一個有私密調度表的封裝器。

由 `copyreg` 模組管理的全域調度表可以 `copyreg.dispatch_table` 呼叫。你可以透過這個方式來基於原始 `copyreg.dispatch_table` 建立一個修改過的版本，作你的專屬用途的調度表。

舉例來：

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

建立了一個 `pickle.Pickler`，其中含有專門處 `SomeClass` 類的專屬調度表。此外，你也可以寫作：

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

這樣可生相似的結果，唯一不同的是往後所有 `MyPickler` 預設都會使用這個專屬調度表。最後，如果將程式寫：

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

則會改變 `copyreg` 模組建、所有使用者共通的調度表。

## 處紀大量狀態的物件

以下的範例展示了如何修改針對特定類封裝時的行。下面的 `TextReader` 類會開一個文字檔案，在每次呼叫其 `readline()` 方法時返回當前行編號與該行內容。如果 `TextReader` 實例被封裝，所有 \* 除了檔案物件之外 \* 的屬性成員都會被保存。在該實例被拆封時，檔案將被重新開，從上次的位置繼續讀取。這個行的達成是透過 `__setstate__()` 和 `__getstate__()` 方法來實作的。

```
class TextReader:
    """列出文字檔案中的行對其進行編號。"""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
```

(繼續下一頁)

(繼續上一頁)

```

    return None

    if line.endswith('\n'):
        line = line[:-1]
    return "%i: %s" % (self.lineno, line)

def __getstate__(self):
    # 從 self.__dict__ 中物件的狀態。包含了所有的實例屬性。
    # 使用 dict.copy() 方法以避免修改原始狀態。
    state = self.__dict__.copy()
    # 移除不可封裝的項目。
    del state['file']
    return state

def __setstate__(self, state):
    # 恢復實例屬性 (即 filename 和 lineno) 。
    self.__dict__.update(state)
    # 恢復到先前開了檔案的狀態。此，我們需要重新開它一直讀取到行數編號相同。
    file = open(self.filename)
    for _ in range(self.lineno):
        file.readline()
    # 存檔。
    self.file = file

```

可以這樣實際使用：

```

>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'

```

## 12.1.6 針對型、函式或特定物件定縮函式

在 3.8 版被加入。

有時候，`dispatch_table` 的彈性空間可能不。尤其當我們想要使用型以外的方式來判斷如何使用自訂封裝、或者我們想要自訂特定函式和類的封裝方法時。

如果是這樣的話，可以繼承 `Pickler` 類實作一個 `reducer_override()` 方法。此方法可以回傳任意的縮元組 (參 `__reduce__()`)、也可以回傳 `NotImplemented` 以回退至原始的行。

如果 `dispatch_table` 和 `reducer_override()` 都被定義了的話，`reducer_override()` 的優先度較高。

### 備

出於效能考量，處以下物件可能不會呼叫 `reducer_override()`：None、True、False，以及 `int`、`float`、`bytes`、`str`、`dict`、`set`、`frozenset`、`list` 和 `tuple` 的實例。

以下是一個簡單的例子，我們示範如何允許封裝和重建給定的類：

```

import io
import pickle

class MyClass:
    my_attribute = 1

class MyPickler(pickle.Pickler):

```

(繼續下一頁)

(繼續上一頁)

```

def reducer_override(self, obj):
    """MyClass 的自訂縮函式。"""
    if getattr(obj, "__name__", None) == "MyClass":
        return type, (obj.__name__, obj.__bases__,
                      {'my_attribute': obj.my_attribute})
    else:
        # 遭遇其他物件，則使用一般的縮方式
        return NotImplemented

f = io.BytesIO()
p = MyPickler(f)
p.dump(MyClass)

del MyClass

unpickled_class = pickle.loads(f.getvalue())

assert isinstance(unpickled_class, type)
assert unpickled_class.__name__ == "MyClass"
assert unpickled_class.my_attribute == 1

```

## 12.1.7 帶外 (Out-of-band) 資料緩衝區

在 3.8 版被加入。

`pickle` 模組會被用於用於傳輸龐大的資料。此時，將記憶體次數降到最低以保持效能變得很重要。然而，`pickle` 模組的正常操作過程中，當它將物件的圖狀結構 (graph-like structure) 轉成連續的位元組串流時，本質上就涉及將資料到封裝流以及從封裝流資料。

如果 \* 供給者 \* (被傳遞物件的型別的實作) 與 \* 消費者 \* (資訊交系統的實作) 都支援由 `pickle` 協定 5 或更高版本提供的帶外傳輸功能，則可以避免此一先天限制。

### 供給者 API

要封裝的大型資料物件，則必須實作一個針對 5 版協定及以上的 `__reduce_ex__()` 方法，該方法應回傳一個 `PickleBuffer` 實例來處理任何大型資料 (而非回傳如 `bytes` 物件)。

一個 `PickleBuffer` 物件 \* 指示 \* 了當下底層的緩衝區狀態適合進行帶外資料傳輸。這些物件仍然相容 `pickle` 模組的一般使用方式。消費者程式也可以選擇介入，指示 `pickle` 他們將自行處理這些緩衝區。

### 消費者 API

一個資訊交系統可以定要自行處理序列化物件圖時生的 `PickleBuffer` 物件。

傳送端需要傳遞一個調用緩衝區的回呼函式給 `Pickler` (或 `dump()` 或 `dumps()` 函式) 的 `buffer_callback` 引數，使每次生成 `PickleBuffer` 時，該物件在處理物件圖時能被呼叫。除了一個簡易標記以外，由 `buffer_callback` 累積的緩衝區資料不會被到 `pickle` 串流中。

接收端需要傳遞一個緩衝區物件給 `Unpickler` (或 `load()` 或 `loads()` 函式) 的 `buffers` 引數。該物件須是一個可代的 (iterable) 緩衝區 (buffer) 物件，其中包含傳遞給 `buffer_callback` 的緩衝區物件。這個可代物件的緩衝區順序應該與它們當初被封裝時傳遞給 `buffer_callback` 的順序相同。這些緩衝區將提供物件重建所需的資料，以使重建器能還原出那個當時生了 `PickleBuffer` 的物件。

在傳送與接收端之間，通訊系統可以自由實作轉移帶外緩衝區資料的機制。該機制可能可以利用共用記憶體機制或根據資料類型特定的壓縮方式來最佳化執行速度。

### 范例

這一個簡單的範例展示了如何實作一個可以參與帶外緩衝區封裝的 `bytearray` 子類：

```

class ZeroCopyByteArray(bytearray):

    def __reduce_ex__(self, protocol):
        if protocol >= 5:
            return type(self)._reconstruct, (PickleBuffer(self),), None
        else:
            # PickleBuffer 在 pickle 協定 <= 4 時禁止使用。
            return type(self)._reconstruct, (bytearray(self),)

    @classmethod
    def _reconstruct(cls, obj):
        with memoryview(obj) as m:
            # 取得對原始緩衝區物件的控制
            obj = m.obj
            if type(obj) is cls:
                # 若原本的緩衝區物件是 ZeroCopyByteArray, 則直接回傳。
                return obj
            else:
                return cls(obj)

```

如果型正確，重建器（`_reconstruct` 類方法）會回傳當時提供緩衝區的物件。這個簡易實作可以模擬一個無行的重建器。

在使用端，我們可以用一般的方式封裝這些物件，當我們拆封時會得到一個原始物件的副本：

```

b = ZeroCopyByteArray(b"abc")
data = pickle.dumps(b, protocol=5)
new_b = pickle.loads(data)
print(b == new_b) # True
print(b is new_b) # False: 曾進行過 運算

```

但如果我們傳一個 `buffer_callback` 在去序列化時正確回傳積累的緩衝資料，我們就能拿回原始的物件：

```

b = ZeroCopyByteArray(b"abc")
buffers = []
data = pickle.dumps(b, protocol=5, buffer_callback=buffers.append)
new_b = pickle.loads(data, buffers=buffers)
print(b == new_b) # True
print(b is new_b) # True: 有進行過

```

此範例是因受限於 `bytearray` 會自行分配記憶體：你無法建立以其他物件的記憶體基礎的 `bytearray` 實例。不過第三方資料型態（如 NumPy 陣列）則可能有這個限制，而允許在不同程序或系統之間傳輸資料時使用零拷貝封裝（或可能地少拷貝次數）。

### 也參考

PEP 574 -- 第 5 版 Pickle 協定的帶外資料（out-of-band data）處

## 12.1.8 限制全域物件

預設情況下，拆封過程將會引入任何在 `pickle` 資料中找到的類或函式。對於許多應用程式來，這種行是不可接受的，因為它讓拆封器能引入執行任意程式碼。請參見以下 `pickle` 資料流在載入時的行：

```

>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntr.")
hello world
0

```

在這個例子中，拆封器會引入 `os.system()` 函式，然後執行命令「echo hello world」。雖然這個例子是無害的，但不難想像可以這個方式輕易執行任意可能對系統造成損害的命令。

基於以上原因，你可能會希望透過自訂 `Unpickler.find_class()` 來控制哪些是能被拆封的內容。與其名稱字面意義暗示的不同，實際上每當你請求一個全域物件（例如，類或函式）時，就會調用 `Unpickler.find_class()`。因此，可以透過這個方法完全禁止全域物件或將其限制在安全的子集合。

以下是一個僅允許從 `builtins` 模組中載入少數安全類型的拆封器（`unpickler`）的例子：

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # 只允許幾個建立的安全類
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # 完全禁止任何其他類
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
                                       (module, name))

def restricted_loads(s):
    """一個模擬 pickle.loads() 的輔助函式"""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

我們剛才實作的的拆封器範例正常運作的樣子：

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\nR.")
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                   b'(S\'getattr(__import__("os"), "system")\'
...                   b'("echo hello world")\nR.')
Traceback (most recent call last):
...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

正如我們的範例所示，必須謹慎審視能被拆封的內容。因此，如果你的應用場景非常關心安全性，你可能需要考慮其他選擇，例如 `xmlrpc.client` 中的 `marshalling` API 或其他第三方解方案。

## 12.1.9 效能

較近期的 `pickle` 協定版本（從 2 版協定開始）`FF`多種常見功能和`FF`建型`FF`提供了高效率的二進位編碼。此外，`pickle` 模組還具備一個透明化的、以 C 語言編寫的最佳化工具。

### 12.1.10 范例

最簡單的使用方式，調用 `dump()` 和 `load()` 函式。：

```
import pickle

# 任意 pickle 支援的物件。
data = {
    'a': [1, 2.0, 3+4j],
    'b': ("string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # 使用可用的最高協定來封裝 'data' 字典。
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

以下範例可以讀取前述程式所封裝的 `pickle` 資料。：

```
import pickle

with open('data.pickle', 'rb') as f:
    # 會自動檢測資料使用的協定版本，因此我們不需要手動指定。
    data = pickle.load(f)
```

索引式資料庫；使用 `pickle` 實作。

##### `copy` 模組

物件的淺層或深度拷貝。

##### `marshal` 模組

`FF`建型`FF`的高效能序列化。

## 解

## 12.2 `copyreg` --- `FF` `pickle` 支援函式

原始碼： `Lib/copyreg.py`

`copyreg` 模組提供了一種用以定義在 `pickle` 特定物件時使用之函式的方式。`pickle` 和 `copy` 模組在 `pickle/copy` 這些物件時使用這些函式。此模組提供有關非類`FF`物件之建構函式的配置資訊。此類建構函式可以是工廠函式 (factory function) 或類`FF`實例。

`copyreg.constructor` (object)

宣告 `object` 是一個有效的建構函式。如果 `object` 不可呼叫（因此不可作`FF`有效的建構函式），則會引發 `TypeError`。

`copyreg.pickle`(*type*, *function*, *constructor\_ob=None*)

宣告 *function* 應該用作 *type* 型之物件的「歸約 (“reduction”)」函式。*function* 必須回傳字串或包含 2 到 6 個元素的元組。有關 *function* 介面的更多詳細資訊，請參閱 [dispatch\\_table](#)。

*constructor\_ob* 參數是一個遺留功能，現在已被忽略，但如果要傳遞它的話則必須是個可呼叫物件。

請注意，pickler 物件或 `pickle.Pickler` 子類之 `dispatch_table` 屬性也可用於宣告歸約函式。

### 12.2.1 范例

下面範例展示如何定義一個 pickle 函式以及如何使用它：

```
>>> import copyreg, copy, pickle
>>> class C:
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

## 12.3 shelve --- Python object persistence

原始碼：[Lib/shelve.py](#)

A "shelf" is a persistent, dictionary-like object. The difference with "dbm" databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects --- anything that the `pickle` module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

`shelve.open`(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of `dbm.open()`.

By default, pickles created with `pickle.DEFAULT_PROTOCOL` are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see [範例](#)). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on `sync()` and `close()`; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

在 3.10 版的變更：`pickle.DEFAULT_PROTOCOL` is now used as the default pickle protocol.

在 3.11 版的變更：Accepts *path-like object* for filename.

**備**

Do not rely on the shelf being closed automatically; always call `close()` explicitly when you don't need it any more, or use `shelve.open()` as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

**警告**

Because the `shelve` module is backed by `pickle`, it is insecure to load a shelf from an untrusted source. Like with `pickle`, loading a shelf can execute arbitrary code.

Shelf objects support most of methods and operations supported by dictionaries (except copying, constructors and operators `|` and `|=`). This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

`Shelf.sync()`

Write back all entries in the cache if the shelf was opened with `writeback` set to `True`. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with `close()`.

`Shelf.close()`

Synchronize and close the persistent `dict` object. Operations on a closed shelf will fail with a `ValueError`.

**也參考**

[Persistent dictionary recipe](#) with widely supported storage formats and having the speed of native dictionaries.

### 12.3.1 Restrictions

- The choice of which database package will be used (such as `dbm.ndbm` or `dbm.gnu`) depends on which interface is available. Therefore it is not safe to open the database directly using `dbm`. The database is also (unfortunately) subject to the limitations of `dbm`, if it is used --- this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The `shelve` module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.
- On macOS `dbm.ndbm` can silently corrupt the database file on updates, which can cause hard crashes when trying to read from the database.

**class** `shelve.Shelf` (`dict`, `protocol=None`, `writeback=False`, `keyencoding='utf-8'`)

A subclass of `collections.abc.MutableMapping` which stores pickled values in the `dict` object.

By default, pickles created with `pickle.DEFAULT_PROTOCOL` are used to serialize values. The version of the pickle protocol can be specified with the `protocol` parameter. See the `pickle` documentation for a discussion of the pickle protocols.

If the `writeback` parameter is `True`, the object will hold a cache of all entries accessed and write them back to the `dict` at `sync` and `close` times. This allows natural operations on mutable entries, but can consume much more memory and make `sync` and `close` take a long time.

The `keyencoding` parameter is the encoding used to encode keys before they are used with the underlying `dict`.

A *Shelf* object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

在 3.2 版的變更: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

在 3.4 版的變更: 新增情境管理器的支援。

在 3.10 版的變更: `pickle.DEFAULT_PROTOCOL` is now used as the default pickle protocol.

**class** `shelve.BsdDbShelf` (*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*)

A subclass of *Shelf* which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` methods. These are available in the third-party `bsddb` module from `pybsddb` but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the *Shelf* class.

**class** `shelve.DbfilenameShelf` (*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

A subclass of *Shelf* which accepts a *filename* instead of a dict-like object. The underlying file will be opened using `dbm.open()`. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the `open()` function. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

### 12.3.2 范例

To summarize the interface (key is a string, data is an arbitrary object):

```
import shelve

d = shelve.open(filename) # open -- file may get suffix added by low-level
                          # library

d[key] = data             # store data at key (overwrites old data if
                          # using an existing key)
data = d[key]            # retrieve a COPY of data at key (raise KeyError
                          # if no such key)
del d[key]               # delete data stored at key (raises KeyError
                          # if no such key)

flag = key in d          # true if the key exists
klist = list(d.keys())   # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]      # this works as expected, but...
d['xx'].append(3)        # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']           # extracts the copy
temp.append(5)           # mutates the copy
d['xx'] = temp           # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()               # close it
```

#### 也參考

##### `dbm` 模組

Generic interface to dbm-style databases.

**`pickle` 模組**Object serialization used by `shelve`.

## 12.4 `marshal` --- 內部 Python 物件序列化

此 module (模組) 包含一個能以二進位制格式來讀寫 Python 值的函式。這種格式是 Python 專屬但獨立於機器架構的 (例如, 你可以在一臺 PC 上寫入某個 Python 值, 再將檔案傳到一臺 Mac 上在那讀取它)。這種格式的細節是有意地不在文件上明的; 它可能在不同 Python 版本中被改變 (雖然這種情況極少發生)。<sup>1</sup>

This is not a general "persistence" module. For general persistence and transfer of Python objects through RPC calls, see the modules `pickle` and `shelve`. The `marshal` module exists mainly to support reading and writing the "pseudo-compiled" code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. The format of code objects is not compatible between Python versions, even if the version of the format is the same. De-serializing a code object in the incorrect Python version has undefined behavior. If you're serializing and de-serializing Python objects, use the `pickle` module instead -- the performance is comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

**警告**

`marshal` module 對於錯誤或惡意構建的資料來是不安全的。永遠不要 `unmarshal` 來自不受信任的或來源未經驗證的資料。

不是所有 Python 物件型都有支援; 一般來, 此 module 只能寫入和讀取不依賴於特定 Python 調用 (invocation) 的物件。下列型是有支援的: 布林 (boolean)、整數、浮點數 (floating-point number)、數、字串、位元組串 (bytes)、位元組陣列 (bytearray)、元組 (tuple)、list、集合 (set)、凍結集合 (frozenset)、dictionary 和程式碼物件 (如 `allow_code` `True`), 需要了解的一點是元組、list、集合、凍結集合和 dictionary 只在其所包含的值也屬於這些型時才會支援。單例 (singleton) 物件 `None`、`Ellipsis` 和 `StopIteration` 也可以被 `marshal` 和 `unmarshal`。對於 `version` 低於 3 的格式, 遞 list、集合和 dictionary 無法被寫入 (見下文)。

有些函式可以讀/寫檔案, 還有些函式可以操作類位元組串物件 (bytes-like object)。

這個 module 定義了以下函式:

```
marshal.dump(value, file, version=version, l, *, allow_code=True)
```

將值寫入被開的檔案。值必須受支援的型, 檔案必須可寫入的 *binary file*。

如果值具有 (或其所包含的物件具有) 不支援的型, 則會引發 `ValueError` 例外 --- 但是垃圾資料 (garbage data) 也將寫入檔案, 物件也無法正確地透過 `load()` 重新讀取。程式碼物件只有在 `allow_code` `True` 時才會支援。

`version` 引數指明 `dump` 應該使用的資料格式 (見下文)。

引發一個附帶引數 `value` 與 `version` 的稽核事件 (*auditing event*) `marshal.dumps`。

在 3.13 版的變更: 新增 `allow_code` 參數。

```
marshal.load(file, l, *, allow_code=True)
```

從開的檔案讀取一個值回傳。如果讀不到有效的值 (例如, 由於資料不同 Python 版本的不相容 `marshal` 格式), 則會引發 `EOFError`、`ValueError` 或 `TypeError`。程式碼物件只有在 `allow_code` `True` 時才會支援。檔案必須可讀取的 *binary file*。

引發一個有附帶引數的稽核事件 `marshal.load`。

<sup>1</sup> 此 module 的名稱來源於 Modula-3 (及其他語言) 的設計者所使用的術語, 他們使用 "marshal" 來表示自包含 (self-contained) 形式資料的傳輸。嚴格來, 將資料從內部形式轉外部形式 (例如用於 RPC 緩衝區) 稱 "marshal", 而其反向過程則稱 "unmarshal"。

**備**

如果透過 `dump()` marshal 了一個包含不支援型的物件，`load()` 會將不可 marshal 的型替 `None`。

在 3.10 版的變更: 使用此呼叫每個程式碼物件引發一個 `code.__new__` 稽核事件。現在它會整個載入操作引發單個 `marshal.load` 事件。

在 3.13 版的變更: 新增 `allow_code` 參數。

`marshal.dumps (value, version=version, /, *, allow_code=True)`

回傳將透過 `dump(value, file)` 來被寫入一個檔案的位元組串物件，其值必須是有支援的型，如果值（或其包含的任一物件）不支援的型則會引發 `ValueError`。程式碼物件只有在 `allow_code true` 時才會支援。

`version` 引數指明 `dumps` 應當使用的資料型（見下文）。

引發一個附帶引數 `value` 與 `version` 的稽核事件 (*auditing event*) `marshal.dumps`。

在 3.13 版的變更: 新增 `allow_code` 參數。

`marshal.loads (bytes, /, *, allow_code=True)`

將 *bytes-like object* 轉一個值。如果找不到有效的值，則會引發 `EOFError`、`ValueError` 或 `TypeError`。程式碼物件只有在 `allow_code true` 時才會支援。輸入中額外的位元組串會被忽略。

引發一個附帶引數 `bytes` 的稽核事件 `marshal.loads`。

在 3.10 版的變更: 使用此呼叫每個程式碼物件引發一個 `code.__new__` 稽核事件。現在它會整個載入操作引發單個 `marshal.loads` 事件。

在 3.13 版的變更: 新增 `allow_code` 參數。

此外，還定義了以下常數：

`marshal.version`

表示 `module` 所使用的格式。第 0 版歷史格式，第 1 版共享了駐留字串 (interned string)，第 2 版對浮點數使用二進位制格式。第 3 版添加了對於物件實例化和遞的支援。目前使用的是第 4 版。

**解**

## 12.5 dbm --- Unix "databases" 的介面

原始碼: `Lib/dbm/__init__.py`

`dbm` is a generic interface to variants of the DBM database:

- `dbm.sqlite3`
- `dbm.gnu`
- `dbm.ndbm`

If none of these modules are installed, the slow-but-simple implementation in module `dbm.dumb` will be used. There is a *third party interface* to the Oracle Berkeley DB.

**exception** `dbm.error`

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named `dbm.error` as the first item --- the latter is used when `dbm.error` is raised.

`dbm.whichdb(filename)`

This function attempts to guess which of the several simple database modules available --- `dbm.sqlite3`, `dbm.gnu`, `dbm.ndbm`, or `dbm.dumb` --- should be used to open a given file.

回傳以下其中一個值：

- `None` if the file can't be opened because it's unreadable or doesn't exist
- the empty string ( `'` ) if the file's format can't be guessed
- a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`

在 3.11 版的變更: `filename` accepts a *path-like object*.

`dbm.open(file, flag='r', mode=0o666)`

Open a database and return the corresponding database object.

#### 參數

- **file** (*path-like object*) -- 要打開的資料庫檔案  
If the database file already exists, the `whichdb()` function is used to determine its type and the appropriate module is used; if it does not exist, the first submodule listed above that can be imported is used.
- **flag** (`str`) --
  - `'r'` (default): Open existing database for reading only.
  - `'w'`: Open existing database for reading and writing.
  - `'c'`: Open database for reading and writing, creating it if it doesn't exist.
  - `'n'`: Always create a new, empty database, open for reading and writing.
- **mode** (`int`) -- The Unix file access mode of the file (default: octal `0o666`), used only when the database has to be created.

在 3.11 版的變更: `file` 接受一個類路徑物件。

The object returned by `open()` supports the same basic functionality as a *dict*; keys and their corresponding values can be stored, retrieved, and deleted, and the `in` operator and the `keys()` method are available, as well as `get()` and `setdefault()` methods.

Key and values are always stored as *bytes*. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a `with` statement, which will automatically close them when done.

在 3.2 版的變更: `get()` and `setdefault()` methods are now available for all `dbm` backends.

在 3.4 版的變更: Added native support for the context management protocol to the objects returned by `open()`.

在 3.8 版的變更: Deleting a key from a read-only database raises a database module specific exception instead of `KeyError`.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'
```

(繼續下一頁)

(繼續上一頁)

```

# Note that the keys are considered bytes now.
assert db[b'www.python.org'] == b'Python Website'
# Notice how the value is now in bytes.
assert db['www.cnn.com'] == b'Cable News Network'

# Often-used methods of the dict interface work too.
print(db.get('python.org', b'not present'))

# Storing a non-string key or value will raise an exception (most
# likely a TypeError).
db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.

```

**也參考****shelve 模組**

Persistence module which stores non-string data.

The individual submodules are described in the following sections.

**12.5.1 dbm.sqlite3 --- SQLite backend for dbm**

在 3.13 版被加入。

原始碼: [Lib/dbm/sqlite3.py](#)

This module uses the standard library `sqlite3` module to provide an SQLite backend for the `dbm` module. The files created by `dbm.sqlite3` can thus be opened by `sqlite3`, or any other SQLite browser, including the SQLite CLI.

適用: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參閱 [WebAssembly 平台](#)。

`dbm.sqlite3.open(filename, f, flag='r', mode=0o666)`

Open an SQLite database. The returned object behaves like a *mapping*, implements a `close()` method, and supports a "closing" context manager via the `with` keyword.

**參數**

- **filename** (*path-like object*) -- 要打開的資料庫路徑
- **flag** (`str`) --
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

**12.5.2 dbm.gnu --- GNU 資料庫管理器**

原始碼: [Lib/dbm/gnu.py](#)

The `dbm.gnu` module provides an interface to the GDBM (GNU dbm) library, similar to the `dbm.ndbm` module, but with additional functionality like crash tolerance.

**備**

The file formats created by `dbm.gnu` and `dbm.ndbm` are incompatible and can not be used interchangeably.

適用: not Android, not iOS, not WASI.

此模組在行動平台或 *WebAssembly* 平台上不支援。

**exception** `dbm.gnu.error`

Raised on `dbm.gnu`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.gnu.open(filename, flag='r', mode=0o666, /)`

Open a GDBM database and return a `gdbm` object.

**參數**

- **filename** (*path-like object*) -- 要打開的資料庫檔案
- **flag** (`str`) --
  - 'r' (default): Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c': Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.

The following additional characters may be appended to control how the database is opened:

- 'f': Open the database in fast mode. Writes to the database will not be synchronized.
- 's': Synchronized mode. Changes to the database will be written immediately to the file.
- 'u': 不要鎖住資料庫。

Not all flags are valid for all versions of GDBM. See the `open_flags` member for a list of supported flag characters.

- **mode** (`int`) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

**引發**

**error** -- 如果一個無效的 `flag` 引數被傳入。

在 3.11 版的變更: `filename` accepts a *path-like object*.

`dbm.gnu.open_flags`

A string of characters the `flag` parameter of `open()` supports.

`gdbm` objects behave similar to *mappings*, but `items()` and `values()` methods are not supported. The following methods are also provided:

`gdbm.firstkey()`

It's possible to loop over every key in the database using this method and the `nextkey()` method. The traversal is ordered by GDBM's internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(key)`

Returns the key that follows *key* in the traversal. The following code prints every key in the database *db*, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k is not None:
    print(k)
    k = db.nextkey(k)
```

`gdbm.reorganize()`

If you have carried out a lot of deletions and would like to shrink the space used by the GDBM file, this routine will reorganize the database. `gdbm` objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`

When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`

關閉 GDBM 資料庫。

`gdbm.clear()`

移除 GDBM 資料庫中所有項目。

在 3.13 版被加入。

### 12.5.3 dbm.ndbm --- 新資料庫管理器

原始碼: [Lib/dbm/ndbm.py](#)

The `dbm.ndbm` module provides an interface to the NDBM (New Database Manager) library. This module can be used with the "classic" NDBM interface or the GDBM compatibility interface.

#### 備註

The file formats created by `dbm.gnu` and `dbm.ndbm` are incompatible and can not be used interchangeably.

#### 警告

The NDBM library shipped as part of macOS has an undocumented limitation on the size of values, which can result in corrupted database files when storing values larger than this limit. Reading such corrupted files can result in a hard crash (segmentation fault).

適用: not Android, not iOS, not WASI.

此模組在行動平台或 *WebAssembly* 平台上不支援。

**exception** `dbm.ndbm.error`

Raised on `dbm.ndbm`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

`dbm.ndbm.library`

Name of the NDBM implementation library used.

```
dbm.ndbm.open(filename, flag='r', mode=0o666, /)
```

Open an NDBM database and return an `ndbm` object.

#### 參數

- **filename** (*path-like object*) -- The basename of the database file (without the `.dir` or `.pag` extensions).
- **flag** (`str`) --
  - `'r'` (default): Open existing database for reading only.
  - `'w'`: Open existing database for reading and writing.
  - `'c'`: Open database for reading and writing, creating it if it doesn't exist.
  - `'n'`: Always create a new, empty database, open for reading and writing.
- **mode** (`int`) -- The Unix file access mode of the file (default: octal `0o666`), used only when the database has to be created.

`ndbm` objects behave similar to *mappings*, but `items()` and `values()` methods are not supported. The following methods are also provided:

在 3.11 版的變更: Accepts *path-like object* for filename.

```
ndbm.close()
```

關閉 NDBM 資料庫。

```
ndbm.clear()
```

移除 NDBM 資料庫中所有項目。

在 3.13 版被加入。

## 12.5.4 dbm.dumb --- 可 式 DBM 實作

原始碼: `Lib/dbm/dumb.py`

### 備

The `dbm.dumb` module is intended as a last resort fallback for the `dbm` module when a more robust module is not available. The `dbm.dumb` module is not written for speed and is not nearly as heavily used as the other database modules.

The `dbm.dumb` module provides a persistent *dict*-like interface which is written entirely in Python. Unlike other `dbm` backends, such as `dbm.gnu`, no external library is required.

`dbm.dumb` 模組定義了以下項目：

**exception** `dbm.dumb.error`

Raised on `dbm.dumb`-specific errors, such as I/O errors. `KeyError` is raised for general mapping errors like specifying an incorrect key.

```
dbm.dumb.open(filename, flag='c', mode=0o666)
```

Open a `dbm.dumb` database. The returned database object behaves similar to a *mapping*, in addition to providing `sync()` and `close()` methods.

#### 參數

- **filename** -- The basename of the database file (without extensions). A new database creates the following files:
  - `filename.dat`
  - `filename.dir`

- **flag** (*str*) --
  - 'r': Open existing database for reading only.
  - 'w': Open existing database for reading and writing.
  - 'c' (default): Open database for reading and writing, creating it if it doesn't exist.
  - 'n': Always create a new, empty database, open for reading and writing.
- **mode** (*int*) -- The Unix file access mode of the file (default: octal 0o666), used only when the database has to be created.

警告

It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to stack depth limitations in Python's AST compiler.

在 3.5 版的變更: `open()` always creates a new database when *flag* is 'n'.

在 3.8 版的變更: A database opened read-only if *flag* is 'r'. A database is not created if it does not exist if *flag* is 'r' or 'w'.

在 3.11 版的變更: *filename* accepts a *path-like object*.

In addition to the methods provided by the `collections.abc.MutableMapping` class, the following methods are provided:

`dumbdbm.sync()`

Synchronize the on-disk directory and data files. This method is called by the `shelve.Shelf.sync()` method.

`dumbdbm.close()`

關閉資料庫。

## 12.6 sqlite3 --- SQLite 資料庫的 DB-API 2.0 介面

**原始碼:** `Lib/sqlite3/` SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The `sqlite3` module was written by Gerhard Häring. It provides an SQL interface compliant with the DB-API 2.0 specification described by **PEP 249**, and requires SQLite 3.15.2 or newer.

此文件包含四個主要章節：

- **教學** 教導如何使用 `sqlite3` 模組。
- **Reference** 描述此模組定義的類與函式。
- **How-to guides** 詳細說明如何處理特定工作。
- **解釋** 深入提供交易 (transaction) 控制的背景。

### 也參考

<https://www.sqlite.org>

The SQLite web page; the documentation describes the syntax and the available data types for the supported SQL dialect.

<https://www.w3schools.com/sql/>

Tutorial, reference and examples for learning SQL syntax.

**PEP 249 - 資料庫 API 規格 2.0**

PEP 由 Marc-André Lemburg 撰寫。

**12.6.1 教學**

In this tutorial, you will create a database of Monty Python movies using basic `sqlite3` functionality. It assumes a fundamental understanding of database concepts, including [cursors](#) and [transactions](#).

First, we need to create a new database and open a database connection to allow `sqlite3` to work with it. Call `sqlite3.connect()` to create a connection to the database `tutorial.db` in the current working directory, implicitly creating it if it does not exist:

```
import sqlite3
con = sqlite3.connect("tutorial.db")
```

The returned `Connection` object `con` represents the connection to the on-disk database.

In order to execute SQL statements and fetch results from SQL queries, we will need to use a database cursor. Call `con.cursor()` to create the `Cursor`:

```
cur = con.cursor()
```

Now that we've got a database connection and a cursor, we can create a database table `movie` with columns for title, release year, and review score. For simplicity, we can just use column names in the table declaration -- thanks to the [flexible typing](#) feature of SQLite, specifying the data types is optional. Execute the `CREATE TABLE` statement by calling `cur.execute(...)`:

```
cur.execute("CREATE TABLE movie(title, year, score)")
```

We can verify that the new table has been created by querying the `sqlite_master` table built-in to SQLite, which should now contain an entry for the `movie` table definition (see [The Schema Table](#) for details). Execute that query by calling `cur.execute(...)`, assign the result to `res`, and call `res.fetchone()` to fetch the resulting row:

```
>>> res = cur.execute("SELECT name FROM sqlite_master")
>>> res.fetchone()
('movie',)
```

We can see that the table has been created, as the query returns a `tuple` containing the table's name. If we query `sqlite_master` for a non-existent table `spam`, `res.fetchone()` will return `None`:

```
>>> res = cur.execute("SELECT name FROM sqlite_master WHERE name='spam'")
>>> res.fetchone() is None
True
```

Now, add two rows of data supplied as SQL literals by executing an `INSERT` statement, once again by calling `cur.execute(...)`:

```
cur.execute("""
    INSERT INTO movie VALUES
        ('Monty Python and the Holy Grail', 1975, 8.2),
        ('And Now for Something Completely Different', 1971, 7.5)
""")
```

The `INSERT` statement implicitly opens a transaction, which needs to be committed before changes are saved in the database (see [Transaction control](#) for details). Call `con.commit()` on the connection object to commit the transaction:

```
con.commit()
```

We can verify that the data was inserted correctly by executing a `SELECT` query. Use the now-familiar `cur.execute(...)` to assign the result to `res`, and call `res.fetchall()` to return all resulting rows:

```
>>> res = cur.execute("SELECT score FROM movie")
>>> res.fetchall()
[(8.2,), (7.5,)]
```

The result is a *list* of two tuples, one per row, each containing that row's score value.

Now, insert three more rows by calling `cur.executemany(...)`:

```
data = [
    ("Monty Python Live at the Hollywood Bowl", 1982, 7.9),
    ("Monty Python's The Meaning of Life", 1983, 7.5),
    ("Monty Python's Life of Brian", 1979, 8.0),
]
cur.executemany("INSERT INTO movie VALUES(?, ?, ?)", data)
con.commit() # Remember to commit the transaction after executing INSERT.
```

Notice that `?` placeholders are used to bind data to the query. Always use placeholders instead of string formatting to bind Python values to SQL statements, to avoid [SQL injection attacks](#) (see [How to use placeholders to bind values in SQL queries](#) for more details).

We can verify that the new rows were inserted by executing a `SELECT` query, this time iterating over the results of the query:

```
>>> for row in cur.execute("SELECT year, title FROM movie ORDER BY year"):
...     print(row)
(1971, 'And Now for Something Completely Different')
(1975, 'Monty Python and the Holy Grail')
(1979, 'Monty Python's Life of Brian')
(1982, 'Monty Python Live at the Hollywood Bowl')
(1983, 'Monty Python's The Meaning of Life')
```

Each row is a two-item *tuple* of `(year, title)`, matching the columns selected in the query.

Finally, verify that the database has been written to disk by calling `con.close()` to close the existing connection, opening a new one, creating a new cursor, then querying the database:

```
>>> con.close()
>>> new_con = sqlite3.connect("tutorial.db")
>>> new_cur = new_con.cursor()
>>> res = new_cur.execute("SELECT title, year FROM movie ORDER BY score DESC")
>>> title, year = res.fetchone()
>>> print(f'The highest scoring Monty Python movie is {title!r}, released in {year}')
The highest scoring Monty Python movie is 'Monty Python and the Holy Grail', released in 1975
>>> new_con.close()
```

You've now created an SQLite database using the `sqlite3` module, inserted data and retrieved values from it in multiple ways.

## 12.6.2 Reference

### Module functions

`sqlite3.connect` (*database*, *timeout=5.0*, *detect\_types=0*, *isolation\_level='DEFERRED'*, *check\_same\_thread=True*, *factory=sqlite3.Connection*, *cached\_statements=128*, *uri=False*, \*, *autocommit=sqlite3.LEGACY\_TRANSACTION\_CONTROL*)

Open a connection to an SQLite database.

#### 參數

- **database** (*path-like object*) -- The path to the database file to be opened. You can pass `":memory:"` to create an SQLite database existing only in memory, and open a connection to it.
- **timeout** (*float*) -- How many seconds the connection should wait before raising an *OperationalError* when a table is locked. If another connection opens a transaction to modify a table, that table will be locked until the transaction is committed. Default five seconds.
- **detect\_types** (*int*) -- Control whether and how data types not *natively supported by SQLite* are looked up to be converted to Python types, using the converters registered with *register\_converter()*. Set it to any combination (using `|`, bitwise or) of *PARSE\_DECLTYPES* and *PARSE\_COLNAMES* to enable this. Column names takes precedence over declared types if both flags are set. Types cannot be detected for generated fields (for example `max(data)`), even when the *detect\_types* parameter is set; *str* will be returned instead. By default (0), type detection is disabled.
- **isolation\_level** (*str | None*) -- Control legacy transaction handling behaviour. See *Connection.isolation\_level* and *Transaction control via the isolation\_level attribute* for more information. Can be "DEFERRED" (default), "EXCLUSIVE" or "IMMEDIATE"; or None to disable opening transactions implicitly. Has no effect unless *Connection.autocommit* is set to *LEGACY\_TRANSACTION\_CONTROL* (the default).
- **check\_same\_thread** (*bool*) -- If True (default), *ProgrammingError* will be raised if the database connection is used by a thread other than the one that created it. If False, the connection may be accessed in multiple threads; write operations may need to be serialized by the user to avoid data corruption. See *threadsafety* for more information.
- **factory** (*Connection*) -- A custom subclass of *Connection* to create the connection with, if not the default *Connection* class.
- **cached\_statements** (*int*) -- The number of statements that *sqlite3* should internally cache for this connection, to avoid parsing overhead. By default, 128 statements.
- **uri** (*bool*) -- If set to True, *database* is interpreted as a URI (Uniform Resource Identifier) with a file path and an optional query string. The scheme part *must* be "file:", and the path can be relative or absolute. The query string allows passing parameters to SQLite, enabling various *How to work with SQLite URIs*.
- **autocommit** (*bool*) -- Control **PEP 249** transaction handling behaviour. See *Connection.autocommit* and *Transaction control via the autocommit attribute* for more information. *autocommit* currently defaults to *LEGACY\_TRANSACTION\_CONTROL*. The default will change to False in a future Python release.

#### 回傳型 F

##### Connection

引發一個附帶引數 *database* 的稽核事件 `sqlite3.connect`。

引發一個附帶引數 `connection_handle` 的稽核事件 `sqlite3.connect/handle`。

在 3.4 版的變更: 新增 *uri* 參數。

在 3.7 版的變更: *database* can now also be a *path-like object*, not only a string.

在 3.10 版的變更: 新增 `sqlite3.connect/handle` 稽核事件。

在 3.12 版的變更: 新增 `autocommit` 參數。

在 3.13 版的變更: Positional use of the parameters `timeout`, `detect_types`, `isolation_level`, `check_same_thread`, `factory`, `cached_statements`, and `uri` is deprecated. They will become keyword-only parameters in Python 3.15.

`sqlite3.complete_statement` (*statement*)

Return `True` if the string *statement* appears to contain one or more complete SQL statements. No syntactic verification or parsing of any kind is performed, other than checking that there are no unclosed string literals and the statement is terminated by a semicolon.

範例:

```
>>> sqlite3.complete_statement("SELECT foo FROM bar;")
True
>>> sqlite3.complete_statement("SELECT foo")
False
```

This function may be useful during command-line input to determine if the entered text seems to form a complete SQL statement, or if additional input is needed before calling `execute()`.

See `runsource()` in `Lib/sqlite3/__main__.py` for real-world use.

`sqlite3.enable_callback_tracebacks` (*flag*, /)

Enable or disable callback tracebacks. By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use `False` to disable the feature again.

#### 備 F

Errors in user-defined function callbacks are logged as unraisable exceptions. Use an `unraisable hook handler` for introspection of the failed callback.

`sqlite3.register_adapter` (*type*, *adapter*, /)

Register an *adapter callable* to adapt the Python type *type* into an SQLite type. The adapter is called with a Python object of type *type* as its sole argument, and must return a value of a *type that SQLite natively understands*.

`sqlite3.register_converter` (*typename*, *converter*, /)

Register the *converter callable* to convert SQLite objects of type *typename* into a Python object of a specific type. The converter is invoked for all SQLite values of type *typename*; it is passed a `bytes` object and should return an object of the desired Python type. Consult the parameter `detect_types` of `connect()` for information regarding how type detection works.

Note: *typename* and the name of the type in your query are matched case-insensitively.

## Module constants

`sqlite3.LEGACY_TRANSACTION_CONTROL`

Set `autocommit` to this constant to select old style (pre-Python 3.12) transaction control behaviour. See *Transaction control via the isolation\_level attribute* for more information.

`sqlite3.PARSE_COLNAMES`

Pass this flag value to the `detect_types` parameter of `connect()` to look up a converter function by using the type name, parsed from the query column name, as the converter dictionary key. The type name must be wrapped in square brackets (`[]`).

```
SELECT p as "p [point]" FROM test; ! will look up converter "point"
```

This flag may be combined with `PARSE_DECLTYPES` using the `|` (bitwise or) operator.

#### `sqlite3.PARSE_DECLTYPES`

Pass this flag value to the `detect_types` parameter of `connect()` to look up a converter function using the declared types for each column. The types are declared when the database table is created. `sqlite3` will look up a converter function using the first word of the declared type as the converter dictionary key. For example:

```
CREATE TABLE test(
  i integer primary key, ! will look up a converter named "integer"
  p point,               ! will look up a converter named "point"
  n number(10)           ! will look up a converter named "number"
)
```

This flag may be combined with `PARSE_COLNAMES` using the `|` (bitwise or) operator.

#### `sqlite3.SQLITE_OK`

#### `sqlite3.SQLITE_DENY`

#### `sqlite3.SQLITE_IGNORE`

Flags that should be returned by the `authorizer_callback callable` passed to `Connection.set_authorizer()`, to indicate whether:

- Access is allowed (`SQLITE_OK`),
- The SQL statement should be aborted with an error (`SQLITE_DENY`)
- The column should be treated as a NULL value (`SQLITE_IGNORE`)

#### `sqlite3.apilevel`

String constant stating the supported DB-API level. Required by the DB-API. Hard-coded to "2.0".

#### `sqlite3.paramstyle`

String constant stating the type of parameter marker formatting expected by the `sqlite3` module. Required by the DB-API. Hard-coded to "qmark".

The named DB-API parameter style is also supported.

#### `sqlite3.sqlite_version`

Version number of the runtime SQLite library as a *string*.

#### `sqlite3.sqlite_version_info`

Version number of the runtime SQLite library as a *tuple* of *integers*.

#### `sqlite3.threadafety`

Integer constant required by the DB-API 2.0, stating the level of thread safety the `sqlite3` module supports. This attribute is set based on the default `threading mode` the underlying SQLite library is compiled with. The SQLite threading modes are:

1. **Single-thread:** In this mode, all mutexes are disabled and SQLite is unsafe to use in more than a single thread at once.
2. **Multi-thread:** In this mode, SQLite can be safely used by multiple threads provided that no single database connection is used simultaneously in two or more threads.
3. **Serialized:** In serialized mode, SQLite can be safely used by multiple threads with no restriction.

The mappings from SQLite threading modes to DB-API 2.0 threadsafety levels are as follows:

SQLite 執行緒 模式	執行緒安 全	SQLITE_THREADSA	DB-API 2.0 meaning
single-thread	0	0	Threads may not share the module
multi-thread	1	2	Threads may share the module, but not connections
serialized	3	1	Threads may share the module, connections and cursors

在 3.11 版的變更: Set *threadsafety* dynamically instead of hard-coding it to 1.

#### `sqlite3.version`

Version number of this module as a *string*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the `pysqlite` package, a third-party library which used to upstream changes to `sqlite3`. Today, it carries no meaning or practical value.

#### `sqlite3.version_info`

Version number of this module as a *tuple* of *integers*. This is not the version of the SQLite library.

Deprecated since version 3.12, will be removed in version 3.14: This constant used to reflect the version number of the `pysqlite` package, a third-party library which used to upstream changes to `sqlite3`. Today, it carries no meaning or practical value.

```
sqlite3.SQLITE_DBCONFIG_DEFENSIVE
sqlite3.SQLITE_DBCONFIG_DQS_DDL
sqlite3.SQLITE_DBCONFIG_DQS_DML
sqlite3.SQLITE_DBCONFIG_ENABLE_FKEY
sqlite3.SQLITE_DBCONFIG_ENABLE_FTS3_TOKENIZER
sqlite3.SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION
sqlite3.SQLITE_DBCONFIG_ENABLE_QPSG
sqlite3.SQLITE_DBCONFIG_ENABLE_TRIGGER
sqlite3.SQLITE_DBCONFIG_ENABLE_VIEW
sqlite3.SQLITE_DBCONFIG_LEGACY_ALTER_TABLE
sqlite3.SQLITE_DBCONFIG_LEGACY_FILE_FORMAT
sqlite3.SQLITE_DBCONFIG_NO_CKPT_ON_CLOSE
sqlite3.SQLITE_DBCONFIG_RESET_DATABASE
sqlite3.SQLITE_DBCONFIG_TRIGGER_EQP
sqlite3.SQLITE_DBCONFIG_TRUSTED_SCHEMA
sqlite3.SQLITE_DBCONFIG_WRITABLE_SCHEMA
```

These constants are used for the `Connection.setconfig()` and `getconfig()` methods.

The availability of these constants varies depending on the version of SQLite Python was compiled with.

在 3.12 版被加入。

#### 也參考

[https://www.sqlite.org/c3ref/c\\_dbconfig\\_defensive.html](https://www.sqlite.org/c3ref/c_dbconfig_defensive.html)  
SQLite docs: Database Connection Configuration Options

## Connection 物件

**class** `sqlite3.Connection`

Each open SQLite database is represented by a `Connection` object, which is created using `sqlite3.connect()`. Their main purpose is creating `Cursor` objects, and *Transaction control*.

### 也參考

- *How to use connection shortcut methods*
- *How to use the connection context manager*

在 3.13 版的變更: A `ResourceWarning` is emitted if `close()` is not called before a `Connection` object is deleted.

An SQLite database connection has the following attributes and methods:

**cursor** (*factory*=`Cursor`)

Create and return a `Cursor` object. The cursor method accepts a single optional parameter *factory*. If supplied, this must be a *callable* returning an instance of `Cursor` or its subclasses.

**blobopen** (*table*, *column*, *row*, */*, *\**, *readonly*=`False`, *name*='main')

Open a `Blob` handle to an existing BLOB (Binary Large Object).

### 參數

- **table** (*str*) -- The name of the table where the blob is located.
- **column** (*str*) -- The name of the column where the blob is located.
- **row** (*str*) -- The name of the row where the blob is located.
- **readonly** (*bool*) -- Set to `True` if the blob should be opened without write permissions. Defaults to `False`.
- **name** (*str*) -- The name of the database where the blob is located. Defaults to "main".

### 引發

`OperationalError` -- When trying to open a blob in a `WITHOUT ROWID` table.

### 回傳型<sup>F</sup>

`Blob`

### 備<sup>F</sup>

The blob size cannot be changed using the `Blob` class. Use the SQL function `zeroblob` to create a blob with a fixed size.

在 3.11 版被加入.

**commit** ()

Commit any pending transaction to the database. If `autocommit` is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was committed by this method.

**rollback** ()

Roll back to the start of any pending transaction. If `autocommit` is `True`, or there is no open transaction, this method does nothing. If `autocommit` is `False`, a new transaction is implicitly opened if a pending transaction was rolled back by this method.

**close()**

Close the database connection. If *autocommit* is `False`, any pending transaction is implicitly rolled back. If *autocommit* is `True` or `LEGACY_TRANSACTION_CONTROL`, no implicit transaction control is executed. Make sure to *commit()* before closing to avoid losing pending changes.

**execute(sql, parameters=(,), /)**

Create a new *Cursor* object and call *execute()* on it with the given *sql* and *parameters*. Return the new cursor object.

**executemany(sql, parameters, /)**

Create a new *Cursor* object and call *executemany()* on it with the given *sql* and *parameters*. Return the new cursor object.

**executescript(sql\_script, /)**

Create a new *Cursor* object and call *executescript()* on it with the given *sql\_script*. Return the new cursor object.

**create\_function(name, nargs, func, \*, deterministic=False)**

Create or remove a user-defined SQL function.

#### 參數

- **name** (*str*) -- The name of the SQL function.
- **narg** (*int*) -- The number of arguments the SQL function can accept. If `-1`, it may take any number of arguments.
- **func** (*callable* | `None`) -- A *callable* that is called when the SQL function is invoked. The callable must return *a type natively supported by SQLite*. Set to `None` to remove an existing SQL function.
- **deterministic** (*bool*) -- If `True`, the created SQL function is marked as *deterministic*, which allows SQLite to perform additional optimizations.

在 3.8 版的變更: 新增 *deterministic* 參數。

範例:

```
>>> import hashlib
>>> def md5sum(t):
...     return hashlib.md5(t).hexdigest()
>>> con = sqlite3.connect(":memory:")
>>> con.create_function("md5", 1, md5sum)
>>> for row in con.execute("SELECT md5(?)", (b"foo",)):
...     print(row)
('acbd18db4cc2f85cedef654fccc4a4d8',)
>>> con.close()
```

在 3.13 版的變更: Passing *name*, *narg*, and *func* as keyword arguments is deprecated. These parameters will become positional-only in Python 3.15.

**create\_aggregate(name, n\_arg, aggregate\_class)**

Create or remove a user-defined SQL aggregate function.

#### 參數

- **name** (*str*) -- The name of the SQL aggregate function.
- **n\_arg** (*int*) -- The number of arguments the SQL aggregate function can accept. If `-1`, it may take any number of arguments.
- **aggregate\_class** (*class* | `None`) -- A class must implement the following methods:
  - *step()*: Add a row to the aggregate.
  - *finalize()*: Return the final result of the aggregate as *a type natively supported by SQLite*.

The number of arguments that the `step()` method must accept is controlled by `n_arg`.

Set to `None` to remove an existing SQL aggregate function.

範例:

```
class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.execute("CREATE TABLE test(i)")
cur.execute("INSERT INTO test(i) VALUES(1)")
cur.execute("INSERT INTO test(i) VALUES(2)")
cur.execute("SELECT mysum(i) FROM test")
print(cur.fetchone()[0])

con.close()
```

在 3.13 版的變更: Passing `name`, `n_arg`, and `aggregate_class` as keyword arguments is deprecated. These parameters will become positional-only in Python 3.15.

**create\_window\_function** (*name*, *num\_params*, *aggregate\_class*, /)

Create or remove a user-defined aggregate window function.

參數

- **name** (*str*) -- The name of the SQL aggregate window function to create or remove.
- **num\_params** (*int*) -- The number of arguments the SQL aggregate window function can accept. If `-1`, it may take any number of arguments.
- **aggregate\_class** (*class* | `None`) -- A class that must implement the following methods:
  - `step()`: Add a row to the current window.
  - `value()`: Return the current value of the aggregate.
  - `inverse()`: Remove a row from the current window.
  - `finalize()`: Return the final result of the aggregate as *a type natively supported by SQLite*.

The number of arguments that the `step()` and `value()` methods must accept is controlled by `num_params`.

Set to `None` to remove an existing SQL aggregate window function.

引發

**NotSupportedError** -- If used with a version of SQLite older than 3.25.0, which does not support aggregate window functions.

在 3.11 版被加入.

範例:

```
# Example taken from https://www.sqlite.org/windowfunctions.html#udfwinfunc
class WindowSumInt:
    def __init__(self):
```

(繼續下一頁)

(繼續上一頁)

```

        self.count = 0

    def step(self, value):
        """Add a row to the current window."""
        self.count += value

    def value(self):
        """Return the current value of the aggregate."""
        return self.count

    def inverse(self, value):
        """Remove a row from the current window."""
        self.count -= value

    def finalize(self):
        """Return the final value of the aggregate.

        Any clean-up actions should be placed here.
        """
        return self.count

con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE test(x, y)")
values = [
    ("a", 4),
    ("b", 5),
    ("c", 3),
    ("d", 8),
    ("e", 1),
]
cur.executemany("INSERT INTO test VALUES(?, ?)", values)
con.create_window_function("sumint", 1, WindowSumInt)
cur.execute("""
    SELECT x, sumint(y) OVER (
        ORDER BY x ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING
    ) AS sum_y
    FROM test ORDER BY x
""")
print(cur.fetchall())
con.close()

```

**create\_collation**(*name*, *callable*, /)

Create a collation named *name* using the collating function *callable*. *callable* is passed two *string* arguments, and it should return an *integer*:

- 1 if the first is ordered higher than the second
- -1 if the first is ordered lower than the second
- 0 if they are ordered equal

The following example shows a reverse sorting collation:

```

def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

```

(繼續下一頁)

```

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.execute("CREATE TABLE test(x)")
cur.executemany("INSERT INTO test(x) VALUES(?)", [("a",), ("b",)])
cur.execute("SELECT x FROM test ORDER BY x COLLATE reverse")
for row in cur:
    print(row)
con.close()

```

Remove a collation function by setting *callable* to `None`.

在 3.11 版的變更: The collation name can contain any Unicode character. Earlier, only ASCII characters were allowed.

#### **interrupt()**

Call this method from a different thread to abort any queries that might be executing on the connection. Aborted queries will raise an *OperationalError*.

#### **set\_authorizer(authorizer\_callback)**

Register *callable* *authorizer\_callback* to be invoked for each attempt to access a column of a table in the database. The callback should return one of *SQLITE\_OK*, *SQLITE\_DENY*, or *SQLITE\_IGNORE* to signal how access to the column should be handled by the underlying SQLite library.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or `None` depending on the first argument. The 4th argument is the name of the database ("main", "temp", etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or `None` if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the `sqlite3` module.

Passing `None` as *authorizer\_callback* will disable the authorizer.

在 3.11 版的變更: Added support for disabling the authorizer using `None`.

在 3.13 版的變更: Passing *authorizer\_callback* as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

#### **set\_progress\_handler(progress\_handler, n)**

Register *callable* *progress\_handler* to be invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with `None` for *progress\_handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise a *DatabaseError* exception.

在 3.13 版的變更: Passing *progress\_handler* as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

#### **set\_trace\_callback(trace\_callback)**

Register *callable* *trace\_callback* to be invoked for each SQL statement that is actually executed by the SQLite backend.

The only argument passed to the callback is the statement (as *str*) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the *Cursor.execute()* methods. Other sources include the *transaction management* of the `sqlite3` module and the execution of triggers defined in the current database.

Passing `None` as `trace_callback` will disable the trace callback.

#### 備註

Exceptions raised in the trace callback are not propagated. As a development and debugging aid, use `enable_callback_tracebacks()` to enable printing tracebacks from exceptions raised in the trace callback.

在 3.3 版被加入。

在 3.13 版的變更: Passing `trace_callback` as a keyword argument is deprecated. The parameter will become positional-only in Python 3.15.

**enable\_load\_extension** (*enabled*, /)

Enable the SQLite engine to load SQLite extensions from shared libraries if *enabled* is `True`; else, disallow loading SQLite extensions. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

#### 備註

The `sqlite3` module is not built with loadable extension support by default, because some platforms (notably macOS) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass the `--enable-loadable-sqlite-extensions` option to **configure**.

引發一個附帶引數 `connection`、`enabled` 的稽核事件 `sqlite3.enable_load_extension`。

在 3.2 版被加入。

在 3.10 版的變更: 加入 `sqlite3.enable_load_extension` 稽核事件。

```
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("CREATE VIRTUAL TABLE recipe USING fts3(name, ingredients)")
con.executescript("""
    INSERT INTO recipe (name, ingredients) VALUES('broccoli stew', 'broccoli_
↪peppers cheese tomatoes');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin stew', 'pumpkin onions_
↪garlic celery');
    INSERT INTO recipe (name, ingredients) VALUES('broccoli pie', 'broccoli cheese_
↪onions flour');
    INSERT INTO recipe (name, ingredients) VALUES('pumpkin pie', 'pumpkin sugar_
↪flour butter');
    """)
for row in con.execute("SELECT rowid, name, ingredients FROM recipe WHERE name_
↪MATCH 'pie'"):
    print(row)
```

**load\_extension** (*path*, /, \*, *entrypoint*=None)

Load an SQLite extension from a shared library. Enable extension loading with `enable_load_extension()` before calling this method.

#### 參數

- **path** (`str`) -- The path to the SQLite extension.
- **entrypoint** (`str` | `None`) -- Entry point name. If `None` (the default), SQLite will come up with an entry point name of its own; see the SQLite docs [Loading an Extension](#) for details.

引發一個附帶引數 `connection`、`path` 的稽核事件 `sqlite3.load_extension`。

在 3.2 版被加入。

在 3.10 版的變更: 加入 `sqlite3.load_extension` 稽核事件。

在 3.12 版的變更: 新增 `entrypoint` 參數。

**iterdump** (`*`, `filter=None`)

Return an *iterator* to dump the database as SQL source code. Useful when saving an in-memory database for later restoration. Similar to the `.dump` command in the `sqlite3` shell.

#### 參數

- **filter** (`str` | `None`) -- An optional `LIKE` pattern for database objects to dump, e.g. `prefix_*`. If `None` (the default), all database objects will be included.

範例:

```
# Convert file example.db to SQL dump file dump.sql
con = sqlite3.connect('example.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
con.close()
```

#### 也參考

[How to handle non-UTF-8 text encodings](#)

在 3.13 版的變更: 新增 `filter` 參數。

**backup** (`target`, `*`, `pages=-1`, `progress=None`, `name='main'`, `sleep=0.250`)

Create a backup of an SQLite database.

Works even if the database is being accessed by other clients or concurrently by the same connection.

#### 參數

- **target** (`Connection`) -- The database connection to save the backup to.
- **pages** (`int`) -- The number of pages to copy at a time. If equal to or less than 0, the entire database is copied in a single step. Defaults to `-1`.
- **progress** (`callback` | `None`) -- If set to a *callable*, it is invoked with three integer arguments for every backup iteration: the *status* of the last iteration, the *remaining* number of pages still to be copied, and the *total* number of pages. Defaults to `None`.
- **name** (`str`) -- The name of the database to back up. Either `"main"` (the default) for the main database, `"temp"` for the temporary database, or the name of a custom database as attached using the `ATTACH DATABASE` SQL statement.
- **sleep** (`float`) -- The number of seconds to sleep between successive attempts to back up remaining pages.

Example 1, copy an existing database into another:

```
def progress(status, remaining, total):
    print(f'Copied {total-remaining} of {total} pages...')

src = sqlite3.connect('example.db')
dst = sqlite3.connect('backup.db')
with dst:
    src.backup(dst, pages=1, progress=progress)
dst.close()
src.close()
```

Example 2, copy an existing database into a transient copy:

```
src = sqlite3.connect('example.db')
dst = sqlite3.connect(':memory:')
src.backup(dst)
dst.close()
src.close()
```

在 3.7 版被加入。

### 也參考

[How to handle non-UTF-8 text encodings](#)

**getlimit** (*category*, /)

Get a connection runtime limit.

#### 參數

**category** (*int*) -- The SQLite limit category to be queried.

#### 回傳型 F

*int*

#### 引發

**ProgrammingError** -- If *category* is not recognised by the underlying SQLite library.

Example, query the maximum length of an SQL statement for *Connection* *con* (the default is 1000000000):

```
>>> con.getlimit(sqlite3.SQLITE_LIMIT_SQL_LENGTH)
1000000000
```

在 3.11 版被加入。

**setlimit** (*category*, *limit*, /)

Set a connection runtime limit. Attempts to increase a limit above its hard upper bound are silently truncated to the hard upper bound. Regardless of whether or not the limit was changed, the prior value of the limit is returned.

#### 參數

- **category** (*int*) -- The SQLite limit category to be set.
- **limit** (*int*) -- The value of the new limit. If negative, the current limit is unchanged.

#### 回傳型 F

*int*

#### 引發

**ProgrammingError** -- If *category* is not recognised by the underlying SQLite library.

Example, limit the number of attached databases to 1 for *Connection* *con* (the default limit is 10):

```
>>> con.setlimit(sqlite3.SQLITE_LIMIT_ATTACHED, 1)
10
>>> con.getlimit(sqlite3.SQLITE_LIMIT_ATTACHED)
1
```

在 3.11 版被加入。

**getconfig** (*op*, /)

Query a boolean connection configuration option.

參數

**op** (*int*) -- A *SQLITE\_DBCONFIG* code.

回傳型

*bool*

在 3.12 版被加入。

**setconfig** (*op*, *enable=True*, /)

Set a boolean connection configuration option.

參數

- **op** (*int*) -- A *SQLITE\_DBCONFIG* code.
- **enable** (*bool*) -- True if the configuration option should be enabled (default); False if it should be disabled.

在 3.12 版被加入。

**serialize** (\*, *name='main'*)

Serialize a database into a *bytes* object. For an ordinary on-disk database file, the serialization is just a copy of the disk file. For an in-memory database or a "temp" database, the serialization is the same sequence of bytes which would be written to disk if that database were backed up to disk.

參數

**name** (*str*) -- The database name to be serialized. Defaults to "main".

回傳型

*bytes*

#### 備

This method is only available if the underlying SQLite library has the serialize API.

在 3.11 版被加入。

**deserialize** (*data*, /, \*, *name='main'*)

Deserialize a *serialized* database into a *Connection*. This method causes the database connection to disconnect from database *name*, and reopen *name* as an in-memory database based on the serialization contained in *data*.

參數

- **data** (*bytes*) -- A serialized database.
- **name** (*str*) -- The database name to deserialize into. Defaults to "main".

引發

- **OperationalError** -- If the database connection is currently involved in a read transaction or a backup operation.
- **DatabaseError** -- If *data* does not contain a valid SQLite database.
- **OverflowError** -- If *len(data)* is larger than  $2^{63} - 1$ .

**備註**

This method is only available if the underlying SQLite library has the `deserialize` API.

在 3.11 版被加入。

**autocommit**

This attribute controls **PEP 249**-compliant transaction behaviour. `autocommit` has three allowed values:

- `False`: Select **PEP 249**-compliant transaction behaviour, implying that `sqlite3` ensures a transaction is always open. Use `commit()` and `rollback()` to close transactions.

This is the recommended value of `autocommit`.

- `True`: Use SQLite's **autocommit mode**. `commit()` and `rollback()` have no effect in this mode.
- `LEGACY_TRANSACTION_CONTROL`: Pre-Python 3.12 (non-**PEP 249**-compliant) transaction control. See `isolation_level` for more details.

This is currently the default value of `autocommit`.

Changing `autocommit` to `False` will open a new transaction, and changing it to `True` will commit any pending transaction.

更多詳情請見 *Transaction control via the autocommit attribute*。

**備註**

The `isolation_level` attribute has no effect unless `autocommit` is `LEGACY_TRANSACTION_CONTROL`.

在 3.12 版被加入。

**in\_transaction**

This read-only attribute corresponds to the low-level SQLite **autocommit mode**.

`True` if a transaction is active (there are uncommitted changes), `False` otherwise.

在 3.2 版被加入。

**isolation\_level**

Controls the *legacy transaction handling mode* of `sqlite3`. If set to `None`, transactions are never implicitly opened. If set to one of `"DEFERRED"`, `"IMMEDIATE"`, or `"EXCLUSIVE"`, corresponding to the underlying SQLite transaction behaviour, *implicit transaction management* is performed.

If not overridden by the `isolation_level` parameter of `connect()`, the default is `"`, which is an alias for `"DEFERRED"`.

**備註**

Using `autocommit` to control transaction handling is recommended over using `isolation_level`. `isolation_level` has no effect unless `autocommit` is set to `LEGACY_TRANSACTION_CONTROL` (the default).

**row\_factory**

The initial `row_factory` for `Cursor` objects created from this connection. Assigning to this attribute does not affect the `row_factory` of existing cursors belonging to this connection, only new ones. Is `None` by default, meaning each row is returned as a `tuple`.

更多詳情請見 *How to create and use row factories*。

**text\_factory**

A *callable* that accepts a *bytes* parameter and returns a text representation of it. The callable is invoked for SQLite values with the `TEXT` data type. By default, this attribute is set to `str`.

更多詳情請見 [How to handle non-UTF-8 text encodings](#)。

**total\_changes**

Return the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

**Cursor 物件**

A `Cursor` object represents a *database cursor* which is used to execute SQL statements, and manage the context of a fetch operation. Cursors are created using `Connection.cursor()`, or by using any of the *connection shortcut methods*.

Cursor objects are *iterators*, meaning that if you `execute()` a `SELECT` query, you can simply iterate over the cursor to fetch the resulting rows:

```
for row in cur.execute("SELECT t FROM data"):
    print(row)
```

**class sqlite3.Cursor**

A *Cursor* instance has the following attributes and methods.

**execute(sql, parameters=(,), /)**

Execute a single SQL statement, optionally binding Python values using *placeholders*.

**參數**

- **sql** (*str*) -- 單一個 SQL 陳述式。
- **parameters** (*dict* | *sequence*) -- Python values to bind to placeholders in *sql*. A *dict* if named placeholders are used. A *sequence* if unnamed placeholders are used. See [How to use placeholders to bind values in SQL queries](#).

**引發**

**ProgrammingError** -- If *sql* contains more than one SQL statement.

If *autocommit* is `LEGACY_TRANSACTION_CONTROL`, *isolation\_level* is not `None`, *sql* is an `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statement, and there is no open transaction, a transaction is implicitly opened before executing *sql*.

Deprecated since version 3.12, will be removed in version 3.14: `DeprecationWarning` is emitted if *named placeholders* are used and *parameters* is a *sequence* instead of a *dict*. Starting with Python 3.14, `ProgrammingError` will be raised instead.

Use `executescript()` to execute multiple SQL statements.

**executemany(sql, parameters, /)**

For every item in *parameters*, repeatedly execute the *parameterized* DML (Data Manipulation Language) SQL statement *sql*.

Uses the same implicit transaction handling as `execute()`.

**參數**

- **sql** (*str*) -- A single SQL DML statement.
- **parameters** (*iterable*) -- An iterable of parameters to bind with the placeholders in *sql*. See [How to use placeholders to bind values in SQL queries](#).

**引發**

**ProgrammingError** -- If *sql* contains more than one SQL statement, or is not a DML statement.

範例：

```
rows = [
    ("row1",),
    ("row2",),
]
# cur 是一個 sqlite3.Cursor 物件
cur.executemany("INSERT INTO data VALUES(?)", rows)
```

**i 備 F**

Any resulting rows are discarded, including DML statements with **RETURNING** clauses.

Deprecated since version 3.12, will be removed in version 3.14: *DeprecationWarning* is emitted if *named placeholders* are used and the items in *parameters* are sequences instead of *dicts*. Starting with Python 3.14, *ProgrammingError* will be raised instead.

**executescript** (*sql\_script*, /)

Execute the SQL statements in *sql\_script*. If the *autocommit* is *LEGACY\_TRANSACTION\_CONTROL* and there is a pending transaction, an implicit **COMMIT** statement is executed first. No other implicit transaction control is performed; any transaction control must be added to *sql\_script*.

*sql\_script* must be a *string*.

範例:

```
# cur 是一個 sqlite3.Cursor 物件
cur.executescript("""
    BEGIN;
    CREATE TABLE person(firstname, lastname, age);
    CREATE TABLE book(title, author, published);
    CREATE TABLE publisher(name, address);
    COMMIT;
""")
```

**fetchone** ()

If *row\_factory* is *None*, return the next row query result set as a *tuple*. Else, pass it to the row factory and return its result. Return *None* if no more data is available.

**fetchmany** (*size=cursor.arraysize*)

Return the next set of rows of a query result as a *list*. Return an empty list if no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If *size* is not given, *arraysize* determines the number of rows to be fetched. If fewer than *size* rows are available, as many rows as are available are returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the *arraysize* attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany* () call to the next.

**fetchall** ()

Return all (remaining) rows of a query result as a *list*. Return an empty list if no rows are available. Note that the *arraysize* attribute can affect the performance of this operation.

**close** ()

Close the cursor now (rather than whenever `__del__` is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

**setinputsizes** (*sizes*, /)

Required by the DB-API. Does nothing in *sqlite3*.

**setoutputsize** (*size*, *column=None*, */*)

Required by the DB-API. Does nothing in `sqlite3`.

**arraysize**

Read/write attribute that controls the number of rows returned by `fetchmany()`. The default value is 1 which means a single row would be fetched per call.

**connection**

Read-only attribute that provides the SQLite database `Connection` belonging to the cursor. A `Cursor` object created by calling `con.cursor()` will have a `connection` attribute that refers to `con`:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
>>> con.close()
```

**description**

Read-only attribute that provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are `None`.

It is set for `SELECT` statements without any matching rows as well.

**lastrowid**

Read-only attribute that provides the row id of the last inserted row. It is only updated after successful `INSERT` or `REPLACE` statements using the `execute()` method. For other statements, after `executemany()` or `executescript()`, or if the insertion failed, the value of `lastrowid` is left unchanged. The initial value of `lastrowid` is `None`.

#### 備 F

Inserts into `WITHOUT ROWID` tables are not recorded.

在 3.6 版的變更: 新增 `REPLACE` 陳述式的支援。

**rowcount**

Read-only attribute that provides the number of modified rows for `INSERT`, `UPDATE`, `DELETE`, and `REPLACE` statements; is `-1` for other statements, including CTE (Common Table Expression) queries. It is only updated by the `execute()` and `executemany()` methods, after the statement has run to completion. This means that any resulting rows must be fetched in order for `rowcount` to be updated.

**row\_factory**

Control how a row fetched from this `Cursor` is represented. If `None`, a row is represented as a `tuple`. Can be set to the included `sqlite3.Row`; or a `callable` that accepts two arguments, a `Cursor` object and the `tuple` of row values, and returns a custom object representing an SQLite row.

Defaults to what `Connection.row_factory` was set to when the `Cursor` was created. Assigning to this attribute does not affect `Connection.row_factory` of the parent connection.

更多詳情請見 [How to create and use row factories](#)。

## Row 物件

**class** `sqlite3.Row`

A `Row` instance serves as a highly optimized `row_factory` for `Connection` objects. It supports iteration, equality testing, `len()`, and `mapping` access by column name and index.

Two `Row` objects compare equal if they have identical column names and values.

更多詳情請見 [How to create and use row factories](#)。

**keys()**

Return a *list* of column names as *strings*. Immediately after a query, it is the first member of each tuple in *Cursor.description*.

在 3.5 版的變更: 新增對切片的支援。

**Blob 物件****class** sqlite3.Blob

在 3.11 版被加入。

A *Blob* instance is a *file-like object* that can read and write data in an SQLite BLOB. Call *len(blob)* to get the size (number of bytes) of the blob. Use indices and *slices* for direct access to the blob data.

Use the *Blob* as a *context manager* to ensure that the blob handle is closed after use.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE test(blob_col blob)")
con.execute("INSERT INTO test(blob_col) VALUES(zeroblob(13))")

# Write to our blob, using two write operations:
with con.blobopen("test", "blob_col", 1) as blob:
    blob.write(b"hello, ")
    blob.write(b"world.")
    # Modify the first and last bytes of our blob
    blob[0] = ord("H")
    blob[-1] = ord("!")

# Read the contents of our blob
with con.blobopen("test", "blob_col", 1) as blob:
    greeting = blob.read()

print(greeting) # outputs "b'Hello, world!'"
con.close()
```

**close()**

Close the blob.

The blob will be unusable from this point onward. An *Error* (or subclass) exception will be raised if any further operation is attempted with the blob.

**read**(length=-1, /)

Read *length* bytes of data from the blob at the current offset position. If the end of the blob is reached, the data up to EOF (End of File) will be returned. When *length* is not specified, or is negative, *read()* will read until the end of the blob.

**write**(data, /)

Write *data* to the blob at the current offset. This function cannot change the blob length. Writing beyond the end of the blob will raise *ValueError*.

**tell()**

Return the current access position of the blob.

**seek**(offset, origin=os.SEEK\_SET, /)

Set the current access position of the blob to *offset*. The *origin* argument defaults to *os.SEEK\_SET* (absolute blob positioning). Other values for *origin* are *os.SEEK\_CUR* (seek relative to the current position) and *os.SEEK\_END* (seek relative to the blob's end).

## PrepareProtocol 物件

**class** `sqlite3.PrepareProtocol`

The PrepareProtocol type's single purpose is to act as a [PEP 246](#) style adaption protocol for objects that can *adapt themselves* to *native SQLite types*.

## 例外

The exception hierarchy is defined by the DB-API 2.0 ([PEP 249](#)).

**exception** `sqlite3.Warning`

This exception is not currently raised by the `sqlite3` module, but may be raised by applications using `sqlite3`, for example if a user-defined function truncates data while inserting. `Warning` is a subclass of `Exception`.

**exception** `sqlite3.Error`

The base class of the other exceptions in this module. Use this to catch all errors with one single `except` statement. `Error` is a subclass of `Exception`.

If the exception originated from within the SQLite library, the following two attributes are added to the exception:

**sqlite\_errorcode**

The numeric error code from the [SQLite API](#)

在 3.11 版被加入。

**sqlite\_errormsg**

The symbolic name of the numeric error code from the [SQLite API](#)

在 3.11 版被加入。

**exception** `sqlite3.InterfaceError`

Exception raised for misuse of the low-level SQLite C API. In other words, if this exception is raised, it probably indicates a bug in the `sqlite3` module. `InterfaceError` is a subclass of `Error`.

**exception** `sqlite3.DatabaseError`

Exception raised for errors that are related to the database. This serves as the base exception for several types of database errors. It is only raised implicitly through the specialised subclasses. `DatabaseError` is a subclass of `Error`.

**exception** `sqlite3.DataError`

Exception raised for errors caused by problems with the processed data, like numeric values out of range, and strings which are too long. `DataError` is a subclass of `DatabaseError`.

**exception** `sqlite3.OperationalError`

Exception raised for errors that are related to the database's operation, and not necessarily under the control of the programmer. For example, the database path is not found, or a transaction could not be processed. `OperationalError` is a subclass of `DatabaseError`.

**exception** `sqlite3.IntegrityError`

Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of `DatabaseError`.

**exception** `sqlite3.InternalError`

Exception raised when SQLite encounters an internal error. If this is raised, it may indicate that there is a problem with the runtime SQLite library. `InternalError` is a subclass of `DatabaseError`.

**exception** `sqlite3.ProgrammingError`

Exception raised for `sqlite3` API programming errors, for example supplying the wrong number of bindings to a query, or trying to operate on a closed `Connection`. `ProgrammingError` is a subclass of `DatabaseError`.

**exception** `sqlite3.NotSupportedError`

Exception raised in case a method or database API is not supported by the underlying SQLite library. For example, setting *deterministic* to `True` in `create_function()`, if the underlying SQLite library does not support deterministic functions. `NotSupportedError` is a subclass of `DatabaseError`.

**SQLite and Python types**

SQLite natively supports the following types: `NULL`, `INTEGER`, `REAL`, `TEXT`, `BLOB`.

The following Python types can thus be sent to SQLite without any problem:

Python type	SQLite type
<code>None</code>	<code>NULL</code>
<code>int</code>	<code>INTEGER</code>
<code>float</code>	<code>REAL</code>
<code>str</code>	<code>TEXT</code>
<code>bytes</code>	<code>BLOB</code>

This is how SQLite types are converted to Python types by default:

SQLite type	Python type
<code>NULL</code>	<code>None</code>
<code>INTEGER</code>	<code>int</code>
<code>REAL</code>	<code>float</code>
<code>TEXT</code>	depends on <code>text_factory</code> , <code>str</code> by default
<code>BLOB</code>	<code>bytes</code>

The type system of the `sqlite3` module is extensible in two ways: you can store additional Python types in an SQLite database via *object adapters*, and you can let the `sqlite3` module convert SQLite types to Python types via *converters*.

**Default adapters and converters (deprecated)****備註**

The default adapters and converters are deprecated as of Python 3.12. Instead, use the *Adapter and converter recipes* and tailor them to your needs.

The deprecated default adapters and converters consist of:

- An adapter for `datetime.date` objects to *strings* in ISO 8601 format.
- An adapter for `datetime.datetime` objects to strings in ISO 8601 format.
- A converter for *declared* "date" types to `datetime.date` objects.
- A converter for *declared* "timestamp" types to `datetime.datetime` objects. Fractional parts will be truncated to 6 digits (microsecond precision).

**備註**

The default "timestamp" converter ignores UTC offsets in the database and always returns a naive `datetime.datetime` object. To preserve UTC offsets in timestamps, either leave converters disabled, or register an offset-aware converter with `register_converter()`.

在 3.12 版之後被 用。

## 命令列介面

The `sqlite3` module can be invoked as a script, using the interpreter's `-m` switch, in order to provide a simple SQLite shell. The argument signature is as follows:

```
python -m sqlite3 [-h] [-v] [filename] [sql]
```

Type `.quit` or CTRL-D to exit the shell.

**-h, --help**

Print CLI help.

**-v, --version**

Print underlying SQLite library version.

在 3.12 版被加入。

## 12.6.3 How-to guides

### How to use placeholders to bind values in SQL queries

SQL operations usually need to use values from Python variables. However, beware of using Python's string operations to assemble queries, as they are vulnerable to [SQL injection attacks](#). For example, an attacker can simply close the single quote and inject `OR TRUE` to select all rows:

```
>>> # Never do this -- insecure!
>>> symbol = input()
' OR TRUE; --
>>> sql = "SELECT * FROM stocks WHERE symbol = '%s'" % symbol
>>> print(sql)
SELECT * FROM stocks WHERE symbol = '' OR TRUE; --'
>>> cur.execute(sql)
```

Instead, use the DB-API's parameter substitution. To insert a variable into a query string, use a placeholder in the string, and substitute the actual values into the query by providing them as a *tuple* of values to the second argument of the cursor's `execute()` method.

An SQL statement may use one of two kinds of placeholders: question marks (qmark style) or named placeholders (named style). For the qmark style, *parameters* must be a *sequence* whose length must match the number of placeholders, or a *ProgrammingError* is raised. For the named style, *parameters* must be an instance of a *dict* (or a subclass), which must contain keys for all named parameters; any extra items are ignored. Here's an example of both styles:

```
con = sqlite3.connect(":memory:")
cur = con.execute("CREATE TABLE lang(name, first_appeared)")

# This is the named style used with executemany():
data = (
    {"name": "C", "year": 1972},
    {"name": "Fortran", "year": 1957},
    {"name": "Python", "year": 1991},
    {"name": "Go", "year": 2009},
)
cur.executemany("INSERT INTO lang VALUES(:name, :year)", data)

# This is the qmark style used in a SELECT query:
params = (1972,)
cur.execute("SELECT * FROM lang WHERE first_appeared = ?", params)
print(cur.fetchall())
con.close()
```

**i 備**

**PEP 249** numeric placeholders are *not* supported. If used, they will be interpreted as named placeholders.

## How to adapt custom Python types to SQLite values

SQLite supports only a limited set of data types natively. To store custom Python types in SQLite databases, *adapt* them to one of the *Python types SQLite natively understands*.

There are two ways to adapt Python objects to SQLite types: letting your object adapt itself, or using an *adapter callable*. The latter will take precedence above the former. For a library that exports a custom type, it may make sense to enable that type to adapt itself. As an application developer, it may make more sense to take direct control by registering custom adapter functions.

## How to write adaptable objects

Suppose we have a `Point` class that represents a pair of coordinates, `x` and `y`, in a Cartesian coordinate system. The coordinate pair will be stored as a text string in the database, using a semicolon to separate the coordinates. This can be implemented by adding a `__conform__(self, protocol)` method which returns the adapted value. The object passed to *protocol* will be of type `PrepareProtocol`.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return f"{self.x};{self.y}"

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(4.0, -3.2),))
print(cur.fetchone()[0])
con.close()
```

## How to register adapter callables

The other possibility is to create a function that converts the Python object to an SQLite-compatible type. This function can then be registered using `register_adapter()`.

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return f"{point.x};{point.y}"

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

cur.execute("SELECT ?", (Point(1.0, 2.5),))
print(cur.fetchone()[0])
con.close()
```

## How to convert SQLite values to custom Python types

Writing an adapter lets you convert *from* custom Python types *to* SQLite values. To be able to convert *from* SQLite values *to* custom Python types, we use *converters*.

Let's go back to the `Point` class. We stored the `x` and `y` coordinates separated via semicolons as strings in SQLite. First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

### 備F

Converter functions are **always** passed a *bytes* object, no matter the underlying SQLite data type.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

We now need to tell `sqlite3` when it should convert a given SQLite value. This is done when connecting to a database, using the `detect_types` parameter of `connect()`. There are three options:

- Implicit: set `detect_types` to `PARSE_DECLTYPES`
- Explicit: set `detect_types` to `PARSE_COLNAMES`
- Both: set `detect_types` to `sqlite3.PARSE_DECLTYPES | sqlite3.PARSE_COLNAMES`. Column names take precedence over declared types.

The following example illustrates the implicit and explicit approaches:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return f"Point({self.x}, {self.y})"

def adapt_point(point):
    return f"{point.x};{point.y}"

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter and converter
sqlite3.register_adapter(Point, adapt_point)
sqlite3.register_converter("point", convert_point)

# 1) Parse using declared types
p = Point(4.0, -3.2)
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.execute("CREATE TABLE test(p point)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
cur.execute("SELECT p FROM test")
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()

# 2) Parse using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.execute("CREATE TABLE test(p)")

cur.execute("INSERT INTO test(p) VALUES(?)", (p,))
```

(繼續下一頁)

(繼續上一頁)

```

cur.execute('SELECT p AS "p [point]" FROM test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()

```

## Adapter and converter recipes

This section shows recipes for common adapters and converters.

```

import datetime
import sqlite3

def adapt_date_iso(val):
    """Adapt datetime.date to ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_iso(val):
    """Adapt datetime.datetime to timezone-naive ISO 8601 date."""
    return val.isoformat()

def adapt_datetime_epoch(val):
    """Adapt datetime.datetime to Unix timestamp."""
    return int(val.timestamp())

sqlite3.register_adapter(datetime.date, adapt_date_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_iso)
sqlite3.register_adapter(datetime.datetime, adapt_datetime_epoch)

def convert_date(val):
    """Convert ISO 8601 date to datetime.date object."""
    return datetime.date.fromisoformat(val.decode())

def convert_datetime(val):
    """Convert ISO 8601 datetime to datetime.datetime object."""
    return datetime.datetime.fromisoformat(val.decode())

def convert_timestamp(val):
    """Convert Unix epoch timestamp to datetime.datetime object."""
    return datetime.datetime.fromtimestamp(int(val))

sqlite3.register_converter("date", convert_date)
sqlite3.register_converter("datetime", convert_datetime)
sqlite3.register_converter("timestamp", convert_timestamp)

```

## How to use connection shortcut methods

Using the `execute()`, `executemany()`, and `executescript()` methods of the `Connection` class, your code can be written more concisely because you don't have to create the (often superfluous) `Cursor` objects explicitly. Instead, the `Cursor` objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a `SELECT` statement and iterate over it directly using only a single call on the `Connection` object.

```

# Create and fill the table.
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(name, first_appeared)")
data = [
    ("C++", 1985),
    ("Objective-C", 1984),
]
con.executemany("INSERT INTO lang(name, first_appeared) VALUES(?, ?)", data)

```

(繼續下一頁)

(繼續上一頁)

```
# Print the table contents
for row in con.execute("SELECT name, first_appeared FROM lang"):
    print(row)

print("I just deleted", con.execute("DELETE FROM lang").rowcount, "rows")

# close() is not a shortcut method and it's not called automatically;
# the connection object should be closed manually
con.close()
```

### How to use the connection context manager

A `Connection` object can be used as a context manager that automatically commits or rolls back open transactions when leaving the body of the context manager. If the body of the `with` statement finishes without exceptions, the transaction is committed. If this commit fails, or if the body of the `with` statement raises an uncaught exception, the transaction is rolled back. If `autocommit` is `False`, a new transaction is implicitly opened after committing or rolling back.

If there is no open transaction upon leaving the body of the `with` statement, or if `autocommit` is `True`, the context manager does nothing.

#### 備註

The context manager neither implicitly opens a new transaction nor closes the connection. If you need a closing context manager, consider using `contextlib.closing()`.

```
con = sqlite3.connect(":memory:")
con.execute("CREATE TABLE lang(id INTEGER PRIMARY KEY, name VARCHAR UNIQUE)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))

# con.rollback() is called after the with block finishes with an exception,
# the exception is still raised and must be caught
try:
    with con:
        con.execute("INSERT INTO lang(name) VALUES(?)", ("Python",))
except sqlite3.IntegrityError:
    print("couldn't add Python twice")

# Connection object used as context manager only commits or rollbacks transactions,
# so the connection object should be closed manually
con.close()
```

### How to work with SQLite URIs

Some useful URI tricks include:

- Open a database in read-only mode:

```
>>> con = sqlite3.connect("file:tutorial.db?mode=ro", uri=True)
>>> con.execute("CREATE TABLE readonly(data)")
Traceback (most recent call last):
OperationalError: attempt to write a readonly database
>>> con.close()
```

- Do not implicitly create a new database file if it does not already exist; will raise `OperationalError` if unable to create a new file:

```
>>> con = sqlite3.connect("file:nosuchdb.db?mode=rw", uri=True)
Traceback (most recent call last):
OperationalError: unable to open database file
```

- Create a shared named in-memory database:

```
db = "file:mem1?mode=memory&cache=shared"
con1 = sqlite3.connect(db, uri=True)
con2 = sqlite3.connect(db, uri=True)
with con1:
    con1.execute("CREATE TABLE shared(data)")
    con1.execute("INSERT INTO shared VALUES(28)")
res = con2.execute("SELECT data FROM shared")
assert res.fetchone() == (28,)

con1.close()
con2.close()
```

More information about this feature, including a list of parameters, can be found in the [SQLite URI documentation](#).

### How to create and use row factories

By default, `sqlite3` represents each row as a *tuple*. If a *tuple* does not suit your needs, you can use the `sqlite3.Row` class or a custom `row_factory`.

While `row_factory` exists as an attribute both on the `Cursor` and the `Connection`, it is recommended to set `Connection.row_factory`, so all cursors created from the connection will use the same row factory.

`Row` provides indexed and case-insensitive named access to columns, with minimal memory overhead and performance impact over a *tuple*. To use `Row` as a row factory, assign it to the `row_factory` attribute:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = sqlite3.Row
```

Queries now return `Row` objects:

```
>>> res = con.execute("SELECT 'Earth' AS name, 6378 AS radius")
>>> row = res.fetchone()
>>> row.keys()
['name', 'radius']
>>> row[0]           # Access by index.
'Earth'
>>> row["name"]     # Access by name.
'Earth'
>>> row["RADIUS"]   # Column names are case-insensitive.
6378
>>> con.close()
```

#### 備註

The `FROM` clause can be omitted in the `SELECT` statement, as in the above example. In such cases, `SQLite` returns a single row with columns defined by expressions, e.g. literals, with the given aliases `expr AS alias`.

You can create a custom `row_factory` that returns each row as a *dict*, with column names mapped to values:

```
def dict_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    return {key: value for key, value in zip(fields, row)}
```

Using it, queries now return a *dict* instead of a *tuple*:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = dict_factory
>>> for row in con.execute("SELECT 1 AS a, 2 AS b"):
...     print(row)
{'a': 1, 'b': 2}
>>> con.close()
```

The following row factory returns a *named tuple*:

```
from collections import namedtuple

def namedtuple_factory(cursor, row):
    fields = [column[0] for column in cursor.description]
    cls = namedtuple("Row", fields)
    return cls._make(row)
```

`namedtuple_factory()` can be used as follows:

```
>>> con = sqlite3.connect(":memory:")
>>> con.row_factory = namedtuple_factory
>>> cur = con.execute("SELECT 1 AS a, 2 AS b")
>>> row = cur.fetchone()
>>> row
Row(a=1, b=2)
>>> row[0] # Indexed access.
1
>>> row.b # Attribute access.
2
>>> con.close()
```

With some adjustments, the above recipe can be adapted to use a *dataclass*, or any other custom class, instead of a *namedtuple*.

### How to handle non-UTF-8 text encodings

By default, `sqlite3` uses `str` to adapt SQLite values with the `TEXT` data type. This works well for UTF-8 encoded text, but it might fail for other encodings and invalid UTF-8. You can use a custom `text_factory` to handle such cases.

Because of SQLite's *flexible typing*, it is not uncommon to encounter table columns with the `TEXT` data type containing non-UTF-8 encodings, or even arbitrary data. To demonstrate, let's assume we have a database with ISO-8859-2 (Latin-2) encoded text, for example a table of Czech-English dictionary entries. Assuming we now have a `Connection` instance `con` connected to this database, we can decode the Latin-2 encoded text using this `text_factory`:

```
con.text_factory = lambda data: str(data, encoding="latin2")
```

For invalid UTF-8 or arbitrary data in stored in `TEXT` table columns, you can use the following technique, borrowed from the `unicode-howto`:

```
con.text_factory = lambda data: str(data, errors="surrogateescape")
```

#### 備註

The `sqlite3` module API does not support strings containing surrogates.

unicode-howto

## 12.6.4 解釋

### Transaction control

`sqlite3` offers multiple methods of controlling whether, when and how database transactions are opened and closed. *Transaction control via the `autocommit` attribute* is recommended, while *Transaction control via the `isolation_level` attribute* retains the pre-Python 3.12 behaviour.

### Transaction control via the `autocommit` attribute

The recommended way of controlling transaction behaviour is through the `Connection.autocommit` attribute, which should preferably be set using the `autocommit` parameter of `connect()`.

It is suggested to set `autocommit` to `False`, which implies **PEP 249**-compliant transaction control. This means:

- `sqlite3` ensures that a transaction is always open, so `connect()`, `Connection.commit()`, and `Connection.rollback()` will implicitly open a new transaction (immediately after closing the pending one, for the latter two). `sqlite3` uses `BEGIN DEFERRED` statements when opening transactions.
- Transactions should be committed explicitly using `commit()`.
- Transactions should be rolled back explicitly using `rollback()`.
- An implicit rollback is performed if the database is `close()`-ed with pending changes.

Set `autocommit` to `True` to enable SQLite's `autocommit` mode. In this mode, `Connection.commit()` and `Connection.rollback()` have no effect. Note that SQLite's `autocommit` mode is distinct from the **PEP 249**-compliant `Connection.autocommit` attribute; use `Connection.in_transaction` to query the low-level SQLite `autocommit` mode.

Set `autocommit` to `LEGACY_TRANSACTION_CONTROL` to leave transaction control behaviour to the `Connection.isolation_level` attribute. See *Transaction control via the `isolation_level` attribute* for more information.

### Transaction control via the `isolation_level` attribute

The recommended way of controlling transactions is via the `autocommit` attribute. See *Transaction control via the `autocommit` attribute*.

If `Connection.autocommit` is set to `LEGACY_TRANSACTION_CONTROL` (the default), transaction behaviour is controlled using the `Connection.isolation_level` attribute. Otherwise, `isolation_level` has no effect.

If the connection attribute `isolation_level` is not `None`, new transactions are implicitly opened before `execute()` and `executemany()` executes `INSERT`, `UPDATE`, `DELETE`, or `REPLACE` statements; for other statements, no implicit transaction handling is performed. Use the `commit()` and `rollback()` methods to respectively commit and roll back pending transactions. You can choose the underlying SQLite transaction behaviour—that is, whether and what type of `BEGIN` statements `sqlite3` implicitly executes—via the `isolation_level` attribute.

If `isolation_level` is set to `None`, no transactions are implicitly opened at all. This leaves the underlying SQLite library in `autocommit` mode, but also allows the user to perform their own transaction handling using explicit SQL statements. The underlying SQLite library `autocommit` mode can be queried using the `in_transaction` attribute.

The `executescript()` method implicitly commits any pending transaction before execution of the given SQL script, regardless of the value of `isolation_level`.

在 3.6 版的變更: `sqlite3` used to implicitly commit an open transaction before DDL statements. This is no longer the case.

在 3.12 版的變更: The recommended way of controlling transactions is now via the `autocommit` attribute.

## 資料壓縮與保存

本章中描述的模組支援使用 `zlib`、`gzip`、`bzip2` 和 `lzma` 演算法進行資料壓縮，以及建立 ZIP 和 tar 格式的存檔。另請參閱 `shutil` 模組提供的 *Archiving operations*。

### 13.1 `zlib` --- 相容於 `gzip` 的壓縮

對於需要資料壓縮的應用程式，此模組提供了能使用 `zlib` 函式庫進行壓縮和解壓縮的函式。`zlib` 函式庫有自己的主頁 <https://www.zlib.net>。已知 Python 模組與早於 1.1.3 的 `zlib` 函式庫版本之間不相容；1.1.3 存在安全漏洞，因此我們建議使用 1.1.4 或更新的版本。

`zlib` 的函式有很多選項，且通常需要按特定順序使用。本文件不打算解所有選項排列組合的效果；相關官方資訊，請參閱 <http://www.zlib.net/manual.html> 上的 `zlib` 手冊。

若要讀寫 `.gz` 文件，請參閱 `gzip` 模組。

該模組中可用的例外和函式是：

**exception** `zlib.error`

當壓縮和解壓縮發生錯誤時引發的例外。

`zlib.adler32(data[, value])`

計算 `data` 的 Adler-32 核對和 (checksum)。(Adler-32 核對和幾乎與 CRC32 一樣可靠，但計算速度更快。) 結果是一個 unsigned (無符號的) 32-bit 整數。如果有提供 `value`，則將其用作核對和的起始值，否則使用預設值 1。傳入 `value` 允許了於多個輸入的串聯 (concatenation) 上計算核對和。該演算法的加密度不高，不該用於身份驗證 (authentication) 或數位簽章 (digital signature)。由於該演算法是核對和演算法而設計的，它不適合作通用的雜演算法。

在 3.0 版的變更：結果總是 unsigned。

`zlib.compress(data, /, level=-1, wbits=MAX_WBITS)`

壓縮 `data` 中的位元組，回傳一個包含壓縮資料的位元組物件。`level` 是從 0 到 9 或 -1 的整數，控制了壓縮的級；1 (`Z_BEST_SPEED`) 最快但壓縮程度較小，9 (`Z_BEST_COMPRESSION`) 最慢但壓縮最多。0 (`Z_NO_COMPRESSION`) 代表不壓縮。預設值 -1 (`Z_DEFAULT_COMPRESSION`)。`Z_DEFAULT_COMPRESSION` 表示預設的速度和壓縮間折衷方案 (目前相當於級 6)。

`wbits` 引數控制了壓縮資料時所使用的歷史緩衝區 (history buffer) 大小 (或「視窗大小」)，以及輸出中是否包含標題和尾末 (trailer)。它可以應用多個值的範圍，預設 15 (`MAX_WBITS`)：

- +9 到 +15: 視窗大小的以二為底的對數，因此範圍在 512 到 32768 之間。較大的值會生成更佳的壓縮，但會用更多的記憶體。生成輸出將包含特定於 `zlib` 的標頭和尾末。
- -9 到 -15: 使用 `wbits` 的對值作視窗大小的對數，同時生成有標頭或尾末核對和的原始輸出串流。
- +25 到 +31 = 16 + (9 到 15): 使用數值的最低 4 位元作視窗大小的對數，同時在輸出中包含基本的 `gzip` 標頭和尾末核對和。

如果發生任何錯誤，則引發 `error` 例外。

在 3.6 版的變更: `level` 現在可以用作關鍵字參數。

在 3.11 版的變更: `wbits` 參數現在可用於設定視窗位元和壓縮型。

```
zlib.compressobj(level=-1, method=DEFLATED, wbits=MAX_WBITS, memLevel=DEF_MEM_LEVEL,
                 strategy=Z_DEFAULT_STRATEGY[, zdict])
```

回傳一個壓縮物件，用於壓縮不能一次全部放入記憶體中的資料串流。

`level` 是壓縮級 -- 從 0 到 9 或 -1 的整數。1 (`Z_BEST_SPEED`) 最快但壓縮程度較小，而 9 (`Z_BEST_COMPRESSION`) 最慢但壓縮最多。0 (`Z_NO_COMPRESSION`) 代表不壓縮。預設值 -1 (`Z_DEFAULT_COMPRESSION`)。 `Z_DEFAULT_COMPRESSION` 表示預設的速度和壓縮間折衷方案（目前相當於級 6）。

`method` 代表壓縮演算法。目前唯一支援的值是 `DEFLATED`。

`wbits` 參數控制歷史緩衝區的大小（或「視窗大小」），以及將使用的標頭和尾末格式。它與前面述的 `compress()` 具有相同的含義。

`memLevel` 引數控制用於壓縮狀態的記憶體大小。有效值範圍 1 到 9。較高的值會使用更多的記憶體，但速度更快生成更小的輸出。

`strategy` 被用於調整壓縮演算法。可用的值 `Z_DEFAULT_STRATEGY`、`Z_FILTERED`、`Z_HUFFMAN_ONLY`、`Z_RLE` (`zlib` 1.2.0.1) 和 `Z_FIXED` (`zlib` 1.2.2.2)。

`zdict` 是事先定義好的壓縮字典。這是一個位元組序列（例如一個 `bytes` 物件），其中包含預期在要壓縮的資料中頻繁出現的子序列。那些預期會最常見的子序列應該出現在字典的尾末。

在 3.3 版的變更: 新增 `zdict` 參數與支援關鍵字引數。

```
zlib.crc32(data[, value])
```

計算 `data` 的 CRC (Cyclic Redundancy Check, 循環冗余核對) 核對和，結果會是一個 unsigned 32-bit 整數。如果 `value` 存在，則將其用作核對和的起始值，否則使用預設值 0。傳入 `value` 允許在多個輸入的串聯上計算核對和。該演算法的加密度不高，不該用於身份驗證或數位簽章。由於該演算法是核對和演算法而設計的，它不適合通用的雜演算法。

在 3.0 版的變更: 結果總是 unsigned。

```
zlib.decompress(data, /, wbits=MAX_WBITS, bufsize=DEF_BUF_SIZE)
```

解壓縮 `data` 中的位元組，回傳包含未壓縮資料的位元組物件。`wbits` 參數依賴於 `data` 的格式，下面將進一步討論。如果有給定 `bufsize`，它會被用作輸出緩衝區的初始大小。如果發生任何錯誤，則引發 `error` 例外。

`wbits` 參數控制歷史緩衝區的大小（或「視窗大小」），以及期望的標頭和尾末格式。它類似於 `compressobj()` 的參數，但接受更多範圍的值：

- +8 到 +15: 視窗大小的以二為底的對數。輸入必須包括一個 `zlib` 標頭和尾末。
- 0: 根據 `zlib` 標頭檔自動定視窗大小。僅有在 `zlib` 1.2.3.5 或更新的版本支援。
- -8 to -15: 使用 `wbits` 的對值作視窗大小的對數，輸入必須是有標頭或尾末的原始串流。
- +24 到 +31 = 16 + (8 到 15): 取值的最低 4 位元作視窗大小的對數，輸入必須包含 `gzip` 標頭和尾末。
- +40 到 +47 = 32 + (8 到 15): 使用值的最低 4 位元作視窗大小的對數，自動接受 `zlib` 或 `gzip` 格式。

當解壓縮一個串流時，視窗大小不得小於最初用於壓縮串流的大小；使用太小的值可能會導致 `error` 例外。預設的 `wbits` 值對應於最大的視窗大小，且需要包含 `zlib` 標頭和尾末。

`bufsize` 是用於保存解壓縮資料的緩衝區的初始大小。如果需要更多空間，緩衝區大小將根據需求來增加，因此你不需要讓該值完全剛好；調整它只會節省幾次對 `malloc()` 的呼叫。

在 3.6 版的變更：`wbits` 和 `bufsize` 可以用作關鍵字引數。

`zlib.decompressobj(wbits=MAX_WBITS[, zdict])`

回傳一個解壓縮物件，用於解壓縮不能一次全部放入記憶體中的資料串流。

`wbits` 引數控制歷史緩衝區的大小（或「視窗大小」），以及期望的標頭和尾末格式。它與前面述的 `decompress()` 具有相同的含義。

`zdict` 參數指定是先定義好的壓縮字典。如果有提供，這必須與生成要解壓縮資料的壓縮器所使用的字典相同。

#### 備

如果 `zdict` 是一個可變物件 (mutable object) (例如一個 `bytearray`)，你不能在呼叫 `decompressobj()` 和第一次呼叫解壓縮器的 `decompress()` 方法之間修改它的內容。

在 3.3 版的變更：新增 `zdict` 參數。

壓縮物件支援以下方法：

`Compress.compress(data)`

壓縮 `data`，回傳一個位元組物件，其中至少包含 `data` 中部分資料的壓縮資料。此資料應串聯到任何先前呼叫 `compress()` 方法所生的輸出。一些輸入可能會保存在內部緩衝區中以供後續處理。

`Compress.flush([mode])`

處理所有待處理的輸入，回傳包含剩餘壓縮輸出的位元組物件。`mode` 可以從以下常數中選擇：`Z_NO_FLUSH`、`Z_PARTIAL_FLUSH`、`Z_SYNC_FLUSH`、`Z_FULL_FLUSH`、`Z_BLOCK` (`zlib` 1.2.3.4) 或 `Z_FINISH`，預設 `Z_FINISH`。除了 `Z_FINISH` 之外，所有常數都允許壓縮更多的資料位元組字串，而 `Z_FINISH` 會完成壓縮串流同時防止壓縮更多資料。在 `mode` 設定 `Z_FINISH` 的情況下呼叫 `flush()` 後，無法再次呼叫 `compress()` 方法；唯一可行的作法是除物件。

`Compress.copy()`

回傳壓縮物件的副本，這可用於有效壓縮一組共用初始前綴的資料。

在 3.8 版的變更：於壓縮物件新增對 `copy.copy()` 和 `copy.deepcopy()` 的支援。

解壓縮物件支援以下方法和屬性：

`Decompress.unused_data`

一個位元組物件，它包含壓縮資料結束之後的任何位元組。也就是，在包含壓縮資料的最後一個位元組可用之前，它會一直保持 `b""`。如果整個位元組字串 (bytestring) 有包含壓縮資料，這會是 `b""`，也就是一個空位元組物件。

`Decompress.unconsumed_tail`

一個位元組物件，包含前一次 `decompress()` 的呼叫因超出了未壓縮資料緩衝區的限制而消耗掉的任何資料。`zlib` 機制尚未看到此資料，因此你必須將其（和可能有和它串聯的其他資料）反饋給後續的 `decompress()` 方法呼叫以獲得正確的輸出。

`Decompress.eof`

一個布林值，代表是否已到達壓縮資料串流的尾末。

這使其能區分有正確建構的壓縮串流和不完整或被截斷的串流。

在 3.3 版被加入。

`Decompress.decompress (data, max_length=0)`

解壓縮 `data` 回傳一個位元組物件，其包含與 `string` 中至少與部分資料相對應的未壓縮資料。此資料應串聯到任何先前呼叫 `decompress()` 方法所產生的輸出。一些輸入資料可能會保存在內部緩衝區中以供後續處理。

如果可選參數 `max_length` 不是零，則回傳值長度將不超過 `max_length`。這代表著不是所有的已壓縮輸入都可以被處理；未使用的資料將被存儲在屬性 `unconsumed_tail` 中。如果要繼續解壓縮，則必須將此位元組字串傳遞給後續對 `decompress()` 的呼叫。如果 `max_length` 零，則整個輸入會被解壓縮，且 `unconsumed_tail` 空。

在 3.6 版的變更: `max_length` 可以用作關鍵字引數。

`Decompress.flush ([length])`

處理所有待處理的輸入，回傳包含剩余未壓縮輸出的位元組物件。呼叫 `flush()` 後，無法再次呼叫 `decompress()` 方法；唯一可行的方法是刪除該物件。

可選參數 `length` 設定了輸出緩衝區的初始大小。

`Decompress.copy ()`

回傳解壓物件的副本，這可用於在資料串流中途保存解壓縮器的狀態，以便在未來某個時間點加速對串流的隨機搜索 (random seek)。

在 3.8 版的變更: 於解壓縮物件新增對 `copy.copy()` 和 `copy.deepcopy()` 支援。

有關正在使用的 `zlib` 函式庫版本資訊可通過以下常數獲得:

`zlib.ZLIB_VERSION`

用於建置模組的 `zlib` 函式庫版本字串。這可能與實際在執行環境 (runtime) 使用的 `zlib` 函式庫不同，後者以 `ZLIB_RUNTIME_VERSION` 提供。

`zlib.ZLIB_RUNTIME_VERSION`

直譯器實際載入的 `zlib` 函式庫版本字串。

在 3.3 版被加入。

## 13.2 `gzip` --- `gzip` 檔案的支援

原始碼: `Lib/gzip.py`

This module provides a simple interface to compress and decompress files just like the GNU programs `gzip` and `gunzip` would.

The data compression is provided by the `zlib` module.

The `gzip` module provides the `GzipFile` class, as well as the `open()`, `compress()` and `decompress()` convenience functions. The `GzipFile` class reads and writes `gzip`-format files, automatically compressing or decompressing the data so that it looks like an ordinary *file object*.

Note that additional file formats which can be decompressed by the `gzip` and `gunzip` programs, such as those produced by `compress` and `pack`, are not supported by this module.

此模組定義了以下項目：

`gzip.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Open a gzip-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of 'r', 'rb', 'a', 'ab', 'w', 'wb', 'x' or 'xb' for binary mode, or 'rt', 'at', 'wt', or 'xt' for text mode. The default is 'rb'.

The *compresslevel* argument is an integer from 0 to 9, as for the *GzipFile* constructor.

For binary mode, this function is equivalent to the *GzipFile* constructor: `GzipFile(filename, mode, compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *GzipFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

在 3.3 版的變更: Added support for *filename* being a file object, support for text mode, and the *encoding*, *errors* and *newline* arguments.

在 3.4 版的變更: 新增 'x'、'xb' 和 'xt' 模式的支援。

在 3.6 版的變更: 接受類路徑物件。

**exception** `gzip.BadGzipFile`

An exception raised for invalid gzip files. It inherits from *OSError*. *EOFError* and *zlib.error* can also be raised for invalid gzip files.

在 3.8 版被加入。

**class** `gzip.GzipFile(filename=None, mode=None, compresslevel=9, fileobj=None, mtime=None)`

Constructor for the *GzipFile* class, which simulates most of the methods of a *file object*, with the exception of the *truncate()* method. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, an *io.BytesIO* object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the **gzip** file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of 'r', 'rb', 'a', 'ab', 'w', 'wb', 'x', or 'xb', depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is 'rb'. In future Python releases the mode of *fileobj* will not be used. It is better to always specify *mode* for writing.

Note that the file is always opened in binary mode. To open a compressed file in text mode, use *open()* (or wrap your *GzipFile* with an *io.TextIOWrapper*).

The *compresslevel* argument is an integer from 0 to 9 controlling the level of compression; 1 is fastest and produces the least compression, and 9 is slowest and produces the most compression. 0 is no compression. The default is 9.

The optional *mtime* argument is the timestamp requested by gzip. The time is in Unix format, i.e., seconds since 00:00:00 UTC, January 1, 1970. If *mtime* is omitted or `None`, the current time is used. Use *mtime = 0* to generate a compressed stream that does not depend on creation time.

See below for the *mtime* attribute that is set when decompressing.

Calling a *GzipFile* object's *close()* method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an *io.BytesIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *io.BytesIO* object's *getvalue()* method.

*GzipFile* supports the *io.BufferedIOBase* interface, including iteration and the *with* statement. Only the *truncate()* method isn't implemented.

*GzipFile* 也提供了以下的方法和屬性：

**peek** (*n*)

Read *n* uncompressed bytes without advancing the file position. At most one single read on the compressed stream is done to satisfy the call. The number of bytes returned may be more or less than requested.

 備 F

While calling `peek()` does not change the file position of the `GzipFile`, it may change the position of the underlying file object (e.g. if the `GzipFile` was constructed with the `fileobj` parameter).

在 3.2 版被加入。

**mode**

'rb' for reading and 'wb' for writing.

在 3.13 版的變更: In previous versions it was an integer 1 or 2.

**mtime**

When decompressing, this attribute is set to the last timestamp in the most recently read header. It is an integer, holding the number of seconds since the Unix epoch (00:00:00 UTC, January 1, 1970). The initial value before reading any headers is `None`.

**name**

The path to the gzip file on disk, as a `str` or `bytes`. Equivalent to the output of `os.fspath()` on the original input path, with no other normalization, resolution or expansion.

在 3.1 版的變更: Support for the `with` statement was added, along with the `mtime` constructor argument and `mtime` attribute.

在 3.2 版的變更: Support for zero-padded and unseekable files was added.

在 3.3 版的變更: `io.BufferedIOBase.read1()` 方法現在已有實作。

在 3.4 版的變更: 新增 'x' 和 'xb' 模式的支援。

在 3.5 版的變更: Added support for writing arbitrary *bytes-like objects*. The `read()` method now accepts an argument of `None`.

在 3.6 版的變更: 接受類路徑物件。

在 3.9 版之後被 F 用: Opening `GzipFile` for writing without specifying the `mode` argument is deprecated.

在 3.12 版的變更: Remove the `filename` attribute, use the `name` attribute instead.

`gzip.compress` (*data*, *compresslevel=9*, \*, *mtime=None*)

Compress the *data*, returning a `bytes` object containing the compressed data. *compresslevel* and *mtime* have the same meaning as in the `GzipFile` constructor above.

在 3.2 版被加入。

在 3.8 版的變更: Added the `mtime` parameter for reproducible output.

在 3.11 版的變更: Speed is improved by compressing all data at once instead of in a streamed fashion. Calls with `mtime` set to 0 are delegated to `zlib.compress()` for better speed. In this situation the output may contain a gzip header "OS" byte value other than 255 "unknown" as supplied by the underlying `zlib` implementation.

在 3.13 版的變更: The gzip header OS byte is guaranteed to be set to 255 when this function is used as was the case in 3.10 and earlier.

`gzip.decompress` (*data*)

Decompress the *data*, returning a `bytes` object containing the uncompressed data. This function is capable of decompressing multi-member gzip data (multiple gzip blocks concatenated together). When the data is certain to contain only one member the `zlib.decompress()` function with `wbits` set to 31 is faster.

在 3.2 版被加入。

在 3.11 版的變更: Speed is improved by decompressing members at once in memory instead of in a streamed fashion.

### 13.2.1 用法范例

如何讀取壓縮檔案的範例:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

如何建立一個壓縮的 GZIP 檔案的範例:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

如何壓縮一個已存在的檔案的範例:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

如何壓縮一個二進位字串的範例:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

#### 也參考

##### `zlib` 模組

The basic data compression module needed to support the `gzip` file format.

### 13.2.2 命令列介面

The `gzip` module provides a simple command line interface to compress or decompress files.

Once executed the `gzip` module keeps the input file(s).

在 3.8 版的變更: Add a new command line interface with a usage. By default, when you will execute the CLI, the default compression level is 6.

#### 命令列選項

##### `file`

如果未指定 `file`, 則從 `sys.stdin` 讀取。

##### `--fast`

Indicates the fastest compression method (less compression).

##### `--best`

Indicates the slowest compression method (best compression).

- `-d, --decompress`  
解壓縮指定的檔案。
- `-h, --help`  
顯示幫助訊息。

## 13.3 bz2 --- bzip2 壓縮的支援

原始碼: `Lib/bz2.py`

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The `bz2` module contains:

- The `open()` function and `BZ2File` class for reading and writing compressed files.
- The `BZ2Compressor` and `BZ2Decompressor` classes for incremental (de)compression.
- The `compress()` and `decompress()` functions for one-shot (de)compression.

### 13.3.1 (De)compression of files

`bz2.open(filename, mode='rb', compresslevel=9, encoding=None, errors=None, newline=None)`

Open a bzip2-compressed file in binary or text mode, returning a *file object*.

As with the constructor for `BZ2File`, the `filename` argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The `mode` argument can be any of `'r'`, `'rb'`, `'w'`, `'wb'`, `'x'`, `'xb'`, `'a'` or `'ab'` for binary mode, or `'rt'`, `'wt'`, `'xt'`, or `'at'` for text mode. The default is `'rb'`.

The `compresslevel` argument is an integer from 1 to 9, as for the `BZ2File` constructor.

For binary mode, this function is equivalent to the `BZ2File` constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the `encoding`, `errors` and `newline` arguments must not be provided.

For text mode, a `BZ2File` object is created, and wrapped in an `io.TextIOWrapper` instance with the specified encoding, error handling behavior, and line ending(s).

在 3.3 版被加入。

在 3.4 版的變更: The `'x'` (exclusive creation) mode was added.

在 3.6 版的變更: Accepts a *path-like object*.

`class bz2.BZ2File(filename, mode='r', *, compresslevel=9)`

Open a bzip2-compressed file in binary mode.

If `filename` is a *str* or *bytes* object, open the named file directly. Otherwise, `filename` should be a *file object*, which will be used to read or write the compressed data.

The `mode` argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If `filename` is a file object (rather than an actual file name), a mode of `'w'` does not truncate the file, and is instead equivalent to `'a'`.

If `mode` is `'w'` or `'a'`, `compresslevel` can be an integer between 1 and 9 specifying the level of compression: 1 produces the least compression, and 9 (default) produces the most compression.

If `mode` is `'r'`, the input file may be the concatenation of multiple compressed streams.

`BZ2File` provides all of the members specified by the `io.BufferedIOBase`, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

`BZ2File` also provides the following methods and attributes:

**peek**(`[n]`)

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

**備 F**

While calling `peek()` does not change the file position of the `BZ2File`, it may change the position of the underlying file object (e.g. if the `BZ2File` was constructed by passing a file object for `filename`).

在 3.3 版被加入.

**fileno**()

Return the file descriptor for the underlying file.

在 3.3 版被加入.

**readable**()

Return whether the file was opened for reading.

在 3.3 版被加入.

**seekable**()

Return whether the file supports seeking.

在 3.3 版被加入.

**writable**()

Return whether the file was opened for writing.

在 3.3 版被加入.

**read1**(`size=-1`)

Read up to `size` uncompressed bytes, while trying to avoid making multiple reads from the underlying stream. Reads up to a buffer's worth of data if `size` is negative.

Returns `b''` if the file is at EOF.

在 3.3 版被加入.

**readinto**(`b`)

Read bytes into `b`.

Returns the number of bytes read (0 for EOF).

在 3.3 版被加入.

**mode**

'rb' for reading and 'wb' for writing.

在 3.13 版被加入.

**name**

The bzip2 file name. Equivalent to the `name` attribute of the underlying `file object`.

在 3.13 版被加入.

在 3.1 版的變更: Support for the `with` statement was added.

在 3.3 版的變更: Support was added for `filename` being a `file object` instead of an actual filename.

The 'a' (append) mode was added, along with support for reading multi-stream files.

在 3.4 版的變更: The 'x' (exclusive creation) mode was added.

在 3.5 版的變更: The `read()` method now accepts an argument of `None`.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.9 版的變更: The `buffering` parameter has been removed. It was ignored and deprecated since Python 3.0. Pass an open file object to control how the file is opened.

The `compresslevel` parameter became keyword-only.

在 3.10 版的變更: This class is thread unsafe in the face of multiple simultaneous readers or writers, just like its equivalent classes in `gzip` and `lzma` have always been.

## 13.3.2 Incremental (de)compression

**class** `bz2.BZ2Compressor` (`compresslevel=9`)

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the `compress()` function instead.

`compresslevel`, if given, must be an integer between 1 and 9. The default is 9.

**compress** (`data`)

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the `flush()` method to finish the compression process.

**flush** ()

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

**class** `bz2.BZ2Decompressor`

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot decompression, use the `decompress()` function instead.

 備F

This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `BZ2File`. If you need to decompress a multi-stream input with `BZ2Decompressor`, you must use a new decompressor for each stream.

**decompress** (`data`, `max_length=-1`)

Decompress `data` (a *bytes-like object*), returning uncompressed data as bytes. Some of `data` may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If `max_length` is nonnegative, returns at most `max_length` bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide `data` as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than `max_length` bytes, or because `max_length` was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

在 3.5 版的變更: 新增 `max_length` 參數。

**eof**

True if the end-of-stream marker has been reached.

在 3.3 版被加入。

**unused\_data**

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

**needs\_input**

False if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

在 3.5 版被加入。

### 13.3.3 One-shot (de)compression

`bz2.compress(data, compresslevel=9)`

Compress *data*, a *bytes-like object*.

*compresslevel*, if given, must be an integer between 1 and 9. The default is 9.

For incremental compression, use a `BZ2Compressor` instead.

`bz2.decompress(data)`

Decompress *data*, a *bytes-like object*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a `BZ2Decompressor` instead.

在 3.3 版的變更: Support for multi-stream inputs was added.

### 13.3.4 用法范例

Below are some examples of typical usage of the `bz2` module.

Using `compress()` and `decompress()` to demonstrate round-trip compression:

```
>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> c = bz2.compress(data)
>>> len(data) / len(c) # Data compression ratio
1.513595166163142
>>> d = bz2.decompress(c)
>>> data == d # Check equality to original object after round-trip
True
```

Using `BZ2Compressor` for incremental compression:

```
>>> import bz2
>>> def gen_data(chunks=10, chunksize=1000):
...     """Yield incremental blocks of chunksize bytes."""
...     for _ in range(chunks):
...         yield b"z" * chunksize
... 
```

(繼續下一頁)

```

>>> comp = bz2.BZ2Compressor()
>>> out = b""
>>> for chunk in gen_data():
...     # Provide data to the compressor object
...     out = out + comp.compress(chunk)
...
>>> # Finish the compression process. Call this once you have
>>> # finished providing data to the compressor.
>>> out = out + comp.flush()

```

The example above uses a very "nonrandom" stream of data (a stream of b"z" chunks). Random data tends to compress poorly, while ordered, repetitive data usually yields a high compression ratio.

Writing and reading a bzip2-compressed file in binary mode:

```

>>> import bz2
>>> data = b"""\
... Donec rhoncus quis sapien sit amet molestie. Fusce scelerisque vel augue
... nec ullamcorper. Nam rutrum pretium placerat. Aliquam vel tristique lorem,
... sit amet cursus ante. In interdum laoreet mi, sit amet ultrices purus
... pulvinar a. Nam gravida euismod magna, non varius justo tincidunt feugiat.
... Aliquam pharetra lacus non risus vehicula rutrum. Maecenas aliquam leo
... felis. Pellentesque semper nunc sit amet nibh ullamcorper, ac elementum
... dolor luctus. Curabitur lacinia mi ornare consectetur vestibulum."""
>>> with bz2.open("myfile.bz2", "wb") as f:
...     # Write compressed data to file
...     unused = f.write(data)
...
>>> with bz2.open("myfile.bz2", "rb") as f:
...     # Decompress data from file
...     content = f.read()
...
>>> content == data # Check equality to original object after round-trip
True

```

## 13.4 lzma --- 使用 LZMA 演算法進行壓縮

在 3.3 版被加入。

原始碼: [Lib/lzma.py](#)

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the .xz and legacy .lzma file formats used by the **xz** utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the `bz2` module. Note that `LZMAFile` and `bz2.BZ2File` are *not* thread-safe, so if you need to use a single `LZMAFile` instance from multiple threads, it is necessary to protect it with a lock.

### exception lzma.LZMAError

This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

### 13.4.1 Reading and writing compressed files

`lzma.open(filename, mode='rb', *, format=None, check=-1, preset=None, filters=None, encoding=None, errors=None, newline=None)`

Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a *str*, *bytes* or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of "r", "rb", "w", "wb", "x", "xb", "a" or "ab" for binary mode, or "rt", "wt", "xt", or "at" for text mode. The default is "rb".

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

For binary mode, this function is equivalent to the *LZMAFile* constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *LZMAFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

在 3.4 版的變更: 新增 "x"、"xb" 和 "xt" 模式的支援。

在 3.6 版的變更: Accepts a *path-like object*.

**class** `lzma.LZMAFile` (*filename=None, mode='r', \*, format=None, check=-1, preset=None, filters=None*)

Open an LZMA-compressed file in binary mode.

An *LZMAFile* can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a *str*, *bytes* or *path-like* object). When wrapping an existing file object, the wrapped file will not be closed when the *LZMAFile* is closed.

The *mode* argument can be either "r" for reading (default), "w" for overwriting, "x" for exclusive creation, or "a" for appending. These can equivalently be given as "rb", "wb", "xb" and "ab" respectively.

If *filename* is a file object (rather than an actual file name), a mode of "w" does not truncate the file, and is instead equivalent to "a".

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

*LZMAFile* supports all the members specified by *io.BufferedIOBase*, except for *detach()* and *truncate()*. Iteration and the *with* statement are supported.

The following method and attributes are also provided:

**peek** (*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

#### 備 F

While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

**mode**

'rb' for reading and 'wb' for writing.

在 3.13 版被加入。

**name**

The lzma file name. Equivalent to the *name* attribute of the underlying *file object*.

在 3.13 版被加入。

在 3.4 版的變更: 新增 "x" 和 "xb" 模式的支援。

在 3.5 版的變更: The *read()* method now accepts an argument of *None*.

在 3.6 版的變更: Accepts a *path-like object*.

## 13.4.2 Compressing and decompressing data in memory

**class** `lzma.LZMACompressor` (*format=FORMAT\_XZ, check=-1, preset=None, filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see *compress()*.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT\_XZ: The .xz container format.**  
This is the default format.
- **FORMAT\_ALONE: The legacy .lzma container format.**  
This format is more limited than .xz -- it does not support integrity checks or multiple filters.
- **FORMAT\_RAW: A raw data stream, not using any container format.**  
This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using `FORMAT_AUTO` (see *LZMADecompressor*).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- `CHECK_NONE`: No integrity check. This is the default (and the only acceptable value) for `FORMAT_ALONE` and `FORMAT_RAW`.
- `CHECK_CRC32`: 32-bit Cyclic Redundancy Check.
- `CHECK_CRC64`: 64-bit Cyclic Redundancy Check. This is the default for `FORMAT_XZ`.
- `CHECK_SHA256`: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an *LZMAError* is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant `PRESET_EXTREME`. If neither *preset* nor *filters* are given, the default behavior is to use `PRESET_DEFAULT` (preset level 6). Higher presets produce smaller output, but make the compression process slower.

### 備 F

In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an *LZMACompressor* object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

**compress** (*data*)

Compress *data* (a *bytes* object), returning a *bytes* object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to `compress()` and `flush()`. The returned data should be concatenated with the output of any previous calls to `compress()`.

**flush** ()

Finish the compression process, returning a *bytes* object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

**class** `lzma.LZMADecompressor` (*format=FORMAT\_AUTO, memlimit=None, filters=None*)

Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see `decompress()`.

The *format* argument specifies the container format that should be used. The default is `FORMAT_AUTO`, which can decompress both `.xz` and `.lzma` files. Other possible values are `FORMAT_XZ`, `FORMAT_ALONE`, and `FORMAT_RAW`.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an `LZMAError` if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

 備 F

This class does not transparently handle inputs containing multiple compressed streams, unlike `decompress()` and `LZMAFile`. To decompress a multi-stream input with `LZMADecompressor`, you must create a new decompressor for each stream.

**decompress** (*data, max\_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to `decompress()`. The returned data should be concatenated with the output of any previous calls to `decompress()`.

If *max\_length* is nonnegative, returns at most *max\_length* bytes of decompressed data. If this limit is reached and further output can be produced, the `needs_input` attribute will be set to `False`. In this case, the next call to `decompress()` may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max\_length* bytes, or because *max\_length* was negative), the `needs_input` attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an `EOFError`. Any data found after the end of the stream is ignored and saved in the `unused_data` attribute.

在 3.5 版的變更: 新增 *max\_length* 參數。

**check**

The ID of the integrity check used by the input stream. This may be `CHECK_UNKNOWN` until enough of the input has been decoded to determine what integrity check it uses.

**eof**

`True` if the end-of-stream marker has been reached.

**unused\_data**

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b''`.

**needs\_input**

False if the `decompress()` method can provide more decompressed data before requiring new uncompressed input.

在 3.5 版被加入。

`lzma.compress(data, format=FORMAT_XZ, check=-1, preset=None, filters=None)`

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See `LZMACompressor` above for a description of the *format*, *check*, *preset* and *filters* arguments.

`lzma.decompress(data, format=FORMAT_AUTO, memlimit=None, filters=None)`

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See `LZMADecompressor` above for a description of the *format*, *memlimit* and *filters* arguments.

### 13.4.3 Miscellaneous

`lzma.is_check_supported(check)`

Return `True` if the given integrity check is supported on this system.

`CHECK_NONE` and `CHECK_CRC32` are always supported. `CHECK_CRC64` and `CHECK_SHA256` may be unavailable if you are using a version of `liblzma` that was compiled with a limited feature set.

### 13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key "id", and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- Compression filters:
  - `FILTER_LZMA1` (for use with `FORMAT_ALONE`)
  - `FILTER_LZMA2` (for use with `FORMAT_XZ` and `FORMAT_RAW`)
- Delta filter:
  - `FILTER_DELTA`
- Branch-Call-Jump (BCJ) filters:
  - `FILTER_X86`
  - `FILTER_IA64`
  - `FILTER_ARM`
  - `FILTER_ARMTHUMB`
  - `FILTER_POWERPC`
  - `FILTER_SPARC`

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- `preset`: A compression preset to use as a source of default values for options that are not specified explicitly.
- `dict_size`: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- `lc`: Number of literal context bits.
- `lp`: Number of literal position bits. The sum `lc + lp` must be at most 4.

- `pb`: Number of position bits; must be at most 4.
- `mode`: `MODE_FAST` or `MODE_NORMAL`.
- `nice_len`: What should be considered a "nice length" for a match. This should be 273 or less.
- `mf`: What match finder to use -- `MF_HC3`, `MF_HC4`, `MF_BT2`, `MF_BT3`, or `MF_BT4`.
- `depth`: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, `dist`. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, `start_offset`. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

### 13.4.5 范例

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

## 13.5 zipfile --- 處理 ZIP 封存檔案

原始碼: Lib/zipfile/

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in [PKZIP Application Note](#).

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

**exception** `zipfile.BadZipFile`

The error raised for bad ZIP files.

在 3.2 版被加入。

**exception** `zipfile.BadZipfile`

Alias of `BadZipFile`, for compatibility with older Python versions.

在 3.2 版之後被用。

**exception** `zipfile.LargeZipFile`

The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

**class** `zipfile.ZipFile`

The class for reading and writing ZIP files. See section [ZipFile 物件](#) for constructor details.

**class** `zipfile.Path`

Class that implements a subset of the interface provided by `pathlib.Path`, including the full `importlib.resources.abc.Traversable` interface.

在 3.8 版被加入。

**class** `zipfile.PyZipFile`

Class for creating ZIP archives containing Python libraries.

**class** `zipfile.ZipInfo` (`filename='NoName'`, `date_time=(1980, 1, 1, 0, 0, 0)`)

Class used to represent information about a member of an archive. Instances of this class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Most users of the `zipfile` module will not need to create these, but only use those created by this module. `filename` should be the full name of the archive member, and `date_time` should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section [ZipInfo 物件](#).

在 3.13 版的變更: A public `compress_level` attribute has been added to expose the formerly protected `_compresslevel`. The older protected name continues to work as a property for backwards compatibility.

`zipfile.is_zipfile(filename)`

Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

在 3.1 版的變更: Support for file and file-like objects.

`zipfile.ZIP_STORED`

The numeric constant for an uncompressed archive member.

`zipfile.ZIP_DEFLATED`

The numeric constant for the usual ZIP compression method. This requires the *zlib* module.

`zipfile.ZIP_BZIP2`

The numeric constant for the BZIP2 compression method. This requires the *bz2* module.

在 3.3 版被加入.

`zipfile.ZIP_LZMA`

The numeric constant for the LZMA compression method. This requires the *lzma* module.

在 3.3 版被加入.

#### 備 F

The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

#### 也參考

##### PKZIP Application Note

Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

##### Info-ZIP 首頁

Information about the Info-ZIP project's ZIP archive programs and development libraries.

## 13.5.1 ZipFile 物件

`class zipfile.ZipFile(file, mode='r', compression=ZIP_STORED, allowZip64=True, compresslevel=None, *, strict_timestamps=True, metadata_encoding=None)`

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a *path-like object*.

The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, `'a'` to append to an existing file, or `'x'` to exclusively create and write a new file. If *mode* is `'x'` and *file* refers to an existing file, a `FileExistsError` will be raised. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is `'a'` and the file does not exist at all, it is created. If *mode* is `'r'` or `'a'`, the file should be seekable.

*compression* is the ZIP compression method to use when writing the archive, and should be `ZIP_STORED`, `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA`; unrecognized values will cause `NotImplementedError` to be raised. If `ZIP_DEFLATED`, `ZIP_BZIP2` or `ZIP_LZMA` is specified but the corresponding module (*zlib*, *bz2* or *lzma*) is not available, `RuntimeError` is raised. The default is `ZIP_STORED`.

If *allowZip64* is `True` (the default) `zipfile` will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is `false` `zipfile` will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using *ZIP\_STORED* or *ZIP\_LZMA* it has no effect. When using *ZIP\_DEFLATED* integers 0 through 9 are accepted (see *zlib* for more information). When using *ZIP\_BZIP2* integers 1 through 9 are accepted (see *bz2* for more information).

The *strict\_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

When mode is `'r'`, *metadata\_encoding* may be set to the name of a codec, which will be used to decode metadata such as the names of members and ZIP comments.

If the file is created with mode `'w'`, `'x'` or `'a'` and then *closed* without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

`ZipFile` is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished--even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

#### 備 F

*metadata\_encoding* is an instance-wide setting for the `ZipFile`. It is not currently possible to set this on a per-member basis.

This attribute is a workaround for legacy implementations which produce archives with names in the current locale encoding or code page (mostly on Windows). According to the `.ZIP` standard, the encoding of metadata may be specified to be either IBM code page (default) or UTF-8 by a flag in the archive header. That flag takes precedence over *metadata\_encoding*, which is a Python-specific extension.

在 3.2 版的變更: 新增 `ZipFile` 作情境管理器使用的能力。

在 3.3 版的變更: 新增對於 *bzip2* 和 *lzma* 壓縮的支援。

在 3.4 版的變更: ZIP64 extensions are enabled by default.

在 3.5 版的變更: Added support for writing to unseekable streams. Added support for the `'x'` mode.

在 3.6 版的變更: Previously, a plain `RuntimeError` was raised for unrecognized compression values.

在 3.6.2 版的變更: The *file* parameter accepts a *path-like object*.

在 3.7 版的變更: Add the *compresslevel* parameter.

在 3.8 版的變更: The *strict\_timestamps* keyword-only parameter.

在 3.11 版的變更: Added support for specifying member name encoding for reading metadata in the zipfile's directory and file headers.

`ZipFile.close()`

Close the archive file. You must call `close()` before exiting your program or essential records will not be written.

`ZipFile.getinfo(name)`

Return a `ZipInfo` object with information about the archive member *name*. Calling `getinfo()` for a name not currently contained in the archive will raise a `KeyError`.

`ZipFile.infolist()`

Return a list containing a `ZipInfo` object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

`ZipFile.namelist()`

Return a list of archive members by name.

`ZipFile.open(name, mode='r', pwd=None, *, force_zip64=False)`

Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a *ZipInfo* object. The *mode* parameter, if included, must be 'r' (the default) or 'w'. *pwd* is the password used to decrypt encrypted ZIP files as a *bytes* object.

*open()* is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With *mode* 'r' the file-like object (*ZipExtFile*) is read-only and provides the following methods: *read()*, *readline()*, *readlines()*, *seek()*, *tell()*, *\_\_iter\_\_()*, *\_\_next\_\_()*. These objects can operate independently of the *ZipFile*.

With *mode*='w', a writable file handle is returned, which supports the *write()* method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a *ValueError*.

In both cases the file-like object has also attributes *name*, which is equivalent to the name of a file within the archive, and *mode*, which is 'rb' or 'wb' depending on the input mode.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass *force\_zip64=True* to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a *ZipInfo* object with *file\_size* set, and use that as the *name* parameter.

#### 備註

The *open()*, *read()* and *extract()* methods can take a filename or a *ZipInfo* object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

在 3.6 版的變更: Removed support of *mode*='U'. Use *io.TextIOWrapper* for reading compressed text files in *universal newlines* mode.

在 3.6 版的變更: *ZipFile.open()* can now be used to write files into the archive with the *mode*='w' option.

在 3.6 版的變更: Calling *open()* on a closed *ZipFile* will raise a *ValueError*. Previously, a *RuntimeError* was raised.

在 3.13 版的變更: Added attributes *name* and *mode* for the writeable file-like object. The value of the *mode* attribute for the readable file-like object was changed from 'r' to 'rb'.

`ZipFile.extract(member, path=None, pwd=None)`

Extract a member from the archive to the current working directory; *member* must be its full name or a *ZipInfo* object. Its file information is extracted as accurately as possible. *path* specifies a different directory to extract to. *member* can be a filename or a *ZipInfo* object. *pwd* is the password used for encrypted files as a *bytes* object.

Returns the normalized path created (a directory or new file).

#### 備註

If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../..foo../..ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

在 3.6 版的變更: Calling *extract()* on a closed *ZipFile* will raise a *ValueError*. Previously, a *RuntimeError* was raised.

在 3.6.2 版的變更: The *path* parameter accepts a *path-like object*.

`ZipFile.extractall(path=None, members=None, pwd=None)`

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by *namelist()*. *pwd* is the password used for encrypted files as a *bytes* object.

#### 警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with "/" or filenames with two dots ". .". This module attempts to prevent that. See *extract()* note.

在 3.6 版的變更: Calling *extractall()* on a closed *ZipFile* will raise a *ValueError*. Previously, a *RuntimeError* was raised.

在 3.6.2 版的變更: The *path* parameter accepts a *path-like object*.

`ZipFile.printdir()`

Print a table of contents for the archive to `sys.stdout`.

`ZipFile.setpassword(pwd)`

Set *pwd* (a *bytes* object) as default password to extract encrypted files.

`ZipFile.read(name, pwd=None)`

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files as a *bytes* object and, if specified, overrides the default password set with *setpassword()*. Calling *read()* on a *ZipFile* that uses a compression method other than *ZIP\_STORED*, *ZIP\_DEFLATED*, *ZIP\_BZIP2* or *ZIP\_LZMA* will raise a *NotImplementedError*. An error will also be raised if the corresponding compression module is not available.

在 3.6 版的變更: Calling *read()* on a closed *ZipFile* will raise a *ValueError*. Previously, a *RuntimeError* was raised.

`ZipFile.testzip()`

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

在 3.6 版的變更: Calling *testzip()* on a closed *ZipFile* will raise a *ValueError*. Previously, a *RuntimeError* was raised.

`ZipFile.write(filename, arcname=None, compress_type=None, compresslevel=None)`

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress\_type* overrides the value given for the *compression* parameter to the constructor for the new entry. Similarly, *compresslevel* will override the constructor if given. The archive must be open with mode 'w', 'x' or 'a'.

#### 備 F

The ZIP file standard historically did not specify a metadata encoding, but strongly recommended CP437 (the original IBM PC encoding) for interoperability. Recent versions allow use of UTF-8 (only). In this module, UTF-8 will automatically be used to write the member names if they contain any non-ASCII characters. It is not possible to write member names in any encoding other than ASCII or UTF-8.

#### 備 F

Archive names should be relative to the archive root, that is, they should not start with a path separator.

**備註**

If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

**備註**

A leading slash in the filename may lead to the archive being impossible to open in some zip programs on Windows systems.

在 3.6 版的變更: Calling `write()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.writestr(zinfo_or_arcname, data, compress_type=None, compresslevel=None)`

Write a file into the archive. The contents is `data`, which may be either a `str` or a `bytes` instance; if it is a `str`, it is encoded as UTF-8 first. `zinfo_or_arcname` is either the file name it will be given in the archive, or a `ZipInfo` instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, `compress_type` overrides the value given for the `compression` parameter to the constructor for the new entry, or in the `zinfo_or_arcname` (if that is a `ZipInfo` instance). Similarly, `compresslevel` will override the constructor if given.

**備註**

When passing a `ZipInfo` instance as the `zinfo_or_arcname` parameter, the compression method used will be that specified in the `compress_type` member of the given `ZipInfo` instance. By default, the `ZipInfo` constructor sets this member to `ZIP_STORED`.

在 3.2 版的變更: `compress_type` 引數。

在 3.6 版的變更: Calling `writestr()` on a `ZipFile` created with mode `'r'` or a closed `ZipFile` will raise a `ValueError`. Previously, a `RuntimeError` was raised.

`ZipFile.mkdir(zinfo_or_directory, mode=511)`

Create a directory inside the archive. If `zinfo_or_directory` is a string, a directory is created inside the archive with the mode that is specified in the `mode` argument. If, however, `zinfo_or_directory` is a `ZipInfo` instance then the `mode` argument is ignored.

The archive must be opened with mode `'w'`, `'x'` or `'a'`.

在 3.11 版被加入。

The following data attributes are also available:

`ZipFile.filename`

Name of the ZIP file.

`ZipFile.debug`

The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.comment`

The comment associated with the ZIP file as a `bytes` object. If assigning a comment to a `ZipFile` instance created with mode `'w'`, `'x'` or `'a'`, it should be no longer than 65535 bytes. Comments longer than this will be truncated.

## 13.5.2 Path Objects

**class** `zipfile.Path` (*root*, *at*=’')

Construct a `Path` object from a `root` zipfile (which may be a `ZipFile` instance or `file` suitable for passing to the `ZipFile` constructor).

`at` specifies the location of this `Path` within the zipfile, e.g. `'dir/file.txt'`, `'dir/'`, or `''`. Defaults to the empty string, indicating the root.

`Path` objects expose the following features of `pathlib.Path` objects:

`Path` objects are traversable using the `/` operator or `joinpath`.

`Path.name`

The final path component.

`Path.open` (*mode*=’r’, \*, *pwd*, \*\*)

Invoke `ZipFile.open()` on the current path. Allows opening for read or write, text or binary through supported modes: `'r'`, `'w'`, `'rb'`, `'wb'`. Positional and keyword arguments are passed through to `io.TextIOWrapper` when opened as text and ignored otherwise. `pwd` is the `pwd` parameter to `ZipFile.open()`.

在 3.9 版的變更: Added support for text and binary modes for open. Default mode is now text.

在 3.11.2 版的變更: The `encoding` parameter can be supplied as a positional argument without causing a `TypeError`. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all `io.TextIOWrapper` arguments, `encoding` included, as keywords.

`Path.iterdir` ()

Enumerate the children of the current directory.

`Path.is_dir` ()

Return `True` if the current context references a directory.

`Path.is_file` ()

Return `True` if the current context references a file.

`Path.is_symlink` ()

Return `True` if the current context references a symbolic link.

在 3.12 版被加入。

在 3.13 版的變更: Previously, `is_symlink` would unconditionally return `False`.

`Path.exists` ()

Return `True` if the current context references a file or directory in the zip file.

`Path.suffix`

The last dot-separated portion of the final component, if any. This is commonly called the file extension.

在 3.11 版被加入: 新增 `Path.suffix` 特性。

`Path.stem`

The final path component, without its suffix.

在 3.11 版被加入: 新增 `Path.stem` 特性。

`Path.suffixes`

A list of the path’s suffixes, commonly called file extensions.

在 3.11 版被加入: 新增 `Path.suffixes` 特性。

`Path.read_text` (\*, \*\*)

Read the current file as unicode text. Positional and keyword arguments are passed through to `io.TextIOWrapper` (except `buffer`, which is implied by the context).

在 3.11.2 版的變更: The `encoding` parameter can be supplied as a positional argument without causing a `TypeError`. As it could in 3.9. Code needing to be compatible with unpatched 3.10 and 3.11 versions must pass all `io.TextIOWrapper` arguments, `encoding` included, as keywords.

`Path.read_bytes()`

Read the current file as bytes.

`Path.joinpath(*other)`

Return a new `Path` object with each of the `other` arguments joined. The following are equivalent:

```
>>> Path(...).joinpath('child').joinpath('grandchild')
>>> Path(...).joinpath('child', 'grandchild')
>>> Path(...) / 'child' / 'grandchild'
```

在 3.10 版的變更: Prior to 3.10, `joinpath` was undocumented and accepted exactly one parameter.

The `zip` project provides backports of the latest path object functionality to older Pythons. Use `zipfile.Path` in place of `zipfile.Path` for early access to changes.

### 13.5.3 PyZipFile 物件

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor, and one additional parameter, `optimize`.

`class zipfile.PyZipFile(file, mode='r', compression=ZIP_STORED, allowZip64=True, optimize=-1)`

在 3.2 版的變更: 新增 `optimize` 參數。

在 3.4 版的變更: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of `ZipFile` objects:

`writepy(pathname, basename="", filterfunc=None)`

Search for files `*.py` and add the corresponding file to the archive.

If the `optimize` parameter to `PyZipFile` was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the `optimize` parameter to `PyZipFile` was `0`, `1` or `2`, only files with that optimization level (see `compile()`) are added to the archive, compiling if necessary.

If `pathname` is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If `pathname` is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

`basename` is intended for internal use only.

`filterfunc`, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If `filterfunc` returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in `test` directories or start with the string `test_`, we can use a `filterfunc` to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
...
>>> zf.writepy('myprog', filterfunc=notests)
```

The `writepy()` method makes archives with file names like this:

```
string.pyc           # Top level name
test/__init__.pyc   # Package directory
test/testall.pyc    # Module test.testall
test/bogus/__init__.pyc # Subpackage directory
test/bogus/myfile.pyc # Submodule test.bogus.myfile
```

在 3.4 版的變更: 新增 *filterfunc* 參數。

在 3.6.2 版的變更: The *pathname* parameter accepts a *path-like object*.

在 3.7 版的變更: Recursion sorts directory entries.

### 13.5.4 ZipInfo 物件

Instances of the *ZipInfo* class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a *ZipInfo* instance for a filesystem file:

**classmethod** *ZipInfo.from\_file*(*filename*, *arcname=None*, \*, *strict\_timestamps=True*)

Construct a *ZipInfo* instance for a file on the filesystem, in preparation for adding it to a zip file.

*filename* should be the path to a file or directory on the filesystem.

If *arcname* is specified, it is used as the name within the archive. If *arcname* is not specified, the name will be the same as *filename*, but with any drive letter and leading path separators removed.

The *strict\_timestamps* argument, when set to `False`, allows to zip files older than 1980-01-01 at the cost of setting the timestamp to 1980-01-01. Similar behavior occurs with files newer than 2107-12-31, the timestamp is also set to the limit.

在 3.6 版被加入。

在 3.6.2 版的變更: The *filename* parameter accepts a *path-like object*.

在 3.8 版的變更: 新增 *strict\_timestamps* 僅限關鍵字參數。

Instances have the following methods and attributes:

*ZipInfo.is\_dir*()

Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

在 3.6 版被加入。

*ZipInfo.filename*

Name of the file in the archive.

*ZipInfo.date\_time*

The time and date of the last modification to the archive member. This is a tuple of six values:

Index	Value
0	Year (>= 1980)
1	Month (one-based)
2	Day of month (one-based)
3	Hours (zero-based)
4	Minutes (zero-based)
5	Seconds (zero-based)

The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`

Type of compression for the archive member.

`ZipInfo.comment`

Comment for the individual archive member as a *bytes* object.

`ZipInfo.extra`

Expansion field data. The [PKZIP Application Note](#) contains some comments on the internal structure of the data contained in this *bytes* object.

`ZipInfo.create_system`

System which created ZIP archive.

`ZipInfo.create_version`

PKZIP version which created ZIP archive.

`ZipInfo.extract_version`

PKZIP version needed to extract archive.

`ZipInfo.reserved`

Must be zero.

`ZipInfo.flag_bits`

ZIP flag bits.

`ZipInfo.volume`

Volume number of file header.

`ZipInfo.internal_attr`

Internal attributes.

`ZipInfo.external_attr`

External file attributes.

`ZipInfo.header_offset`

Byte offset to the file header.

`ZipInfo.CRC`

CRC-32 of the uncompressed file.

`ZipInfo.compress_size`

Size of the compressed data.

`ZipInfo.file_size`

Size of the uncompressed file.

### 13.5.5 Command-Line Interface

The *zipfile* module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

### Command-line options

```
-l <zipfile>
--list <zipfile>
    List files in a zipfile.
-c <zipfile> <source1> ... <sourceN>
--create <zipfile> <source1> ... <sourceN>
    Create zipfile from source files.
-e <zipfile> <output_dir>
--extract <zipfile> <output_dir>
    Extract zipfile into target directory.
-t <zipfile>
--test <zipfile>
    Test whether the zipfile is valid or not.
--metadata-encoding <encoding>
    Specify encoding of member names for -l, -e and -t.
    在 3.11 版被加入.
```

### 13.5.6 Decompression pitfalls

The extraction in `zipfile` module might fail due to some pitfalls listed below.

#### From file itself

Decompression may fail due to incorrect password / CRC checksum / ZIP format or unsupported compression method / decryption.

#### File System limitations

Exceeding limitations on different file systems can cause decompression failed. Such as allowable characters in the directory entries, length of the file name, length of the pathname, size of a single file, and number of files, etc.

#### Resources limitations

The lack of memory or disk volume would lead to decompression failed. For example, decompression bombs (aka [ZIP bomb](#)) apply to `zipfile` library that can cause disk volume exhaustion.

#### Interruption

Interruption during the decompression, such as pressing control-C or killing the decompression process may result in incomplete decompression of the archive.

## Default behaviors of extraction

Not knowing the default extraction behaviors can cause unexpected decompression results. For example, when extracting the same archive twice, it overwrites files without asking.

## 13.6 tarfile --- 讀取與寫入 tar 封存檔案

原始碼: [Lib/tarfile.py](#)

The `tarfile` module makes it possible to read and write tar archives, including those using `gzip`, `bz2` and `lzma` compression. Use the `zipfile` module to read or write `.zip` files, or the higher-level functions in `shutil`.

Some facts and figures:

- reads and writes `gzip`, `bz2` and `lzma` compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including `longname` and `longlink` extensions, read-only support for all variants of the `sparse` extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

在 3.3 版的變更: Added support for `lzma` compression.

在 3.12 版的變更: Archives are extracted using a `filter`, which makes it possible to either limit surprising/dangerous features, or to acknowledge that they are expected and the archive is fully trusted. By default, archives are fully trusted, but this default is deprecated and slated to change in Python 3.14.

`tarfile.open` (*name=None, mode='r', fileobj=None, bufsize=10240, \*\*kwargs*)

Return a `TarFile` object for the pathname `name`. For detailed information on `TarFile` objects and the keyword arguments that are allowed, see `TarFile` 物件.

`mode` has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

mode	action
'r' 或 'r:*	Open for reading with transparent compression (recommended).
'r:'	Open for reading exclusively without compression.
'r:gz'	Open for reading with gzip compression.
'r:bz2'	Open for reading with bzip2 compression.
'r:xz'	Open for reading with lzma compression.
'x' 或 'x:'	Create a tarfile exclusively without compression. Raise a <code>FileExistsError</code> exception if it already exists.
'x:gz'	Create a tarfile with gzip compression. Raise a <code>FileExistsError</code> exception if it already exists.
'x:bz2'	Create a tarfile with bzip2 compression. Raise a <code>FileExistsError</code> exception if it already exists.
'x:xz'	Create a tarfile with lzma compression. Raise a <code>FileExistsError</code> exception if it already exists.
'a' 或 'a:'	Open for appending with no compression. The file is created if it does not exist.
'w' 或 'w:'	Open for uncompressed writing.
'w:gz'	Open for gzip compressed writing.
'w:bz2'	Open for bzip2 compressed writing.
'w:xz'	Open for lzma compressed writing.

Note that 'a:gz', 'a:bz2' or 'a:xz' is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, `ReadError` is raised. Use *mode* 'r' to avoid this. If a compression method is not supported, `CompressionError` is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes 'w:gz', 'x:gz', 'w|gz', 'w:bz2', 'x:bz2', 'w|bz2', `tarfile.open()` accepts the keyword argument *compresslevel* (default 9) to specify the compression level of the file.

For modes 'w:xz' and 'x:xz', `tarfile.open()` accepts the keyword argument *preset* to specify the compression level of the file.

For special purposes, there is a second format for *mode*: 'filemode|[compression]'. `tarfile.open()` will return a `TarFile` object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a `read()` or `write()` method (depending on the *mode*) that works with bytes. *bufsize* specifies the blocksize and defaults to 20 \* 512 bytes. Use this variant in combination with e.g. `sys.stdin.buffer`, a socket *file object* or a tape device. However, such a `TarFile` object is limited in that it does not allow random access, see 範例. The currently possible modes:

Mode	Action
'r *'	Open a <i>stream</i> of tar blocks for reading with transparent compression.
'r '	Open a <i>stream</i> of uncompressed tar blocks for reading.
'r gz'	Open a gzip compressed <i>stream</i> for reading.
'r bz2'	Open a bzip2 compressed <i>stream</i> for reading.
'r xz'	Open an lzma compressed <i>stream</i> for reading.
'w '	Open an uncompressed <i>stream</i> for writing.
'w gz'	Open a gzip compressed <i>stream</i> for writing.
'w bz2'	Open a bzip2 compressed <i>stream</i> for writing.
'w xz'	Open an lzma compressed <i>stream</i> for writing.

在 3.5 版的變更: The 'x' (exclusive creation) mode was added.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

在 3.12 版的變更: The *compresslevel* keyword argument also works for streams.

#### class `tarfile.TarFile`

Class for reading and writing tar archives. Do not use this class directly: use `tarfile.open()` instead. See `TarFile` 物件.

#### `tarfile.is_tarfile(name)`

Return `True` if *name* is a tar archive file, that the `tarfile` module can read. *name* may be a *str*, file, or file-like object.

在 3.9 版的變更: Support for file and file-like objects.

The `tarfile` module defines the following exceptions:

#### exception `tarfile.TarError`

Base class for all `tarfile` exceptions.

#### exception `tarfile.ReadError`

Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

#### exception `tarfile.CompressionError`

Is raised when a compression method is not supported or when the data cannot be decoded properly.

#### exception `tarfile.StreamError`

Is raised for the limitations that are typical for stream-like `TarFile` objects.

**exception** `tarfile.ExtractError`

Is raised for *non-fatal* errors when using `TarFile.extract()`, but only if `TarFile.errorlevel== 2`.

**exception** `tarfile.HeaderError`

Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

**exception** `tarfile.FilterError`

Base class for members *refused* by filters.

**tarinfo**

Information about the member that the filter refused to extract, as `TarInfo`.

**exception** `tarfile.AbsolutePathError`

Raised to refuse extracting a member with an absolute path.

**exception** `tarfile.OutsideDestinationError`

Raised to refuse extracting a member outside the destination directory.

**exception** `tarfile.SpecialFileError`

Raised to refuse extracting a special file (e.g. a device or pipe).

**exception** `tarfile.AbsoluteLinkError`

Raised to refuse extracting a symbolic link with an absolute path.

**exception** `tarfile.LinkOutsideDestinationError`

Raised to refuse extracting a symbolic link pointing outside the destination directory.

The following constants are available at the module level:

`tarfile.ENCODING`

The default character encoding: 'utf-8' on Windows, the value returned by `sys.getfilesystemencoding()` otherwise.

`tarfile.REGTYPE``tarfile.AREGTYPE`

A regular file *type*.

`tarfile.LNKTYPE`

A link (inside tarfile) *type*.

`tarfile.SYMTYPE`

A symbolic link *type*.

`tarfile.CHRTYPE`

A character special device *type*.

`tarfile.BLKTYPE`

A block special device *type*.

`tarfile.DIRTYPE`

A directory *type*.

`tarfile.FIFOTYPE`

A FIFO special device *type*.

`tarfile.CONTTYPE`

A contiguous file *type*.

`tarfile.GNUTYPE_LONGNAME`

A GNU tar longname *type*.

`tarfile.GNUTYPE_LONGLINK`

A GNU tar longlink *type*.

`tarfile.GNUTYPE_SPARSE`

A GNU tar sparse file *type*.

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section *Supported tar formats* for details.

`tarfile.USTAR_FORMAT`

POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`

GNU tar format.

`tarfile.PAX_FORMAT`

POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`

The default format for creating archives. This is currently `PAX_FORMAT`.

在 3.8 版的變更: The default format for new archives was changed to `PAX_FORMAT` from `GNU_FORMAT`.

## 13.6.1 TarFile 物件

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see *TarInfo 物件* for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the *範例* section for a use case.

在 3.2 版被加入: Added support for the context management protocol.

```
class tarfile.TarFile (name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT, tarinfo=TarInfo,
                      dereference=False, ignore_zeros=False, encoding=ENCODING,
                      errors='surrogateescape', pax_headers=None, debug=0, errorlevel=1, stream=False)
```

All following arguments are optional and can be accessed as instance attributes as well.

*name* is the pathname of the archive. *name* may be a *path-like object*. It can be omitted if *fileobj* is given. In this case, the file object's `name` attribute is used if it exists.

*mode* is either 'r' to read from an existing archive, 'a' to append data to an existing file, 'w' to create a new file overwriting an existing one, or 'x' to create a new file only if it does not already exist.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s `mode`. *fileobj* will be used from position 0.

### 備 F

*fileobj* is not closed, when `TarFile` is closed.

*format* controls the archive format for writing. It must be one of the constants `USTAR_FORMAT`, `GNU_FORMAT` or `PAX_FORMAT` that are defined at module level. When reading, *format* will be automatically detected, even if different formats are present in a single archive.

The *tarinfo* argument can be used to replace the default `TarInfo` class with a different one.

If *dereference* is `False`, add symbolic and hard links to the archive. If it is `True`, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore\_zeros* is `False`, treat an empty block as the end of the archive. If it is `True`, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

*debug* can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to `sys.stderr`.

*errorlevel* controls how extraction errors are handled, see *the corresponding attribute*.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section *Unicode issues* for in-depth information.

The *pax\_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is `PAX_FORMAT`.

If *stream* is set to `True` then while reading the archive info about files in the archive are not cached, saving memory.

在 3.2 版的變更: Use 'surrogateescape' as the default for the *errors* argument.

在 3.5 版的變更: The 'x' (exclusive creation) mode was added.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

在 3.13 版的變更: 新增 *stream* 參數。

**classmethod** `TarFile.open(...)`

Alternative constructor. The `tarfile.open()` function is actually a shortcut to this classmethod.

`TarFile.getmember(name)`

Return a `TarInfo` object for member *name*. If *name* can not be found in the archive, `KeyError` is raised.

 備 F

If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

`TarFile.getmembers()`

Return the members of the archive as a list of `TarInfo` objects. The list has the same order as the members in the archive.

`TarFile.getnames()`

Return the members as a list of their names. It has the same order as the list returned by `getmembers()`.

`TarFile.list(verbose=True, *, members=None)`

Print a table of contents to `sys.stdout`. If *verbose* is `False`, only the names of the members are printed. If it is `True`, output similar to that of `ls -l` is produced. If optional *members* is given, it must be a subset of the list returned by `getmembers()`.

在 3.5 版的變更: 新增 *members* 參數。

`TarFile.next()`

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

`TarFile.extractall` (*path='.'*, *members=None*, \*, *numeric\_owner=False*, *filter=None*)

Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric\_owner* is `True`, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

The *filter* argument specifies how *members* are modified or rejected before extraction. See [Extraction filters](#) for details. It is recommended to set this explicitly depending on which *tar* features you need to support.

#### 警告

Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.

Set `filter='data'` to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

在 3.5 版的變更: 新增 *numeric\_owner* 參數。

在 3.6 版的變更: The *path* parameter accepts a *path-like object*.

在 3.12 版的變更: 新增 *filter* 參數。

`TarFile.extract` (*member*, *path=""*, *set\_attrs=True*, \*, *numeric\_owner=False*, *filter=None*)

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a `TarInfo` object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set\_attrs* is false.

The *numeric\_owner* and *filter* arguments are the same as for `extractall()`.

#### 備 F

The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

#### 警告

參 F `extractall()` 的警告。

Set `filter='data'` to prevent the most dangerous security issues, and read the [Extraction filters](#) section for details.

在 3.2 版的變更: 增加 *set\_attrs* 參數。

在 3.5 版的變更: 新增 *numeric\_owner* 參數。

在 3.6 版的變更: The *path* parameter accepts a *path-like object*.

在 3.12 版的變更: 新增 *filter* 參數。

`TarFile.extractfile` (*member*)

Extract a member from the archive as a file object. *member* may be a filename or a `TarInfo` object. If *member* is a regular file or a link, an `io.BufferedReader` object is returned. For all other existing members, `None` is returned. If *member* does not appear in the archive, `KeyError` is raised.

在 3.3 版的變更: Return an `io.BufferedReader` object.

在 3.13 版的變更: The returned `io.BufferedReader` object has the `mode` attribute which is always equal to `'rb'`.

`TarFile.errorlevel`: `int`

If `errorlevel` is 0, errors are ignored when using `TarFile.extract()` and `TarFile.extractall()`. Nevertheless, they appear as error messages in the debug output when `debug` is greater than 0. If 1 (the default), all *fatal* errors are raised as `OSError` or `FilterError` exceptions. If 2, all *non-fatal* errors are raised as `TarError` exceptions as well.

Some exceptions, e.g. ones caused by wrong argument types or data corruption, are always raised.

Custom *extraction filters* should raise `FilterError` for *fatal* errors and `ExtractError` for *non-fatal* ones.

Note that when an exception is raised, the archive may be partially extracted. It is the user's responsibility to clean up.

`TarFile.extraction_filter`

在 3.12 版被加入.

The *extraction filter* used as a default for the `filter` argument of `extract()` and `extractall()`.

The attribute may be `None` or a callable. String names are not allowed for this attribute, unlike the `filter` argument to `extract()`.

If `extraction_filter` is `None` (the default), calling an extraction method without a `filter` argument will raise a `DeprecationWarning`, and fall back to the `fully_trusted` filter, whose dangerous behavior matches previous versions of Python.

In Python 3.14+, leaving `extraction_filter=None` will cause extraction methods to use the `data` filter by default.

The attribute may be set on instances or overridden in subclasses. It also is possible to set it on the `TarFile` class itself to set a global default, although, since it affects all uses of `tarfile`, it is best practice to only do so in top-level applications or *site configuration*. To set a global default this way, a filter function needs to be wrapped in `staticmethod()` to prevent injection of a `self` argument.

`TarFile.add` (`name`, `arcname=None`, `recursive=True`, `*`, `filter=None`)

Add the file `name` to the archive. `name` may be any type of file (directory, fifo, symbolic link, etc.). If given, `arcname` specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting `recursive` to `False`. Recursion adds entries in sorted order. If `filter` is given, it should be a function that takes a `TarInfo` object argument and returns the changed `TarInfo` object. If it instead returns `None` the `TarInfo` object will be excluded from the archive. See 範例 for an example.

在 3.2 版的變更: 新增 `filter` 參數。

在 3.7 版的變更: Recursion adds entries in sorted order.

`TarFile.addfile` (`tarinfo`, `fileobj=None`)

Add the `TarInfo` object `tarinfo` to the archive. If `tarinfo` represents a non zero-size regular file, the `fileobj` argument should be a *binary file*, and `tarinfo.size` bytes are read from it and added to the archive. You can create `TarInfo` objects directly, or by using `gettaringo()`.

在 3.13 版的變更: `fileobj` must be given for non-zero-sized regular files.

`TarFile.gettarinfo` (`name=None`, `arcname=None`, `fileobj=None`)

Create a `TarInfo` object from the result of `os.stat()` or equivalent on an existing file. The file is either named by `name`, or specified as a *file object* `fileobj` with a file descriptor. `name` may be a *path-like object*. If given, `arcname` specifies an alternative name for the file in the archive, otherwise, the name is taken from `fileobj`'s `name` attribute, or the `name` argument. The name should be a text string.

You can modify some of the `TarInfo`'s attributes before you add it using `addfile()`. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as `size` may need modifying. This is the case for objects such as `GzipFile`. The `name` may also be modified, in which case `arcname` could be a dummy string.

在 3.6 版的變更: The *name* parameter accepts a *path-like object*.

`TarFile.close()`

Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

`TarFile.pax_headers`: *dict*

A dictionary containing key-value pairs of pax global headers.

## 13.6.2 TarInfo 物件

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

*TarInfo* objects are returned by *TarFile*'s methods *getmember()*, *getmembers()* and *gettinfo()*.

Modifying the objects returned by *getmember()* or *getmembers()* will affect all subsequent operations on the archive. For cases where this is unwanted, you can use *copy.copy()* or call the *replace()* method to create a modified copy in one step.

Several attributes can be set to `None` to indicate that a piece of metadata is unused or unknown. Different *TarInfo* methods handle `None` differently:

- The *extract()* or *extractall()* methods will ignore the corresponding metadata, leaving it set to a default.
- *addfile()* will fail.
- *list()* will print a placeholder string.

**class** `tarfile.TarInfo` (*name=""*)

Create a *TarInfo* object.

**classmethod** `TarInfo.frombuf` (*buf*, *encoding*, *errors*)

Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

**classmethod** `TarInfo.fromtarfile` (*tarfile*)

Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

`TarInfo.tobuf` (*format=DEFAULT\_FORMAT*, *encoding=ENCODING*, *errors='surrogateescape'*)

Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

在 3.2 版的變更: Use 'surrogateescape' as the default for the *errors* argument.

A *TarInfo* object has the following public data attributes:

`TarInfo.name`: *str*

Name of the archive member.

`TarInfo.size`: *int*

Size in bytes.

`TarInfo.mtime`: *int* | *float*

Time of last modification in seconds since the *epoch*, as in *os.stat\_result.st\_mtime*.

在 3.12 版的變更: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

`TarInfo.mode`: *int*

Permission bits, as for *os.chmod()*.

在 3.12 版的變更: Can be set to `None` for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

**TarInfo.type**

File type. *type* is usually one of these constants: *REGTYPE*, *AREGTYPE*, *LNKTYPE*, *SYMTYPE*, *DIRTYPE*, *FIFOTYPE*, *CONTTYPE*, *CHRTYPE*, *BLKTYPE*, *GNUTYPE\_SPARSE*. To determine the type of a *TarInfo* object more conveniently, use the *is\*()* methods below.

**TarInfo.linkname: str**

Name of the target file name, which is only present in *TarInfo* objects of type *LNKTYPE* and *SYMTYPE*.

For symbolic links (*SYMTYPE*), the *linkname* is relative to the directory that contains the link. For hard links (*LNKTYPE*), the *linkname* is relative to the root of the archive.

**TarInfo.uid: int**

User ID of the user who originally stored this member.

在 3.12 版的變更: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

**TarInfo.gid: int**

Group ID of the user who originally stored this member.

在 3.12 版的變更: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

**TarInfo.uname: str**

User name.

在 3.12 版的變更: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

**TarInfo.gname: str**

Group name.

在 3.12 版的變更: Can be set to *None* for *extract()* and *extractall()*, causing extraction to skip applying this attribute.

**TarInfo.chksum: int**

Header checksum.

**TarInfo.devmajor: int**

Device major number.

**TarInfo.devminor: int**

Device minor number.

**TarInfo.offset: int**

The tar header starts here.

**TarInfo.offset\_data: int**

The file's data starts here.

**TarInfo.sparse**

Sparse member information.

**TarInfo.pax\_headers: dict**

A dictionary containing key-value pairs of an associated pax extended header.

**TarInfo.replace** (*name=...*, *mtime=...*, *mode=...*, *linkname=...*, *uid=...*, *gid=...*, *uname=...*, *gname=...*, *deep=True*)

在 3.12 版被加入.

Return a *new* copy of the *TarInfo* object with the given attributes changed. For example, to return a *TarInfo* with the group name set to 'staff', use:

```
new_tarinfo = old_tarinfo.replace(gname='staff')
```

By default, a deep copy is made. If *deep* is false, the copy is shallow, i.e. `pax_headers` and any custom attributes are shared with the original `TarInfo` object.

A `TarInfo` object also provides some convenient query methods:

`TarInfo.isfile()`

Return *True* if the `TarInfo` object is a regular file.

`TarInfo.isreg()`

Same as `isfile()`.

`TarInfo.isdir()`

Return *True* if it is a directory.

`TarInfo.issym()`

Return *True* if it is a symbolic link.

`TarInfo.islnk()`

Return *True* if it is a hard link.

`TarInfo.ischr()`

Return *True* if it is a character device.

`TarInfo.isblk()`

Return *True* if it is a block device.

`TarInfo.isfifo()`

Return *True* if it is a FIFO.

`TarInfo.isdev()`

Return *True* if it is one of character device, block device or FIFO.

### 13.6.3 Extraction filters

在 3.12 版被加入。

The `tar` format is designed to capture all details of a UNIX-like filesystem, which makes it very powerful. Unfortunately, the features make it easy to create tar files that have unintended -- and possibly malicious -- effects when extracted. For example, extracting a tar file can overwrite arbitrary files in various ways (e.g. by using absolute paths, `..` path components, or symlinks that affect later members).

In most cases, the full functionality is not needed. Therefore, `tarfile` supports extraction filters: a mechanism to limit functionality, and thus mitigate some of the security issues.

#### 也參考

##### PEP 706

Contains further motivation and rationale behind the design.

The *filter* argument to `TarFile.extract()` or `extractall()` can be:

- the string `'fully_trusted'`: Honor all metadata as specified in the archive. Should be used if the user trusts the archive completely, or implements their own complex verification.
- the string `'tar'`: Honor most `tar`-specific features (i.e. features of UNIX-like filesystems), but block features that are very likely to be surprising or malicious. See `tar_filter()` for details.
- the string `'data'`: Ignore or block most features specific to UNIX-like filesystems. Intended for extracting cross-platform data archives. See `data_filter()` for details.

- None (default): Use `TarFile.extraction_filter`.

If that is also None (the default), raise a `DeprecationWarning`, and fall back to the 'fully\_trusted' filter, whose dangerous behavior matches previous versions of Python.

In Python 3.14, the 'data' filter will become the default instead. It's possible to switch earlier; see `TarFile.extraction_filter`.

- A callable which will be called for each extracted member with a `TarInfo` describing the member and the destination path to where the archive is extracted (i.e. the same path is used for all members):

```
filter(member: TarInfo, path: str, /) -> TarInfo | None
```

The callable is called just before each member is extracted, so it can take the current state of the disk into account. It can:

- return a `TarInfo` object which will be used instead of the metadata in the archive, or
- return `None`, in which case the member will be skipped, or
- raise an exception to abort the operation or skip the member, depending on `errorlevel`. Note that when extraction is aborted, `extractall()` may leave the archive partially extracted. It does not attempt to clean up.

### Default named filters

The pre-defined, named filters are available as functions, so they can be reused in custom filters:

`tarfile.fully_trusted_filter(member, path)`

Return *member* unchanged.

This implements the 'fully\_trusted' filter.

`tarfile.tar_filter(member, path)`

Implements the 'tar' filter.

- Strip leading slashes (/ and `os.sep`) from filenames.
- *Refuse* to extract files with absolute paths (in case the name is absolute even after stripping slashes, e.g. `C:/foo` on Windows). This raises `AbsolutePathError`.
- *Refuse* to extract files whose absolute path (after following symlinks) would end up outside the destination. This raises `OutsideDestinationError`.
- Clear high mode bits (setuid, setgid, sticky) and group/other write bits (`S_IWGRP` | `S_IWOTH`).

Return the modified `TarInfo` member.

`tarfile.data_filter(member, path)`

Implements the 'data' filter. In addition to what `tar_filter` does:

- *Refuse* to extract links (hard or soft) that link to absolute paths, or ones that link outside the destination. This raises `AbsoluteLinkError` or `LinkOutsideDestinationError`.  
Note that such files are refused even on platforms that do not support symbolic links.
- *Refuse* to extract device files (including pipes). This raises `SpecialFileError`.
- For regular files, including hard links:
  - Set the owner read and write permissions (`S_IRUSR` | `S_IWUSR`).
  - Remove the group & other executable permission (`S_IXGRP` | `S_IXOTH`) if the owner doesn't have it (`S_IXUSR`).
- For other files (directories), set `mode` to `None`, so that extraction methods skip applying permission bits.
- Set user and group info (`uid`, `gid`, `uname`, `gname`) to `None`, so that extraction methods skip setting it.

Return the modified `TarInfo` member.

## Filter errors

When a filter refuses to extract a file, it will raise an appropriate exception, a subclass of `FilterError`. This will abort the extraction if `TarFile.errorlevel` is 1 or more. With `errorlevel=0` the error will be logged and the member will be skipped, but extraction will continue.

## Hints for further verification

Even with `filter='data'`, `tarfile` is not suited for extracting untrusted files without prior inspection. Among other issues, the pre-defined filters do not prevent denial-of-service attacks. Users should do additional checks.

Here is an incomplete list of things to consider:

- Extract to a *new temporary directory* to prevent e.g. exploiting pre-existing links, and to make it easier to clean up after a failed extraction.
- When working with untrusted data, use external (e.g. OS-level) limits on disk, memory and CPU usage.
- Check filenames against an allow-list of characters (to filter out control characters, confusables, foreign path separators, etc.).
- Check that filenames have expected extensions (discouraging files that execute when you “click on them”, or extension-less files like Windows special device names).
- Limit the number of extracted files, total size of extracted data, filename length (including symlink length), and size of individual files.
- Check for files that would be shadowed on case-insensitive filesystems.

Also note that:

- Tar files may contain multiple versions of the same file. Later ones are expected to overwrite any earlier ones. This feature is crucial to allow updating tape archives, but can be abused maliciously.
- `tarfile` does not protect against issues with “live” data, e.g. an attacker tinkering with the destination (or source) directory while extraction (or archiving) is in progress.

## Supporting older Python versions

Extraction filters were added to Python 3.12, but may be backported to older versions as security updates. To check whether the feature is available, use e.g. `hasattr(tarfile, 'data_filter')` rather than checking the Python version.

The following examples show how to support Python versions with and without the feature. Note that setting `extraction_filter` will affect any subsequent operations.

- Fully trusted archive:

```
my_tarfile.extraction_filter = (lambda member, path: member)
my_tarfile.extractall()
```

- Use the 'data' filter if available, but revert to Python 3.11 behavior ('fully\_trusted') if this feature is not available:

```
my_tarfile.extraction_filter = getattr(tarfile, 'data_filter',
                                       (lambda member, path: member))
my_tarfile.extractall()
```

- Use the 'data' filter; *fail* if it is not available:

```
my_tarfile.extractall(filter=tarfile.data_filter)
```

或:

```
my_tarfile.extraction_filter = tarfile.data_filter
my_tarfile.extractall()
```

- Use the 'data' filter; *warn* if it is not available:

```
if hasattr(tarfile, 'data_filter'):
    my_tarfile.extractall(filter='data')
else:
    # remove this when no longer needed
    warn_the_user('Extracting may be unsafe; consider updating Python')
    my_tarfile.extractall()
```

### Stateful extraction filter example

While *tarfile*'s extraction methods take a simple *filter* callable, custom filters may be more complex objects with an internal state. It may be useful to write these as context managers, to be used like this:

```
with StatefulFilter() as filter_func:
    tar.extractall(path, filter=filter_func)
```

Such a filter can be written as, for example:

```
class StatefulFilter:
    def __init__(self):
        self.file_count = 0

    def __enter__(self):
        return self

    def __call__(self, member, path):
        self.file_count += 1
        return member

    def __exit__(self, *exc_info):
        print(f'{self.file_count} files extracted')
```

## 13.6.4 Command-Line Interface

在 3.4 版被加入。

The *tarfile* module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the `-e` option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar other-dir/
```

For a list of the files in a tar archive, use the `-l` option:

```
$ python -m tarfile -l monty.tar
```

## 命令列選項

```
-l <tarfile>
--list <tarfile>
    List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>
--create <tarfile> <source1> ... <sourceN>
    Create tarfile from source files.

-e <tarfile> [<output_dir>]
--extract <tarfile> [<output_dir>]
    Extract tarfile into the current directory if output_dir is not specified.

-t <tarfile>
--test <tarfile>
    Test whether the tarfile is valid or not.

-v, --verbose
    Verbose output.

--filter <filtername>
    Specifies the filter for --extract. See Extraction filters for details. Only string names are accepted (that is, fully_trusted, tar, and data).
```

## 13.6.5 范例

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall(filter='data')
tar.close()
```

How to extract a subset of a tar archive with `TarFile.extractall()` using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a `gzip` compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is ", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the `filter` parameter in `TarFile.add()`:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

## 13.6.6 Supported tar formats

There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 `ustar` format (`USTAR_FORMAT`). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (`GNU_FORMAT`). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 `pax` format (`PAX_FORMAT`). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. Modern tar implementations, including GNU tar, `bsdtar/libarchive` and `star`, fully support extended `pax` features; some old or unmaintained libraries may not, but should treat `pax` archives as if they were in the universally supported `ustar` format. It is the current default format for new archives.

It extends the existing `ustar` format with extra headers for information that cannot be stored otherwise. There are two flavours of `pax` headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a `pax` header is encoded in `UTF-8` for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient `V7` format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 `pax` format, but is not compatible.

## 13.6.7 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a `UTF-8` system cannot be

read correctly on a *Latin-1* system if it contains non-ASCII characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in *tarfile* are controlled by the *encoding* and *errors* keyword arguments of the *TarFile* class.

*encoding* defines the character encoding to use for the metadata in the archive. The default value is *sys.getfilesystemencoding()* or 'ascii' as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is 'surrogateescape' which Python also uses for its file system calls, see *File Names, Command Line Arguments, and Environment Variables*.

For *PAX\_FORMAT* archives (the default), *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

## 14.1 csv --- CSV 檔案讀取及寫入

原始碼: [Lib/csv.py](#)

所謂的 CSV (Comma Separated Values) 檔案格式是試算表及資料庫中最常見的匯入、匯出檔案格式。在嘗試以 **RFC 4180** 中的標準化方式來描述格式之前，CSV 格式已經使用了許多年。由於缺少一個完善定義的標準，意味著各個不同的應用程式會在資料產生及銷毀時有微妙的差別。這些不同之處使得從不同資料來源處理 CSV 檔案時會非常擾人。儘管如此，雖然分隔符號和引號字元有所不同，整體的格式非常相似，可以寫個單一模組來高效率的操作這樣的資料，讓程式設計師可以隱藏讀取及寫入資料的細節。

csv 模組實作透過 class 去讀取、寫入 CSV 格式的表格資料。它讓程式設計師可以說出：「以 Excel 首選寫入該種格式的資料」或是「從 Excel 產生的檔案來讀取資料」，且無需知道這是 Excel 所使用的 CSV 格式等精確的細節。程式設計師也可以描述其他應用程式所理解的 CSV 格式或他們自行定義具有特殊意義的 CSV 格式。

csv 模組的 `reader` 及 `writer` 物件可以讀取及寫入序列。程式設計師也可以透過 `DictReader` 及 `DictWriter` class (類) 使用 dictionary (字典) 讀取及寫入資料。

### 也參考

#### PEP 305 - CSV 檔案 API

Python Enhancement Proposal (PEP) 所提出的 Python 附加功能。

### 14.1.1 模組內容

csv 模組定義了以下函式：

`csv.reader(csvfile, dialect='excel', **fmtparams)`

回傳一個讀取器物件 (*reader object*) 處理在指定的 `csvfile` 中的每一行，`csvfile` 必須是字串的可迭代物件 (iterable of strings)，其中每個字串都要是讀取器所定義的 csv 格式，`csvfile` 通常是個類檔案物

件或者 list。如果 *csvfile* 是個檔案物件，則需開時使用 `newline=''`。<sup>1</sup> *dialect* 一個可選填的參數，可以用特定的 CSV dialect (方言) 定義一組參數。它可能 *Dialect* 的一個子類 (subclass) 的實例或是由 `list_dialects()` 函式回傳的多個字串中的其中之一。另一個可選填的關鍵字引數 *fmtparams* 可以在這個 dialect 中覆寫 (override) 個的格式化參數 (formatting parameter)。關於 dialect 及格式化參數的完整說明，請見段落 *Dialect* 與格式參數。

從 CSV 檔案讀取的每一列會回傳一個字串列表。除非格式選項 `QUOTE_NONNUMERIC` 有被指定 (在這個情之下，有引號的欄位都會被轉成浮點數)，否則不會進行自動資料型轉。

一個簡短的用法範例：

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

`csv.writer(csvfile, dialect='excel', **fmtparams)`

回傳一個寫入器物件 (writer object)，其負責在給定的類檔案物件 (file-like object) 上將使用者的資料轉成分隔字串 (delimited string)。 *csvfile* 可以具有 `write()` method 的任何物件。若 *csvfile* 一個檔案物件，它應該使用 `newline=''` 開。<sup>1</sup> *dialect* 一個可選填的參數，可以用特定的 CSV dialect 定義一組參數。它可能 *Dialect* 的一個子類的實例或是由 `list_dialects()` 函式回傳的多個字串中的其中之一。另一個可選填的關鍵字引數 *fmtparams* 可以在這個 dialect 中覆寫個的格式化參數。關於 dialect 及格式化參數的完整說明，請見段落 *Dialect* 與格式參數。了更容易與有實作 DB API 的模組互相接合，`None` 值會被寫成空字串。雖然這不是一個可逆的變，這使得 `dump` (傾印) SQL NULL 資料值到 CSV 檔案上就無需讓 `cursor.fetch*` 呼叫回傳的資料進行預處理 (preprocessing)。其余非字串的資料則會在寫入之前用 `str()` 函式進行字串化 (stringify)。

一個簡短的用法範例：

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                           quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

`csv.register_dialect(name[, dialect[, **fmtparams]])`

將 *dialect* 與 *name* 進行關聯 (associate)。 *name* 必須字串。這個 dialect 可以透過傳遞 *Dialect* 的子類進行指定；或是關鍵字引數 *fmtparams*；或是以上兩者皆是，透過關鍵字引數來覆寫 dialect 的參數。關於 dialect 及格式化參數的完整說明，請見段落 *Dialect* 與格式參數。

`csv.unregister_dialect(name)`

從 dialect 表 (registry) 中，除與 *name* 關聯的 dialect。若 *name* 如果不是的 dialect 名稱，則會生一個 `Error`。

`csv.get_dialect(name)`

回傳一個與 *name* 關聯的 dialect。若 *name* 如果不是的 dialect 名稱，則會生一個 `Error`。這個函式會回傳一個 immutable (不可變物件) *Dialect*。

`csv.list_dialects()`

回傳所有已的 dialect 名稱。

`csv.field_size_limit([new_limit])`

回傳當前的剖析器 (parser) 允許的最大字串大小。如果 *new\_limit* 被給定，則會變成新的最大字串大小。

`csv` 模組定義了下列的類：

<sup>1</sup> 如果 `newline=''` 有被指定，則嵌入引號中的行符號不會被正確直譯，使用 `\r\n` 行尾 (linending) 的平台會寫入額外的 `\r`。自從 `csv` 模組有自己 (統一的) 行處理方式，因此指定 `newline=''` 會永遠是安全的。

**class** `csv.DictReader` (*f*, *fieldnames=None*, *restkey=None*, *restval=None*, *dialect='excel'*, \**args*, \*\**kwds*)

建立一個物件，其運作上就像一般的讀取器，但可以將每一列資訊 `map`（對映）到 `dict` 中，可以透過選填的參數 `fieldnames` 設定 `key`。

參數 `fieldnames` 是一個 `sequence`。如果 `fieldnames` 被省略了，檔案 `f` 中第一列的值會被當作欄位標題，且於結果中會被省略。如果 `fieldname` 有提供，它們就會被使用，且第一列會被包含在結果中。不管欄位標題是如何限定的，`dictionary` 都會保留原始的排序。

如果一列資料中的欄位比欄位標題還多，其余的資料及以 `restkey`（預設 `None`）特指的欄位標題會放入列表當中儲存。如果一個非空的（non-blank）列中的欄位比欄位標題還少，缺少的值則會填入 `restval`（預設 `None`）的值。

所有其他選填的引數或關鍵字引數皆會傳遞至下層的 `reader` 實例。

如果傳遞至 `fieldnames` 的引數是個代器，則會被迫成一個 `list`。

在 3.6 版的變更：回傳的列已成型 `OrderedDict`。

在 3.8 版的變更：回傳的列已成型 `dict`。

一個簡短的用法範例：

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
{'first_name': 'John', 'last_name': 'Cleese'}
```

**class** `csv.DictWriter` (*f*, *fieldnames*, *restval=""*, *extrasaction='raise'*, *dialect='excel'*, \**args*, \*\**kwds*)

建立一個物件，其運作上就像一般的寫入器，但可以將 `dictionary map` 到輸出的列上。參數 `fieldnames` 是一個鍵值的 `sequence` 且可以辨識 `dictionary` 中傳遞至 `writerow()` method 寫入至檔案 `f` 中的值。如果 `dictionary` 中缺少了 `fieldnames` 的鍵值，則會寫入選填的參數 `restval` 的值。如果傳遞至 `writerow()` method 的 `dictionary` 包含了一個 `fieldnames` 中不存在的鍵值，選填的參數 `extrasaction` 可以指出該執行的動作。如果它被設定 `'raise'`，預設會觸發 `ValueError`。如果它被設定 `'ignore'`，`dictionary` 中額外的值會被忽略。其他選填的引數或關鍵字引數皆會傳遞至下層的 `writer` 實例。

請記得這不像類 `DictReader`，在類 `DictWriter` 中，參數 `fieldnames` 不是選填的。

如果傳遞至 `fieldnames` 的引數是個代器，則會被迫成一個 `list`。

一個簡短的用法範例：

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

**class** `csv.Dialect`

類 `Dialect` 是一個容器類，其屬性（attribute）包含如何處理雙引號、空白、分隔符號等資訊。由於缺少一個嚴謹的 CSV 技術規範，不同的應用程式會出有巧妙不同的 CSV 資料。`Dialect` 實例定義了 `reader` 以及 `writer` 的實例該如何表示。

所有可用的 *Dialect* 名稱會透過 `list_dialects()` 回傳，且它們可以透過特定 *reader* 及 *writer* 類型的初始器 (`initializer`, `__init__`) 函式進行，就像這樣：

```
import csv

with open('students.csv', 'w', newline='') as csvfile:
    writer = csv.writer(csvfile, dialect='unix')
```

**class** `csv.excel`

類 `excel` 定義了透過 Excel 生的 CSV 檔案的慣用屬性。它被 `excel` 的 `dialect` 名稱 'excel'。

**class** `csv.excel_tab`

類 `excel_tab` 定義了透過 Excel 生以 Tab 作分隔的 CSV 檔案的慣用屬性。它被 `excel-tab` 的 `dialect` 名稱 'excel-tab'。

**class** `csv.unix_dialect`

類 `unix_dialect` 定義了透過 UNIX 系統生的 CSV 檔案的慣用屬性，`unix_dialect` 使用 '\n' 作行符號且所有欄位都被引號包覆起來。它被 `unix` 的 `dialect` 名稱 'unix'。

在 3.2 版被加入。

**class** `csv.Sniffer`

類 `Sniffer` 被用來推斷 CSV 檔案的格式。

類 `Sniffer` 提供了兩個 `method`：

**sniff** (*sample*, *delimiters=None*)

分析給定的 *sample* 且回傳一個 *Dialect* 子類，反應出找到的格式參數。如果給定選填的參數 *delimiters*，它會被解釋一個字串且含有可能、有效的分隔字元。

**has\_header** (*sample*)

如果第一列的文字顯示將作一系列的欄位標題，會分析 *sample* 文字（假定他是 CSV 格式）回傳 `True`。檢查每一欄時，會考慮是否滿足兩個關鍵標準其中之一，判斷 *sample* 是否包含標題：

- 第二列至第 *n* 列包含數字
- 第二列到第 *n* 列包含的字串中至少有一個值的長度與該行的假定標題的長度不同。

對第一列之後的二十個列進行取樣；如果超過一半的行及列滿足條件，則返回 `True`。

### 備

此方法是一個粗略的發，可能會生陽性及陰性 (false positives and negatives)。

一個 `Sniffer` 的使用範例：

```
with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... 在這邊處理 CSV 檔案 ...
```

`csv` 模組定義了以下常數：

**csv.QUOTE\_ALL**

引導 `writer` 物件引用所有欄位。

**csv.QUOTE\_MINIMAL**

引導 `writer` 物件只引用包含特殊字元的欄位，例如：分隔符號、引號、或是分行符號的其他字元。

**csv.QUOTE\_NONNUMERIC**

引導 *writer* 物件引用所有非數字的欄位。

引導 *reader* 物件轉回所有非引用的欄位回 *float*。

**csv.QUOTE\_NONE**

引導 *writer* 物件不得引用欄位。當前的分隔符號出現在輸出資料時，在他之前的字元是當前的 \* 逸出字元 (escape character)\*。如果回有設定 \* 逸出字元 \*，若遇到任何字元需要逸出，寫入器則會引發 *Error*。

引導 *reader* 物件不對引號進行特回處理。

**csv.QUOTE\_NOTNULL**

引導 *writer* 物件引用所有非 *None* 的欄位。這與 *QUOTE\_ALL* 相似，除非如果欄位值回 *None*，該欄位則被寫成空 (回有引號) 字串。

引導 *reader* 物件將空 (回有引號) 欄位直譯 (interpret) 回 *None*，否則會和 *QUOTE\_ALL* 有相同的表現方式。

在 3.12 版被加入。

**csv.QUOTE\_STRINGS**

引導 *writer* 物件永遠在字串的欄位前後放置引號。這與 *QUOTE\_NONNUMERIC* 相似，除非如果欄位值回 *None*，該欄位則被寫成空 (回有引號) 字串。

引導 *reader* 物件將空 (回有引號) 字串直譯回 *None*，否則會和 *QUOTE\_ALL* 有相同的表現方式。

在 3.12 版被加入。

*csv* 模組定義下列例外：

**exception csv.Error**

當偵測到錯誤時，任何函式都可以引發。

## 14.1.2 Dialect 與格式參數

回了讓指定輸入及輸出紀回的格式更方便，特定的格式化參數會被組成 *dialect*。一個 *dialect* 是 *Dialect* class 的子類回，其包含多個描述 CSV 檔案格式的多個屬性。當建立 *reader* 或 *writer* 物件時，程式設計師可以指定一個字串或是一個 *Dialect* 的子類回作回 *dialect* 參數。此外，或是作回替代，在 *dialect* 參數中，程式設計師可以指定個回的格式化參數，其與 *Dialect* 類回定義的屬性具有相同的名字。

*Dialect* 支援下列屬性：

**Dialect.delimiter**

一個單一字元 (one-character) 的字串可已用來分割欄位。預設回 `'`。

**Dialect.doublequote**

控制 *quotechar* 的實例何時出現在欄位之中，回讓它們自己被放在引號之回。當屬性回 *True*，字元會是雙引號。若回 *False*，在 *quotechar* 之前會先使用 *escapechar* 作回前綴字。預設回 *True*。

在輸出時，若 *doublequote* 是 *False* 且逸出字元回有被設定，當一個引號在欄位中被發現時，*Error* 會被引發。

**Dialect.escapechar**

一個會被寫入器使用的單一字元的字串，當 *quoting* 設定回 *QUOTE\_NONE* 時逸出分隔符號；當 *doublequote* 設定回 *False* 時逸出引號。在讀取時，逸出字元會移除後面的字元以及任何特殊意義。預設回 *None*，表示禁止逸出。

在 3.11 版的變更: *escapechar* 回空是不被接受的。

**Dialect.lineterminator**

由 *writer* 回生被用來分行的字串。預設回 `'\r\n'`。

**備**

`reader` 是 hard-coded 辨 `'\r'` or `'\n'` 作行尾 (end-of-line), 忽略分行符號。未來可能會改變這個行。

**Dialect.quotechar**

一個單一字元的字串被用於引用包含特殊字元的欄位, 像是 `delimiter`、`quotechar` 或是行字元。預設 `'`。

在 3.11 版的變更: `quotechar` 空是不被允許的。

**Dialect.quoting**

控制 `writer` 何時生引號, 以及 `reader` 如何辨識引號。他可以使用任何 `QUOTE_*` 常數且預設 `QUOTE_MINIMAL`。

**Dialect.skipinitialspace**

若 `True`, 在緊接著分隔符號後的空格會被忽略。預設 `False`。

**Dialect.strict**

若 `True`, 若有錯誤的 CSV 輸入則會引發 `Error`。預設 `False`。

### 14.1.3 讀取器物件

讀取器物件 (`reader()` 函式回傳的 `DictReader` 實例與物件) 有下列公用方法 (public method):

**csvreader.\_\_next\_\_()**

回傳一個列表讀入器的可代物件的下一列內容 (若該物件是由 `reader()` 回傳) 或是一個 `dict` (若 `DictReader` 實例), 會依據當前的 `Dialect` 進行剖析。通常會用 `next(reader)` 來進行呼叫。

讀取器物件有下列公用屬性 (public attributes):

**csvreader.dialect**

`dialect` 的唯讀述, 會被剖析器使用。

**csvreader.line\_num**

來源代器所讀取的行數。這與回傳的紀數不同, 因可以進行跨行紀。

`DictReader` 物件有下列公用屬性:

**DictReader.fieldnames**

若在建立物件時有作參數傳遞, 這個屬性會在第一次存取之前或是第一筆資料被讀取之前進行初始化 (initialize)。

### 14.1.4 寫入器物件

`writer` 物件 (`writer()` 函式回傳的 `DictWriter` 實例與物件) 有下列公用方法。對於 `writer` 物件而言, 一個列中必須一個可代的字串或是數字; 對於 `DictWriter` 物件而言, 則必須一個 `dictionary`, 且可以對應欄位標題至字串或數字 (會先透過 `str()` 進行傳遞)。請注意, 在寫入數 (complex number) 時會用小括號 (parens) 包起來。這可能在其他程式讀取 CSV 檔案時導致某些問題 (假設他們完全支援雜數字)。

**csvwriter.writerow(row)**

將參數 `row` 寫入至寫入器的檔案物件中, 依照當前的 `Dialect` 進行格式化。回傳下層檔案物件 `write` 方法的回傳值。

在 3.5 版的變更: 新增對任意可代物件 (arbitrary iterables) 的支援。

**csvwriter.writerows(rows)**

將 `rows` 中所有元素 (上述的一個可代的 `row` 物件) 寫入至寫入器的檔案物件中, 依照當前的 `dialect` 進行格式化。

寫入器物件有下列公用屬性:

`csvwriter.dialect`

`dialect` 的唯讀描述，會被寫入器使用。

`DictWriter` 物件有下列公用方法：

`DictWriter.writeheader()`

將具欄位標題的一列（於建構函式 (constructor) 中指定的）寫入至寫入器的檔案物件中，依照當前的 `dialect` 進行格式化。回傳內部呼叫 `csvwriter.writerow()` 的回傳值。

在 3.2 版被加入。

在 3.8 版的變更: `writeheader()` 現在也會回傳內部呼叫 `csvwriter.writerow()` 的回傳值。

## 14.1.5 范例

最簡單的讀取 CSV 檔案範例：

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

讀取一個其他格式的檔案：

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

相對最簡單、可行的寫入範例：

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

當 `open()` 被使用於開讀一個 CSV 檔案，該檔案會預設使用系統預設的編碼格式（請見 `locale.getencoding()`），解碼 `unicode`。若要使用不同編碼格式進行檔案解碼，請使用 `open` 函式的 `encoding` 引數：

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

同理可以應用到使用不同編碼格式進行寫入：當開輸出檔案時，指定 `encoding` 引數。

一個新的 `dialect`：

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

稍微進階的讀取器用法 -- 取及回報錯誤：

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
```

(繼續下一頁)

(繼續上一頁)

```
try:
    for row in reader:
        print(row)
except csv.Error as e:
    sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

而當模組無法直接支援剖析字串時，仍可以輕鬆的解：

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

解

## 14.2 configparser --- 設定檔剖析器

原始碼：Lib/configparser.py

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

### 備

This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

### 也參考

#### *tomllib* 模組

TOML is a well-specified format for application configuration files. It is specifically designed to be an improved version of INI.

#### *shlex* 模組

Support for creating Unix shell-like mini-languages which can also be used for application configuration files.

#### *json* 模組

The *json* module implements a subset of JavaScript syntax which is sometimes used for configuration, but does not support comments.

### 14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[forge.example]
User = hg
```

(繼續下一頁)

(繼續上一頁)

```
[topsecret.server.example]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. `configparser` classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                    'Compression': 'yes',
...                    'CompressionLevel': '9'}
>>> config['forge.example'] = {}
>>> config['forge.example']['User'] = 'hg'
>>> config['topsecret.server.example'] = {}
>>> topsecret = config['topsecret.server.example']
>>> topsecret['Port'] = '50022' # mutates the parser
>>> topsecret['ForwardX11'] = 'no' # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...     config.write(configfile)
...
...

```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['forge.example', 'topsecret.server.example']
>>> 'forge.example' in config
True
>>> 'python.org' in config
False
>>> config['forge.example']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.example']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['forge.example']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['forge.example']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which

provides default values for all other sections<sup>1</sup>. Note also that keys in sections are case-insensitive and stored in lowercase<sup>1</sup>.

It is possible to read several configurations into a single `ConfigParser`, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1

>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

This behaviour is equivalent to a `ConfigParser.read()` call with several files passed to the `filenames` parameter.

## 14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide `getboolean()`. This method is case-insensitive and recognizes Boolean values from 'yes'/'no', 'on'/'off', 'true'/'false' and '1'/'0'<sup>1</sup>. For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['forge.example'].getboolean('ForwardX11')
True
>>> config.getboolean('forge.example', 'Compression')
True
```

Apart from `getboolean()`, config parsers also provide equivalent `getint()` and `getfloat()` methods. You can register your own converters and customize the provided ones.<sup>1</sup>

## 14.2.3 Fallback Values

As with a dictionary, you can use a section's `get()` method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
```

(繼續下一頁)

<sup>1</sup> Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the *Customizing Parser Behaviour* section.

(繼續上一頁)

```
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the 'CompressionLevel' key was specified only in the 'DEFAULT' section. If we try to get it from the section 'topsecret.server.example', we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level `get()` method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('forge.example', 'monster',
...           fallback='No such things as monsters')
'No such things as monsters'
```

The same `fallback` argument can be used with the `getint()`, `getfloat()` and `getboolean()` methods, for example:

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

## 14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (= or : by default<sup>Page 594, 1</sup>). By default, section names are case sensitive but keys are not<sup>Page 594, 1</sup>. Leading and trailing whitespace is removed from keys and values. Values can be omitted if the parser is configured to allow it<sup>Page 594, 1</sup>, in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

By default, a valid section name can be any string that does not contain `\n`. To change this, see `ConfigParser.SECTCRE`.

The first section name may be omitted if the parser is configured to allow an unnamed top level section with `allow_unnamed_section=True`. In this case, the keys/values may be retrieved by `UNNAMED_SECTION` as in `config[UNNAMED_SECTION]`.

Configuration files may include comments, prefixed by specific characters (# and ; by default<sup>Page 594, 1</sup>). Comments may appear on their own on an otherwise empty line, possibly indented.<sup>Page 594, 1</sup>

舉例來<sup>F</sup>:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
```

(繼續下一頁)

```

or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
       I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.

    [Sections Can Be Indented]
        can_values_be_as_well = True
        does_that_mean_anything_special = False
        purpose = formatting for readability
        multiline_values = are
            handled just fine as
            long as they are indented
            deeper than the first line
            of a value
        # Did I mention we can indent comments, too?

```

## 14.2.5 Unnamed Sections

The name of the first section (or unique) may be omitted and values retrieved by the `UNNAMED_SECTION` attribute.

```

>>> config = """
... option = value
...
... [ Section 2 ]
... another = val
... """
>>> unnamed = configparser.ConfigParser(allow_unnamed_section=True)
>>> unnamed.read_string(config)
>>> unnamed.get(configparser.UNNAMED_SECTION, 'option')
'value'

```

## 14.2.6 Interpolation of values

On top of the core functionality, `ConfigParser` supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

**class** `configparser.BasicInterpolation`

The default implementation used by `ConfigParser`. It enables values to contain format strings which refer to other values in the same section, or values in the special default section<sup>Page 594, 1</sup>. Additional default values can be provided on initialization.

舉例來:

```
[Paths]
home_dir: /Users
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures

[Escape]
# use a %% to escape the % sign (% is the only character that needs to be escaped):
gain: 80%%
```

In the example above, `ConfigParser` with `interpolation` set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With `interpolation` set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

#### class `configparser.ExtendedInterpolation`

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures

[Escape]
# use a $$ to escape the $ sign ($ is the only character that needs to be escaped):
cost: $$80
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

## 14.2.7 Mapping Protocol Access

在 3.2 版被加入。

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of `configparser`, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

`configparser` objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner<sup>Page 594, 1</sup>. E.g. for `option` in `parser["section"]` yields only `optionxformed` option key names. This means lowercased keys by default. At the same time, for a section that holds the key 'a', both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a *KeyError*.
- `DEFAULTSECT` cannot be removed from the parser:
  - trying to delete it raises *ValueError*,
  - `parser.clear()` leaves it intact,
  - `parser.popitem()` never returns it.
- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic `configparser` API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section\_name, section\_proxy* pairs including the `DEFAULTSECT`). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option, value* pairs for a specified section, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

## 14.2.8 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. `configparser` goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

Hint: if you want to specify default values for a specific section, use `read_dict()` before you read the actual file.

- *dict\_type*, default value: `dict`

This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the standard dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

An alternative dictionary type can be used for example to sort sections and options on write-back.

Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys will be ordered. For example:

```

>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                               'key2': 'value2',
...                               'key3': 'value3'},
...                 'section2': {'keyA': 'valueA',
...                               'keyB': 'valueB',
...                               'keyC': 'valueC'},
...                 'section3': {'foo': 'x',
...                               'bar': 'y',
...                               'baz': 'z'}})
>>> parser.sections()
['section1', 'section2', 'section3']
>>> [option for option in parser['section3']]
['foo', 'bar', 'baz']

```

- `allow_no_value`, default value: `False`

Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `configparser`. The `allow_no_value` parameter to the constructor can be used to indicate that such values should be accepted:

```

>>> import configparser

>>> sample_config = """
... [mysqld]
...   user = mysql
...   pid-file = /var/run/mysqld/mysqld.pid
...   skip-external-locking
...   old_passwords = 1
...   skip-bdb
...   # we don't need ACID today
...   skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
...
KeyError: 'does-not-exist'

```

- `delimiters`, default value: `('=', ':')`

Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

See also the `space_around_delimiters` argument to `ConfigParser.write()`.

- `comment_prefixes`, default value: `('#, ';'')`
- `inline_comment_prefixes`, default value: `None`

Comment prefixes are strings that indicate the start of a valid comment within a config file. `comment_prefixes` are used only on otherwise empty lines (optionally indented) whereas `inline_comment_prefixes` can be used

after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and '#' and ';' are used as prefixes for whole line comments.

在 3.2 版的變更: In previous versions of *configparser* behaviour matched `comment_prefixes=(';', '#')` and `inline_comment_prefixes=(';', '#')`.

Please note that config parsers don't support escaping of comment prefixes so using *inline\_comment\_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline\_comment\_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...
... [hashes]
... shebang =
...     ${hash}!/usr/bin/env python
...     ${hash} -*- coding: utf-8 -*-
...
... extensions =
...     enabled_extension
...     another_extension
...     #disabled_by_comment
...     yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...     line #2
...     line #3
... """)
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3
```

- *strict*, default value: True

When set to True, the parser will not allow for any section or option duplicates while reading from a single source (using *read\_file()*, *read\_string()* or *read\_dict()*). It is recommended to use strict parsers in new applications.

在 3.2 版的變更: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty\_lines\_in\_values*, default value: True

In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```
[Section]
key = multiline
    value with a gotcha

this = is still a part of the multiline value of 'key'
```

This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- `default_section`, default value: `configparser.DEFAULTSECT` (that is: "DEFAULT")

The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called "DEFAULT" but this can be customized to point to any other valid section name. Some typical values include: "general" or "common". The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- `interpolation`, default value: `configparser.BasicInterpolation`

Interpolation behaviour may be customized by providing a custom handler through the `interpolation` argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the [dedicated documentation section](#). `RawConfigParser` has a default value of `None`.

- `converters`, default value: not set

Config parsers provide option value getters that perform type conversion. By default `getint()`, `getfloat()`, and `getboolean()` are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add `getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

#### `ConfigParser.BOOLEAN_STATES`

By default when using `getboolean()`, config parsers consider the following values `True`: '1', 'yes', 'true', 'on' and the following values `False`: '0', 'no', 'false', 'off'. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include `accept/reject` or `enabled/disabled`.

#### `ConfigParser.optionxform(option)`

This method transforms option names on every read, get, or set operation. The default converts the name to

lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']
```

#### 備F

The `optionxform` function transforms option names to a canonical form. This should be an idempotent function: if the name is already in canonical form, it should be returned unchanged.

#### ConfigParser.SECTCRE

A compiled regular expression used to parse section headers. The default matches `[section]` to the name "section". Whitespace is considered part of the section name, thus `[ larch ]` will be read as a section of name " larch ". Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [ Section 2 ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', ' Section 2 ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^\]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

#### 備F

While `ConfigParser` objects also use an `OPTCRE` attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options `allow_no_value` and `delimiters`.

## 14.2.9 Legacy API Examples

Mainly because of backwards compatibility concerns, `configparser` provides also a legacy API with explicit `get/set` methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-raw mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use `ConfigParser`:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False)) # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))  # -> "%(bar)s is %(baz)s!"

# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))
```

(繼續下一頁)

(繼續上一頁)

```
# The optional *fallback* argument can be used to provide a fallback value
print(cfg.get('Section1', 'foo'))
# -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
# -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
# -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
# -> None
```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```
import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))      # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))      # -> "Life is hard!"
```

## 14.2.10 ConfigParser 物件

```
class configparser.ConfigParser (defaults=None, dict_type=dict, allow_no_value=False, *,
    delimiters=('=', ':'), comment_prefixes=(';', '#'),
    inline_comment_prefixes=None, strict=True,
    empty_lines_in_values=True,
    default_section=configparser.DEFAULTSECT,
    interpolation=BasicInterpolation(), converters={},
    allow_unnamed_section=False)
```

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict\_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment\_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline\_comment\_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is *True* (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*. When *empty\_lines\_in\_values* is *False* (default: *True*), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow\_no\_value* is *True* (default: *False*), options without values are accepted; the value held for these is *None* and they are serialized without the trailing delimiter.

When *default\_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named "DEFAULT"). This value can be retrieved and changed at runtime using the *default\_section* instance attribute. This won't re-evaluate an already parsed config file, but will be used when writing parsed settings to a new config file.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. None can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*.

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. For example, using the default implementation of *optionxform()* (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding *get\*()* method on the parser object and section proxies.

When *allow\_unnamed\_section* is `True` (default: `False`), the first section name can be omitted. See the *"Unnamed Sections" section*.

It is possible to read several configurations into a single *ConfigParser*, where the most recently added configuration has the highest priority. Any conflicting keys are taken from the more recent configuration while the previously existing keys are retained. The example below reads in an `override.ini` file, which will override any conflicting keys from the `example.ini` file.

```
[DEFAULT]
ServerAliveInterval = -1
```

```
>>> config_override = configparser.ConfigParser()
>>> config_override['DEFAULT'] = {'ServerAliveInterval': '-1'}
>>> with open('override.ini', 'w') as configfile:
...     config_override.write(configfile)
...
>>> config_override = configparser.ConfigParser()
>>> config_override.read(['example.ini', 'override.ini'])
['example.ini', 'override.ini']
>>> print(config_override.get('DEFAULT', 'ServerAliveInterval'))
-1
```

在 3.1 版的變更: The default *dict\_type* is `collections.OrderedDict`.

在 3.2 版的變更: *allow\_no\_value*, *delimiters*, *comment\_prefixes*, *strict*, *empty\_lines\_in\_values*, *default\_section* and *interpolation* were added.

在 3.5 版的變更: 新增 *converters* 引數。

在 3.7 版的變更: The *defaults* argument is read with *read\_dict()*, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

在 3.8 版的變更: The default *dict\_type* is *dict*, since it now preserves insertion order.

在 3.13 版的變更: Raise a *MultilineContinuationError* when *allow\_no\_value* is `True`, and a key without a value is continued with an indented line.

在 3.13 版的變更: 新增 *allow\_unnamed\_section* 引數。

**defaults()**

Return a dictionary containing the instance-wide defaults.

**sections()**

Return a list of the sections available; the *default section* is not included in the list.

**add\_section(section)**

Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised. The name of the section must be a string; if not, *TypeError* is raised.

在 3.2 版的變更: Non-string section names raise *TypeError*.

**has\_section** (*section*)

Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

**options** (*section*)

Return a list of options available in the specified *section*.

**has\_option** (*section*, *option*)

If the given *section* exists, and contains the given *option*, return *True*; otherwise return *False*. If the specified *section* is *None* or an empty string, DEFAULT is assumed.

**read** (*filenames*, *encoding=None*)

Attempt to read and parse an iterable of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string, a *bytes* object or a *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify an iterable of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the iterable will be read.

If none of the named files exist, the *ConfigParser* instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using *read\_file()* before calling *read()* for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

在 3.2 版的變更: Added the *encoding* parameter. Previously, all files were read using the default encoding for *open()*.

在 3.6.1 版的變更: The *filenames* parameter accepts a *path-like object*.

在 3.7 版的變更: The *filenames* parameter accepts a *bytes* object.

**read\_file** (*f*, *source=None*)

Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a *name* attribute, that is used for *source*; the default is '<???'>'.

在 3.2 版被加入: 取代 *readfp()*。

**read\_string** (*string*, *source=<string>*)

Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, '<string>' is used. This should commonly be a filesystem path or a URL.

在 3.2 版被加入。

**read\_dict** (*dictionary*, *source=<dict>*)

Load configuration from any object that provides a dict-like *items()* method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, <dict> is used.

This method can be used to copy state between parsers.

在 3.2 版被加入。

**get** (*section*, *option*, \*, *raw=False*, *vars=None*[, *fallback* ])

Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *DEFAULTSECT* in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. *None* can be provided as a *fallback* value.

All the '%' interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

在 3.2 版的變更: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

**getint** (*section*, *option*, \*, *raw=False*, *vars=None*[, *fallback* ])

A convenience method which coerces the *option* in the specified *section* to an integer. See *get()* for explanation of *raw*, *vars* and *fallback*.

**getfloat** (*section*, *option*, \*, *raw=False*, *vars=None*[, *fallback* ])

A convenience method which coerces the *option* in the specified *section* to a floating-point number. See *get()* for explanation of *raw*, *vars* and *fallback*.

**getboolean** (*section*, *option*, \*, *raw=False*, *vars=None*[, *fallback* ])

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are '1', 'yes', 'true', and 'on', which cause this method to return *True*, and '0', 'no', 'false', and 'off', which cause it to return *False*. These string values are checked in a case-insensitive manner. Any other value will cause it to raise *ValueError*. See *get()* for explanation of *raw*, *vars* and *fallback*.

**items** (*raw=False*, *vars=None*)

**items** (*section*, *raw=False*, *vars=None*)

When *section* is not given, return a list of *section\_name*, *section\_proxy* pairs, including *DEFAULTSECT*.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the *get()* method.

在 3.8 版的變更: Items present in *vars* no longer appear in the result. The previous behaviour mixed actual parser options with variables provided for interpolation.

**set** (*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. *option* and *value* must be strings; if not, *TypeError* is raised.

**write** (*fileobject*, *space\_around\_delimiters=True*)

Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future *read()* call. If *space\_around\_delimiters* is true, delimiters between keys and values are surrounded by spaces.

#### 備 F

Comments in the original configuration file are not preserved when writing the configuration back. What is considered a comment, depends on the given values for *comment\_prefix* and *inline\_comment\_prefix*.

**remove\_option** (*section*, *option*)

Remove the specified *option* from the specified *section*. If the section does not exist, raise *NoSectionError*. If the option existed to be removed, return *True*; otherwise return *False*.

**remove\_section** (*section*)

Remove the specified *section* from the configuration. If the section in fact existed, return *True*. Otherwise return *False*.

**optionxform** (*option*)

Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before `optionxform()` is called.

**configparser.UNNAMED\_SECTION**

A special object representing a section name used to reference the unnamed section (see *Unnamed Sections*).

**configparser.MAX\_INTERPOLATION\_DEPTH**

The maximum depth for recursive interpolation for `get()` when the `raw` parameter is false. This is relevant only when the default `interpolation` is used.

### 14.2.11 RawConfigParser 物件

```
class configparser.RawConfigParser (defaults=None, dict_type=dict, allow_no_value=False, *,
                                     delimiters=('=', ':'), comment_prefixes=(';', '#'),
                                     inline_comment_prefixes=None, strict=True,
                                     empty_lines_in_values=True,
                                     default_section=configparser.DEFAULTSECT,
                                     interpolation=BasicInterpolation(), converters={},
                                     allow_unnamed_section=False)
```

Legacy variant of the `ConfigParser`. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

在 3.2 版的變更: `allow_no_value`, `delimiters`, `comment_prefixes`, `strict`, `empty_lines_in_values`, `default_section` and `interpolation` were added.

在 3.5 版的變更: 新增 `converters` 引數。

在 3.8 版的變更: The default `dict_type` is `dict`, since it now preserves insertion order.

在 3.13 版的變更: 新增 `allow_unnamed_section` 引數。

**備**

Consider using `ConfigParser` instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

**add\_section** (*section*)

Add a section named *section* to the instance. If a section by the given name already exists, `DuplicateSectionError` is raised. If the *default section* name is passed, `ValueError` is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

**set** (*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with `raw` parameters set to true) for

*internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

### 14.2.12 例外

**exception** `configparser.Error`

Base class for all other *configparser* exceptions.

**exception** `configparser.NoSectionError`

Exception raised when a specified section is not found.

**exception** `configparser.DuplicateSectionError`

Exception raised if *add\_section()* is called with the name of a section that is already present or in strict parsers when a section is found more than once in a single input file, string or dictionary.

在 3.2 版的變更: Added the optional *source* and *lineno* attributes and parameters to *\_\_init\_\_()*.

**exception** `configparser.DuplicateOptionError`

Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

**exception** `configparser.NoOptionError`

Exception raised when a specified option is not found in the specified section.

**exception** `configparser.InterpolationError`

Base class for exceptions raised when problems occur performing string interpolation.

**exception** `configparser.InterpolationDepthError`

Exception raised when string interpolation cannot be completed because the number of iterations exceeds *MAX\_INTERPOLATION\_DEPTH*. Subclass of *InterpolationError*.

**exception** `configparser.InterpolationMissingOptionError`

Exception raised when an option referenced from a value does not exist. Subclass of *InterpolationError*.

**exception** `configparser.InterpolationSyntaxError`

Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of *InterpolationError*.

**exception** `configparser.MissingSectionHeaderError`

Exception raised when attempting to parse a file which has no section headers.

**exception** `configparser.ParsingError`

Exception raised when errors occur attempting to parse a file.

在 3.12 版的變更: The *filename* attribute and *\_\_init\_\_()* constructor argument were removed. They have been available using the name *source* since 3.2.

**exception** `configparser.MultilineContinuationError`

Exception raised when a key without a corresponding value is continued with an indented line.

在 3.13 版被加入.

 解

## 14.3 tomllib --- 剖析 TOML 檔案

在 3.11 版被加入.

原始碼: [Lib/tomllib](#)

此模組提供了剖析 TOML 1.0.0 (Tom's Obvious Minimal Language, <https://toml.io>) 的一個介面，此模組不支援寫入 TOML。

### 也參考

Tomli-W 套件是一個 TOML 編寫器，可以與此模組結合使用，以提供標準函式庫中 *marshal* 和 *pickle* 模組之使用者所熟悉的寫入 API。

### 也參考

TOML 工具套件是一個保留風格且具有讀寫能力的 TOML 函式庫。若要編輯已存在的 TOML 文件，建議用它來替此模組。

此模組定義了以下函式：

`tomllib.load(fp, /, *, parse_float=float)`

讀取一個 TOML 檔案。第一個引數應一個可讀取的二進位檔案物件。回傳一個 *dict*。用這個轉表將 TOML 型轉成 Python 的。

`parse_float` 會被呼叫於要解碼的每個 TOML 浮點數字串。預設情況下，這相當於 `float(num_str)`。若有使用另一種資料型或剖析器的 TOML 浮點數（例如 `decimal.Decimal`），這就派得上用場。可呼叫物件不得回傳 *dict* 或 *list*，否則會引發 `ValueError`。

不合格的 TOML 文件會使得 `TOMLDecodeError` 被引發。

`tomllib.loads(s, /, *, parse_float=float)`

自一個 *str* 物件載入成 TOML。回傳一個 *dict*。用這個轉表轉 TOML 型成 Python 的。`parse_float` 引數和 `load()` 中的相同。

不合格的 TOML 文件會使得 `TOMLDecodeError` 被引發。

以下可用的例外：

**exception** `tomllib.TOMLDecodeError`

`ValueError` 的子類。

## 14.3.1 范例

剖析一個 TOML 檔案：

```
import tomllib

with open("pyproject.toml", "rb") as f:
    data = tomllib.load(f)
```

剖析一個 TOML 字串：

```
import tomllib

toml_str = """
python-version = "3.11.0"
python-implementation = "CPython"
"""

data = tomllib.loads(toml_str)
```

### 14.3.2 轉表

TOML	Python
TOML 文件	dict
string	str
integer	int
float	float (可透過 <code>parse_float</code> 調整)
boolean	bool
偏移日期時間 (offset date-time)	<code>datetime.datetime</code> (設定 <code>tzinfo</code> 屬性 <code>datetime.timezone</code> 的實例)
本地日期時間 (local date-time)	<code>datetime.datetime</code> (設定 <code>tzinfo</code> <code>None</code> )
本地日期 (local date)	<code>datetime.date</code>
本地時間 (local time)	<code>datetime.time</code>
array	list
table	dict
行表格 (inline table)	dict
表格陣列 (array of tables)	dict 串列 (list of dicts)

## 14.4 netrc --- netrc 檔案處理

原始碼: `Lib/netrc.py`

`netrc` 類能剖析 (parse) 封裝 (encapsulate) `netrc` 檔案格式，以供 Unix `ftp` 程式和其他 FTP 用端使用。

```
class netrc.netrc([file])
```

`netrc` 實例或其子類實例能封裝來自 `netrc` 檔案的資料。可用初始化引數 (如有給定) 指定要剖析的檔案，如果未給定引數，則將讀取 (由 `os.path.expanduser()` 指定的) 使用者主目錄中的 `.netrc` 檔案，否則將引發 `FileNotFoundError` 例外。剖析錯誤會引發 `NetrcParseError`，其帶有包括檔案名稱、列號和終止 token 的診斷資訊。如果在 POSIX 系統上未指定引數，且若檔案所有權或權限不安全 (擁有者與運行該行程的使用者不同，或者可供任何其他使用者讀取或寫入)，存有密碼的 `.netrc` 檔案將會引發 `NetrcParseError`。這實作了與 `ftp` 和其他使用 `.netrc` 程式等效的安全行。

在 3.4 版的變更: 新增了 POSIX 權限檢查。

在 3.7 版的變更: 當未傳遞 `file` 引數時，`os.path.expanduser()` 可用於查找 `.netrc` 檔案的位置。

在 3.10 版的變更: `netrc` 在使用特定語言環境編碼前會先嘗試 UTF-8 編碼。`netrc` 檔案中的條目就不再需要包含所有 token，缺少的 token 值被預設空字串。現在所有 token 及其值都可以包含任意字元，例如空格和非 ASCII 字元。如果登入名稱匿名，就不會觸發安全檢查。

```
exception netrc.NetrcParseError
```

當原始文本中遇到語法錯誤時，`netrc` 類會引發例外。此例外的實例提供了三個有趣的屬性：

**msg**

錯誤的文字解釋。

**filename**

原始檔案的名稱。

**lineno**

發現錯誤的列號。

### 14.4.1 netrc 物件

`netrc` 實例具有以下方法：

`netrc.authenticators (host)`

回傳 `host` 身份驗證器的三元素 `tuple` (`login`, `account`, `password`)。如果 `netrc` 檔案不包含給定主機的條目，則回傳與 `'default'` 條目關聯的 `tuple`。如果無匹配主機且預設條目也不可用則回傳 `None`。

`netrc.__repr__()`

將類資料傾印 (`dump`) `netrc` 檔案格式的字串。(這會將解移除，可能會對條目重新排序。)

`netrc` 的實例具有公開實例變數：

`netrc.hosts`

將主機名稱對映到 (`login`, `account`, `password`) `tuple` 的字典。`'default'` 條目 (如存在) 表示該名稱對應到的主機 (`pseudo-host`)。

`netrc.macros`

巨集 (`macro`) 名稱與字串 `list` (串列) 的對映字典。

## 14.5 plistlib --- 生和剖析 Apple .plist 檔案

原始碼：[Lib/plistlib.py](#)

This module provides an interface for reading and writing the "property list" files used by Apple, primarily on macOS and iOS. This module supports both binary and XML plist files.

The property list (`.plist`) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the `dump()` and `load()` functions.

To work with plist data in bytes or string objects, use `dumps()` and `loads()`.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), `bytes`, `bytearray` or `datetime.datetime` objects.

在 3.4 版的變更: New API, old API deprecated. Support for binary format plists added.

在 3.8 版的變更: Support added for reading and writing `UID` tokens in binary plists as used by `NSKeyedArchiver` and `NSKeyedUnarchiver`.

在 3.9 版的變更: Old API removed.

#### 也參考

##### [PList manual page](#)

Apple's documentation of the file format.

This module defines the following functions:

`plistlib.load (fp, *, fmt=None, dict_type=dict, aware_datetime=False)`

Read a plist file. `fp` should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The `fmt` is the format of the file and the following values are valid:

- `None`: Autodetect the file format
- `FMT_XML`: XML file format
- `FMT_BINARY`: Binary plist format

The `dict_type` is the type used for dictionaries that are read from the plist file.

When `aware_datetime` is true, fields with type `datetime.datetime` will be created as *aware object*, with `tzinfo` as `datetime.UTC`.

XML data for the `FMT_XML` format is parsed using the Expat parser from `xml.parsers.expat` -- see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises `InvalidFileException` when the file cannot be parsed.

在 3.4 版被加入。

在 3.13 版的變更: The keyword-only parameter `aware_datetime` has been added.

```
plistlib.loads(data, *, fmt=None, dict_type=dict, aware_datetime=False)
```

Load a plist from a bytes or string object. See `load()` for an explanation of the keyword arguments.

在 3.4 版被加入。

在 3.13 版的變更: `data` can be a string when `fmt` equals `FMT_XML`.

```
plistlib.dump(value, fp, *, fmt=FMT_XML, sort_keys=True, skipkeys=False, aware_datetime=False)
```

Write `value` to a plist file. `fp` should be a writable, binary file object.

The `fmt` argument specifies the format of the plist file and can be one of the following values:

- `FMT_XML`: XML formatted plist file
- `FMT_BINARY`: Binary formatted plist file

When `sort_keys` is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When `skipkeys` is false (the default) the function raises `TypeError` when a key of a dictionary is not a string, otherwise such keys are skipped.

When `aware_datetime` is true and any field with type `datetime.datetime` is set as an *aware object*, it will convert to UTC timezone before writing it.

A `TypeError` will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An `OverflowError` will be raised for integer values that cannot be represented in (binary) plist files.

在 3.4 版被加入。

在 3.13 版的變更: The keyword-only parameter `aware_datetime` has been added.

```
plistlib.dumps(value, *, fmt=FMT_XML, sort_keys=True, skipkeys=False, aware_datetime=False)
```

Return `value` as a plist-formatted bytes object. See the documentation for `dump()` for an explanation of the keyword arguments of this function.

在 3.4 版被加入。

The following classes are available:

```
class plistlib.UID(data)
```

Wraps an `int`. This is used when reading or writing `NSKeyedArchiver` encoded data, which contains UID (see `PList` manual).

It has one attribute, `data`, which can be used to retrieve the `int` value of the UID. `data` must be in the range `0 <= data < 2**64`.

在 3.8 版被加入。

The following constants are available:

`plistlib.FMT_XML`

The XML format for plist files.

在 3.4 版被加入.

`plistlib.FMT_BINARY`

The binary format for plist files

在 3.4 版被加入.

### 14.5.1 范例

Generating a plist:

```
import datetime
import plistlib

pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.now()
)
print(plistlib.dumps(pl).decode())
```

Parsing a plist:

```
import plistlib

plist = b"<plist version='1.0'>
<dict>
  <key>foo</key>
  <string>bar</string>
</dict>
</plist>"
pl = plistlib.loads(plist)
print(pl["foo"])
```

本章所描述的模組實作了多種加密演算法。它們可以在安裝時選擇是否一同安裝。以下概述：

## 15.1 hashlib --- 安全雜項與訊息摘要

原始碼：[Lib/hashlib.py](#)

該模組實作了許多不同安全雜項和訊息摘要演算法的通用介面，其中包括 FIPS 安全雜項演算法 SHA1、SHA224、SHA256、SHA384、SHA512（定義於 FIPS 180-4 標準）、SHA-3 系列（定義於 FIPS 202 標準）以及 RSA 的 MD5 演算法（定義於網際網路 RFC 1321）。「安全雜項 (secure hash)」和「訊息摘要 (message digest)」這兩個術語是可以互換的。較舊的演算法稱作訊息摘要、現代則較常稱之安全雜項。

### 備註

如果你需要 `adler32` 或 `crc32` 雜項函式，可以在 `zlib` 模組中找到它們。

### 15.1.1 雜項演算法

每種種類的 `hash` 都有一個以其命名的建構函式方法。全部都會回傳具有相同簡單介面的雜項物件。例如：可使用 `sha256()` 來建立 SHA-256 雜項物件。現在你可以使用 `update` 方法向此物件提供類位元組物件 (`bytes-like objects`)（通常是 `bytes`）。在任何時候，你都可以使用 `digest()` 或 `hexdigest()` 方法來要求它提供迄今為止傳遞給它的資料串聯的摘要 (`digest`)。

為了允許多執行緒 (`multithreading`)，Python `GIL` 被釋放，同時在其建構函式或 `.update` 方法中計算一次提供超過 2047 位元組資料的雜項值。

此模組中始終存在的雜項演算法之建構函式有 `sha1()`、`sha224()`、`sha256()`、`sha384()`、`sha512()`、`sha3_224()`、`sha3_256()`、`sha3_384()`、`sha3_512()`、`shake_128()`、`shake_256()`、`blake2b()` 和 `blake2s()`。`md5()` 通常也可用，但如果你使用罕見的「符合 FIPS (FIPS compliant)」的 Python 建置版本，它可能不存在或者不被允許使用。以上會對應到 `algorithms_guaranteed`。

如果你的 Python 發行版的 `hashlib` 與提供其他演算法的 OpenSSL 版本鏈結，也可能有其他演算法可用。其他則不保證可用於在所有安裝上，且只能以名稱來透過 `new()` 存取。請參閱 `algorithms_available`。

**警告**

某些演算法具有已知的雜碰撞 (hash collision) 弱點 (包括 MD5 和 SHA1)。請參  [Attacks on cryptographic hash algorithms](#) 和本文件後面的也參考部分。

在 3.6 版被加入: 新增了 SHA3 (Keccak) 和 SHAKE 建構函式 `sha3_224()`、`sha3_256()`、`sha3_384()`、`sha3_512()`、`shake_128()`、`shake_256()`。也新增了 `blake2b()` 和 `blake2s()`。在 3.9 版的變更: 所有 `hashlib` 建構函式都用一個僅限關鍵字引數 (keyword-only argument) `usedforsecurity`, 其預設值 `True`。`False` 值則會允許在受限環境中使用不安全 (`insecure`) 和阻塞的 (`blocked`) 雜演算法。`False` 表示雜演算法未在安全情境中使用, 例如作一種非加密用途的單向壓縮函式。

在 3.9 版的變更: `Hashlib` 現在使用 `OpenSSL` 中的 SHA3 和 SHAKE (如果有提供的話)。

在 3.12 版的變更: 對於鏈結之 `OpenSSL` 未提供的任何 MD5、SHA1、SHA2 或 SHA3 演算法, 我們會回退使用 `HACL*` 專案中經過驗證的實作。

## 15.1.2 用法

獲取位元組字串 `b"Nobody inspects the spammish repetition"` 的摘要:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd\xae\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\xf7\xbcN\x84:\xa6\xaf\x0c\x95\x0fK\
↪x94\x06'
>>> m.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

更濃縮:

```
>>> hashlib.sha256(b"Nobody inspects the spammish repetition").hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

## 15.1.3 建構函式

`hashlib.new(name, [data, ], *, usedforsecurity=True)`

是一個通用建構函式, 它將目標演算法的字串 `name` 作其第一個參數。它還允許使用者取得上面列出的雜值以及 `OpenSSL` 函式庫可能提供的任何其他演算法。

使用 `new()` 和演算法名稱:

```
>>> h = hashlib.new('sha256')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'031edd7d41651593c5fe5c006fa5752b37fddff7bc4e843aa6af0c950f4b9406'
```

`hashlib.md5([data, ], *, usedforsecurity=True)`

`hashlib.sha1([data, ], *, usedforsecurity=True)`

`hashlib.sha224([data, ], *, usedforsecurity=True)`

`hashlib.sha256([data, ], *, usedforsecurity=True)`

`hashlib.sha384([data, ], *, usedforsecurity=True)`

`hashlib.sha512([data, ], *, usedforsecurity=True)`

```
hashlib.sha3_224([data, ], *, usedforsecurity=True)
```

```
hashlib.sha3_256([data, ], *, usedforsecurity=True)
```

```
hashlib.sha3_384([data, ], *, usedforsecurity=True)
```

```
hashlib.sha3_512([data, ], *, usedforsecurity=True)
```

諸如此類的附名建構函式比將演算法名稱傳遞給 `new()` 更快。

### 15.1.4 屬性

Hashlib 提供以下常數模組屬性：

**hashlib.algorithms\_guaranteed**

包含所有平台上該模組保證支援的雜`H`演算法名稱的集合。請注意，`'md5'` 有出現在此列表中，`H`管有一些上游供應商提供了奇怪的「符合 FIPS (FIPS compliant)」的 Python 建置，`H`將其排除在外。在 3.2 版被加入。

**hashlib.algorithms\_available**

包含正在運行的 Python 直譯器中可用的雜`H`演算法名稱的集合。這些名稱在傳遞給 `new()` 時將被識`H`。 `algorithms_guaranteed` 都會是它的一個子集。相同的演算法可能會以不同的名稱多次出現在該集合中（多虧了 OpenSSL）。

在 3.2 版被加入。

### 15.1.5 雜`H`物件

以下的值皆`H`建構函式回傳之雜`H`物件的常數屬性：

**hash.digest\_size**

生成雜`H`的大小（以位元組`H`單位）。

**hash.block\_size**

雜`H`演算法的`H`部區塊大小（以位元組`H`單位）。

雜`H`物件具有以下屬性：

**hash.name**

該雜`H`的規範名稱，都會是小寫，且都會適合作`Hnew()`的參數以建立此型`H`的另一個雜`H`。

在 3.4 版的變更: `name` 屬性自 CPython 誕生以來就存在於其中，但直到 Python 3.4 才正式確立，因此在某些平台上可能不存在。

雜`H`物件具有以下方法：

**hash.update(data)**

使用類位元組物件來更新雜`H`物件。重`H`呼叫相當於連接所有引數的單一呼叫：`m.update(a)`；`m.update(b)` 等價於 `m.update(a+b)`。

**hash.digest()**

回傳目前有傳遞給 `update()` 方法的資料之摘要。這是一個大小`Hdigest_size`的位元組物件，它可能包含從 0 到 255 的整個範圍`H`的位元組。

**hash.hexdigest()**

與 `digest()` 類似，只不過摘要會是作`H`雙倍長度的字串物件回傳，僅包含十六進位數字。這可用於在電子郵件或其他非二進位環境中安全地交`H`值。

**hash.copy()**

回傳雜`H`物件的副本（「`H``H` (clone)」），這可用於高效率地計算出共享同一初始子字串的資料之摘要。

### 15.1.6 SHAKE 可變長度摘要

```
hashlib.shake_128([data, ]*, usedforsecurity=True)
```

```
hashlib.shake_256([data, ]*, usedforsecurity=True)
```

`shake_128()` 和 `shake_256()` 演算法提供了可變長度摘要，其 `length_in_bits//2` 最高 128 或 256 位元安全性。因此，他們的摘要方法會需要長度。最大長度不受 SHAKE 演算法限制。

```
shake.digest(length)
```

回傳目前有傳遞給 `update()` 方法的資料之摘要。這是一個大小 `length` 的位元組物件，可能包含從 0 到 255 的整個範圍的位元組。

```
shake.hexdigest(length)
```

與 `digest()` 類似，只不過摘要作雙倍長度的字串物件回傳，僅包含十六進位數字。這可用於交電子郵件或其他非二進位環境中的值。

範例：

```
>>> h = hashlib.shake_256(b'Nobody inspects the spammish repetition')
>>> h.hexdigest(20)
'44709d6fcb83d92a76dcb0b668c98e1b1d3dafe7'
```

### 15.1.7 檔案雜

`hashlib` 模組提供了一個輔助函式，用於對檔案或類檔案物件 (file-like object) 進行有效率的雜。

```
hashlib.file_digest(fileobj, digest, /)
```

回傳已用檔案物件內容更新的摘要物件。

`fileobj` 必須是以二進位模式讀取的類檔案物件。它接受來自 `open()` 的檔案物件、`BytesIO` 實例、來自 `socket.socket.makefile()` 的 `SocketIO` 物件等。該函式可以繞過 Python 的 I/O 直接使用 `fileno()` 中的檔案描述器 (file descriptor)。在此函式回傳或引發後，必須假定 `fileobj` 處於未知狀態 (unknown state)。由呼叫者固定是否關閉 `fileobj`。

`digest` 必須是名稱作 `str` 的雜演算法、雜建構函式或會回傳雜物件的可呼叫函式。

範例：

```
>>> import io, hashlib, hmac
>>> with open(hashlib.__file__, "rb") as f:
...     digest = hashlib.file_digest(f, "sha256")
...
>>> digest.hexdigest()
'...'
```

```
>>> buf = io.BytesIO(b"somedata")
>>> mac1 = hmac.HMAC(b"key", digestmod=hashlib.sha512)
>>> digest = hashlib.file_digest(buf, lambda: mac1)
```

```
>>> digest is mac1
True
>>> mac2 = hmac.HMAC(b"key", b"somedata", digestmod=hashlib.sha512)
>>> mac1.digest() == mac2.digest()
True
```

在 3.11 版被加入。

## 15.1.8 密鑰的生成

密鑰生成 (key derivation) 和密鑰延伸 (key stretching) 演算法專為安全密碼雜而設計。像是 `sha1(password)` 這樣過於單純的演算法無法抵抗暴力攻擊。一個好的密碼雜函式必須是可調校的 (tunable)、緩慢的，且含有包含 salt (鹽)。

`hashlib.pbkdf2_hmac` (*hash\_name, password, salt, iterations, dklen=None*)

該函式提供基於密碼的 PKCS#5 密鑰生成函式 2。它使用 HMAC 作為隨機函式 (pseudorandom function)。

字串 *hash\_name* 是 HMAC 的雜摘要演算法所需的名稱，例如 `sha1` 或 `sha256`。*password* 和 *salt* 被直譯為位元組緩衝區。應用程式和函式庫應為 *password* 設下合理的長度限制 (例如 1024)。*salt* 應該是來自適當來源 (例如 `os.urandom()`) 且大約 16 或更多位元組。

應根據雜演算法和計算能力選擇 *iterations* 次數。截至 2022 年，建議進行數十萬次 SHA-256 迭代。有關什麼以及如何選擇最適合你的應用程式的基本原理，請讀 NIST-SP-800-132 的 Appendix A.2.2。stackexchange pbkdf2 迭代問題上的答案有詳細解釋。

*dklen* 是生成的密鑰長度。如果 *dklen* 為 `None`，則會使用雜演算法 *hash\_name* 的摘要大小，例如 SHA-512 為 64。

```
>>> from hashlib import pbkdf2_hmac
>>> our_app_iters = 500_000 # Application specific, read above.
>>> dk = pbkdf2_hmac('sha256', b'password', b'bad salt' * 2, our_app_iters)
>>> dk.hex()
'15530bba69924174860db778f2c6f8104d3aaf9d26241840c8c4a641c8d000a9'
```

僅當有使用 OpenSSL 編譯 Python 時該函式才可用。

在 3.4 版被加入。

在 3.12 版的變更: 該函式現在僅在有使用 OpenSSL 建置 Python 時可用。緩慢的純 Python 實作已被刪除。

`hashlib.scrypt` (*password, \*, salt, n, r, p, maxmem=0, dklen=64*)

該函式提供 (如 RFC 7914 中所定義的) `scrypt` 基於密碼的密鑰衍生函式。

*password* 和 *salt* 必須是類位元組物件。應用程式和函式庫應為 *password* 設下合理的長度限制 (例如 1024)。*salt* 應該是來自適當來源 (例如 `os.urandom()`) 且大約 16 或更多位元組。

*n* 是 CPU/記憶體開銷數、*r* 是區塊大小、*p* 平行化數、*maxmem* 記憶體限制 (OpenSSL 1.1.0 預設 32 MiB)。*dklen* 是生成密鑰的長度。

在 3.6 版被加入。

## 15.1.9 BLAKE2

BLAKE2 是在 RFC 7693 中定義的加密雜函式，有兩種類型：

- **BLAKE2b**，針對 64 位元平台進行了最佳化，可生成 1 到 64 位元組之間任意大小的摘要，
- **BLAKE2s**，針對 8 至 32 位元平台進行了最佳化，可生成 1 至 32 位元組之間任意大小的摘要。

BLAKE2 支援密鑰模式 (keyed mode) (更快、更簡單的 HMAC 替代品)、加鹽雜 (salted hashing)、個人化和樹狀雜。

該模組中的雜物件遵循標準函式庫的 `hashlib` 物件 API。

### 建立雜物件

新的雜物件是透過呼叫建構函式建立的：

```
hashlib.blake2b(data=b", *, digest_size=64, key=b", salt=b", person=b", fanout=1, depth=1, leaf_size=0,
node_offset=0, node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

```
hashlib.blake2s (data=b", *, digest_size=32, key=b", salt=b", person=b", fanout=1, depth=1, leaf_size=0,
                 node_offset=0, node_depth=0, inner_size=0, last_node=False, usedforsecurity=True)
```

這些函式回傳相應的雜物件以計算 BLAKE2b 或 BLAKE2s。他們可以選擇用這些通用參數：

- *data*: 要雜的初始資料塊 (data chunk)，它必須是類位元組物件。它只能作位置引數傳遞。
- *digest\_size*: 輸出摘要的大小 (以位元組單位)。
- *key*: 用於密鑰雜的密鑰 (BLAKE2b 最多 64 位元組、BLAKE2s 最多 32 位元組)。
- *salt*: 用於隨機雜的鹽 (BLAKE2b 最多 16 個位元組、BLAKE2s 最多 8 個位元組)。
- *person*: 個人化字串 (BLAKE2b 最多 16 個位元組、BLAKE2s 最多 8 個位元組)。

下表顯示了一般參數的限制 (以位元組單位)：

雜	digest_size	len(key)	len(salt)	len(person)
BLAKE2b	64	64	16	16
BLAKE2s	32	32	8	8

### 備

BLAKE2 規範定義了鹽和個人化參數的固定長度，但為了方便起見，此實作接受任意大小的位元組字串，最多可達指定長度。如果參數的長度小於指定的長度，則用零補滿，所以像是 `b'salt` 和 `b'salt\x00` 是相同的值。(但 *key* 的情況非如此。)

這些大小可作模組常數使用，如下所述。

建構函式還接受以下樹狀雜參數：

- *fanout*: 扇出 (0 到 255，如果無限制則 0、順序模式 1)。
- *depth*: 樹的最大深度 (1 到 255，如果無限制則 255、順序模式 1)。
- *leaf\_size*: 葉的最大位元組長度 (0 到  $2^{32}-1$ ，如果無限制或處於順序模式則 0)。
- *node\_offset*: 節點偏移量 (BLAKE2b 0 到  $2^{64}-1$ ，BLAKE2s 0 到  $2^{48}-1$ ，0 表示第一個、最左邊、葉子或在順序模式下)。
- *node\_depth*: 節點深度 (0 到 255，葉 0，或在順序模式下)。
- *inner\_size*: 內部摘要大小 (BLAKE2b 0 到 64，BLAKE2s 0 到 32，順序模式 0)。
- *last\_node*: 布林值，代表處理的節點是否最後一個 (False 代表順序模式)。

關於樹狀雜的綜合回顧，請參 BLAKE2 規範中的第 2.10 節。

### 常數

`blake2b.SALT_SIZE`

`blake2s.SALT_SIZE`

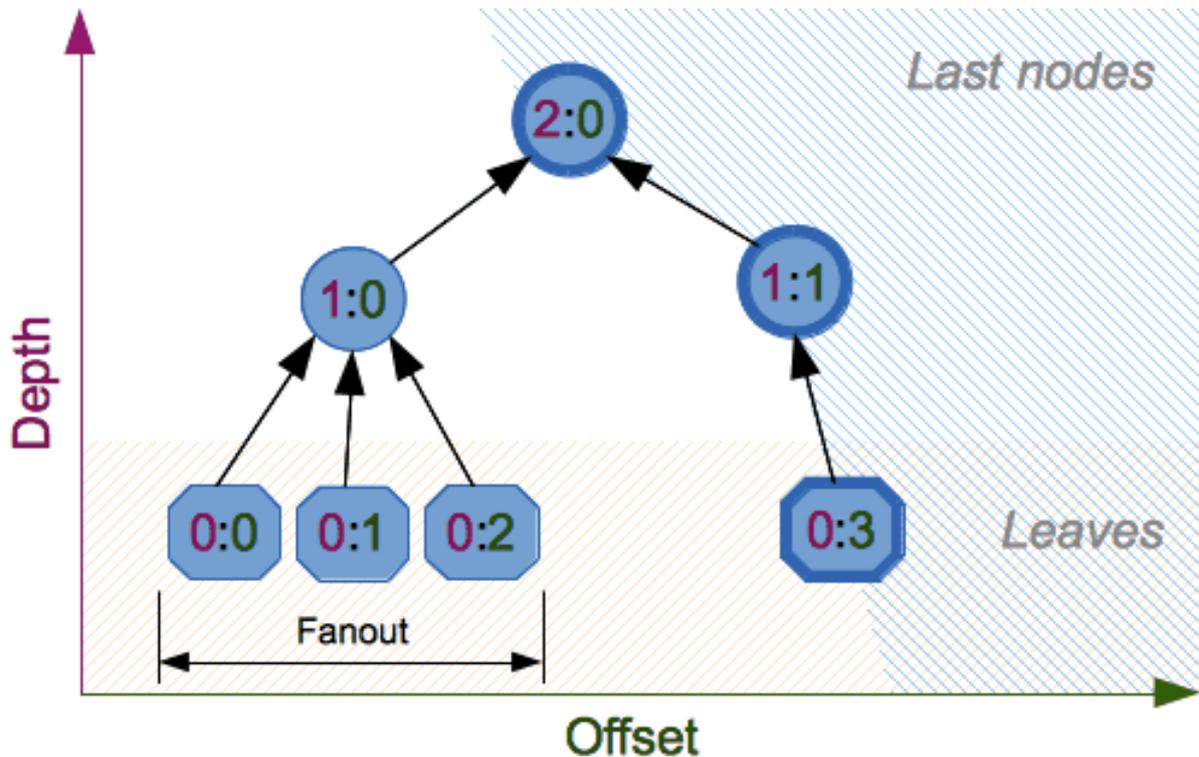

鹽長度 (建構函式接受的最大長度)。

`blake2b.PERSON_SIZE`

`blake2s.PERSON_SIZE`

個人化字串長度 (建構函式接受的最大長度)。

`blake2b.MAX_KEY_SIZE`

`blake2s.MAX_KEY_SIZE`

最大密鑰大小。

`blake2b.MAX_DIGEST_SIZE`

`blake2s.MAX_DIGEST_SIZE`

雜`h`函式可以輸出的最大摘要大小。

## 范例

### 簡單雜`h`

要計算某些資料的雜`h`值，你應該首先透過呼叫適當的建構函式 (`blake2b()` 或 `blake2s()`) 以建構一個雜`h`物件，然後透過於物件呼叫 `update()` 來以資料對它更新，最後透過呼叫 `digest()` (或對於十六進位編碼字串則 `hexdigest()`) 從物件中獲得摘要。

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()

↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3'
↪'
```

作`h`一個快捷方式，你可以將要更新的第一個資料塊作`h`位置引數直接傳遞給建構函式：

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()

↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3'
↪'
```

你可以根據需求來多次呼叫 `hash.update()` 以`h`代更新雜`h`：

```

>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
...
>>> h.hexdigest()
↪ '6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3'
↪ '

```

### 使用不同的摘要大小

BLAKE2 有可調整的摘要大小，BLAKE2b 最多 64 位元組，BLAKE2s 最多 32 位元組。例如，要在不改變輸出大小的情況下用 BLAKE2b 替 SHA-1，我們可以指定 BLAKE2b 生成 20 位元組的摘要：

```

>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20

```

具有不同摘要大小的雜物件具有完全不同的輸出（較短的雜值不是較長雜值的前綴）；即使輸出長度相同，BLAKE2b 和 BLAKE2s 也會生不同的輸出：

```

>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'

```

### 密鑰雜 (Keyed hashing)

密鑰雜可用於身份驗證，作基於雜的訊息驗證碼 (Hash-based message authentication code) (HMAC) 的更快、更簡單的替代方案。由於繼承自 BLAKE 的不可微特性 (indifferentiability property)，BLAKE2 可以安全地用於 prefix-MAC 模式。

此範例示範了如何使用密鑰 b'pseudorandom key' 獲取訊息 b'message data' 的 (十六進位編碼) 128 位元驗證碼：

```

>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363fff7401e02026f4a4687d4863ced'

```

舉一個實際的例子，網頁應用程式可以對發送給使用者的 cookie 進行對稱簽名 (symmetrically sign)，然後驗證它們以確保它們有被篡改：

```

>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>

```

(繼續下一頁)

(繼續上一頁)

```

>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0}, {1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False

```

儘管有原生密鑰雜函模式，BLAKE2 還是可以透過 `hmac` 模組用於建構 HMAC：

```

>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'

```

### 隨機雜函 (Randomized hashing)

透過設定 `salt` 參數，使用者可以向雜函式引入隨機化。隨機雜函在防止針對數位簽章中雜函式的碰撞攻擊 (collision attacks) 非常有用。

隨機雜函是這樣的情而設計的：一方 (訊息準備者) 生成全部或部分訊息由另一方 (訊息簽名者) 簽名。如果訊息準備者能發現加密雜函式發生碰撞 (collision，即兩條訊息生相同的雜函值)，那他們可能會準備有意義的訊息版本，該版本將生相同的雜函值和數位簽章，但結果不同 (例如，將 \$1,000,000 轉入賬，而不是 \$10)。加密雜函式的設計以抗碰撞性主要目標，但當前對加密雜函式攻擊的關注可能會導致給定的加密雜函式所提供的抗碰撞性低於預期。隨機雜函透過降低準備者在數位簽章生成過程中生成最終生相同雜函值的兩個或多個訊息的可能性，簽名者提供額外的保護——即便嘗試去找到雜函式碰撞的發生是實際可行的。然而，若訊息的所有部分都是由簽名者所準備好的，使用隨機雜函可能會降低數位簽章提供的安全性。

(NIST SP-800-106 「數位簽章的隨機雜函 (Randomized Hashing for Digital Signatures)」)

在 BLAKE2 中，鹽在初始化期間作雜函式的一次性輸入被處理，而不是作每個壓縮函式的輸入。

#### 警告

使用 BLAKE2 或任何其他通用加密雜函式 (例如 SHA-256) 的加鹽雜函 (或單純雜函) 不適合對密碼進行雜函處理。有關更多資訊，請參 BLAKE2 FAQ。

```

>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'

```

(繼續下一頁)

(繼續上一頁)

```

>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True

```

## 個人化

有時候雜函式不同目的相同輸入生成不同的摘要是很有用的。引用 Skein 雜函式的作者的話：

我們建議所有應用程式設計者認真考慮這樣做；我們已經看到許多協議，其中在協議的一個部分中計算的雜函式可以在完全不同的部分中使用，因兩次雜函式計算是在相似或相關的資料上完成的，且攻擊者可以限制應用程式將雜函式輸入設相同的。對協議中使用的每個雜函式進行個人化可以立即阻止此類攻擊。

(Skein 雜函式系列，第 21 頁)

BLAKE2 可以透過將位元組傳遞給 *person* 引數來做個人化：

```

>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778de59f383a3'

```

個人化與密鑰模式還可以一起用於從單個密鑰得出不同的密鑰。

```

>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWPlYk1e/nWfu0WSEb0KRcjhDeP/o=

```

## 樹狀模式

下面是對具有兩個葉節點的最小樹進行雜函式處理的範例：

```

10
 / \
00 01

```

此範例使用 64-byte 部摘要，回傳 32-byte 最終摘要：

```

>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...             leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...             node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...             leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...             node_offset=1, node_depth=0, last_node=True)
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...             leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...             node_offset=0, node_depth=1, last_node=True)
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'

```

## 作人員

**BLAKE2** 由 *Jean-Philippe Aumasson*、*Samuel Neves*、*Zooko Wilcox-O’Hearn* 和 *Christian Winnerlein* 設計，基於由 *Jean-Philippe Aumasson*、*Luca Henzen*、*Willi Meier* 和 *Raphael C.-W. Phan* 所建立的 **SHA-3** 最終版本 **BLAKE**。

它使用 *Daniel J. Bernstein* 設計的 **ChaCha** 密碼的核心演算法。

標準函式庫實作是基於 **pyblake2** 模組。它是由 *Dmitry Chestnykh* 在 *Samuel Neves* 的 C 版本實作基礎所編寫的。該文件是由 *Dmitry Chestnykh* 編寫從 **pyblake2** 過來的。

*Christian Heimes* Python 重寫了部分 C 程式碼。

以下公開領域貢獻適用於 C 雜函式實作、擴充程式碼和此文件：

在法律允許的範圍內，作者已將該軟體的所有版權以及相關和鄰接權利奉獻給全球的公開領域。該軟體的發布有任何授權 (warranty)。

## 15.2 hmac --- 基於金鑰雜的訊息驗證

原始碼: Lib/hmac.py

此模組 (module) 實現了 RFC 2014 所描述的 HMAC 演算法。

`hmac.new(key, msg=None, digestmod)`

回傳一個新的 hmac 物件。`key` 是一個指定密鑰的 bytes (位元組) 或 bytearray 物件。如果提供了 `msg`, 將會呼叫 `update(msg)` 方法。`digestmod` 是 HMAC 物件所用的摘要名稱、摘要建構函式 (constructor) 或模組。它可以是適用於 `hashlib.new()` 的任何名稱。管該引數的位置在後, 但它 是必須的。

在 3.4 版的變更: 參數 `key` 可以 bytes 或 bytearray 物件。參數 `msg` 可以 `hashlib` 所支援的任意型。參數 `digestmod` 可以雜演算法的名稱。

在 3.8 版的變更: `digestmod` 引數現在是必須的。請將其作關鍵字引數傳入以避免當你 有初始 `msg` 時導致的麻煩。

`hmac.digest(key, msg, digest)`

基於給定密鑰 `key` 和 `digest` 回傳 `msg` 的摘要。此函式等價於 `HMAC(key, msg, digest).digest()`, 但使用了優化的 C 或行實作 (inline implementation), 對放入記憶體的消息能處理得更快。參數 `key`、`msg` 和 `digest` 在 `new()` 中具有相同含義。

作 CPython 的實現細節, C 的優化實作只有當 `digest` 字串 且是一個 OpenSSL 所支援的摘要演算法的名稱時才會被使用。

在 3.7 版被加入。

HMAC 物件具有下列方法 (method):

`HMAC.update(msg)`

用 `msg` 來更新 hmac 物件。重呼叫相當於單次呼叫傳入所有引數的拼接結果: `m.update(a); m.update(b)` 等價於 `m.update(a + b)`。

在 3.4 版的變更: 參數 `msg` 可以是 `hashlib` 所支援的任何型。

`HMAC.digest()`

回傳當前已傳給 `update()` 方法的 bytes 摘要。這個 bytes 物件的長度會與傳給建構函式的摘要 `digest_size` 的長度相同。它可以包含 NUL bytes 以及 non-ASCII bytes。

### 警告

在一個例行的驗證事務運行期間, 將 `digest()` 的輸出與外部提供的摘要進行比較時, 建議使用 `compare_digest()` 函式而不是 `==` 運算子以少被定時攻擊時的漏洞。

HMAC.**hexdigest** ()

像是 `digest()` 但摘要的回傳形式是兩倍長度的字串，且此字串只包含十六進位數位。這可以被用於在電子郵件或其他非二進位制環境中安全地交數據。

#### 警告

在一個例行的驗證事務運行期間，將 `hexdigest()` 的輸出與外部提供的摘要進行比較時，建議使用 `compare_digest()` 函式而不是 `==` 運算子以少被定時攻擊時的漏洞。

HMAC.**copy** ()

回傳 hmac 物件的拷貝 (“clone”)。這可以被用來有效率地計算那些共享相同初始子字串的字串的摘要。

一個 hash 物件具有以下屬性：

HMAC.**digest\_size**

以 bytes 表示最終 HMAC 摘要的大小。

HMAC.**block\_size**

以 bytes 表示雜演算法的部區塊大小。

在 3.4 版被加入。

HMAC.**name**

HMAC 的正准名稱總是小寫形式，例如 `hmac-md5`。

在 3.4 版被加入。

在 3.10 版的變更：未寫入文件的屬性 `HMAC.digest_cons`，`HMAC.inner` 和 `HMAC.outer` 已被移除。

這個模組還提供了下列輔助函式：

`hmac.compare_digest(a, b)`

回傳 `a == b`。此函式使用一種經專門設計的方式通過避免基於容的短路行來防止定時分析，使得它適合處理密碼學。`a` 和 `b` 必須相同的型：可以是 `str` (僅限 ASCII，如 `HMAC.hexdigest()` 的回傳值)，或者是 *bytes-like object*。

#### 備

如果 `a` 和 `b` 具有不同的長度，或者如果發生了錯誤，定時攻擊在理論上可以獲取有關 `a` 和 `b` 的型和長度的訊息—但不能獲取他們的值。

在 3.3 版被加入。

在 3.10 版的變更：此函式在可能的情下會在部使用 OpenSSL 的 `CRYPTO_memcmp()`。

#### 也參考

`hashlib` 模組

Python 模組提供安全的雜函式。

## 15.3 secrets --- 生用於管理機密的安全亂數

在 3.6 版被加入。

原始碼： `Lib/secrets.py`

`secrets` 模組可用於生成高加密度的亂數，適合用來管理諸如密碼、帳號認證、安全性權杖 (security tokens) 這類資料，以及管理其他相關的機密資料。

尤其應優先使用 `secrets` 作預設來替代 `random` 模組中的預設亂數生成器 (pseudo-random number generator)，該模組被設計用於建模和模擬，而非用於安全性和加密。

也參考

PEP 506

### 15.3.1 亂數

`secrets` 模組使你得以存取作業系統所提供安全性最高的亂數生成器。

**class** `secrets.SystemRandom`

一個用來生成亂數的類，用的是作業系統提供的最高品質來源。請參 `random.SystemRandom` 以獲取更多細節。

`secrets.choice(seq)`

從一非空序列中，回傳一個隨機選取的元素。

`secrets.randbelow(exclusive_upper_bound)`

回傳一個  $[0, exclusive\_upper\_bound)$  範圍之隨機整數。

`secrets.randbits(k)`

回傳一個具  $k$  個隨機位元的非負整數。

### 15.3.2 生成權杖 (token)

`secrets` 模組提供了一些生成安全性權杖的函式，適合用於諸如重設密碼、難以猜測的 URL，或類似的應用。

`secrets.token_bytes([nbytes=None])`

回傳一個隨機位元組字串，其中含有 `nbytes` 位元組的數字。如果 `nbytes` 為 `None` 或未提供，則會使用一合理預設值。

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

`secrets.token_hex([nbytes=None])`

回傳一以十六進位表示的隨機字串。字串具有 `nbytes` 個隨機位元組，每個位元組會轉成兩個十六進位的數字。如果 `nbytes` 為 `None` 或未提供，則會使用一個合理的預設值。

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

`secrets.token_urlsafe([nbytes=None])`

回傳一個 URL 安全的隨機文本字串，包含 `nbytes` 個隨機位元組。文本將使用 Base64 編碼，因此平均來每個位元組會對應到約 1.3 個字元。如果 `nbytes` 為 `None` 或未提供，則會使用一個合理的預設值。

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

#### 權杖應當使用多少個位元組？

為了在面對暴力攻擊時能保證安全，權杖必須具有足夠的隨機性。不幸的是，對隨機性是否足夠的標準，會隨著電腦越來越強大而在更短時間內進行更多猜測而不斷提高。在 2015 年時，人們認為 32 位元組 (256 位元) 的隨機性對於 `secrets` 模組所預期的一般使用場景來說是足夠的。

對於想自行管理權杖長度的使用者，你可以對各種 `token_*` 函式明白地指定 `int` 引數（argument）來指定權杖要使用的隨機性程度。該引數以位元組數來表示要使用的隨機性程度。

否則，如未提供引數，或者如果引數 `None`，則 `token_*` 函式則會使用一個合理的預設值。

#### 備

該預設值可能在任何時候被改變，包括在維護版本更新的時候。

### 15.3.3 其他函式

`secrets.compare_digest(a, b)`

如果字串或類位元組串物件 `a` 與 `b` 相等則回傳 `True`，否則回傳 `False`，以“固定時間比較（constant-time compare）”的處理方式可降低時序攻擊的風險。請參 `hmac.compare_digest()` 以了解更多細節。

### 15.3.4 應用技巧和典範實務（best practices）

本節展示了一些使用 `secrets` 來管理基本安全等級的應用技巧和典範實務。

生八個字元長的字母數字密碼：

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
password = ''.join(secrets.choice(alphabet) for i in range(8))
```

#### 備

應用程式不能以可復原的格式存儲密碼，無論是用純文本還是經過加密。它們應當先加鹽（salt），再使用高加密度的單向（不可逆）雜函式來生雜值。

生十個字元長的字母數字密碼，其中包含至少一個小寫字母，至少一個大寫字母以及至少三個數字：

```
import string
import secrets
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(secrets.choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
        and any(c.isupper() for c in password)
        and sum(c.isdigit() for c in password) >= 3):
        break
```

生 XKCD 風格的 passphrase:

```
import secrets
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(secrets.choice(words) for i in range(4))
```

生難以猜測的暫時性 URL，含回復密碼時所用的一個安全性權杖：

```
import secrets
url = 'https://example.com/reset=' + secrets.token_urlsafe()
```

## 通用作業系統服務

此章節所描述的模組 (module) 提供了作業系統特性的使用介面，例如檔案與時鐘，(幾乎) 在所有作業系統上皆能使用。這些介面通常是參考 Unix 或 C 的介面來實作，不過在其他大多數系統上也能使用。以下概述：

## 16.1 os --- 各種作業系統介面

原始碼：Lib/os.py

該模組提供了一種便利的方式來操作與作業系統相關的功能。如果你想讀取或寫入檔案，請參閱 `open()`，如果你想操作檔案路徑，請參閱 `os.path` 模組，如果你想透過命令列查看所有檔案中的所有內容，請查看 `fileinput` 模組。要建立臨時檔案和目錄，請參閱 `tempfile` 模組，要操作高級檔案和目錄，請參閱 `shutil` 模組。

關於這些功能的可用性說明：

- Python 所有創建作業系統相關的模組設計是這樣：只要有相同的函式可使用，就會使用相同的介面 (interface)。舉例來說，`os.stat(path)` 函式會以相同格式回傳關於 `path` 的統計資訊 (這剛好來自於 POSIX 的介面)。
- 對於特定的作業系統獨有的擴充功能也可以透過 `os` 取得，但使用它們的時候對於可移植性無疑會是個問題。
- 所有接受檔案路徑和檔案名稱的函式皆接受位元組 (bytes) 和字串物件 (string objects)，且如果回傳檔案路徑或檔案名稱，則會輸出相同型別的物件。
- 在 VxWorks，不支援 `os.popen`、`os.fork`、`os.execv` 和 `os.spawn*p*`。
- 在 WebAssembly 平台和 Android 與 iOS 上，大部分 `os` 模組無法使用或行不同。與行程 (process) (例如 `fork()`、`execve()`) 與資源 (例如 `nice()`) 相關的 API 不可使用。其他諸如 `getuid()` 和 `getpid()` 的相關 API 是 emulated 或 stubs。WebAssembly 平台也缺少訊號相關支援 (例如 `kill()`、`wait()`)。

### 備註

在檔案名稱和路徑找不到或無效的時候，或引數型別正確但作業系統不接受的時候，在此模組中的所有函式都會引發 `OSError` (或其子類)。

**exception** `os.error`

建例外 `OSError` 的 名。

**os.name**

The name of the operating system dependent module imported. The following names have currently been registered: 'posix', 'nt', 'java'.

### 也參考

`sys.platform` has a finer granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

## 16.1.1 File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the *filesystem encoding and error handler* to perform this conversion (see `sys.getfilesystemencoding()`).

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.1 版的變更: On some systems, conversion using the file system encoding may fail. In this case, Python uses the *surrogateescape encoding error handler*, which means that undecodable bytes are replaced by a Unicode character `U+DCxx` on decoding, and these are again translated to the original byte on encoding.

The *file system encoding* must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions can raise `UnicodeError`.

另請參 `locale encoding`。

## 16.1.2 Python UTF-8 模式

在 3.7 版被加入: 更多資訊請見 **PEP 540**。

Python 在 UTF-8 模式下會忽略 `locale encoding` 且制使用 UTF-8 去編碼:

- Use UTF-8 as the *filesystem encoding*.
- `sys.getfilesystemencoding()` 回傳 'utf-8'。
- `locale.getpreferredencoding()` returns 'utf-8' (the `do_setlocale` argument has no effect).
- `sys.stdin`, `sys.stdout`, and `sys.stderr` all use UTF-8 as their text encoding, with the surrogateescape *error handler* being enabled for `sys.stdin` and `sys.stdout` (`sys.stderr` continues to use `backslashreplace` as it does in the default locale-aware mode)
- On Unix, `os.device_encoding()` returns 'utf-8' rather than the device encoding.

Note that the standard stream settings in UTF-8 mode can be overridden by `PYTHONIOENCODING` (just as they can be in the default locale-aware mode).

As a consequence of the changes in those lower level APIs, other higher level APIs also exhibit different default behaviours:

- Command line arguments, environment variables and filenames are decoded to text using the UTF-8 encoding.
- `os.fsdecode()` and `os.fsencode()` use the UTF-8 encoding.
- `open()`, `io.open()`, and `codecs.open()` use the UTF-8 encoding by default. However, they still use the strict error handler by default so that attempting to open a binary file in text mode is likely to raise an exception rather than producing nonsense data.

The *Python UTF-8 Mode* is enabled if the `LC_CTYPE` locale is `C` or `POSIX` at Python startup (see the `PyConfig_Read()` function).

It can be enabled or disabled using the `-X utf8` command line option and the `PYTHONUTF8` environment variable.

If the `PYTHONUTF8` environment variable is not set at all, then the interpreter defaults to using the current locale settings, *unless* the current locale is identified as a legacy ASCII-based locale (as described for `PYTHONCOERCECLOCALE`), and locale coercion is either disabled or fails. In such legacy locales, the interpreter will default to enabling UTF-8 mode unless explicitly instructed not to do so.

The Python UTF-8 Mode can only be enabled at the Python startup. Its value can be read from `sys.flags.utf8_mode`.

See also the UTF-8 mode on Windows and the *filesystem encoding and error handler*.

#### PEP 686

Python 3.15 預設使用 *Python UTF-8 模式*

## 16.1.3 行程參數

These functions and data items provide information and operate on the current process and user.

`os.ctermid()`

Return the filename corresponding to the controlling terminal of the process.

適用: Unix, not WASI.

`os.environ`

A *mapping* object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the `os` module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in `os.environ`, except for changes made by modifying `os.environ` directly.

This mapping may be used to modify the environment as well as query the environment. `putenv()` will be called automatically when the mapping is modified.

On Unix, keys and values use `sys.getfilesystemencoding()` and `'surrogateescape'` error handler. Use `environb` if you would like to use a different encoding.

On Windows, the keys are converted to uppercase. This also applies when getting, setting, or deleting an item. For example, `environ['monty'] = 'python'` maps the key `'MONTY'` to the value `'python'`.

### 備 F

Calling `putenv()` directly does not change `os.environ`, so it's better to modify `os.environ`.

### 備 F

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

You can delete items in this mapping to unset environment variables. `unsetenv()` will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

在 3.9 版的變更: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

**os.environb**

Bytes version of *environ*: a *mapping* object where both keys and values are *bytes* objects representing the process environment. *environ* and *environb* are synchronized (modifying *environb* updates *environ*, and vice versa).

*environb* is only available if *supports\_bytes\_environ* is True.

在 3.2 版被加入。

在 3.9 版的變更: Updated to support **PEP 584**'s merge (`|`) and update (`|=`) operators.

**os.chdir** (*path*)**os.fchdir** (*fd*)**os.getcwd** ()

These functions are described in *Files and Directories*.

**os.fsencode** (*filename*)

Encode *path-like filename* to the *filesystem encoding and error handler*; return *bytes* unchanged.

*fsdecode* () is the reverse function.

在 3.2 版被加入。

在 3.6 版的變更: Support added to accept objects implementing the *os.PathLike* interface.

**os.fsdecode** (*filename*)

Decode the *path-like filename* from the *filesystem encoding and error handler*; return *str* unchanged.

*fsencode* () is the reverse function.

在 3.2 版被加入。

在 3.6 版的變更: Support added to accept objects implementing the *os.PathLike* interface.

**os.fspath** (*path*)

Return the file system representation of the path.

If *str* or *bytes* is passed in, it is returned unchanged. Otherwise `__fspath__` () is called and its value is returned as long as it is a *str* or *bytes* object. In all other cases, *TypeError* is raised.

在 3.6 版被加入。

**class os.PathLike**

An *abstract base class* for objects representing a file system path, e.g. *pathlib.PurePath*.

在 3.6 版被加入。

**abstractmethod** `__fspath__` ()

Return the file system path representation of the object.

The method should only return a *str* or *bytes* object, with the preference being for *str*.

**os.getenv** (*key*, *default=None*)

Return the value of the environment variable *key* as a string if it exists, or *default* if it doesn't. *key* is a string. Note that since *getenv* () uses *os.environ*, the mapping of *getenv* () is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with *sys.getfilesystemencoding* () and 'surrogateescape' error handler. Use *os.getenvb* () if you would like to use a different encoding.

適用: Unix, Windows.

**os.getenvb** (*key*, *default=None*)

Return the value of the environment variable *key* as bytes if it exists, or *default* if it doesn't. *key* must be bytes. Note that since *getenvb* () uses *os.environb*, the mapping of *getenvb* () is similarly also captured on import, and the function may not reflect future environment changes.

*getenvb* () is only available if *supports\_bytes\_environ* is True.

適用: Unix.

在 3.2 版被加入.

os.**get\_exec\_path** (*env=None*)

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is None, *environ* is used.

在 3.2 版被加入.

os.**getegid** ()

Return the effective group id of the current process. This corresponds to the "set id" bit on the file being executed in the current process.

適用: Unix, not WASI.

os.**geteuid** ()

Return the current process's effective user id.

適用: Unix, not WASI.

os.**getgid** ()

Return the real group id of the current process.

適用: Unix.

The function is a stub on WASI, see [WebAssembly 平台](#) for more information.

os.**getgrouplist** (*user, group, /*)

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

適用: Unix, not WASI.

在 3.3 版被加入.

os.**getgroups** ()

Return list of supplemental group ids associated with the current process.

適用: Unix, not WASI.

#### 備 註

On macOS, *getgroups* () behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of 10.5 or earlier, *getgroups* () returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to *setgroups* () if suitably privileged. If built with a deployment target greater than 10.5, *getgroups* () returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to *setgroups* (), and its length is not limited to 16. The deployment target value, `MACOSX_DEPLOYMENT_TARGET`, can be obtained with `sysconfig.get_config_var()`.

os.**getlogin** ()

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use `getpass.getuser` () since the latter checks the environment variables LOGNAME or USERNAME to find out who the user is, and falls back to `pwd.getpwuid(os.getuid()) [0]` to get the login name of the current real user id.

適用: Unix, Windows, not WASI.

os.getpgid(*pid*)

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

適用: Unix, not WASI.

os.getpgrp()

Return the id of the current process group.

適用: Unix, not WASI.

os.getpid()

Return the current process id.

The function is a stub on WASI, see [WebAssembly 平台](#) for more information.

os.getppid()

Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

適用: Unix, Windows, not WASI.

在 3.2 版的變更: 新增對 Windows 的支援。

os.getpriority(*which*, *who*)

Get program scheduling priority. The value *which* is one of `PRIO_PROCESS`, `PRIO_PGRP`, or `PRIO_USER`, and *who* is interpreted relative to *which* (a process identifier for `PRIO_PROCESS`, process group identifier for `PRIO_PGRP`, and a user ID for `PRIO_USER`). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

適用: Unix, not WASI.

在 3.3 版被加入。

os.PRIO\_PROCESS

os.PRIO\_PGRP

os.PRIO\_USER

Parameters for the `getpriority()` and `setpriority()` functions.

適用: Unix, not WASI.

在 3.3 版被加入。

os.PRIO\_DARWIN\_THREAD

os.PRIO\_DARWIN\_PROCESS

os.PRIO\_DARWIN\_BG

os.PRIO\_DARWIN\_NONUI

Parameters for the `getpriority()` and `setpriority()` functions.

適用: macOS

在 3.12 版被加入。

os.getresuid()

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

適用: Unix, not WASI.

在 3.2 版被加入。

os.getresgid()

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

適用: Unix, not WASI.

在 3.2 版被加入。

`os.getuid()`

Return the current process's real user id.

適用: Unix.

The function is a stub on WASI, see [WebAssembly 平台](#) for more information.

`os.initgroups(username, gid, /)`

Call the system `initgroups()` to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

適用: Unix, not WASI, not Android.

在 3.2 版被加入。

`os.putenv(key, value, /)`

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however, calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`. This also applies to `getenv()` and `getenvb()`, which respectively use `os.environ` and `os.environb` in their implementations.

**備 F**

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

引發一個附帶引數 `key`、`value` 的稽核事件 `os.putenv`。

在 3.9 版的變更: The function is now always available.

`os.setegid(egid, /)`

Set the current process's effective group id.

適用: Unix, not WASI, not Android.

`os.seteuid(euid, /)`

Set the current process's effective user id.

適用: Unix, not WASI, not Android.

`os.setgid(gid, /)`

Set the current process' group id.

適用: Unix, not WASI, not Android.

`os.setgroups(groups, /)`

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

適用: Unix, not WASI.

**備 F**

On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for `getgroups()` for cases where it may not return the same group list set by calling `setgroups()`.

`os.setns(fd, nstype=0)`

Reassociate the current thread with a Linux namespace. See the *setns(2)* and *namespaces(7)* man pages for more details.

If *fd* refers to a `/proc/pid/ns/` link, `setns()` reassociates the calling thread with the namespace associated with that link, and *nstype* may be set to one of the *CLONE\_NEW\** constants to impose constraints on the operation (0 means no constraints).

Since Linux 5.8, *fd* may refer to a PID file descriptor obtained from `pidfd_open()`. In this case, `setns()` reassociates the calling thread into one or more of the same namespaces as the thread referred to by *fd*. This is subject to any constraints imposed by *nstype*, which is a bit mask combining one or more of the *CLONE\_NEW\** constants, e.g. `setns(fd, os.CLONE_NEWUTS | os.CLONE_NEWPID)`. The caller's memberships in unspecified namespaces are left unchanged.

*fd* can be any object with a `fileno()` method, or a raw file descriptor.

This example reassociates the thread with the `init` process's network namespace:

```
fd = os.open("/proc/1/ns/net", os.O_RDONLY)
os.setns(fd, os.CLONE_NEWNET)
os.close(fd)
```

適用: Linux >= 3.0 with glibc >= 2.14.

在 3.12 版被加入。

#### 也參考

`unshare()` 函式。

`os.setpgrp()`

Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

適用: Unix, not WASI.

`os.setpgid(pid, pgrp, /)`

Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

適用: Unix, not WASI.

`os.setpriority(which, who, priority)`

Set program scheduling priority. The value *which* is one of *PRIO\_PROCESS*, *PRIO\_PGRP*, or *PRIO\_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO\_PROCESS*, process group identifier for *PRIO\_PGRP*, and a user ID for *PRIO\_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

適用: Unix, not WASI.

在 3.3 版被加入。

`os.setregid(rgid, egid, /)`

Set the current process's real and effective group ids.

適用: Unix, not WASI, not Android.

`os.setresgid(rgid, egid, sgid, /)`

Set the current process's real, effective, and saved group ids.

適用: Unix, not WASI, not Android.

在 3.2 版被加入。

`os.setresuid(ruid, euid, suid, /)`

Set the current process's real, effective, and saved user ids.

適用: Unix, not WASI, not Android.

在 3.2 版被加入。

`os.setreuid(ruid, euid, /)`

Set the current process's real and effective user ids.

適用: Unix, not WASI, not Android.

`os.getsid(pid, /)`

Call the system call `getsid()`. See the Unix manual for the semantics.

適用: Unix, not WASI.

`os.setsid()`

Call the system call `setsid()`. See the Unix manual for the semantics.

適用: Unix, not WASI.

`os.setuid(uid, /)`

Set the current process's user id.

適用: Unix, not WASI, not Android.

`os.strerror(code, /)`

Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, `ValueError` is raised.

`os.supports_bytes_environ`

True if the native OS type of the environment is bytes (eg. `False` on Windows).

在 3.2 版被加入。

`os.umask(mask, /)`

Set the current numeric umask and return the previous umask.

The function is a stub on WASI, see [WebAssembly 平台](#) for more information.

`os.uname()`

Returns information identifying the current operating system. The return value is an object with five attributes:

- `sysname` - 作業系統名稱
- `nodename` - name of machine on network (implementation-defined)
- `release` - operating system release
- `version` - 作業系統版本
- `machine` - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing `sysname`, `nodename`, `release`, `version`, and `machine` in that order.

Some systems truncate `nodename` to 8 characters or to the leading component; a better way to get the hostname is `socket.gethostname()` or even `socket.gethostbyaddr(socket.gethostname())`.

On macOS, iOS and Android, this returns the *kernel* name and version (i.e., 'Darwin' on macOS and iOS; 'Linux' on Android). `platform.uname()` can be used to get the user-facing operating system name and version on iOS and Android.

適用: Unix.

在 3.3 版的變更: Return type changed from a tuple to a tuple-like object with named attributes.

`os.unsetenv(key, /)`

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Deletion of items in `os.environ` is automatically translated into a corresponding call to `unsetenv()`; however, calls to `unsetenv()` don't update `os.environ`, so it is actually preferable to delete items of `os.environ`.

引發一個附帶引數 *key* 的稽核事件 `os.unsetenv`。

在 3.9 版的變更: The function is now always available and is also available on Windows.

`os.unshare(flags)`

Disassociate parts of the process execution context, and move them into a newly created namespace. See the `unshare(2)` man page for more details. The *flags* argument is a bit mask, combining zero or more of the `CLONE_* constants`, that specifies which parts of the execution context should be unshared from their existing associations and moved to a new namespace. If the *flags* argument is 0, no changes are made to the calling process's execution context.

適用: Linux >= 2.6.16.

在 3.12 版被加入。

## 16.1.4 File Object Creation

These functions create new *file objects*. (See also `open()` for opening file descriptors.)

`os.fdopen(fd, *args, **kwargs)`

Return an open file object connected to the file descriptor *fd*. This is an alias of the `open()` built-in function and accepts the same arguments. The only difference is that the first argument of `fdopen()` must always be an integer.

## 16.1.5 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name "file descriptor" is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a *file object* when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

`os.close(fd)`

Close file descriptor *fd*.

### 備 F

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

`os.closerange(fd_low, fd_high, l)`

Close all file descriptors from *fd\_low* (inclusive) to *fd\_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

`os.copy_file_range(src, dst, count, offset_src=None, offset_dst=None)`

Copy *count* bytes from file descriptor *src*, starting from offset *offset\_src*, to file descriptor *dst*, starting from offset *offset\_dst*. If *offset\_src* is `None`, then *src* is read from the current position; respectively for *offset\_dst*.

In Linux kernel older than 5.3, the files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with *errno* set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations, such as the use of reflinks (i.e., two or more inodes that share pointers to the same copy-on-write disk blocks; supported file systems include btrfs and XFS) and server-side copy (in the case of NFS).

The function copies bytes between two file descriptors. Text options, like the encoding and the line ending, are ignored.

The return value is the amount of bytes copied. This could be less than the amount requested.

### 備 F

On Linux, `os.copy_file_range()` should not be used for copying a range of a pseudo file from a special filesystem like `procfs` and `sysfs`. It will always copy no bytes and return 0 as if the file was empty because of a known Linux kernel issue.

適用: Linux >= 4.5 with glibc >= 2.27.

在 3.8 版被加入。

**os.device\_encoding** (*fd*)

Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return *None*.

On Unix, if the *Python UTF-8 Mode* is enabled, return 'UTF-8' rather than the device encoding.

在 3.10 版的變更: On Unix, the function now implements the Python UTF-8 Mode.

**os.dup** (*fd*, *l*)

Return a duplicate of file descriptor *fd*. The new file descriptor is *non-inheritable*.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is *inheritable*.

適用: not WASI.

在 3.4 版的變更: The new file descriptor is now non-inheritable.

**os.dup2** (*fd*, *fd2*, *inheritable=True*)

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is *inheritable* by default or non-inheritable if *inheritable* is *False*.

適用: not WASI.

在 3.4 版的變更: Add the optional *inheritable* parameter.

在 3.7 版的變更: Return *fd2* on success. Previously, *None* was always returned.

**os.fchmod** (*fd*, *mode*)

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

引發一個附帶引數 *path*、*mode*、*dir\_fd* 的稽核事件 `os.chmod`。

適用: Unix, Windows.

The function is limited on WASI, see *WebAssembly* 平台 for more information.

在 3.13 版的變更: 新增對 Windows 的支援。

**os.fchown** (*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See *chown()*. As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

引發一個附帶引數 *path*、*uid*、*gid*、*dir\_fd* 的稽核事件 `os.chown`。

適用: Unix.

The function is limited on WASI, see *WebAssembly* 平台 for more information.

**os.fdatasync** (*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

適用: Unix.

備F

This function is not available on MacOS.

**os.fpathconf** (*fd*, *name*, *l*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

適用: Unix.

#### `os.fstat` (*fd*)

Get the status of the file descriptor *fd*. Return a `stat_result` object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

#### 也參考

The `stat()` function.

#### `os.fstatvfs` (*fd*, */*)

Return information about the filesystem containing the file associated with file descriptor *fd*, like `statvfs()`.

As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

適用: Unix.

#### `os.fsync` (*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the `MS_commit()` function.

If you're starting with a buffered Python *file object* *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

適用: Unix, Windows.

#### `os.ftruncate` (*fd*, *length*, */*)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

引發一個附帶引數 *fd*、*length* 的稽核事件 `os.truncate`。

適用: Unix, Windows.

在 3.5 版的變更: 新增對 Windows 的支援

#### `os.get_blocking` (*fd*, */*)

Get the blocking mode of the file descriptor: `False` if the `O_NONBLOCK` flag is set, `True` if the flag is cleared.

另請參閱 `set_blocking()` 與 `socket.socket.setblocking()`。

適用: Unix, Windows.

The function is limited on WASI, see [WebAssembly 平台](#) for more information.

On Windows, this function is limited to pipes.

在 3.5 版被加入。

在 3.12 版的變更: 新增對 Windows 上的 pipe 支援。

#### `os.grantpt` (*fd*, */*)

Grant access to the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the C standard library function `grantpt()`.

適用: Unix, not WASI.

在 3.13 版被加入。

`os.isatty(fd, /)`

Return `True` if the file descriptor `fd` is open and connected to a tty(-like) device, else `False`.

`os.lockf(fd, cmd, len, /)`

Apply, test or remove a POSIX lock on an open file descriptor. `fd` is an open file descriptor. `cmd` specifies the command to use - one of `F_LOCK`, `F_TLOCK`, `F_ULOCK` or `F_TEST`. `len` specifies the section of the file to lock.

引發一個附帶引數 `fd`、`cmd`、`len` 的稽核事件 `os.lockf`。

適用: Unix.

在 3.3 版被加入.

`os.F_LOCK`

`os.F_TLOCK`

`os.F_ULOCK`

`os.F_TEST`

Flags that specify what action `lockf()` will take.

適用: Unix.

在 3.3 版被加入.

`os.login_tty(fd, /)`

Prepare the tty of which `fd` is a file descriptor for a new login session. Make the calling process a session leader; make the tty the controlling tty, the stdin, the stdout, and the stderr of the calling process; close `fd`.

適用: Unix, not WASI.

在 3.11 版被加入.

`os.lseek(fd, pos, whence, /)`

Set the current position of file descriptor `fd` to position `pos`, modified by `whence`, and return the new position in bytes relative to the start of the file. Valid values for `whence` are:

- `SEEK_SET` or 0 -- set `pos` relative to the beginning of the file
- `SEEK_CUR` or 1 -- set `pos` relative to the current file position
- `SEEK_END` or 2 -- set `pos` relative to the end of the file
- `SEEK_HOLE` -- set `pos` to the next data location, relative to `pos`
- `SEEK_DATA` -- set `pos` to the next data hole, relative to `pos`

在 3.3 版的變更: Add support for `SEEK_HOLE` and `SEEK_DATA`.

`os.SEEK_SET`

`os.SEEK_CUR`

`os.SEEK_END`

Parameters to the `lseek()` function and the `seek()` method on *file-like objects*, for `whence` to adjust the file position indicator.

**`SEEK_SET`**

Adjust the file position relative to the beginning of the file.

**`SEEK_CUR`**

Adjust the file position relative to the current file position.

**`SEEK_END`**

Adjust the file position relative to the end of the file.

Their values are 0, 1, and 2, respectively.

`os.SEEK_HOLE`

**os.SEEK\_DATA**

Parameters to the `lseek()` function and the `seek()` method on *file-like objects*, for seeking file data and holes on sparsely allocated files.

**SEEK\_DATA**

Adjust the file offset to the next location containing data, relative to the seek position.

**SEEK\_HOLE**

Adjust the file offset to the next location containing a hole, relative to the seek position. A hole is defined as a sequence of zeros.

**備 F**

These operations only make sense for filesystems that support them.

適用: Linux >= 3.1, macOS, Unix

在 3.3 版被加入。

**os.open(path, flags, mode=0o777, \*, dir\_fd=None)**

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like `O_RDONLY` and `O_WRONLY`) are defined in the `os` module. In particular, on Windows adding `O_BINARY` is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the *dir\_fd* parameter.

引發一個附帶引數 `path`、`mode`、`flags` 的稽核事件 `open`。

在 3.4 版的變更: The new file descriptor is now non-inheritable.

**備 F**

This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file object, use `fdopen()`.

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

在 3.6 版的變更: Accepts a *path-like object*.

The following constants are options for the *flags* parameter to the `open()` function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the `open(2)` manual page on Unix or the MSDN on Windows.

`os.O_RDONLY`

`os.O_WRONLY`

`os.O_RDWR`

`os.O_APPEND`

`os.O_CREAT`

`os.O_EXCL`

os.O\_TRUNC

The above constants are available on Unix and Windows.

os.O\_DSYNC

os.O\_RSYNC

os.O\_SYNC

os.O\_NDELAY

os.O\_NONBLOCK

os.O\_NOCTTY

os.O\_CLOEXEC

The above constants are only available on Unix.

在 3.3 版的變更: Add `O_CLOEXEC` constant.

os.O\_BINARY

os.O\_NOINHERIT

os.O\_SHORT\_LIVED

os.O\_TEMPORARY

os.O\_RANDOM

os.O\_SEQUENTIAL

os.O\_TEXT

The above constants are only available on Windows.

os.O\_EVTONLY

os.O\_FSYNC

os.O\_SYMLINK

os.O\_NOFOLLOW\_ANY

The above constants are only available on macOS.

在 3.10 版的變更: Add `O_EVTONLY`, `O_FSYNC`, `O_SYMLINK` and `O_NOFOLLOW_ANY` constants.

os.O\_ASYNC

os.O\_DIRECT

os.O\_DIRECTORY

os.O\_NOFOLLOW

os.O\_NOATIME

os.O\_PATH

os.O\_TMPFILE

os.O\_SHLOCK

os.O\_EXLOCK

The above constants are extensions and not present if they are not defined by the C library.

在 3.4 版的變更: Add `O_PATH` on systems that support it. Add `O_TMPFILE`, only available on Linux Kernel 3.11 or newer.

os.openpty()

Open a new pseudo-terminal pair. Return a pair of file descriptors (`master`, `slave`) for the `pty` and the `tty`, respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the `pty` module.

適用: Unix, not WASI.

在 3.4 版的變更: The new file descriptors are now non-inheritable.

**os.pipe()**

Create a pipe. Return a pair of file descriptors (*r*, *w*) usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

適用: Unix, Windows.

在 3.4 版的變更: The new file descriptors are now non-inheritable.

**os.pipe2(flags, /)**

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: *O\_NONBLOCK*, *O\_CLOEXEC*. Return a pair of file descriptors (*r*, *w*) usable for reading and writing, respectively.

適用: Unix, not WASI.

在 3.3 版被加入.

**os.posix\_fallocate(fd, offset, len, /)**

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

適用: Unix.

在 3.3 版被加入.

**os.posix\_fadvise(fd, offset, len, advice, /)**

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The *advice* applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of *POSIX\_FADV\_NORMAL*, *POSIX\_FADV\_SEQUENTIAL*, *POSIX\_FADV\_RANDOM*, *POSIX\_FADV\_NOREUSE*, *POSIX\_FADV\_WILLNEED* or *POSIX\_FADV\_DONTNEED*.

適用: Unix.

在 3.3 版被加入.

**os.POSIX\_FADV\_NORMAL****os.POSIX\_FADV\_SEQUENTIAL****os.POSIX\_FADV\_RANDOM****os.POSIX\_FADV\_NOREUSE****os.POSIX\_FADV\_WILLNEED****os.POSIX\_FADV\_DONTNEED**

Flags that can be used in *advice* in *posix\_fadvise()* that specify the access pattern that is likely to be used.

適用: Unix.

在 3.3 版被加入.

**os.pread(fd, n, offset, /)**

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

適用: Unix.

在 3.3 版被加入.

**os.posix\_openpt(oflag, /)**

Open and return a file descriptor for a master pseudo-terminal device.

Calls the C standard library function *posix\_openpt()*. The *oflag* argument is used to set file status flags and file access modes as specified in the manual page of *posix\_openpt()* of your system.

The returned file descriptor is *non-inheritable*. If the value *O\_CLOEXEC* is available on the system, it is added to *oflag*.

適用: Unix, not WASI.

在 3.13 版被加入.

`os.preadv` (*fd*, *buffers*, *offset*, *flags=0*, *l*)

Read from a file descriptor *fd* at a position of *offset* into mutable *bytes-like objects buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- `RWF_HIPRI`
- `RWF_NOWAIT`

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (`sysconf()` value '`SC_IOV_MAX`') on the number of buffers that can be used.

Combine the functionality of `os.readv()` and `os.pread()`.

適用: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

在 3.7 版被加入.

`os.RWF_NOWAIT`

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set `errno` to `errno.EAGAIN`.

適用: Linux >= 4.14.

在 3.7 版被加入.

`os.RWF_HIPRI`

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the `O_DIRECT` flag.

適用: Linux >= 4.6.

在 3.7 版被加入.

`os.ptsnam` (*fd*, *l*)

Return the name of the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the reentrant C standard library function `ptsnam_r()` if it is available; otherwise, the C standard library function `ptsnam()`, which is not guaranteed to be thread-safe, is called.

適用: Unix, not WASI.

在 3.13 版被加入.

`os.pwrite` (*fd*, *str*, *offset*, *l*)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

適用: Unix.

在 3.3 版被加入.

`os.pwritev(fd, buffers, offset, flags=0, l)`

Write the *buffers* contents to file descriptor *fd* at an offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- `RWF_DSYNC`
- `RWF_SYNC`
- `RWF_APPEND`

Return the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of `os.writev()` and `os.pwrite()`.

適用: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

在 3.7 版被加入。

`os.RWF_DSYNC`

Provide a per-write equivalent of the `O_DSYNC` `os.open()` flag. This flag effect applies only to the data range written by the system call.

適用: Linux >= 4.7.

在 3.7 版被加入。

`os.RWF_SYNC`

Provide a per-write equivalent of the `O_SYNC` `os.open()` flag. This flag effect applies only to the data range written by the system call.

適用: Linux >= 4.7.

在 3.7 版被加入。

`os.RWF_APPEND`

Provide a per-write equivalent of the `O_APPEND` `os.open()` flag. This flag is meaningful only for `os.pwritev()`, and its effect applies only to the data range written by the system call. The *offset* argument does not affect the write operation; the data is always appended to the end of the file. However, if the *offset* argument is `-1`, the current file *offset* is updated.

適用: Linux >= 4.16.

在 3.10 版被加入。

`os.read(fd, n, l)`

Read at most *n* bytes from file descriptor *fd*.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

#### 備 F

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`os.sendfile(out_fd, in_fd, offset, count)`

`os.sendfile(out_fd, in_fd, offset, count, headers=(), trailers=(), flags=0)`

Copy *count* bytes from file descriptor *in\_fd* to file descriptor *out\_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return 0.

The first function notation is supported by all platforms that define `sendfile()`.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in\_fd* and the position of *in\_fd* is updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in\_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of 0 for *count* specifies to send until the end of *in\_fd* is reached.

All platforms support sockets as *out\_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

適用: Unix, not WASI.

#### 備

For a higher-level wrapper of `sendfile()`, see `socket.socket.sendfile()`.

在 3.3 版被加入。

在 3.9 版的變更: Parameters *out* and *in* was renamed to *out\_fd* and *in\_fd*.

`os.SF_NODISKIO`

`os.SF_MNOWAIT`

`os.SF_SYNC`

Parameters to the `sendfile()` function, if the implementation supports them.

適用: Unix, not WASI.

在 3.3 版被加入。

`os.SF_NOCACHE`

Parameter to the `sendfile()` function, if the implementation supports it. The data won't be cached in the virtual memory and will be freed afterwards.

適用: Unix, not WASI.

在 3.11 版被加入。

`os.set_blocking(fd, blocking, /)`

Set the blocking mode of the specified file descriptor. Set the `O_NONBLOCK` flag if *blocking* is `False`, clear the flag otherwise.

另請參 `get_blocking()` 與 `socket.socket.setblocking()`。

適用: Unix, Windows.

The function is limited on WASI, see [WebAssembly 平台](#) for more information.

On Windows, this function is limited to pipes.

在 3.5 版被加入。

在 3.12 版的變更: 新增對 Windows 上的 pipe 支援。

`os.splice` (*src*, *dst*, *count*, *offset\_src=None*, *offset\_dst=None*)

Transfer *count* bytes from file descriptor *src*, starting from offset *offset\_src*, to file descriptor *dst*, starting from offset *offset\_dst*. At least one of the file descriptors must refer to a pipe. If *offset\_src* is `None`, then *src* is read from the current position; respectively for *offset\_dst*. The offset associated to the file descriptor that refers to a pipe must be `None`. The files pointed to by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with *errno* set to *errno.EXDEV*.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

Upon successful completion, returns the number of bytes spliced to or from the pipe. A return value of 0 means end of input. If *src* refers to a pipe, then this means that there was no data to transfer, and it would not make sense to block because there are no writers connected to the write end of the pipe.

適用: Linux >= 2.6.17 with glibc >= 2.5

在 3.10 版被加入.

`os.SPLICE_F_MOVE`

`os.SPLICE_F_NONBLOCK`

`os.SPLICE_F_MORE`

在 3.10 版被加入.

`os.readv` (*fd*, *buffers*, *l*)

Read from a file descriptor *fd* into a number of mutable *bytes-like objects* *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (`sysconf()` value `'SC_IOV_MAX'`) on the number of buffers that can be used.

適用: Unix.

在 3.3 版被加入.

`os.tcgetpgrp` (*fd*, *l*)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by `os.open()`).

適用: Unix, not WASI.

`os.tcsetpgrp` (*fd*, *pg*, *l*)

Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by `os.open()`) to *pg*.

適用: Unix, not WASI.

`os.ttyname` (*fd*, *l*)

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

適用: Unix.

`os.unlockpt` (*fd*, *l*)

Unlock the slave pseudo-terminal device associated with the master pseudo-terminal device to which the file descriptor *fd* refers. The file descriptor *fd* is not closed upon failure.

Calls the C standard library function `unlockpt()`.

適用: Unix, not WASI.

在 3.13 版被加入.

`os.write(fd, str, /)`

Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

**備 F**

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To write a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdout` or `sys.stderr`, use its `write()` method.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`os.writev(fd, buffers, /)`

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value 'SC\_IOV\_MAX') on the number of buffers that can be used.

適用: Unix.

在 3.3 版被加入.

### Querying the size of a terminal

在 3.3 版被加入.

`os.get_terminal_size(fd=STDOUT_FILENO, /)`

Return the size of the terminal window as `(columns, lines)`, tuple of type `terminal_size`.

The optional argument *fd* (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an `OSError` is raised.

`shutil.get_terminal_size()` is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

適用: Unix, Windows.

**class** `os.terminal_size`

A subclass of tuple, holding `(columns, lines)` of the terminal window size.

**columns**

Width of the terminal window in characters.

**lines**

Height of the terminal window in characters.

### Inheritance of File Descriptors

在 3.4 版被加入.

A file descriptor has an "inheritable" flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using *spawn\** functions, all inheritable handles and all inheritable file descriptors are inherited. Using the *subprocess* module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the *close\_fds* parameter is `False`.

On WebAssembly platforms, the file descriptor cannot be modified.

`os.get_inheritable` (*fd*, *l*)

Get the "inheritable" flag of the specified file descriptor (a boolean).

`os.set_inheritable` (*fd*, *inheritable*, *l*)

Set the "inheritable" flag of the specified file descriptor.

`os.get_handle_inheritable` (*handle*, *l*)

Get the "inheritable" flag of the specified handle (a boolean).

適用: Windows.

`os.set_handle_inheritable` (*handle*, *inheritable*, *l*)

Set the "inheritable" flag of the specified handle.

適用: Windows.

## 16.1.6 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the *os* module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`.)

You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using `os.supports_fd`. If this functionality is unavailable, using it will raise a `NotImplementedError`.

If the function also supports *dir\_fd* or *follow\_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir\_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir\_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

You can check whether or not *dir\_fd* is supported for a particular function on your platform using `os.supports_dir_fd`. If it's unavailable, using it will raise a `NotImplementedError`.

- **not following symlinks:** If *follow\_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python will call the `l...` variant of the function.)

You can check whether or not *follow\_symlinks* is supported for a particular function on your platform using `os.supports_follow_symlinks`. If it's unavailable, using it will raise a `NotImplementedError`.

`os.access` (*path*, *mode*, \*, *dir\_fd=None*, *effective\_ids=False*, *follow\_symlinks=True*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a `suid/sgid` environment to test if the invoking user has the specified access to *path*. *mode* should be `F_OK` to test the existence of *path*, or it can be the inclusive OR of one or more of `R_OK`, `W_OK`, and `X_OK` to test permissions. Return `True` if access is allowed, `False` if not. See the Unix man page `access(2)` for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective\_ids* is `True`, `access()` will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective\_ids* may not be supported on your platform; you can check whether or not it is available using `os.supports_effective_ids`. If it is unavailable, using it will raise a `NotImplementedError`.

**備**

Using `access()` to check if a user is authorized to e.g. open a file before actually doing so using `open()` creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

**備**

I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

在 3.3 版的變更: 新增 `dir_fd`、`effective_ids` 與 `follow_symlinks` 參數。

在 3.6 版的變更: Accepts a *path-like object*.

- os.F\_OK
- os.R\_OK
- os.W\_OK
- os.X\_OK

Values to pass as the *mode* parameter of `access()` to test the existence, readability, writability and executability of *path*, respectively.

- os.chdir(*path*)

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

This function can raise `OSError` and subclasses such as `FileNotFoundError`, `PermissionError`, and `NotADirectoryError`.

引發一個附帶引數 *path* 的稽核事件 `os.chdir`。

在 3.3 版的變更: Added support for specifying *path* as a file descriptor on some platforms.

在 3.6 版的變更: Accepts a *path-like object*.

- os.chflags(*path*, *flags*, \*, *follow\_symlinks=True*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the `stat` module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`

- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.UF_COMPRESSED`
- `stat.UF_HIDDEN`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

This function can support *not following symlinks*.

引發一個附帶引數 `path`、`flags` 的稽核事件 `os.chflags`。

適用: Unix, not WASI.

在 3.3 版的變更: 新增 `follow_symlinks` 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.chmod(path, mode, *, dir_fd=None, follow_symlinks=True)`

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the `stat` module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IREAD`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`
- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

This function can support *specifying a file descriptor, paths relative to directory descriptors and not following symlinks*.

## 備F

Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored. The default value of `follow_symlinks` is `False` on Windows.

The function is limited on WASI, see [WebAssembly 平台](#) for more information.

引發一個附帶引數 `path`、`mode`、`dir_fd` 的稽核事件 `os.chmod`。

在 3.3 版的變更: Added support for specifying `path` as an open file descriptor, and the `dir_fd` and `follow_symlinks` arguments.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.13 版的變更: Added support for a file descriptor and the `follow_symlinks` argument on Windows.

`os.chown(path, uid, gid, *, dir_fd=None, follow_symlinks=True)`

Change the owner and group id of `path` to the numeric `uid` and `gid`. To leave one of the ids unchanged, set it to `-1`.

This function can support *specifying a file descriptor, paths relative to directory descriptors and not following symlinks*.

See `shutil.chown()` for a higher-level function that accepts names in addition to numeric ids.

引發一個附帶引數 `path`、`uid`、`gid`、`dir_fd` 的稽核事件 `os.chown`。

適用: Unix.

The function is limited on WASI, see [WebAssembly 平台](#) for more information.

在 3.3 版的變更: Added support for specifying `path` as an open file descriptor, and the `dir_fd` and `follow_symlinks` arguments.

在 3.6 版的變更: Supports a *path-like object*.

`os.chroot(path)`

Change the root directory of the current process to `path`.

適用: Unix, not WASI, not Android.

在 3.6 版的變更: Accepts a *path-like object*.

`os.fchdir(fd)`

Change the current working directory to the directory represented by the file descriptor `fd`. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

引發一個附帶引數 `path` 的稽核事件 `os.chdir`。

適用: Unix.

`os.getcwd()`

Return a string representing the current working directory.

`os.getcwdb()`

Return a bytestring representing the current working directory.

在 3.8 版的變更: The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see [PEP 529](#) for the rationale. The function is no longer deprecated on Windows.

`os.lchflags(path, flags)`

Set the flags of `path` to the numeric `flags`, like `chflags()`, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

引發一個附帶引數 `path`、`flags` 的稽核事件 `os.chflags`。

適用: Unix, not WASI.

在 3.6 版的變更: Accepts a *path-like object*.

`os.lchmod(path, mode)`

Change the mode of *path* to the numeric *mode*. If *path* is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

`lchmod()` is not part of POSIX, but Unix implementations may have it if changing the mode of symbolic links is supported.

引發一個附帶引數 `path`、`mode`、`dir_fd` 的稽核事件 `os.chmod`。

適用: Unix, Windows, not Linux, FreeBSD >= 1.3, NetBSD >= 1.3, not OpenBSD

在 3.6 版的變更: Accepts a *path-like object*.

在 3.13 版的變更: 新增對 Windows 的支援。

`os.lchown(path, uid, gid)`

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

引發一個附帶引數 `path`、`uid`、`gid`、`dir_fd` 的稽核事件 `os.chown`。

適用: Unix.

在 3.6 版的變更: Accepts a *path-like object*.

`os.link(src, dst, *, src_dir_fd=None, dst_dir_fd=None, follow_symlinks=True)`

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src\_dir\_fd* and/or *dst\_dir\_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

引發一個附帶引數 `src`、`dst`、`src_dir_fd`、`dst_dir_fd` 的稽核事件 `os.link`。

適用: Unix, Windows.

在 3.2 版的變更: 新支援 Windows。

在 3.3 版的變更: 新增 `src_dir_fd`、`dst_dir_fd` 與 `follow_symlinks` 參數。

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

`os.listdir(path='.')`

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

*path* may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the `PathLike` interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

引發一個附帶引數 `path` 的稽核事件 `os.listdir`。

#### 備 F

To encode `str` filenames to `bytes`, use `fsencode()`.

#### 也參考

The `scandir()` function returns directory entries along with file attribute information, giving better performance for many common use cases.

在 3.2 版的變更: The *path* parameter became optional.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor.

在 3.6 版的變更: Accepts a *path-like object*.

#### `os.listdirives()`

Return a list containing the names of drives on a Windows system.

A drive name typically looks like 'C:\\'. Not every drive name will be associated with a volume, and some may be inaccessible for a variety of reasons, including permissions, network connectivity or missing media. This function does not test for access.

May raise *OSError* if an error occurs collecting the drive names.

引發一個不附帶引數的稽核事件 `os.listdirives`。

適用: Windows

在 3.12 版被加入。

#### `os.listmounts(volume)`

Return a list containing the mount points for a volume on a Windows system.

*volume* must be represented as a GUID path, like those returned by `os.listvolumes()`. Volumes may be mounted in multiple locations or not at all. In the latter case, the list will be empty. Mount points that are not associated with a volume will not be returned by this function.

The mount points return by this function will be absolute paths, and may be longer than the drive name.

Raises *OSError* if the volume is not recognized or if an error occurs collecting the paths.

引發一個附帶引數 *volume* 的稽核事件 `os.listmounts`。

適用: Windows

在 3.12 版被加入。

#### `os.listvolumes()`

Return a list containing the volumes in the system.

Volumes are typically represented as a GUID path that looks like \\?\Volume{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}\. Files can usually be accessed through a GUID path, permissions allowing. However, users are generally not familiar with them, and so the recommended use of this function is to retrieve mount points using `os.listmounts()`.

May raise *OSError* if an error occurs collecting the volumes.

引發一個不附帶引數的稽核事件 `os.listvolumes`。

適用: Windows

在 3.12 版被加入。

#### `os.lstat(path, *, dir_fd=None)`

Perform the equivalent of an `lstat()` system call on the given path. Similar to `stat()`, but does not follow symbolic links. Return a *stat\_result* object.

On platforms that do not support symbolic links, this is an alias for `stat()`.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

#### 也參考

The `stat()` function.

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: 新增 `dir_fd` 參數。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.8 版的變更: On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for `stat()`.

`os.mkdir(path, mode=0o777, *, dir_fd=None)`

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, `FileExistsError` is raised. If a parent directory in the path does not exist, `FileNotFoundError` is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call `chmod()` explicitly to set them.

On Windows, a *mode* of `0o700` is specifically handled to apply access control to the new directory such that only the current user and administrators have access. Other values of *mode* are ignored.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the `tempfile` module's `tempfile.mkdtemp()` function.

引發一個附帶引數 `path`、`mode`、`dir_fd` 的稽核事件 `os.mkdir`。

在 3.3 版的變更: 新增 `dir_fd` 參數。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.13 版的變更: Windows now handles a *mode* of `0o700`.

`os.makedirs(name, mode=0o777, exist_ok=False)`

Recursive directory creation function. Like `mkdir()`, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to `mkdir()` for creating the leaf directory; see *the mkdir() description* for how it is interpreted. To set the file permission bits of any newly created parent directories you can set the umask before invoking `makedirs()`. The file permission bits of existing parent directories are not changed.

If *exist\_ok* is `False` (the default), a `FileExistsError` is raised if the target directory already exists.

#### 備註

`makedirs()` will become confused if the path elements to create include *pardir* (eg. `..` on UNIX systems).

This function handles UNC paths correctly.

引發一個附帶引數 `path`、`mode`、`dir_fd` 的稽核事件 `os.mkdir`。

在 3.2 版的變更: 新增 `exist_ok` 參數。

在 3.4.1 版的變更: Before Python 3.4.1, if *exist\_ok* was `True` and the directory existed, `makedirs()` would still raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See [bpo-21082](#).

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: The *mode* argument no longer affects the file permission bits of newly created intermediate-level directories.

`os.mkfifo` (*path*, *mode=0o666*, \*, *dir\_fd=None*)

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with `os.unlink()`). Generally, FIFOs are used as rendezvous between "client" and "server" type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that `mkfifo()` doesn't open the FIFO --- it just creates the rendezvous point.

適用: Unix, not WASI.

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.mknod` (*path*, *mode=0o600*, *device=0*, \*, *dir\_fd=None*)

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

適用: Unix, not WASI.

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.major` (*device*, *l*)

Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.minor` (*device*, *l*)

Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

`os.makedev` (*major*, *minor*, *l*)

Compose a raw device number from the major and minor device numbers.

`os.pathconf` (*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

This function can support *specifying a file descriptor*.

適用: Unix.

在 3.6 版的變更: Accepts a *path-like object*.

`os.pathconf_names`

Dictionary mapping names accepted by `pathconf()` and `fpathconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用: Unix.

`os.readlink(path, *, dir_fd=None)`

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a *PathLike* interface), the result will also be a string object, and the call may raise a `UnicodeDecodeError`. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

When trying to resolve a path that may contain links, use `realpath()` to properly handle recursion and platform differences.

適用: Unix, Windows.

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object* on Unix.

在 3.8 版的變更: Accepts a *path-like object* and a bytes object on Windows.

Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\` prefix) rather than the optional "print name" field that was previously returned.

`os.remove(path, *, dir_fd=None)`

Remove (delete) the file *path*. If *path* is a directory, an `OSError` is raised. Use `rmdir()` to remove directories. If the file does not exist, a `FileNotFoundError` is raised.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to `unlink()`.

引發一個附帶引數 *path*、*dir\_fd* 的稽核事件 `os.remove`。

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.removedirs(name)`

Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory 'foo/bar/baz', and then remove 'foo/bar' and 'foo' if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

引發一個附帶引數 *path*、*dir\_fd* 的稽核事件 `os.remove`。

在 3.6 版的變更: Accepts a *path-like object*.

`os.rename(src, dst, *, src_dir_fd=None, dst_dir_fd=None)`

Rename the file or directory *src* to *dst*. If *dst* exists, the operation will fail with an `OSError` subclass in a number of cases:

On Windows, if *dst* exists a `FileExistsError` is always raised. The operation may fail if *src* and *dst* are on different filesystems. Use `shutil.move()` to support moves to a different filesystem.

On Unix, if *src* is a file and *dst* is a directory or vice-versa, an `IsADirectoryError` or a `NotADirectoryError` will be raised respectively. If both are directories and *dst* is empty, *dst* will be silently replaced. If *dst* is a non-empty directory, an `OSError` is raised. If both are files, *dst* will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src\_dir\_fd* and/or *dst\_dir\_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use `replace()`.

引發一個附帶引數 `src`、`dst`、`src_dir_fd`、`dst_dir_fd` 的稽核事件 `os.rename`。

在 3.3 版的變更: 新增 `src_dir_fd` 與 `dst_dir_fd` 參數。

在 3.6 版的變更: Accepts a *path-like object* for `src` and `dst`.

`os.rename` (*old*, *new*)

Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`.

**備 F**

This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

引發一個附帶引數 `src`、`dst`、`src_dir_fd`、`dst_dir_fd` 的稽核事件 `os.rename`。

在 3.6 版的變更: Accepts a *path-like object* for `old` and `new`.

`os.replace` (*src*, *dst*, \*, *src\_dir\_fd=None*, *dst\_dir\_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, `OSError` will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src\_dir\_fd* and/or *dst\_dir\_fd* to supply *paths relative to directory descriptors*.

引發一個附帶引數 `src`、`dst`、`src_dir_fd`、`dst_dir_fd` 的稽核事件 `os.rename`。

在 3.3 版被加入。

在 3.6 版的變更: Accepts a *path-like object* for `src` and `dst`.

`os.rmdir` (*path*, \*, *dir\_fd=None*)

Remove (delete) the directory *path*. If the directory does not exist or is not empty, a `FileNotFoundError` or an `OSError` is raised respectively. In order to remove whole directory trees, `shutil.rmtree()` can be used.

This function can support *paths relative to directory descriptors*.

引發一個附帶引數 `path`、`dir_fd` 的稽核事件 `os.rmdir`。

在 3.3 版的變更: 新增 `dir_fd` 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.scandir` (*path*='.')

Return an iterator of `os.DirEntry` objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using `scandir()` instead of `listdir()` can significantly increase the performance of code that also needs file type or file attribute information, because `os.DirEntry` objects expose this information if the operating system provides it when scanning a directory. All `os.DirEntry` methods may perform a system call, but `is_dir()` and `is_file()` usually only require a system call for symbolic links; `os.DirEntry.stat()` always requires a system call on Unix but only requires one for symbolic links on Windows.

*path* may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the `PathLike` interface), the type of the `name` and `path` attributes of each `os.DirEntry` will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

引發一個附帶引數 `path` 的稽核事件 `os.scandir`。

The `scandir()` iterator supports the *context manager* protocol and has the following method:

`scandir.close()`

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the `with` statement.

在 3.6 版被加入。

The following example shows a simple use of `scandir()` to display all the files (excluding directories) in the given `path` that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

#### 備 F

On Unix-based systems, `scandir()` uses the system's `opendir()` and `readdir()` functions. On Windows, it uses the Win32 `FindFirstFileW` and `FindNextFileW` functions.

在 3.5 版被加入。

在 3.6 版的變更: Added support for the *context manager* protocol and the `close()` method. If a `scandir()` iterator is neither exhausted nor explicitly closed a `ResourceWarning` will be emitted in its destructor.

The function accepts a *path-like object*.

在 3.7 版的變更: Added support for *file descriptors* on Unix.

#### **class** `os.DirEntry`

Object yielded by `scandir()` to expose the file path and other file attributes of a directory entry.

`scandir()` will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling `scandir()`, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise `OSError`. If you need very fine-grained control over errors, you can catch `OSError` when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the `PathLike` interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

##### **name**

The entry's base filename, relative to the `scandir()` `path` argument.

The `name` attribute will be `bytes` if the `scandir()` `path` argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

##### **path**

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where `scandir_path` is the `scandir()` `path` argument. The path is only absolute if the `scandir()` `path` argument was absolute. If the `scandir()` `path` argument was a *file descriptor*, the `path` attribute is the same as the `name` attribute.

The `path` attribute will be `bytes` if the `scandir()` `path` argument is of type `bytes` and `str` otherwise. Use `fsdecode()` to decode byte filenames.

#### `inode()`

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

#### `is_dir(*, follow_symlinks=True)`

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If `follow_symlinks` is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` along with `stat.S_ISDIR()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless `follow_symlinks` is `False`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

#### `is_file(*, follow_symlinks=True)`

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If `follow_symlinks` is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per `is_dir()`.

#### `is_symlink()`

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call `os.path.islink()` to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise `OSError`, such as `PermissionError`, but `FileNotFoundError` is caught and not raised.

#### `is_junction()`

Return `True` if this entry is a junction (even if broken); return `False` if the entry points to a regular directory, any kind of file, a symlink, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call `os.path.isjunction()` to fetch up-to-date information.

在 3.12 版被加入。

#### `stat(*, follow_symlinks=True)`

Return a `stat_result` object for this entry. This method follows symbolic links by default; to `stat` a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if `follow_symlinks` is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the `stat_result` are always set to zero. Call `os.stat()` to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for `follow_symlinks` `True` and `False`. Call `os.stat()` to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of `pathlib.Path`. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()`, `is_junction()`, and `stat()` methods.

在 3.5 版被加入。

在 3.6 版的變更: Added support for the `PathLike` interface. Added support for `bytes` paths on Windows.

在 3.12 版的變更: The `st_ctime` attribute of a stat result is deprecated on Windows. The file creation time is properly available as `st_birthtime`, and in the future `st_ctime` may be changed to return zero or the metadata change time, if available.

`os.stat(path, *, dir_fd=None, follow_symlinks=True)`

Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given `path`. `path` may be specified as either a string or bytes -- directly or indirectly through the `PathLike` interface -- or as an open file descriptor. Return a `stat_result` object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use `lstat()`.

This function can support *specifying a file descriptor* and *not following symlinks*.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the `os.path.realpath()` function to resolve the path name as far as possible and call `lstat()` on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

範例:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

### 也參考

`fstat()` 和 `lstat()` 函式。

在 3.3 版的變更: 新增 `dir_fd` 與 `follow_symlinks` 參數, 指定一個檔案描述器而非路徑。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.8 版的變更: On Windows, all reparse points that can be resolved by the operating system are now followed, and passing `follow_symlinks=False` disables following all name surrogate reparse points. If the operating system reaches a reparse point that it is not able to follow, `stat` now returns the information for the original path as if `follow_symlinks=False` had been specified instead of raising an error.

**class** `os.stat_result`

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of `os.stat()`, `os.fstat()` and `os.lstat()`.

屬性:

**st\_mode**

File mode: file type and file mode bits (permissions).

**st\_ino**

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the file index on Windows

**st\_dev**

Identifier of the device on which this file resides.

**st\_nlink**

Number of hard links.

**st\_uid**

User identifier of the file owner.

**st\_gid**

Group identifier of the file owner.

**st\_size**

Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

**st\_atime**

Time of most recent access expressed in seconds.

**st\_mtime**

Time of most recent content modification expressed in seconds.

**st\_ctime**

Time of most recent metadata change expressed in seconds.

在 3.12 版的變更: `st_ctime` is deprecated on Windows. Use `st_birthtime` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

**st\_atime\_ns**

Time of most recent access expressed in nanoseconds as an integer.

在 3.3 版被加入.

**st\_mtime\_ns**

Time of most recent content modification expressed in nanoseconds as an integer.

在 3.3 版被加入.

**st\_ctime\_ns**

Time of most recent metadata change expressed in nanoseconds as an integer.

在 3.3 版被加入.

在 3.12 版的變更: `st_ctime_ns` is deprecated on Windows. Use `st_birthtime_ns` for the file creation time. In the future, `st_ctime` will contain the time of the most recent metadata change, as for other platforms.

**st\_birthtime**

Time of file creation expressed in seconds. This attribute is not always available, and may raise *AttributeError*.

在 3.12 版的變更: `st_birthtime` is now available on Windows.

**st\_birthtime\_ns**

Time of file creation expressed in nanoseconds as an integer. This attribute is not always available, and may raise *AttributeError*.

在 3.12 版被加入。

**備註**

The exact meaning and resolution of the `st_atime`, `st_mtime`, `st_ctime` and `st_birthtime` attributes depend on the operating system and the file system. For example, on Windows systems using the FAT32 file systems, `st_mtime` has 2-second resolution, and `st_atime` has only 1-day resolution. See your operating system documentation for details.

Similarly, although `st_atime_ns`, `st_mtime_ns`, `st_ctime_ns` and `st_birthtime_ns` are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store `st_atime`, `st_mtime`, `st_ctime` and `st_birthtime` cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use `st_atime_ns`, `st_mtime_ns`, `st_ctime_ns` and `st_birthtime_ns`.

On some Unix systems (such as Linux), the following attributes may also be available:

**st\_blocks**

Number of 512-byte blocks allocated for file. This may be smaller than `st_size/512` when the file has holes.

**st\_blksize**

”Preferred” blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

**st\_rdev**

Type of device if an inode device.

**st\_flags**

User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

**st\_gen**

File generation number.

On Solaris and derivatives, the following attributes may also be available:

**st\_fstype**

String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

**st\_rsize**

Real size of the file.

**st\_creator**

Creator of the file.

**st\_type**

File type.

On Windows systems, the following attributes are also available:

#### `st_file_attributes`

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` <`stat.FILE_ATTRIBUTE_ARCHIVE`> constants in the `stat` module.

在 3.5 版被加入。

#### `st_reparse_tag`

When `st_file_attributes` has the `FILE_ATTRIBUTE_REPARSE_POINT` set, this field contains the tag identifying the type of reparse point. See the `IO_REPARSE_TAG_*` constants in the `stat` module.

The standard module `stat` defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a `stat_result` instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order `st_mode`, `st_ino`, `st_dev`, `st_nlink`, `st_uid`, `st_gid`, `st_size`, `st_atime`, `st_mtime`, `st_ctime`. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

在 3.5 版的變更: Windows now returns the file index as `st_ino` when available.

在 3.7 版的變更: Added the `st_fstype` member to Solaris/derivatives.

在 3.8 版的變更: 在 Windows 上新增 `st_reparse_tag` 成員。

在 3.8 版的變更: On Windows, the `st_mode` member now identifies special files as `S_IFCHR`, `S_IFIFO` or `S_IFBLK` as appropriate.

在 3.12 版的變更: On Windows, `st_ctime` is deprecated. Eventually, it will contain the last metadata change time, for consistency with other platforms, but for now still contains creation time. Use `st_birthtime` for the creation time.

On Windows, `st_ino` may now be up to 128 bits, depending on the file system. Previously it would not be above 64 bits, and larger file identifiers would be arbitrarily packed.

On Windows, `st_rdev` no longer returns a value. Previously it would contain the same as `st_dev`, which was incorrect.

在 Windows 上新增 `st_birthtime` 成員。

#### `os.statvfs(path)`

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`, `f_fsid`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of `setuid/setgid` bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

適用: Unix.

在 3.2 版的變更: 新增 `ST_RDONLY` 與 `ST_NOSUID` 常數。

在 3.3 版的變更: Added support for specifying `path` as an open file descriptor.

在 3.4 版的變更: The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增 `f_fsid` 屬性。

#### `os.supports_dir_fd`

A *set* object indicating which functions in the `os` module accept an open file descriptor for their *dir\_fd* parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the *dir\_fd* parameter is not available on all platforms Python supports. For consistency's sake, functions that may support *dir\_fd* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for *dir\_fd* is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its *dir\_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if `os.stat()` accepts open file descriptors for *dir\_fd* on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently *dir\_fd* parameters only work on Unix platforms; none of them work on Windows.

在 3.3 版被加入。

#### `os.supports_effective_ids`

A *set* object indicating whether `os.access()` permits specifying `True` for its *effective\_ids* parameter on the local platform. (Specifying `False` for *effective\_ids* is always supported on all platforms.) If the local platform supports it, the collection will contain `os.access()`; otherwise it will be empty.

This expression evaluates to `True` if `os.access()` supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently *effective\_ids* is only supported on Unix platforms; it does not work on Windows.

在 3.3 版被加入。

#### `os.supports_fd`

A *set* object indicating which functions in the `os` module permit specifying their *path* parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as *path* arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if `os.chdir()` accepts open file descriptors for *path* on your local platform:

```
os.chdir in os.supports_fd
```

在 3.3 版被加入。

#### `os.supports_follow_symlinks`

A *set* object indicating which functions in the `os` module accept `False` for their *follow\_symlinks* parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement *follow\_symlinks* is not available on all platforms Python supports. For consistency's sake, functions that may support *follow\_symlinks* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for *follow\_symlinks* is always supported on all platforms.)

To check whether a particular function accepts `False` for its *follow\_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling `os.stat()` on the local platform:

```
os.stat in os.supports_follow_symlinks
```

在 3.3 版被加入。

`os.symlink(src, dst, target_is_directory=False, *, dir_fd=None)`

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target\_is\_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target\_is\_directory* is ignored.

This function can support *paths relative to directory descriptors*.

#### 備 F

On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the `SeCreateSymbolicLinkPrivilege` privilege is required, or the process must be run as an administrator.

`OSError` is raised when the function is called by an unprivileged user.

引發一個附帶引數 *src*、*dst*、*dir\_fd* 的稽核事件 `os.symlink`。

適用: Unix, Windows.

The function is limited on WASI, see [WebAssembly 平台](#) for more information.

在 3.2 版的變更: Added support for Windows 6.0 (Vista) symbolic links.

在 3.3 版的變更: Added the *dir\_fd* parameter, and now allow *target\_is\_directory* on non-Windows platforms.

在 3.6 版的變更: Accepts a *path-like object* for *src* and *dst*.

在 3.8 版的變更: Added support for unelevated symlinks on Windows with Developer Mode.

`os.sync()`

Force write of everything to disk.

適用: Unix.

在 3.3 版被加入。

`os.truncate(path, length)`

Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

引發一個附帶引數 *path*、*length* 的稽核事件 `os.truncate`。

適用: Unix, Windows.

在 3.3 版被加入。

在 3.5 版的變更: 新增對 Windows 的支援

在 3.6 版的變更: Accepts a *path-like object*.

`os.unlink(path, *, dir_fd=None)`

Remove (delete) the file *path*. This function is semantically identical to `remove()`; the `unlink` name is its traditional Unix name. Please see the documentation for `remove()` for further information.

引發一個附帶引數 *path*、*dir\_fd* 的稽核事件 `os.remove`。

在 3.3 版的變更: 新增 *dir\_fd* 參數。

在 3.6 版的變更: Accepts a *path-like object*.

`os.utime(path, times=None, *, [ns, ]dir_fd=None, follow_symlinks=True)`

Set the access and modified times of the file specified by *path*.

*utime()* takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent *stat()* call, depending on the resolution with which your operating system records access and modification times; see *stat()*. The best way to preserve exact times is to use the *st\_atime\_ns* and *st\_mtime\_ns* fields from the *os.stat()* result object with the *ns* parameter to *utime()*.

This function can support *specifying a file descriptor, paths relative to directory descriptors and not following symlinks*.

引發一個附帶引數 *path*、*times*、*ns*、*dir\_fd* 的稽核事件 `os.utime`。

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor, and the *dir\_fd*, *follow\_symlinks*, and *ns* parameters.

在 3.6 版的變更: Accepts a *path-like object*.

`os.walk(top, topdown=True, onerror=None, followlinks=False)`

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

*dirpath* is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (including symlinks to directories, and excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and *walk()* will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform *walk()* about directories the caller creates or renames before it resumes *walk()* again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the *scandir()* call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an *OSError* instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the *filename* attribute of the exception object.

By default, *walk()* will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

**i 備**

Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. `walk()` does not keep track of the directories it visited already.

**i 備**

If you pass a relative pathname, don't change the current working directory between resumptions of `walk()`. `walk()` never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example (simple implementation of `shutil.rmtree()`), walking the tree bottom-up is essential, `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
os.rmdir(top)
```

引發一個附帶引數 `top`、`topdown`、`onerror`、`followlinks` 的稽核事件 `os.walk`。

在 3.5 版的變更: This function now calls `os.scandir()` instead of `os.listdir()`, making it faster by reducing the number of calls to `os.stat()`.

在 3.6 版的變更: Accepts a *path-like object*.

`os.fwalk(top='.', topdown=True, onerror=None, *, follow_symlinks=False, dir_fd=None)`

This behaves exactly like `walk()`, except that it yields a 4-tuple (`dirpath`, `dirnames`, `filenames`, `dirfd`), and it supports `dir_fd`.

`dirpath`, `dirnames` and `filenames` are identical to `walk()` output, and `dirfd` is a file descriptor referring to the directory `dirpath`.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the `fwalk()` default value for `follow_symlinks` is `False`.

**i 備**

Since `fwalk()` yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with `dup()`) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/email'):
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end="")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS') # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

引發一個附帶引數 `top`、`topdown`、`onerror`、`follow_symlinks`、`dir_fd` 的稽核事件 `os.fwalk`。  
適用: Unix.

在 3.3 版被加入。

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增對 *bytes* 路徑的支援。

`os.memfd_create` (*name* [, *flags*=`os.MFD_CLOEXEC` ])

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is *non-inheritable*.

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

適用: Linux >= 3.17 with glibc >= 2.27.

在 3.8 版被加入。

```
os.MFD_CLOEXEC
os.MFD_ALLOW_SEALING
os.MFD_HUGETLB
os.MFD_HUGE_SHIFT
os.MFD_HUGE_MASK
os.MFD_HUGE_64KB
os.MFD_HUGE_512KB
os.MFD_HUGE_1MB
os.MFD_HUGE_2MB
os.MFD_HUGE_8MB
os.MFD_HUGE_16MB
os.MFD_HUGE_32MB
```

os.**MFD\_HUGE\_256MB**  
 os.**MFD\_HUGE\_512MB**  
 os.**MFD\_HUGE\_1GB**  
 os.**MFD\_HUGE\_2GB**  
 os.**MFD\_HUGE\_16GB**

這些旗標可以傳給 `memfd_create()`。

適用: Linux >= 3.17 with glibc >= 2.27

MFD\_HUGE\* 旗標僅在 Linux 4.14 以上可用。

在 3.8 版被加入。

os.**eventfd**(*initval*[, *flags*=os.EFD\_CLOEXEC])

Create and return an event file descriptor. The file descriptors supports raw `read()` and `write()` with a buffer size of 8, `select()`, `poll()` and similar. See man page `eventfd(2)` for more information. By default, the new file descriptor is *non-inheritable*.

*initval* is the initial value of the event counter. The initial value must be a 32 bit unsigned integer. Please note that the initial value is limited to a 32 bit unsigned int although the event counter is an unsigned 64 bit integer with a maximum value of  $2^{64}-2$ .

*flags* can be constructed from `EFD_CLOEXEC`, `EFD_NONBLOCK`, and `EFD_SEMAPHORE`.

If `EFD_SEMAPHORE` is specified and the event counter is non-zero, `eventfd_read()` returns 1 and decrements the counter by one.

If `EFD_SEMAPHORE` is not specified and the event counter is non-zero, `eventfd_read()` returns the current event counter value and resets the counter to zero.

If the event counter is zero and `EFD_NONBLOCK` is not specified, `eventfd_read()` blocks.

`eventfd_write()` increments the event counter. Write blocks if the write operation would increment the counter to a value larger than  $2^{64}-2$ .

範例:

```
import os

# semaphore with start value '1'
fd = os.eventfd(1, os.EFD_SEMAPHORE | os.EFD_CLOEXEC)
try:
    # acquire semaphore
    v = os.eventfd_read(fd)
    try:
        do_work()
    finally:
        # release semaphore
        os.eventfd_write(fd, v)
finally:
    os.close(fd)
```

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.10 版被加入。

os.**eventfd\_read**(*fd*)

Read value from an `eventfd()` file descriptor and return a 64 bit unsigned int. The function does not verify that *fd* is an `eventfd()`.

適用: Linux >= 2.6.27

在 3.10 版被加入。

`os.eventfd_write(fd, value)`

Add *value* to an *eventfd()* file descriptor. *value* must be a 64 bit unsigned int. The function does not verify that *fd* is an *eventfd()*.

適用: Linux >= 2.6.27

在 3.10 版被加入。

`os.EFD_CLOEXEC`

Set close-on-exec flag for new *eventfd()* file descriptor.

適用: Linux >= 2.6.27

在 3.10 版被加入。

`os.EFD_NONBLOCK`

設定新的 *eventfd()* 檔案描述器的 *O\_NONBLOCK* 狀態旗標。

適用: Linux >= 2.6.27

在 3.10 版被加入。

`os.EFD_SEMAPHORE`

Provide semaphore-like semantics for reads from an *eventfd()* file descriptor. On read the internal counter is decremented by one.

適用: Linux >= 2.6.30

在 3.10 版被加入。

## Timer File Descriptors

在 3.13 版被加入。

These functions provide support for Linux's *timer file descriptor* API. Naturally, they are all only available on Linux.

`os.timerfd_create(clockid, /, *, flags=0)`

Create and return a timer file descriptor (*timerfd*).

The file descriptor returned by *timerfd\_create()* supports:

- *read()*
- *select()*
- *poll()*

The file descriptor's *read()* method can be called with a buffer size of 8. If the timer has already expired one or more times, *read()* returns the number of expirations with the host's endianness, which may be converted to an *int* by `int.from_bytes(x, byteorder=sys.byteorder)`.

*select()* and *poll()* can be used to wait until timer expires and the file descriptor is readable.

*clockid* must be a valid *clock ID*, as defined in the *time* module:

- *time.CLOCK\_REALTIME*
- *time.CLOCK\_MONOTONIC*
- *time.CLOCK\_BOOTTIME* (Since Linux 3.15 for *timerfd\_create*)

If *clockid* is *time.CLOCK\_REALTIME*, a settable system-wide real-time clock is used. If system clock is changed, timer setting need to be updated. To cancel timer when system clock is changed, see *TFD\_TIMER\_CANCEL\_ON\_SET*.

If *clockid* is *time.CLOCK\_MONOTONIC*, a non-settable monotonically increasing clock is used. Even if the system clock is changed, the timer setting will not be affected.

If *clockid* is *time.CLOCK\_BOOTTIME*, same as *time.CLOCK\_MONOTONIC* except it includes any time that the system is suspended.

The file descriptor's behaviour can be modified by specifying a *flags* value. Any of the following variables may be used, combined using bitwise OR (the `|` operator):

- `TFD_NONBLOCK`
- `TFD_CLOEXEC`

If `TFD_NONBLOCK` is not set as a flag, `read()` blocks until the timer expires. If it is set as a flag, `read()` doesn't block, but if there hasn't been an expiration since the last call to `read()`, `read()` raises `OSError` with `errno` is set to `errno.EAGAIN`.

`TFD_CLOEXEC` is always set by Python automatically.

The file descriptor must be closed with `os.close()` when it is no longer needed, or else the file descriptor will be leaked.

### 也參考

`timerfd_create(2)` 手冊頁。

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入。

`os.timerfd_settime(fd, l, *, flags=flags, initial=0.0, interval=0.0)`

Alter a timer file descriptor's internal timer. This function operates the same interval timer as `timerfd_settime_ns()`.

`fd` must be a valid timer file descriptor.

The timer's behaviour can be modified by specifying a *flags* value. Any of the following variables may be used, combined using bitwise OR (the `|` operator):

- `TFD_TIMER_ABSTIME`
- `TFD_TIMER_CANCEL_ON_SET`

The timer is disabled by setting *initial* to zero (0). If *initial* is equal to or greater than zero, the timer is enabled. If *initial* is less than zero, it raises an `OSError` exception with `errno` set to `errno.EINVAL`

By default the timer will fire when *initial* seconds have elapsed. (If *initial* is zero, timer will fire immediately.)

However, if the `TFD_TIMER_ABSTIME` flag is set, the timer will fire when the timer's clock (set by *clockid* in `timerfd_create()`) reaches *initial* seconds.

The timer's interval is set by the *interval float*. If *interval* is zero, the timer only fires once, on the initial expiration. If *interval* is greater than zero, the timer fires every time *interval* seconds have elapsed since the previous expiration. If *interval* is less than zero, it raises `OSError` with `errno` set to `errno.EINVAL`

If the `TFD_TIMER_CANCEL_ON_SET` flag is set along with `TFD_TIMER_ABSTIME` and the clock for this timer is `time.CLOCK_REALTIME`, the timer is marked as cancelable if the real-time clock is changed discontinuously. Reading the descriptor is aborted with the error `ECANCELED`.

Linux manages system clock as UTC. A daylight-savings time transition is done by changing time offset only and doesn't cause discontinuous system clock change.

Discontinuous system clock change will be caused by the following events:

- `settimeofday`
- `clock_settime`
- set the system date and time by `date` command

Return a two-item tuple of (`next_expiration`, `interval`) from the previous timer state, before this function executed.

↪ 也參考

`timerfd_create(2)`, `timerfd_settime(2)`, `settimeofday(2)`, `clock_settime(2)`, and `date(1)`.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`timerfd_settime_ns`(*fd*, *l*, \*, *flags=0*, *initial=0*, *interval=0*)

Similar to `timerfd_settime()`, but use time as nanoseconds. This function operates the same interval timer as `timerfd_settime()`.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`timerfd_gettime`(*fd*, *l*)

Return a two-item tuple of floats (`next_expiration`, `interval`).

`next_expiration` denotes the relative time until next the timer next fires, regardless of if the `TFD_TIMER_ABSTIME` flag is set.

`interval` denotes the timer's interval. If zero, the timer will only fire once, after `next_expiration` seconds have elapsed.

↪ 也參考

`timerfd_gettime(2)`

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`timerfd_gettime_ns`(*fd*, *l*)

Similar to `timerfd_gettime()`, but return time as nanoseconds.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`TFD_NONBLOCK`

A flag for the `timerfd_create()` function, which sets the `O_NONBLOCK` status flag for the new timer file descriptor. If `TFD_NONBLOCK` is not set as a flag, `read()` blocks.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`TFD_CLOEXEC`

A flag for the `timerfd_create()` function, If `TFD_CLOEXEC` is set as a flag, set close-on-exec flag for new file descriptor.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

os.`TFD_TIMER_ABSTIME`

A flag for the `timerfd_settime()` and `timerfd_settime_ns()` functions. If this flag is set, `initial` is interpreted as an absolute value on the timer's clock (in UTC seconds or nanoseconds since the Unix Epoch).

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入.

**os.TFD\_TIMER\_CANCEL\_ON\_SET**

A flag for the `timerfd_settime()` and `timerfd_settime_ns()` functions along with `TFD_TIMER_ABSTIME`. The timer is cancelled when the time of the underlying clock changes discontinuously.

適用: Linux >= 2.6.27 with glibc >= 2.8

在 3.13 版被加入。

**Linux extended attributes**

在 3.3 版被加入。

These functions are all available on Linux only.

**os.getxattr** (*path*, *attribute*, \*, *follow\_symlinks=True*)

Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the `PathLike` interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

引發一個附帶引數 *path*、*attribute* 的稽核事件 `os.getxattr`。

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

**os.listxattr** (*path=None*, \*, *follow\_symlinks=True*)

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is None, `listxattr()` will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

引發一個附帶引數 *path* 的稽核事件 `os.listxattr`。

在 3.6 版的變更: Accepts a *path-like object*.

**os.removexattr** (*path*, *attribute*, \*, *follow\_symlinks=True*)

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the `PathLike` interface). If it is a string, it is encoded with the *filesystem encoding and error handler*.

This function can support *specifying a file descriptor* and *not following symlinks*.

引發一個附帶引數 *path*、*attribute* 的稽核事件 `os.removexattr`。

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

**os.setxattr** (*path*, *attribute*, *value*, *flags=0*, \*, *follow\_symlinks=True*)

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the `PathLike` interface). If it is a str, it is encoded with the *filesystem encoding and error handler*. *flags* may be `XATTR_REPLACE` or `XATTR_CREATE`. If `XATTR_REPLACE` is given and the attribute does not exist, `ENODATA` will be raised. If `XATTR_CREATE` is given and the attribute already exists, the attribute will not be created and `EEXIST` will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

**備 F**

A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

引發一個附帶引數 *path*、*attribute*、*value*、*flags* 的稽核事件 `os.setxattr`。

在 3.6 版的變更: Accepts a *path-like object* for *path* and *attribute*.

**os.XATTR\_SIZE\_MAX**

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

**os.XATTR\_CREATE**

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must create an attribute.

**os.XATTR\_REPLACE**

This is a possible value for the flags argument in `setxattr()`. It indicates the operation must replace an existing attribute.

**16.1.7 行程管理**

These functions may be used to create and manage processes.

The various `exec*` functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

**os.abort()**

Generate a `SIGABRT` signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that calling this function will not call the Python signal handler registered for `SIGABRT` with `signal.signal()`.

**os.add\_dll\_directory(path)**

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through `sys.path`), and also by `ctypes`.

Remove the directory by calling `close()` on the returned object or using it in a `with` statement.

See the [Microsoft documentation](#) for more information about how DLLs are loaded.

引發一個附帶引數 `path` 的稽核事件 `os.add_dll_directory`。

適用: Windows.

在 3.8 版被加入: Previous versions of CPython would resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching `PATH` or the current working directory, and OS functions such as `AddDllDirectory` having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the porting notes for information on updating libraries.

**os.execl(path, arg0, arg1, ...)****os.execlp(path, arg0, arg1, ..., env)****os.execlpe(file, arg0, arg1, ..., env)****os.execlpe(file, arg0, arg1, ..., env)****os.execv(path, args)****os.execve(path, args, env)****os.execvp(file, args)****os.execvpe(file, args, env)**

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as `OSError` exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or `os.fsync()` before calling an `exec*` function.

The "l" and "v" variants of the `exec*` functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written;

the individual parameters simply become additional parameters to the `execl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the `args` parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a "p" near the end (`execlp()`, `execlpe()`, `execvp()`, and `execvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `exec*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `execl()`, `execlp()`, `execv()`, and `execve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path. Relative paths must include at least one slash, even on Windows, as plain names will not be resolved.

For `execlp()`, `execlpe()`, `execve()`, and `execvpe()` (note that these all end in "e"), the `env` parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process' environment); the functions `execl()`, `execlp()`, `execv()`, and `execvp()` all cause the new process to inherit the environment of the current process.

For `execve()` on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using `os.supports_fd`. If it is unavailable, using it will raise a `NotImplementedError`.

引發一個附帶引數 `path`、`args`、`env` 的稽核事件 `os.exec`。

適用: Unix, Windows, not WASI, not Android, not iOS.

在 3.3 版的變更: Added support for specifying *path* as an open file descriptor for `execve()`.

在 3.6 版的變更: Accepts a *path-like object*.

#### `os._exit(n)`

Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

#### **i** 備 F

The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

#### **i** 備 F

Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

#### `os.EX_OK`

Exit code that means no error occurred. May be taken from the defined value of `EXIT_SUCCESS` on some platforms. Generally has a value of zero.

適用: Unix, Windows.

#### `os.EX_USAGE`

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

適用: Unix, not WASI.

#### `os.EX_DATAERR`

Exit code that means the input data was incorrect.

適用: Unix, not WASI.

**os.EX\_NOINPUT**

Exit code that means an input file did not exist or was not readable.

適用: Unix, not WASI.

**os.EX\_NOUSER**

Exit code that means a specified user did not exist.

適用: Unix, not WASI.

**os.EX\_NOHOST**

Exit code that means a specified host did not exist.

適用: Unix, not WASI.

**os.EX\_UNAVAILABLE**

Exit code that means that a required service is unavailable.

適用: Unix, not WASI.

**os.EX\_SOFTWARE**

Exit code that means an internal software error was detected.

適用: Unix, not WASI.

**os.EX\_OSERR**

Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

適用: Unix, not WASI.

**os.EX\_OSFILE**

Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

適用: Unix, not WASI.

**os.EX\_CANTCREAT**

Exit code that means a user specified output file could not be created.

適用: Unix, not WASI.

**os.EX\_IOERR**

Exit code that means that an error occurred while doing I/O on some file.

適用: Unix, not WASI.

**os.EX\_TEMPFAIL**

Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

適用: Unix, not WASI.

**os.EX\_PROTOCOL**

Exit code that means that a protocol exchange was illegal, invalid, or not understood.

適用: Unix, not WASI.

**os.EX\_NOPERM**

Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

適用: Unix, not WASI.

**os.EX\_CONFIG**

Exit code that means that some kind of configuration error occurred.

適用: Unix, not WASI.

**os.EX\_NOTFOUND**

Exit code that means something like “an entry was not found”.

適用: Unix, not WASI.

**os.fork()**

Fork a child process. Return 0 in the child and the child’s process id in the parent. If an error occurs *OSError* is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using `fork()` from a thread.

引發一個不附帶引數的稽核事件 `os.fork`。

**警告**

If you use TLS sockets in an application calling `fork()`, see the warning in the *ssl* documentation.

**警告**

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

在 3.8 版的變更: Calling `fork()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

在 3.12 版的變更: If Python is able to detect that your process has multiple threads, `os.fork()` now raises a *DeprecationWarning*.

We chose to surface this as a warning, when detectable, to better inform developers of a design problem that the POSIX platform specifically notes as not supported. Even in code that *appears* to work, it has never been safe to mix threading with `os.fork()` on POSIX platforms. The CPython runtime itself has always made API calls that are not safe for use in the child process when threads existed in the parent (such as `malloc` and `free`).

Users of macOS or users of `libc` or `malloc` implementations other than those typically found in `glibc` to date are among those already more likely to experience deadlocks running such code.

See [this discussion on fork being incompatible with threads](#) for technical details of why we’re surfacing this longstanding platform compatibility problem to developers.

適用: POSIX, not WASI, not Android, not iOS.

**os.forkpty()**

Fork a child process, using a new pseudo-terminal as the child’s controlling terminal. Return a pair of (`pid`, `fd`), where `pid` is 0 in the child, the new child’s process id in the parent, and `fd` is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

引發一個不附帶引數的稽核事件 `os.forkpty`。

**警告**

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using *urllib.request*.

在 3.8 版的變更: Calling `forkpty()` in a subinterpreter is no longer supported (*RuntimeError* is raised).

在 3.12 版的變更: If Python is able to detect that your process has multiple threads, this now raises a *DeprecationWarning*. See the longer explanation on `os.fork()`.

適用: Unix, not WASI, not Android, not iOS.

`os.kill(pid, sig, /)`

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL\_C\_EVENT* and *signal.CTRL\_BREAK\_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the `TerminateProcess` API, and the exit code will be set to *sig*.

另請參閱 `signal.thread_kill()`。

引發一個附帶引數 *pid*、*sig* 的稽核事件 `os.kill`。

適用: Unix, Windows, not WASI, not iOS.

在 3.2 版的變更: 新支援 Windows。

`os.killpg(pgid, sig, /)`

Send the signal *sig* to the process group *pgid*.

引發一個附帶引數 *pgid*、*sig* 的稽核事件 `os.killpg`。

適用: Unix, not WASI, not iOS.

`os.nice(increment, /)`

Add *increment* to the process's "niceness". Return the new niceness.

適用: Unix, not WASI.

`os.pidfd_open(pid, flags=0)`

Return a file descriptor referring to the process *pid* with *flags* set. This descriptor can be used to perform process management without races and signals.

更多細節請見 `pidfd_open(2)` 手冊頁。

適用: Linux >= 5.3, Android >= *build-time* API level 31

在 3.9 版被加入。

`os.PIDFD_NONBLOCK`

This flag indicates that the file descriptor will be non-blocking. If the process referred to by the file descriptor has not yet terminated, then an attempt to wait on the file descriptor using `waitid(2)` will immediately return the error *EAGAIN* rather than blocking.

適用: Linux >= 5.10

在 3.12 版被加入。

`os.plock(op, /)`

Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

適用: Unix, not WASI, not iOS.

`os.popen(cmd, mode='r', buffering=-1)`

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *buffering* argument have the same meaning as the corresponding argument to the built-in `open()` function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `-signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, `waitstatus_to_exitcode()` can be used to convert the `close` method result (exit status) into an exit code if it is not `None`. On Windows, the `close` method result is directly the exit code (or `None`).

This is implemented using `subprocess.Popen`; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

適用: not WASI, not Android, not iOS.

### 備 F

The *Python UTF-8 Mode* affects encodings used for `cmd` and pipe contents.

`popen()` is a simple wrapper around `subprocess.Popen`. Use `subprocess.Popen` or `subprocess.run()` to control options like encodings.

`os.posix_spawn(path, argv, env, *, file_actions=None, setpgroup=None, resetids=False, setsid=False, setmask=(), setsigdef=(), scheduler=None)`

Wraps the `posix_spawn()` C library API for use from Python.

Most users should use `subprocess.run()` instead of `posix_spawn()`.

The positional-only arguments `path`, `args`, and `env` are similar to `execve()`. `env` is allowed to be `None`, in which case current process' environment is used.

The `path` parameter is the path to the executable file. The `path` should contain a directory. Use `posix_spawnnp()` to pass an executable file without directory.

The `file_actions` argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's `fork()` and `exec()` steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

`os.POSIX_SPAWN_OPEN`

`(os.POSIX_SPAWN_OPEN, fd, path, flags, mode)`

Performs `os.dup2(os.open(path, flags, mode), fd)`.

`os.POSIX_SPAWN_CLOSE`

`(os.POSIX_SPAWN_CLOSE, fd)`

Performs `os.close(fd)`.

`os.POSIX_SPAWN_DUP2`

`(os.POSIX_SPAWN_DUP2, fd, new_fd)`

Performs `os.dup2(fd, new_fd)`.

`os.POSIX_SPAWN_CLOSEFROM`

`(os.POSIX_SPAWN_CLOSEFROM, fd)`

Performs `os.closerange(fd, INF)`.

These tuples correspond to the C library `posix_spawn_file_actions_addopen()`, `posix_spawn_file_actions_addclose()`, `posix_spawn_file_actions_adddup2()`, and `posix_spawn_file_actions_addclosefrom_np()` API calls used to prepare for the `posix_spawn()` call itself.

The `setpgroup` argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of `setpgroup` is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library `POSIX_SPAWN_SETPGROUP` flag.

If the `resetids` argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file,

their effect will override the setting of the effective UID and GID. This argument corresponds to the C library `POSIX_SPAWN_RESETEIDS` flag.

If the `setsid` argument is `True`, it will create a new session ID for `posix_spawn`. `setsid` requires `POSIX_SPAWN_SETSID` or `POSIX_SPAWN_SETSID_NP` flag. Otherwise, `NotImplementedError` is raised.

The `sigmask` argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library `POSIX_SPAWN_SETSIGMASK` flag.

The `sigdef` argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library `POSIX_SPAWN_SETSIGDEF` flag.

The `scheduler` argument must be a tuple containing the (optional) scheduler policy and an instance of `sched_param` with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library `POSIX_SPAWN_SETSCHEDPARAM` and `POSIX_SPAWN_SETSCHEDULER` flags.

引發一個附帶引數 `path`、`argv`、`env` 的稽核事件 `os.posix_spawn`。

在 3.8 版被加入。

在 3.13 版的變更: `env` parameter accepts `None`. `os.POSIX_SPAWN_CLOSEFROM` is available on platforms where `posix_spawn_file_actions_addclosefrom_np()` exists.

適用: Unix, not WASI, not Android, not iOS.

`os.posix_spawnp` (*path*, *argv*, *env*, \*, *file\_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *sigmask=()*, *sigdef=()*, *scheduler=None*)

Wraps the `posix_spawnp()` C library API for use from Python.

Similar to `posix_spawn()` except that the system searches for the *executable* file in the list of directories specified by the `PATH` environment variable (in the same way as for `execvp(3)`).

引發一個附帶引數 `path`、`argv`、`env` 的稽核事件 `os.posix_spawn`。

在 3.8 版被加入。

適用: POSIX, not WASI, not Android, not iOS.

見 `posix_spawn()` 文件。

`os.register_at_fork` (\*, *before=None*, *after\_in\_parent=None*, *after\_in\_child=None*)

Register callables to be executed when a new child process is forked using `os.fork()` or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after\_in\_parent* is a function called from the parent process after forking a child process.
- *after\_in\_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical *subprocess* launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

適用: Unix, not WASI, not Android, not iOS.

在 3.7 版被加入。

`os.spawnl` (*mode*, *path*, ...)

`os.spawnle` (*mode*, *path*, ..., *env*)

`os.spawnlp` (*mode*, *file*, ...)

- os.`spawnlpe` (*mode*, *file*, ..., *env*)
- os.`spawnv` (*mode*, *path*, *args*)
- os.`spawnve` (*mode*, *path*, *args*, *env*)
- os.`spawnvp` (*mode*, *file*, *args*)
- os.`spawnvpe` (*mode*, *file*, *args*, *env*)

Execute the program *path* in a new process.

(Note that the `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the *Replacing Older Functions with the subprocess Module* section.)

If *mode* is `P_NOWAIT`, this function returns the process id of the new process; if *mode* is `P_WAIT`, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the `waitpid()` function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises `OSError` exception.

The "l" and "v" variants of the `spawn*` functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*` () functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second "p" near the end (`spawnlp()`, `spawnlpe()`, `spawnvp()`, and `spawnvpe()`) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the `spawn*e` variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, `spawnl()`, `spawnle()`, `spawnv()`, and `spawnve()`, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For `spawnle()`, `spawnlpe()`, `spawnve()`, and `spawnvpe()` (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions `spawnl()`, `spawnlp()`, `spawnv()`, and `spawnvp()` all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to `spawnlp()` and `spawnvpe()` are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

引發一個附帶引數 *mode*、*path*、*args*、*env* 的稽核事件 `os.spawn`。

適用: Unix, Windows, not WASI, not Android, not iOS.

`spawnlp()`, `spawnlpe()`, `spawnvp()` and `spawnvpe()` are not available on Windows. `spawnle()` and `spawnve()` are not thread-safe on Windows; we advise you to use the `subprocess` module instead.

在 3.6 版的變更: Accepts a *path-like object*.

- os.`P_NOWAIT`
- os.`P_NOWAITO`

Possible values for the *mode* parameter to the `spawn*` family of functions. If either of these values is given, the `spawn*` functions will return as soon as the new process has been created, with the process id as the return value.

適用: Unix, Windows.

**os.P\_WAIT**

Possible value for the *mode* parameter to the *spawn\** family of functions. If this is given as *mode*, the *spawn\** functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

適用: Unix, Windows.

**os.P\_DETACH****os.P\_OVERLAY**

Possible values for the *mode* parameter to the *spawn\** family of functions. These are less portable than those listed above. *P\_DETACH* is similar to *P\_NOWAIT*, but the new process is detached from the console of the calling process. If *P\_OVERLAY* is used, the current process will be replaced; the *spawn\** function will not return.

適用: Windows.

**os.startfile**(*path* [, *operation*] [, *arguments*] [, *cwd*] [, *show\_cmd* ])

Start a file with its associated application.

When *operation* is not specified, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the `start` command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a "command verb" that specifies what should be done with the file. Common verbs documented by Microsoft are 'open', 'print' and 'edit' (to be used on files) as well as 'explore' and 'find' (to be used on directories).

When launching an application, specify *arguments* to be passed as a single string. This argument may have no effect when using this function to launch a document.

The default working directory is inherited, but may be overridden by the *cwd* argument. This should be an absolute path. A relative *path* will be resolved against this argument.

Use *show\_cmd* to override the default window style. Whether this has any effect will depend on the application being launched. Values are integers as supported by the `Win32 ShellExecute()` function.

`startfile()` returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory or *cwd*. If you want to use an absolute path, make sure the first character is not a slash ('/') Use `pathlib` or the `os.path.normpath()` function to ensure that paths are properly encoded for Win32.

To reduce interpreter startup overhead, the `Win32 ShellExecute()` function is not resolved until this function is first called. If the function cannot be resolved, `NotImplementedError` will be raised.

引發一個附帶引數 *path*、*operation* 的稽核事件 `os.startfile`。

引發一個附帶引數 *path*、*operation*、*arguments*、*cwd*、*show\_cmd* 的稽核事件 `os.startfile/2`。

適用: Windows.

在 3.10 版的變更: Added the *arguments*, *cwd* and *show\_cmd* arguments, and the `os.startfile/2` audit event.

**os.system**(*command*)

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for `wait()`.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable `COMSPEC`: it is usually `cmd.exe`, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the [Replacing Older Functions with the subprocess Module](#) section in the `subprocess` documentation for some helpful recipes.

On Unix, `waitstatus_to_exitcode()` can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

引發一個附帶引數 `command` 的稽核事件 `os.system`。

適用: Unix, Windows, not WASI, not Android, not iOS.

#### `os.times()`

Returns the current global process times. The return value is an object with five attributes:

- `user` - 使用者時間
- `system` - 系統時間
- `children_user` - 所有子行程的使用者時間
- `children_system` - 所有子行程的系統時間
- `elapsed` - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing `user`, `system`, `children_user`, `children_system`, and `elapsed` in that order.

See the Unix manual page [times\(2\)](#) and [times\(3\)](#) manual page on Unix or the [GetProcessTimes MSDN](#) on Windows. On Windows, only `user` and `system` are known; the other attributes are zero.

適用: Unix, Windows.

在 3.3 版的變更: Return type changed from a tuple to a tuple-like object with named attributes.

#### `os.wait()`

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

If there are no children that could be waited for, `ChildProcessError` is raised.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

適用: Unix, not WASI, not Android, not iOS.

#### 也參考

The other `wait*()` functions documented below can be used to wait for the completion of a specific child process and have more options. `waitpid()` is the only one also available on Windows.

#### `os.waitid(idtype, id, options, /)`

Wait for the completion of a child process.

`idtype` can be `P_PID`, `P_PGID`, `P_ALL`, or (on Linux) `P_PIDFD`. The interpretation of `id` depends on it; see their individual descriptions.

`options` is an OR combination of flags. At least one of `WEXITED`, `WSTOPPED` or `WCONTINUED` is required; `WNOHANG` and `WNOWAIT` are additional optional flags.

The return value is an object representing the data contained in the `siginfo_t` structure with the following attributes:

- `si_pid` (process ID)
- `si_uid` (real user ID of the child)
- `si_signo` (always `SIGCHLD`)

- `si_status` (the exit status or signal number, depending on `si_code`)
- `si_code` (see `CLD_EXITED` for possible values)

If `WNOHANG` is specified and there are no matching children in the requested state, `None` is returned. Otherwise, if there are no matching children that could be waited for, `ChildProcessError` is raised.

適用: Unix, not WASI, not Android, not iOS.

在 3.3 版被加入.

在 3.13 版的變更: This function is now available on macOS as well.

`os.waitpid(pid, options, /)`

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id `pid`, and return a tuple containing its process id and exit status indication (encoded as for `wait()`). The semantics of the call are affected by the value of the integer `options`, which should be 0 for normal operation.

If `pid` is greater than 0, `waitpid()` requests status information for that specific process. If `pid` is 0, the request is for the status of any child in the process group of the current process. If `pid` is -1, the request pertains to any child of the current process. If `pid` is less than -1, status is requested for any process in the process group `-pid` (the absolute value of `pid`).

`options` is an OR combination of flags. If it contains `WNOHANG` and there are no matching children in the requested state, `(0, 0)` is returned. Otherwise, if there are no matching children that could be waited for, `ChildProcessError` is raised. Other options that can be used are `WUNTRACED` and `WCONTINUED`.

On Windows: Wait for completion of a process given by process handle `pid`, and return a tuple containing `pid`, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A `pid` less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer `options` has no effect. `pid` can refer to any process whose id is known, not necessarily a child process. The `spawn*` functions called with `P_NOWAIT` return suitable process handles.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

適用: Unix, Windows, not WASI, not Android, not iOS.

在 3.5 版的變更: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](#) for the rationale).

`os.wait3(options)`

Similar to `waitpid()`, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The `options` argument is the same as that provided to `waitpid()` and `wait4()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

適用: Unix, not WASI, not Android, not iOS.

`os.wait4(pid, options)`

Similar to `waitpid()`, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The arguments to `wait4()` are the same as those provided to `waitpid()`.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exitcode.

適用: Unix, not WASI, not Android, not iOS.

`os.P_PID`

`os.P_PGID`

`os.P_ALL`

**os.P\_PIDFD**

These are the possible values for *idtype* in `waitid()`. They affect how *id* is interpreted:

- `P_PID` - wait for the child whose PID is *id*.
- `P_PGID` - wait for any child whose progress group ID is *id*.
- `P_ALL` - wait for any child; *id* is ignored.
- `P_PIDFD` - wait for the child identified by the file descriptor *id* (a process file descriptor created with `pidfd_open()`).

適用: Unix, not WASI, not Android, not iOS.

 備

`P_PIDFD` is only available on Linux  $\geq$  5.4.

在 3.3 版被加入.

在 3.9 版被加入: The `P_PIDFD` constant.

**os.WCONTINUED**

This *options* flag for `waitpid()`, `wait3()`, `wait4()`, and `waitid()` causes child processes to be reported if they have been continued from a job control stop since they were last reported.

適用: Unix, not WASI, not Android, not iOS.

**os.WEXITED**

This *options* flag for `waitid()` causes child processes that have terminated to be reported.

The other `wait*` functions always report children that have terminated, so this option is not available for them.

適用: Unix, not WASI, not Android, not iOS.

在 3.3 版被加入.

**os.WSTOPPED**

This *options* flag for `waitid()` causes child processes that have been stopped by the delivery of a signal to be reported.

This option is not available for the other `wait*` functions.

適用: Unix, not WASI, not Android, not iOS.

在 3.3 版被加入.

**os.WUNTRACED**

This *options* flag for `waitpid()`, `wait3()`, and `wait4()` causes child processes to also be reported if they have been stopped but their current state has not been reported since they were stopped.

This option is not available for `waitid()`.

適用: Unix, not WASI, not Android, not iOS.

**os.WNOHANG**

This *options* flag causes `waitpid()`, `wait3()`, `wait4()`, and `waitid()` to return right away if no child process status is available immediately.

適用: Unix, not WASI, not Android, not iOS.

**os.WNOWAIT**

This *options* flag causes `waitid()` to leave the child in a waitable state, so that a later `wait*()` call can be used to retrieve the child status information again.

This option is not available for the other `wait*` functions.

適用: Unix, not WASI, not Android, not iOS.

os.CLD\_EXITED  
 os.CLD\_KILLED  
 os.CLD\_DUMPED  
 os.CLD\_TRAPPED  
 os.CLD\_STOPPED  
 os.CLD\_CONTINUED

These are the possible values for `si_code` in the result returned by `waitid()`.

適用: Unix, not WASI, not Android, not iOS.

在 3.3 版被加入。

在 3.9 版的變更: Added `CLD_KILLED` and `CLD_STOPPED` values.

os.waitstatus\_to\_exitcode(status)

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where `signum` is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a `ValueError`.

On Windows, return `status` shifted right by 8 bits.

On Unix, if the process is being traced or if `waitpid()` was called with `WUNTRACED` option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

### 也參考

`WIFEXITED()`, `WEXITSTATUS()`, `WIFSIGNALED()`, `WTERMSIG()`, `WIFSTOPPED()`, `WSTOPSIG()` functions.

適用: Unix, Windows, not WASI, not Android, not iOS.

在 3.9 版被加入。

The following functions take a process status code as returned by `system()`, `wait()`, or `waitpid()` as a parameter. They may be used to determine the disposition of a process.

os.WCOREDUMP(status, /)

Return `True` if a core dump was generated for the process, otherwise return `False`.

This function should be employed only if `WIFSIGNALED()` is true.

適用: Unix, not WASI, not Android, not iOS.

os.WIFCONTINUED(status)

Return `True` if a stopped child has been resumed by delivery of `SIGCONT` (if the process has been continued from a job control stop), otherwise return `False`.

參閱 `WCONTINUED` 選項。

適用: Unix, not WASI, not Android, not iOS.

os.WIFSTOPPED (status)

Return True if the process was stopped by delivery of a signal, otherwise return False.

WIFSTOPPED() only returns True if the waitpid() call was done using WUNTRACED option or when the process is being traced (see ptrace(2)).

適用: Unix, not WASI, not Android, not iOS.

os.WIFSIGNALED (status)

Return True if the process was terminated by a signal, otherwise return False.

適用: Unix, not WASI, not Android, not iOS.

os.WIFEXITED (status)

Return True if the process exited terminated normally, that is, by calling exit() or \_exit(), or by returning from main(); otherwise return False.

適用: Unix, not WASI, not Android, not iOS.

os.WEXITSTATUS (status)

Return the process exit status.

This function should be employed only if WIFEXITED() is true.

適用: Unix, not WASI, not Android, not iOS.

os.WSTOPSIG (status)

Return the signal which caused the process to stop.

This function should be employed only if WIFSTOPPED() is true.

適用: Unix, not WASI, not Android, not iOS.

os.WTERMSIG (status)

Return the number of the signal that caused the process to terminate.

This function should be employed only if WIFSIGNALED() is true.

適用: Unix, not WASI, not Android, not iOS.

## 16.1.8 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

在 3.3 版被加入.

The following scheduling policies are exposed if they are supported by the operating system.

os.SCHED\_OTHER

The default scheduling policy.

os.SCHED\_BATCH

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

os.SCHED\_IDLE

Scheduling policy for extremely low priority background tasks.

os.SCHED\_SPORADIC

Scheduling policy for sporadic server programs.

os.SCHED\_FIFO

A First In First Out scheduling policy.

os.SCHED\_RR

A round-robin scheduling policy.

**os.SCHED\_RESET\_ON\_FORK**

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

**class os.sched\_param** (*sched\_priority*)

This class represents tunable scheduling parameters used in `sched_setparam()`, `sched_setscheduler()`, and `sched_getparam()`. It is immutable.

At the moment, there is only one possible parameter:

**sched\_priority**

The scheduling priority for a scheduling policy.

**os.sched\_get\_priority\_min** (*policy*)

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

**os.sched\_get\_priority\_max** (*policy*)

Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

**os.sched\_setscheduler** (*pid, policy, param, /*)

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a `sched_param` instance.

**os.sched\_getscheduler** (*pid, /*)

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

**os.sched\_setparam** (*pid, param, /*)

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a `sched_param` instance.

**os.sched\_getparam** (*pid, /*)

Return the scheduling parameters as a `sched_param` instance for the process with PID *pid*. A *pid* of 0 means the calling process.

**os.sched\_rr\_get\_interval** (*pid, /*)

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

**os.sched\_yield** ()

Voluntarily relinquish the CPU. See `sched_yield(2)` for details.

**os.sched\_setaffinity** (*pid, mask, /*)

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

**os.sched\_getaffinity** (*pid, /*)

Return the set of CPUs the process with PID *pid* is restricted to.

If *pid* is zero, return the set of CPUs the calling thread of the current process is restricted to.

也請見 `process_cpu_count()` 函式。

## 16.1.9 Miscellaneous System Information

**os.confstr** (*name, /*)

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in *confstr\_names*, an *OSError* is raised with *errno.EINVAL* for the error number.

適用: Unix.

#### os.confstr\_names

Dictionary mapping names accepted by *confstr()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用: Unix.

#### os.cpu\_count()

Return the number of logical CPUs in the **system**. Returns *None* if undetermined.

The *process\_cpu\_count()* function can be used to get the number of logical CPUs usable by the calling thread of the **current process**.

在 3.4 版被加入。

在 3.13 版的變更: If `-X cpu_count` is given or `PYTHON_CPU_COUNT` is set, *cpu\_count()* returns the overridden value *n*.

#### os.getloadavg()

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises *OSError* if the load average was unobtainable.

適用: Unix.

#### os.process\_cpu\_count()

Get the number of logical CPUs usable by the calling thread of the **current process**. Returns *None* if undetermined. It can be less than *cpu\_count()* depending on the CPU affinity.

The *cpu\_count()* function can be used to get the number of logical CPUs in the **system**.

If `-X cpu_count` is given or `PYTHON_CPU_COUNT` is set, *process\_cpu\_count()* returns the overridden value *n*.

也請見 *sched\_getaffinity()* 函式。

在 3.13 版被加入。

#### os.sysconf(name, /)

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for *confstr()* apply here as well; the dictionary that provides information on the known names is given by *sysconf\_names*.

適用: Unix.

#### os.sysconf\_names

Dictionary mapping names accepted by *sysconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

適用: Unix.

在 3.11 版的變更: Add 'SC\_MINSIGSTKSZ' name.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

#### os.curdir

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via *os.path*.

**os.pardir**

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via `os.path`.

**os.sep**

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames --- use `os.path.split()` and `os.path.join()` --- but it is occasionally useful. Also available via `os.path`.

**os.altsep**

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via `os.path`.

**os.extsep**

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via `os.path`.

**os.pathsep**

The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or  `';'`  for Windows. Also available via `os.path`.

**os.defpath**

The default search path used by `exec*p*` and `spawn*p*` if the environment doesn't have a `'PATH'` key. Also available via `os.path`.

**os.linesep**

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use `os.linesep` as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

**os.devnull**

The file path of the null device. For example:  `'/dev/null '` for POSIX,  `'nul '` for Windows. Also available via `os.path`.

**os.RTLD\_LAZY****os.RTLD\_NOW****os.RTLD\_GLOBAL****os.RTLD\_LOCAL****os.RTLD\_NODELETE****os.RTLD\_NOLOAD****os.RTLD\_DEEPBIND**

Flags for use with the `setdlopenflags()` and `getdlopenflags()` functions. See the Unix manual page `dlopen(3)` for what the different flags mean.

在 3.3 版被加入。

## 16.1.10 Random numbers

**os.getrandom(size, flags=0)**

Get up to `size` random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The `flags` argument is a bit mask that can contain zero or more of the following values ORed together: `os.GRND_RANDOM` and `os.GRND_NONBLOCK`.

See also the [Linux `getrandom\(\)` manual page](#).

適用: Linux >= 3.17.

在 3.6 版被加入.

os.**urandom** (*size*, /)

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the [PEP 524](#) for the rationale. On Linux, the `getrandom()` function can be used to get random bytes in non-blocking mode (using the `GRND_NONBLOCK` flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the `NotImplementedError` exception is raised.

On Windows, it will use `BCryptGenRandom()`.

### 也參考

The `secrets` module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see `random.SystemRandom`.

在 3.5 版的變更: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

在 3.5.2 版的變更: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

在 3.6 版的變更: On Linux, `getrandom()` is now used in blocking mode to increase the security.

在 3.11 版的變更: On Windows, `BCryptGenRandom()` is used instead of `CryptGenRandom()` which is deprecated.

os.**GRND\_NONBLOCK**

By default, when reading from `/dev/random`, `getrandom()` blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the `GRND_NONBLOCK` flag is set, then `getrandom()` does not block in these cases, but instead immediately raises `BlockingIOError`.

在 3.6 版被加入.

os.**GRND\_RANDOM**

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

在 3.6 版被加入.

## 16.2 io — 處理資料串流的核心工具

原始碼: [Lib/io.py](#)

## 16.2.1 總覽

`io` 模組替 Python 提供處理各種類型 IO 的主要工具。有三種主要的 IO 類型：文字 I/O (*text I/O*)、二進位 I/O (*binary I/O*) 以及原始 I/O (*raw I/O*)。這些均泛用 (generic) 類型，且每種類型都可以使用各式後端儲存 (backing store)。任一種屬於這些類型的具體物件稱 *file object*。其它常見的名詞還有資料串流 (*stream*) 以及類檔案物件 (*file-like objects*)。

無論其類型何，每個具體的資料串流物件也將具有各種能力：唯讀的、只接受寫入的、或者讀寫兼具的。它還允許任意的隨機存取（向前或向後尋找至任意位置），或者只能依順序存取（例如 `socket` 或 `pipe` 的情形下）。

所有的資料串流都會謹慎處理你所提供的資料的型。舉例來，提供一個 `str` 物件給二進位資料串流的 `write()` 方法將會引發 `TypeError`。同樣地，若提供一個 `bytes` 物件給文字資料串流的 `write()` 方法，也會引發同樣的錯誤。

在 3.3 版的變更：原本會引發 `IOError` 的操作，現在將改成引發 `OSError`。因 `IOError` 現在是 `OSError` 的別名。

### 文字 I/O

文字 I/O 要求和出 `str` 物件。這意味著每當後端儲存原生 `bytes` 時（例如在檔案的情形下），資料的編碼與解碼會以清楚易懂的方式進行，也可選擇同時轉特定於平台的行字元。

建立文字資料串流最簡單的方法是使用 `open()`，可選擇性地指定編碼：

```
f = open("myfile.txt", "r", encoding="utf-8")
```

記憶體的文字資料串流也可以使用 `StringIO` 物件建立：

```
f = io.StringIO("some initial text data")
```

文字資料串流 API 的詳細說明在 `TextIOBase` 文件當中。

### 二進位 (Binary) I/O

二進位 I/O（也稱緩衝 I/O (*buffered I/O*)）要求的是類位元組物件 (*bytes-like objects*) 且生 `bytes` 物件。不進行編碼、解碼或者行字元轉。這種類型的資料串流可用於各種非文字資料，以及需要手動控制對文字資料的處理時。

建立二進位資料串流最簡單的方法是使用 `open()`，在 `mode` 字串中加入 `'b'`：

```
f = open("myfile.jpg", "rb")
```

記憶體的二進位資料串流也可以透過 `BytesIO` 物件來建立：

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

二進位資料串流 API 的詳細說明在 `BufferedIOBase` 文件當中。

其它函式庫模組可能提供額外的方法來建立文字或二進位資料串流。例如 `socket.socket.makefile()`。

### 原始 (Raw) I/O

原始 I/O（也稱無緩衝 I/O (*unbuffered I/O*)）通常作二進位以及文字資料串流的低階 *building-block* 使用；在使用者程式碼中直接操作原始資料串流很少有用。然而，你可以透過以無緩衝的二進位模式開一個檔案來建立一個原始資料串流：

```
f = open("myfile.jpg", "rb", buffering=0)
```

原始串流 API 在 `RawIOBase` 文件中有詳細描述。

## 16.2.2 文字編碼

`TextIOWrapper` 和 `open()` 預設編碼是根據區域設定的 (locale-specific) (`locale.getencoding()`)。

然而，許多開發人員在開以 UTF-8 編碼的文字檔案（例如：JSON、TOML、Markdown 等）時忘記指定編碼，因多數 Unix 平台預設使用 UTF-8 區域設定。這會導致錯誤，因對於大多數 Windows 使用者來，預設地區編碼非 UTF-8。舉例來：

```
# May not work on Windows when non-ASCII characters in the file.
with open("README.md") as f:
    long_description = f.read()
```

因此，烈建議在開文字檔案時，明確指定編碼。若你想使用 UTF-8 編碼，請傳入 `encoding="utf-8"`。若想使用目前的地區編碼，Python 3.10 以後的版本支援使用 `encoding="locale"`。

### 也參考

#### Python UTF-8 模式

在 Python UTF-8 模式下，可以將預設編碼從特定地區編碼改 UTF-8。

#### PEP 686

Python 3.15 將預設使用 Python UTF-8 模式。

### 選擇性加入的編碼警告

在 3.10 版被加入：更多資訊請見 [PEP 597](#)。

要找出哪些地方使用到預設的地區編碼，你可以用 `-x warn_default_encoding` 命令列選項，或者設定環境變數 `PYTHONWARNDEFAULTENCODING`。當使用到預設編碼時，會引發 `EncodingWarning`。

如果你正在提供一個使用 `open()` 或 `TextIOWrapper` 且傳遞 `encoding=None` 作參數的 API，你可以使用 `text_encoding()`。如此一來如果 API 的呼叫方有傳遞 `encoding`，呼叫方就會發出一個 `EncodingWarning`。然而，對於新的 API，請考慮預設使用 UTF-8（即 `encoding="utf-8"`）。

## 16.2.3 高階模組介面

### io.DEFAULT\_BUFFER\_SIZE

一個包含模組中緩衝 I/O 類所使用的預設緩衝區大小的整數。若可能的話，`open()` 會使用檔案的 `blksize`（透過 `os.stat()` 取得）。

io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True, opener=None)

這是建函式 `open()` 的代名。

此函式會引發一個帶有引數 `path`、`mode` 以及 `flags` 的稽核事件 (auditing event) `open`。`mode` 與 `flags` 引數可能已經被修改或者從原始呼叫中被推斷出來。

io.open\_code(path)

以 'rb' 模式開提供的檔案。此函式應用於意圖將內容視可執行的程式碼的情況下。

`path` 應該要屬於 `str` 類，且是個對路徑。

這個函式的行可能會被之前對 `PyFile_SetOpenCodeHook()` 的呼叫覆寫。然而，假設 `path` 是個 `str` 且對路徑，則 `open_code(path)` 總是與 `open(path, 'rb')` 有相同行。覆寫這個行是對檔案進行額外驗證或預處理。

在 3.8 版被加入。

io.text\_encoding(encoding, stacklevel=2, /)

這是個輔助函式，適用於使用 `open()` 或 `TextIOWrapper` 且具有 `encoding=None` 參數的可呼叫物件。

若 `encoding` 不 None，此函式將回傳 `encoding`。否則，將根據 `UTF-8 Mode` 回傳 "locale" 或 "utf-8"。

若 `sys.flags.warn_default_encoding` 為真，且 `encoding` 為 `None`，此函式會發出一個 `EncodingWarning`。 `stacklevel` 指定警告在哪層發出。範例：

```
def read_text(path, encoding=None):
    encoding = io.text_encoding(encoding) # stacklevel=2
    with open(path, encoding) as f:
        return f.read()
```

在此範例中，對於 `read_text()` 的呼叫方會引發一個 `EncodingWarning`。

更多資訊請見文字編碼。

在 3.10 版被加入。

在 3.11 版的變更：當 UTF-8 模式用且 `encoding` 為 `None` 時，`text_encoding()` 會回傳“utf-8”。

#### exception `io.BlockingIOError`

這是建成的 `BlockingIOError` 例外的相容性名。

#### exception `io.UnsupportedOperation`

當在資料串流上呼叫不支援的操作時，會引發繼承自 `OSError` 與 `ValueError` 的例外。

#### 也參考

`sys`

包含標準的 IO 資料串流：`sys.stdin`、`sys.stdout` 以及 `sys.stderr`。

## 16.2.4 類階層

I/O 串流的實作是由多個類組合成的階層結構所構成。首先是 *abstract base classes*（抽象基底類，ABCs），它們被用來規範各種不同類型的串流，接著具體類會提供標準串流的實作。

#### 備

為了協助具體串流類的實作，抽象基底類提供了某些方法的預設實作。舉例來說，`BufferedIOBase` 提供未經最佳化的 `readinto()` 與 `readline()` 實作。

I/O 階層結構的最上層是抽象基底類 `IOBase`。它定義了串流的基礎的介面。然而，請注意，讀取串流與寫入串流之間有分離；若不支援給定的操作，實作是允許引發 `UnsupportedOperation` 例外的。

抽象基底類 `RawIOBase` 繼承 `IOBase`。此類處理對串流的位元組讀寫。`FileIO` 則繼承 `RawIOBase` 來提供一個介面以存取機器檔案系統的檔案。

抽象基底類 `BufferedIOBase` 繼承 `IOBase`。此類緩衝原始二進位串流 (`RawIOBase`)。它的子類 `BufferedWriter`、`BufferedReader` 與 `BufferedRWPair` 分別緩衝可寫、可讀、可讀也可寫的原始二進位串流。類 `BufferedRandom` 則提供一個對可搜尋串流 (seekable stream) 的緩衝介面。另一個類 `BufferedIOBase` 的子類 `BytesIO`，是一個記憶體位元組串流。

抽象基底類 `TextIOBase` 繼承 `IOBase`。此類處理文本位元組串流，處理字串的編碼和解碼。類 `TextIOWrapper` 繼承自 `TextIOBase`，這是個對緩衝原始串流 (`BufferedIOBase`) 的緩衝文本介面。最後，`StringIO` 是個文字記憶體串流。

引數名稱不是規範的一部份，只有 `open()` 的引數將作關鍵字引數。

以下表格總結了 `io` 模組提供的抽象基底類 (ABC)：

抽象基底類 (ABC)	繼承	Stub 方法	Mixin 方法與屬性
<code>IOBase</code>		<code>fileno</code> 、 <code>seek</code> 和 <code>truncate</code>	<code>close</code> 、 <code>closed</code> 、 <code>__enter__</code> 、 <code>__exit__</code> 、 <code>flush</code> 、 <code>isatty</code> 、 <code>__iter__</code> 、 <code>__next__</code> 、 <code>readable</code> 、 <code>readline</code> 、 <code>readlines</code> 、 <code>seekable</code> 、 <code>tell</code> 、 <code>writable</code> 與 <code>writelines</code>
<code>RawIOBase</code>	<code>IOBase</code>	<code>readinto</code> 和 <code>write</code>	繼承自 <code>IOBase</code> 的方法， <code>read</code> 與 <code>readall</code>
<code>BufferedIOBase</code>	<code>IOBase</code>	<code>detach</code> 、 <code>read</code> 、 <code>read1</code> 和 <code>write</code>	繼承自 <code>IOBase</code> 的方法， <code>readinto</code> 與 <code>readinto1</code>
<code>TextIOBase</code>	<code>IOBase</code>	<code>detach</code> 、 <code>read</code> 、 <code>readline</code> 和 <code>write</code>	繼承自 <code>IOBase</code> 的方法， <code>encoding</code> 、 <code>errors</code> 與 <code>newlines</code>

## I/O 基礎類

`class io.IOBase`

所有 I/O 類的抽象基礎類。

許多方法提供了空的抽象實作，衍生類可以選擇性地覆寫這些方法；預設的實作代表一個無法讀取、寫入或搜尋的檔案。

即使 `IOBase` 因實作的簽名差巨大而有宣告 `read()` 或 `write()` 方法，實作與用端應把這些方法視作介面的一部份。此外，當呼叫不被它們支援的操作時，可能會引發 `ValueError` (或 `UnsupportedOperation`) 例外。

The basic type used for binary data read from or written to a file is `bytes`. Other *bytes-like objects* are accepted as method arguments too. Text I/O classes work with `str` data.

請注意，在一個已經關閉的串流上呼叫任何方法（即使只是查詢）都是未定義的。在這種情況下，實作可能會引發 `ValueError` 例外。

`IOBase` (and its subclasses) supports the iterator protocol, meaning that an `IOBase` object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See `readline()` below.

`IOBase` 也是個情境管理器，因此支援 `with` 陳述式。在這個例子中，`file` 會在 `with` 陳述式執行完畢後關閉——即使發生了異常。

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

`IOBase` 提供這些資料屬性與方法：

`close()`

清除關閉這個串流。若檔案已經關閉，則此方法有作用。一旦檔案被關閉，任何對檔案的操作（例如讀取或寫入）將引發 `ValueError` 異常。

为了方便起見，允許多次呼叫這個方法；然而，只有第一次呼叫會有效果。

`closed`

如果串流已關閉，則 `True`。

`fileno()`

如果串流存在，則回傳其底層的檔案描述器（一個整數）。如果 IO 物件不使用檔案描述器，則會引發一個 `OSError` 例外。

`flush()`

如果適用，清空串流的寫入緩衝區。對於唯讀和非阻塞串流，此操作不會執行任何操作。

**isatty()**

如果串流是互動式的（即連接到終端機/tty 設備），則回傳 True。

**readable()**

如果串流可以被讀取，則回傳 True。如果是 False，`read()` 將會引發 `OSError` 例外。

**readline(size=-1, /)**

從串流讀取回傳一行。如果指定了 `size`，則最多讀取 `size` 個位元組。

對於二進位檔案，行結束符總是 `b'\n'`；對於文字檔案，可以使用 `open()` 函式的 `newline` 引數來選擇識的行結束符號。

**readlines(hint=-1, /)**

從串流讀取回傳一個含有一或多行的 list。可以指定 `hint` 來控制讀取的行數：如果到目前止所有行的總大小（以位元組/字元計）超過 `hint`，則不會再讀取更多行。

`hint` 值 0 或更小，以及 None，都被視為有提供 `hint`。

請注意，已經可以使用 `for line in file: ...` 在檔案物件上進行代，而不一定需要呼叫 `file.readlines()`。

**seek(offset, whence=os.SEEK\_SET, /)**

將串流位置改變到給定的位元組 `offset`，此位置是相對於由 `whence` 指示的位置解釋的，回傳新的對位置。`whence` 的值可：

- `os.SEEK_SET` 或 0 -- 串流的起點（預設值）；`offset` 應零或正數
- `os.SEEK_CUR` 或 1 -- 目前串流位置；`offset` 可以是負數
- `os.SEEK_END` 或 2 -- 串流的結尾；`offset` 通常是負數

在 3.1 版被加入：`SEEK_*` 常數。

在 3.3 版被加入：某些作業系統可以支援額外的值，例如 `os.SEEK_HOLE` 或 `os.SEEK_DATA`。檔案的合法值取於它是以文字模式還是二進位模式開。

**seekable()**

如果串流支援隨機存取，則回傳 True。如果是 False，則 `seek()`、`tell()` 和 `truncate()` 會引發 `OSError`。

**tell()**

回傳目前串流的位置。

**truncate(size=None, /)**

將串流的大小調整指定的 `size` 位元組（如果有指定 `size`，則調整目前位置）。目前串流位置不會改變。這種調整可以擴展或縮當前檔案大小。在擴展的情況下，新檔案區域的容取於平台（在大多數系統上，額外的位元組會被填充零）。回傳新的檔案大小。

在 3.5 版的變更：Windows 現在在擴展時會對檔案進行零填充 (zero-fill)。

**writable()**

如果串流支援寫入，則回傳 True。如果是 False，`write()` 和 `truncate()` 將會引發 `OSError`。

**writelines(lines, /)**

將一個包含每一行的 list 寫入串流。這不會新增行分隔符號，因此通常提供的每一行末尾都有一個行分隔符號。

**\_\_del\_\_()**

物件銷做準備。`IOBase` 提供了這個方法的預設實作，該實作會呼叫實例的 `close()` 方法。

**class io.RawIOBase**

原始二進位串流的基底類。它繼承自 `IOBase`。

原始二進位串流通常提供對底層作業系統設備或 API 的低階存取，不嘗試將其封裝在高階基元 (primitive) 中（這項功能在緩衝二進位串流和文字串流中的更高階層級完成，後面的頁面會有描述）。

`RawIOBase` 除了 `IOBase` 的方法外，還提供以下這些方法：

**read** (*size=-1*, /)

從物件中讀取最多 *size* 個位元組回傳。方便起見，如果 *size* 未指定或 `-1`，則回傳直到檔案結尾 (EOF) 的所有位元組。否則，只會進行一次系統呼叫。如果作業系統呼叫回傳的位元組少於 *size*，則可能回傳少於 *size* 的位元組。

如果回傳了 0 位元組，且 *size* 不是 0，這表示檔案結尾 (end of file)。如果物件處於非阻塞模式且有可用的位元組，則回傳 `None`。

預設的實作會遵守 `readall()` 和 `readinto()` 的實作。

**readall** ()

讀取回傳串流中直到檔案結尾的所有位元組，必要時使用多次對串流的呼叫。

**readinto** (*b*, /)

將位元組讀入一個預先分配的、可寫的 *bytes-like object* (類位元組物件) *b* 中，回傳讀取的位元組數量。例如，*b* 可能是一個 `bytearray`。如果物件處於非阻塞模式且有可用的位元組，則回傳 `None`。

**write** (*b*, /)

將給定的 *bytes-like object* (類位元組物件)，*b*，寫入底層的原始串流，回傳寫入的位元組大小。根據底層原始串流的具體情況，這可能少於 *b* 的位元組長度，尤其是當它處於非阻塞模式時。如果原始串流設置非阻塞且無法立即寫入任何單一位元組，則回傳 `None`。呼叫者在此方法回傳後可以釋放或變更 *b*，因此實作應該只在方法呼叫期間存取 *b*。

**class io.BufferedIOBase**

支援某種緩衝的二進位串流的基底類。它繼承自 `IOBase`。

與 `RawIOBase` 的主要差別在於，`read()`、`readinto()` 及 `write()` 方法將分嘗試讀取所請求的盡可能多的輸入，或消耗所有給定的輸出，即使可能需要進行多於一次的系統呼叫。

此外，如果底層的原始串流處於非阻塞模式且無法提供或接收足量的資料，這些方法可能會引發 `BlockingIOError` 例外；與 `RawIOBase` 不同之處在於，它們永遠不會回傳 `None`。

此外，`read()` 方法不存在一個遵從 `readinto()` 的預設實作。

一個典型的 `BufferedIOBase` 實作不應該繼承自一個 `RawIOBase` 的實作，而是應該改用包裝的方式，像 `BufferedWriter` 和 `BufferedReader` 那樣的作法。

`BufferedIOBase` 除了提供或覆寫來自 `IOBase` 的資料屬性和方法以外，還包含了這些：

**raw**

底層的原始串流 (一個 `RawIOBase` 實例)，`BufferedIOBase` 處理的對象。這不是 `BufferedIOBase` API 的一部分，且在某些實作可能不存在。

**detach** ()

將底層的原始串流從緩衝區中分離出來，回傳它。

在原始串流被分離後，緩衝區處於一個不可用的狀態。

某些緩衝區，如 `BytesIO`，有單一原始串流的概念可從此方法回傳。它們會引發 `UnsupportedOperation`。

在 3.1 版被加入。

**read** (*size=-1*, /)

讀取回傳最多 *size* 個位元組。如果引數被省略、`None` 或負值，將讀取回傳資料直到達到 EOF 止。如果串流已經處於 EOF，則回傳一個空的 *bytes* 物件。

如果引數正數，且底層原始串流不是互動式的，可能會發出多次原始讀取來滿足位元組數量 (除非首先達到 EOF)。但對於互動式原始串流，最多只會發出一一次原始讀取，且短少的資料不表示 EOF 即將到來。

如果底層原始串流處於非阻塞模式，且當前有可用資料，則會引發 `BlockingIOError`。

**read1** (*size=-1*, /)

讀取回傳最多 *size* 個位元組，最多呼叫一次底層原始串流的 `read()` (或 `readinto()`) 方法。如果你正在 `BufferedIOBase` 物件之上實作自己的緩衝區，這可能會很有用。

如果 *size* 是 `-1` (預設值)，則會回傳任意數量的位元組 (除非達到 EOF，否則會超過零)。

**readinto** (*b*, /)

讀取位元組到一個預先分配的、可寫的 *bytes-like object* *b* 當中，回傳讀取的位元組數量。例如，*b* 可能是一個 `bytearray`。

類似於 `read()`，除非後者是互動式的，否則可能會對底層原始串流發出多次讀取。

如果底層原始串流處於非阻塞模式，且當前有可用資料，則會引發 `BlockingIOError`。

**readinto1** (*b*, /)

讀取位元組到一個預先分配的、可寫的 *bytes-like object* *b* 中，最多呼叫一次底層原始串流的 `read()` (或 `readinto()`) 方法。此方法回傳讀取的位元組數量。

如果底層原始串流處於非阻塞模式，且當前有可用資料，則會引發 `BlockingIOError`。

在 3.5 版被加入。

**write** (*b*, /)

寫入給定的 *bytes-like object*，*b*，回傳寫入的位元組數量 (總是等於 *b* 的長度，以位元組計，因如果寫入失敗將會引發 `OSError`)。根據實際的實作，這些位元組可能會立即寫入底層串流，或出於性能和延遲的緣故而被留在緩衝區當中。

當處於非阻塞模式時，如果需要將資料寫入原始串流，但它無法接受所有資料而不阻塞，則會引發 `BlockingIOError`。

呼叫者可以在此方法回傳後釋放或變更 *b*，因此實作應該僅在方法呼叫期間存取 *b*。

## 原始檔案 I/O

**class** `io.FileIO` (*name*, *mode='r'*, *closefd=True*, *opener=None*)

一個代表包含位元組資料的 OS 層級檔案的原始二進制串流。它繼承自 `RawIOBase`。

*name* 可以是兩種事物之一：

- 代表將要打開的檔案路徑的一個字元串或 *bytes* 物件。在這種情況下，*closefd* 必須是 `True` (預設值)，否則將引發錯誤。
- an integer representing the number of an existing OS-level file descriptor to which the resulting `FileIO` object will give access. When the `FileIO` object is closed this fd will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. `FileExistsError` will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The `read()` (when called with a positive argument), `readinto()` and `write()` methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing `os.open` as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

See the `open()` built-in function for examples on using the *opener* parameter.

在 3.3 版的變更: The *opener* parameter was added. The `'x'` mode was added.

在 3.4 版的變更: The file is now non-inheritable.

`FileIO` provides these data attributes in addition to those from `RawIOBase` and `IOBase`:

**mode**

The mode as given in the constructor.

**name**

The file name. This is the file descriptor of the file when no name is given in the constructor.

**Buffered Streams**

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

**class** `io.BytesIO(initial_bytes=b'')`

A binary stream using an in-memory bytes buffer. It inherits from `BufferedIOBase`. The buffer is discarded when the `close()` method is called.

The optional argument `initial_bytes` is a *bytes-like object* that contains initial data.

`BytesIO` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

**getbuffer()**

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

**備註**

As long as the view exists, the `BytesIO` object cannot be resized or closed.

在 3.2 版被加入。

**getvalue()**

Return *bytes* containing the entire contents of the buffer.

**read1(size=-1, /)**

In `BytesIO`, this is the same as `read()`.

在 3.7 版的變更: The `size` argument is now optional.

**readinto1(b, /)**

In `BytesIO`, this is the same as `readinto()`.

在 3.5 版被加入。

**class** `io.BufferedReader(raw, buffer_size=DEFAULT_BUFFER_SIZE)`

A buffered binary stream providing higher-level access to a readable, non seekable `RawIOBase` raw binary stream. It inherits from `BufferedIOBase`.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a `BufferedReader` for the given readable `raw` stream and `buffer_size`. If `buffer_size` is omitted, `DEFAULT_BUFFER_SIZE` is used.

`BufferedReader` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

**peek(size=0, /)**

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

**read** (*size*=-1, /)

Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

**read1** (*size*=-1, /)

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

在 3.7 版的變更: The *size* argument is now optional.

**class** `io.BufferedWriter` (*raw*, *buffer\_size*=`DEFAULT_BUFFER_SIZE`)

A buffered binary stream providing higher-level access to a writeable, non seekable `RawIOBase` raw binary stream. It inherits from `BufferedIOBase`.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying `RawIOBase` object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable *raw* stream. If the *buffer\_size* is not given, it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

**flush** ()

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

**write** (*b*, /)

Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

**class** `io.BufferedReader` (*raw*, *buffer\_size*=`DEFAULT_BUFFER_SIZE`)

A buffered binary stream providing higher-level access to a seekable `RawIOBase` raw binary stream. It inherits from `BufferedReader` and `BufferedWriter`.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer\_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedReader` is capable of anything `BufferedReader` or `BufferedWriter` can do. In addition, `seek()` and `tell()` are guaranteed to be implemented.

**class** `io.BufferedRWPair` (*reader*, *writer*, *buffer\_size*=`DEFAULT_BUFFER_SIZE`, /)

A buffered binary stream providing higher-level access to two non seekable `RawIOBase` raw binary streams--one readable, the other writeable. It inherits from `BufferedIOBase`.

*reader* and *writer* are `RawIOBase` objects that are readable and writeable respectively. If the *buffer\_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

警告

`BufferedRWPair` does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use `BufferedReader` instead.

## 文字 I/O

**class** `io.TextIOBase`

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits from `IOBase`.

`TextIOBase` provides or overrides these data attributes and methods in addition to those from `IOBase`:

**encoding**

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

**errors**

The error setting of the decoder or encoder.

**newlines**

A string, a tuple of strings, or `None`, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

**buffer**

The underlying binary buffer (a `BufferedIOBase` instance) that `TextIOBase` deals with. This is not part of the `TextIOBase` API and may not exist in some implementations.

**detach()**

Separate the underlying binary buffer from the `TextIOBase` and return it.

After the underlying buffer has been detached, the `TextIOBase` is in an unusable state.

Some `TextIOBase` implementations, like `StringIO`, may not have the concept of an underlying buffer and calling this method will raise `UnsupportedOperation`.

在 3.1 版被加入。

**read** (*size=-1, /*)

Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or `None`, reads until EOF.

**readline** (*size=-1, /*)

Read until newline or EOF and return a single *str*. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

**seek** (*offset, whence=SEEK\_SET, /*)

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is `SEEK_SET`.

- `SEEK_SET` or 0: seek from the start of the stream (the default); *offset* must either be a number returned by `TextIOBase.tell()`, or zero. Any other *offset* value produces undefined behaviour.
- `SEEK_CUR` or 1: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- `SEEK_END` or 2: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

在 3.1 版被加入: `SEEK_*` 常數。

**tell()**

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

**write** (*s, /*)

Write the string *s* to the stream and return the number of characters written.

```
class io.TextIOWrapper (buffer, encoding=None, errors=None, newline=None, line_buffering=False,
                        write_through=False)
```

A buffered text stream providing higher-level access to a *BufferedIOBase* buffered binary stream. It inherits from *TextIOBase*.

*encoding* gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getencoding()*. *encoding="locale"* can be used to specify the current locale's encoding explicitly. See 文字編碼 for more information.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled. Pass 'strict' to raise a *ValueError* exception if there is an encoding error (the default of *None* has the same effect), or pass 'ignore' to ignore errors. (Note that ignoring encoding errors can lead to data loss.) 'replace' causes a replacement marker (such as '?') to be inserted where there is malformed data. 'backslashreplace' causes malformed data to be replaced by a backslashed escape sequence. When writing, 'xmlcharrefreplace' (replace with the appropriate XML character reference) or 'namereplace' (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with *codecs.register\_error()* is also valid.

*newline* controls how line endings are handled. It can be *None*, '', '\n', '\r', and '\r\n'. It works as follows:

- When reading input from the stream, if *newline* is *None*, *universal newlines* mode is enabled. Lines in the input can end in '\n', '\r', or '\r\n', and these are translated into '\n' before being returned to the caller. If *newline* is '', universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is *None*, any '\n' characters written are translated to the system default line separator, *os.linesep*. If *newline* is '' or '\n', no translation takes place. If *newline* is any of the other legal values, any '\n' characters written are translated to the given string.

If *line\_buffering* is *True*, *flush()* is implied when a call to write contains a newline character or a carriage return.

If *write\_through* is *True*, calls to *write()* are guaranteed not to be buffered: any data written on the *TextIOWrapper* object is immediately handled to its underlying binary *buffer*.

在 3.3 版的變更: The *write\_through* argument has been added.

在 3.3 版的變更: The default *encoding* is now *locale.getpreferredencoding(False)* instead of *locale.getpreferredencoding()*. Don't change temporary the locale encoding using *locale.setlocale()*, use the current locale encoding instead of the user preferred encoding.

在 3.10 版的變更: The *encoding* argument now supports the "locale" dummy encoding name.

*TextIOWrapper* provides these data attributes and methods in addition to those from *TextIOBase* and *IOBase*:

#### **line\_buffering**

Whether line buffering is enabled.

#### **write\_through**

Whether writes are passed immediately to the underlying binary buffer.

在 3.7 版被加入。

```
reconfigure (*, encoding=None, errors=None, newline=None, line_buffering=None, write_through=None)
```

Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line\_buffering* and *write\_through*.

Parameters not specified keep current settings, except *errors='strict'* is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

在 3.7 版被加入。

在 3.11 版的變更: The method supports `encoding="locale"` option.

**seek** (*cookie*, *whence*=`os.SEEK_SET`, /)

Set the stream position. Return the new stream position as an *int*.

Four operations are supported, given by the following argument combinations:

- `seek(0, SEEK_SET)`: Rewind to the start of the stream.
- `seek(cookie, SEEK_SET)`: Restore a previous position; *cookie* **must be** a number returned by `tell()`.
- `seek(0, SEEK_END)`: Fast-forward to the end of the stream.
- `seek(0, SEEK_CUR)`: Leave the current stream position unchanged.

Any other argument combinations are invalid, and may raise exceptions.

### 也參考

`os.SEEK_SET`, `os.SEEK_CUR`, and `os.SEEK_END`.

**tell** ()

Return the stream position as an opaque number. The return value of `tell()` can be given as input to `seek()`, to restore a previous stream position.

**class** `io.StringIO` (*initial\_value*="", *newline*="\n")

A text stream using an in-memory text buffer. It inherits from `TextIOBase`.

The text buffer is discarded when the `close()` method is called.

The initial value of the buffer can be set by providing *initial\_value*. If newline translation is enabled, newlines will be encoded as if by `write()`. The stream is positioned at the start of the buffer which emulates opening an existing file in a `w+` mode, making it ready for an immediate write from the beginning or for a write that would overwrite the initial value. To emulate opening a file in an `a+` mode ready for appending, use `f.seek(0, io.SEEK_END)` to reposition the stream at the end of the buffer.

The *newline* argument works like that of `TextIOWrapper`, except that when writing output to the stream, if *newline* is `None`, newlines are written as `\n` on all platforms.

`StringIO` provides this method in addition to those from `TextIOBase` and `IOBase`:

**getvalue** ()

Return a *str* containing the entire contents of the buffer. Newlines are decoded as if by `read()`, although the stream position is not changed.

使用範例:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

`class io.IncrementalNewlineDecoder`

A helper codec that decodes newlines for *universal newlines* mode. It inherits from *codecs.IncrementalDecoder*.

## 16.2.5 Performance

This section discusses the performance of the provided concrete I/O implementations.

### 二進位 (Binary) I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

### 文字 I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, *tell()* and *seek()* are both quite slow due to the reconstruction algorithm used.

*StringIO*, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

### Multi-threading

*FileIO* objects are thread-safe to the extent that the operating system calls (such as *read(2)* under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

*TextIOWrapper* objects are not thread-safe.

### Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a *signal* handler. If a thread tries to re-enter a buffered object which it is already accessing, a *RuntimeError* is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the *open()* function will wrap a buffered object inside a *TextIOWrapper*. This includes standard streams and therefore affects the built-in *print()* function as well.

## 16.3 time --- 時間存取與轉 F

這個模組提供了各種與時間相關的函式。若要查看相關功能，請參 F *datetime* 和 *calendar* 模組。

雖然這個模組隨時可用，但 F 非所有函式在所有平台上都可用。這個模組中定義的大多數函式都會呼叫 C 語言平台的函式庫中具有相同名稱的函式。由於這些函式的語義因平台而 F，所以偶爾查 F 平台文件可能會有所幫助。

以下是對一些術語和慣例的 F 明。

- *epoch* 是起始的時間點，即 `time.gmtime(0)` 的回傳值。在所有平台上，它是 1970 年 1 月 1 日，00:00:00 (UTC)。

- 術語 *seconds since the epoch* (紀元秒數) 是指從 epoch (紀元) 開始經過的總秒數，通常不包括 leap seconds。在所有符合 POSIX 標準的平台上，leap seconds (閏秒) 都不計入這個總數。
- 這個模組中的函式可能無法處理 epoch 之前或遠未來的日期和時間。未來的臨界點由 C 函式庫定；對於 32 位元系統來通常是在 2038 年。
- 函式 `strptime()` 在給定 %Y 格式碼時可以剖析 (parse) 兩位數的年份。當剖析兩位數的年份時，它們會根據 POSIX 和 ISO C 標準進行轉：69--99 的值對映到 1969--1999，0--68 的值對映到 2000--2068。
- UTC 是 Coordinated Universal Time --- 世界協調時間 (原稱格林威治標準時間，或 GMT)。縮寫 UTC 不是寫錯，而是英文和法文之間折衷的結果。
- DST 是 Daylight Saving Time (日光節約時間)，一年中的某些時段 (通常) 將會時區調整一小時。DST 的規則是根據當地法律定的，且可能每年不同。C 函式庫有一個包含當地規則的表 (通常會了靈活性而從系統文件中讀取)，在這方面是唯一的真正依據。
- 各種即時 (real-time) 函式的精確度可能低於其值或引數所表示的單位所建議的精確度。例如，在大多數 Unix 系統上，時鐘每秒只「跳」50 次或 100 次。
- 另一方面，`time()` 和 `sleep()` 的精確度比它們的在 Unix 的等效函式更高：時間以浮點數表示，`time()` 回傳最精確的可用時間 (如果可以會使用 Unix 的 `gettimeofday()`)，而 `sleep()` 可以接受帶有非零分數的時間 (如果可以會使用 Unix 的 `select()` 來實作)。
- 由 `gmtime()`、`localtime()` 和 `strptime()` 回傳，由 `asctime()`、`mktime()` 和 `strftime()` 接受的時間值，是一個 9 個整數的序列。`gmtime()`、`localtime()` 和 `strptime()` 的回傳值也各個欄位提供屬性名稱。

關於這些物件的述請見 `struct_time`。

在 3.3 版的變更：當平台支援對應的 `struct tm` 成員時，`struct_time` 型被擴展以提供 `tm_gmtoff` 和 `tm_zone` 屬性。

在 3.6 版的變更：`struct_time` 的屬性 `tm_gmtoff` 和 `tm_zone` 現在在所有平台上都可用。

- 使用以下函式在時間表示之間進行轉：

轉來源	轉目標	使用
紀元秒數	世界協調時間的 <code>struct_time</code>	<code>gmtime()</code>
紀元秒數	本地時間的 <code>struct_time</code>	<code>localtime()</code>
世界協調時間的 <code>struct_time</code>	紀元秒數	<code>calendar.timegm()</code>
本地時間的 <code>struct_time</code>	紀元秒數	<code>mktime()</code>

### 16.3.1 函式

`time.asctime([t])`

將由 `gmtime()` 或 `localtime()` 回傳的元組或 `struct_time` 表示的時間轉以下格式的字串：'Sun Jun 20 23:21:05 1993'。日期欄位兩個字元長，如果日期是個位數，則用空格填充，例如：'Wed Jun 9 04:26:40 1993'。

如果提供 `t`，則使用由 `localtime()` 回傳的當前時間。`asctime()` 不使用區域資訊。

#### 備

與同名的 C 函式不同，`asctime()` 不會添加結尾的行字元。

`time.thread_getcpuclockid(thread_id)`

指定的 `thread_id` 回傳執行緒專用 CPU-time 時鐘的 `clk_id`。

使用 `threading.get_ident()` 或 `threading.Thread` 物件的 `ident` 屬性來獲取適用於 `thread_id` 的值。

**警告**

傳遞無效或過期的 `thread_id` 可能會導致未定義的行為，例如分段錯誤 (segmentation fault)。

適用: Unix

若需更多資訊，請參閱 `pthread_getcpuclockid(3)` 的說明文件。

在 3.7 版被加入。

`time.clock_getres (clk_id)`

回傳指定時鐘 `clk_id` 的解析度 (精確度)。有關 `clk_id` 可接受的值的串列，請參閱時鐘 ID 常數。

適用: Unix.

在 3.3 版被加入。

`time.clock_gettime (clk_id) → float`

回傳指定時鐘 `clk_id` 的時間。有關 `clk_id` 可接受的值的串列，請參閱時鐘 ID 常數。

使用 `clock_gettime_ns()` 以避免 `float` 型造成的精確度損失。

適用: Unix.

在 3.3 版被加入。

`time.clock_gettime_ns (clk_id) → int`

類似於 `clock_gettime()`，但回傳以奈秒 (nanoseconds) 單位的時間。

適用: Unix.

在 3.7 版被加入。

`time.clock_settime (clk_id, time: float)`

設定指定時鐘 `clk_id` 的時間。目前，`CLOCK_REALTIME` 是 `clk_id` 唯一可以接受的值。

使用 `clock_settime_ns()` 以避免 `float` 型造成的精確度損失。

適用: Unix, not Android, not iOS.

在 3.3 版被加入。

`time.clock_settime_ns (clk_id, time: int)`

類似於 `clock_settime()`，但設定以奈秒單位的時間。

適用: Unix, not Android, not iOS.

在 3.7 版被加入。

`time.ctime ([secs])`

將自 `epoch` 起以秒表示的時間轉成表示當地時間且符合以下格式的字串: 'Sun Jun 20 23:21:05 1993'。日期欄位兩個字元長，如果日期是個位數，則用空格填充，例如: 'Wed Jun 9 04:26:40 1993'。

如果未提供 `secs` 或其 `None`，則使用由 `time()` 回傳的當前時間。`ctime(secs)` 等同於 `asctime(localtime(secs))`。`ctime()` 不使用區域資訊。

`time.get_clock_info (name)`

獲取指定時鐘的資訊作命名空間物件。支援的時鐘名稱及讀取他們的值的對應函式如下:

- 'monotonic': `time.monotonic()`
- 'perf\_counter': `time.perf_counter()`
- 'process\_time': `time.process_time()`
- 'thread\_time': `time.thread_time()`
- 'time': `time.time()`

其結果具有以下屬性：

- *adjustable*: 如果時鐘可以自動（例如，透過 NTP 常駐程式）或由系統管理員手動更改，則 `True`，否則 `False`
- *implementation*: 用於獲取時鐘的值的底層 C 函式名稱。有關可能的值，請參閱時鐘 ID 常數。
- *monotonic*: 如果時鐘不能倒轉，則 `True`，否則 `False`
- *resolution*: 以秒 (*float*) 單位的時鐘的解析度

在 3.3 版被加入。

`time.gmtime([secs])`

將自 *epoch* 起以秒表示的時間轉為 UTC 中的 *struct\_time*，其中 *dst* 旗標始終為零。如果未提供 *secs* 或其為 `None`，則使用由 *time()* 回傳的當前時間。忽略秒的分數部分。關於 *struct\_time* 物件的描述，請參閱上文。此函式的反運算請參閱 *calendar.timegm()*。

`time.localtime([secs])`

類似於 *gmtime()*，但轉為當地時間。如果未提供 *secs* 或其為 `None`，則使用由 *time()* 回傳的當前時間。當 DST 適用於給定時間時，*dst* 旗標會被設定為 1。

如果時間戳超出 C 平台的 *localtime()* 或 *gmtime()* 函式支援的範圍，*localtime()* 可能會引發 *OverflowError*；在 *localtime()* 或 *gmtime()* 失敗時，會引發 *OSError*。通常會把年份限制在 1970 年到 2038 年之間。

`time.mktime(t)`

這是 *localtime()* 的反函式。其引數是表示當地時間（不是 UTC）的 *struct\_time* 或完整的 9 元組（因為需要 *dst* 旗標；如果 *dst* 未知，則使用 -1 作為 *dst* 旗標）。它回傳一個浮點數，以與 *time()* 相容。如果輸入值不能表示有效時間，將引發 *OverflowError* 或 *ValueError*（取決於無效值是被 Python 還是底層 C 函式庫捕獲）。它能生成時間的最早日期根據平台而有所不同。

`time.monotonic() → float`

回傳單調時鐘（monotonic clock，即不能倒轉的時鐘）的值（以帶有小數的秒數表示）。該時鐘不受系統時鐘更新的影響。回傳值的參考點有定義，因此只有兩次呼叫結果之間的差才是有效的。

時鐘：

- 在 Windows 上，呼叫 *QueryPerformanceCounter()* 和 *QueryPerformanceFrequency()*。
- 在 macOS 上，呼叫 *mach\_absolute\_time()* 和 *mach\_timebase\_info()*。
- 在 HP-UX 上，呼叫 *gethrtime()*。
- 如果可以的話，呼叫 *clock\_gettime(CLOCK\_HIGHRES)*。
- 否則，呼叫 *clock\_gettime(CLOCK\_MONOTONIC)*。

使用 *monotonic\_ns()* 以避免 *float* 型造成的精確度損失。

在 3.3 版被加入。

在 3.5 版的變更：此函式現在始終可用且涵蓋整個系統。

在 3.10 版的變更：在 macOS 上，此函式現在涵蓋整個系統。

`time.monotonic_ns() → int`

類似於 *monotonic()*，但回傳以奈秒單位的時間。

在 3.7 版被加入。

`time.perf_counter() → float`

回傳性能計數器的值（以帶有小數的秒數表示），即具有最高可用解析度來測量短時間間隔的時鐘。它包括睡眠時經過的時間，且涵蓋整個系統。回傳值的參考點有定義，因此只有兩次呼叫結果之間的差才是有效的。

在 CPython 上，使用與 *time.monotonic()* 相同的時鐘，且其單調時鐘（即不能倒轉的時鐘）。

使用 *perf\_counter\_ns()* 以避免 *float* 型造成的精確度損失。

在 3.3 版被加入。

在 3.10 版的變更: 在 Windows 上, 此函式現在涵蓋整個系統。

在 3.13 版的變更: 使用與 `time.monotonic()` 相同的時鐘。

`time.perf_counter_ns()` → *int*

類似於 `perf_counter()`, 但回傳以奈秒單位的時間。

在 3.7 版被加入。

`time.process_time()` → *float*

回傳當前行程的系統和用 CPU 時間之和 (以帶有小數的秒數表示)。它不包括睡眠時經過的時間。根據定義, 它涵蓋整個行程。回傳值的參考點有定義, 因此只有兩次呼叫結果之間的差才是有效的。

使用 `process_time_ns()` 以避免 *float* 型造成的精確度損失。

在 3.3 版被加入。

`time.process_time_ns()` → *int*

類似於 `process_time()`, 但回傳以奈秒單位的時間。

在 3.7 版被加入。

`time.sleep(secs)`

在一個給定的秒數暫停呼叫執行緒 (calling thread) 的執行。引數可以是浮點數, 以表示更精確的睡眠時間。

如果睡眠被訊號中斷且訊號處理器未引發例外, 則睡眠將以重新計算過的逾時 (timeout) 重新開始。

由於系統中其他活動的調度, 暫停時間可能會比請求的時間長任意的量。

### Windows 實作

在 Windows 上, 如果 `secs` 零, 則執行緒將其剩餘的時間片段讓給任何準備運行的其他執行緒。如果有其他執行緒準備運行, 該函式將立即回傳, 而執行緒會繼續執行。在 Windows 8.1 及更新的版本中, 此實作使用高解析度計時器, 其解析度 100 奈秒。如果 `secs` 零, 則使用 `Sleep(0)`。

### Unix 實作

- 如果可以, 使用 `clock_nanosleep()` (解析度: 1 奈秒);
- 或者使用 `nanosleep()` (解析度: 1 奈秒);
- 或使用 `select()` (解析度: 1 微秒)。

#### 備

To emulate a "no-op", use `pass` instead of `time.sleep(0)`.

To voluntarily relinquish the CPU, specify a real-time *scheduling policy* and use `os.sched_yield()` instead.

引發一個帶有引數 `secs` 的稽核事件 (auditing event) `time.sleep`。

在 3.5 版的變更: 即使睡眠被訊號中斷, 此函式現在至少還是會睡眠 `secs`, 除非訊號處理器引發例外 (理由請參 PEP 475)。

在 3.11 版的變更: 在 Unix 上, 如果可以的話現在會使用 `clock_nanosleep()` 和 `nanosleep()` 函式。在 Windows 上, 現在使用可等待的計時器。

在 3.13 版的變更: 引發一個稽核事件。

`time.strptime(format[, t])`

將由 `gmtime()` 或 `localtime()` 回傳代表時間的一個元組或 `struct_time` 轉由 `format` 引數指定的字串。如果未提供 `t`，則使用由 `localtime()` 回傳的當前時間。`format` 必須是一個字串。如果 `t` 中的任何欄位超出允許範圍，將會引發 `ValueError`。

0 在時間元組中的任何位置都是合法引數；如果元組中出現常見的錯誤，該值將被制更改正確的值。

以下指令可以嵌入在 `format` 字串中。它們顯示時不帶可選的欄位寬度和精度規範，在 `strptime()` 的結果中被標示的字元替：

指令	意義	解
%a	區域設定的間日 (weekday) 縮寫名稱。	
%A	區域設定的完整間日名稱。	
%b	區域設定的縮寫月份名稱。	
%B	區域設定的完整月份名稱。	
%c	區域設定的合適的日期和時間的表示法。	
%d	月份中的日期，表示十進位數 [01,31]。	
%f	<b>微秒，表示十進位數 [000000,999999]。</b>	(1)
%H	小時 (24 小時制)，表示十進位數 [00,23]。	
%I	小時 (12 小時制)，表示十進位數 [01,12]。	
%j	一年中的第幾天，表示十進位數 [001,366]。	
%m	月份，表示十進位數 [01,12]。	
%M	分鐘，表示十進位數 [00,59]。	
%p	區域設定中相當於 AM 或 PM 的表示。	(2)
%S	秒，表示十進位數 [00,61]。	(3)
%U	一年中的數 (星期天作一的第一天)，表示十進位數 [00,53]。新的一年中，在第一個星期天之前的所有日子都被認定第 0 。	(4)
%u	一中的日期 (周一 1; 日 7)，表示十進位數 [1,7]。	
%w	間日，表示十進位數 [0(星期天),6]。	
%W	一年中的數 (星期一作一的第一天)，表示十進位數 [00,53]。新的一年中，在第一個星期一之前的所有日子都被認定第 0 。	(4)
%x	區域設定的合適的日期表示法。	
%X	區域設定的合適的時間表示法。	
%y	去掉世紀的年份，表示十進位數 [00,99]。	
%Y	帶世紀的年份，表示十進位數。	
%z	時區偏移量，表示與 UTC/GMT 的正或負時間差，形式 +HHMM 或 -HHMM，其中 H 代表十進位的小時數碼 (digits)，M 代表十進位的分鐘數碼 [-23:59, +23:59]。 <sup>1</sup>	
%Z	時區名稱 (如果不存在時區，則無字元)。已被用。 <sup>Page 716.1</sup>	
%G	ISO 8601 年 (類似於 %Y，但遵循 ISO 8601 日年的規則)。	

%V  
ISO 8601 數 (以十進位數表示 [01,53])。年份的第一是包含該年第一個星期四的那一

解：

- (1) `%f` 格式的指令僅適用於 `strptime()`，不適用於 `strftime()`。然而，在 `datetime.datetime.strptime()` 和 `datetime.datetime.strftime()` 其中的 `%f` 格式的指令適用於微秒。
- (2) 當與 `strptime()` 函式一起使用時，`%p` 指令僅在使用 `%I` 指令剖析小時時影響輸出小時的欄位。
- (3) 範圍確實是從 0 到 61；數值 60 在表示 leap seconds 的時間戳中是有效的，而數值 61 是出於歷史因素而被支援。
- (4) 當與 `strptime()` 函式一起使用時，`%U` 和 `%W` 僅在指定間的某天和年份時用於計算中。

以下是一個範例，其一種與 RFC 2822 網際網路電子郵件標準中指定的日期格式兼容的格式<sup>1</sup>：

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

某些平台可能支援額外的指令，但只有這列出的指令具有 ANSI C 標準化的意義。要查看你的平台上支援的完整格式碼集，請參閱 `strftime(3)` 文件。

在某些平台上，可選的欄位寬度和精度規範可以以此順序緊跟在指令初始的 '%' 之後；這也是不可 (portable) 的。欄位寬度通常 2，除了 %j 3。

`time.strptime(string[, format])`

根據格式剖析表示時間的字串。回傳值是 `struct_time`，如同由 `gmtime()` 或 `localtime()` 回傳的一樣。

`format` 參數使用與 `strftime()` 相同的指令；預設 "%a %b %d %H:%M:%S %Y"，與 `ctime()` 回傳的格式匹配。如果 `string` 無法根據 `format` 解析，或剖析後有多餘的資料，將引發 `ValueError`。當無法推斷更精確的值時，用來填充任何缺失資料的預設值 (1900, 1, 1, 0, 0, 0, 0, 1, -1)。 `string` 和 `format` 都必須是字串。

例如：

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                  tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

對 %Z 指令的支援基於 `tzname` 中包含的值以及 `daylight` 是否 true。因此，除了識始終已知的 UTC 和 GMT（且被考慮非日光節約時區）外，這是特定於平台的。

僅支援文檔中指定的指令。由於 `strftime()` 是根據每個平台實作的，有時它可以提供比列出的還要更多的指令。但是 `strptime()` 與任何平台無關，因此不一定支援所有未記載支援的指令。

**class** `time.struct_time`

由 `gmtime()`、`localtime()` 和 `strptime()` 回傳的時間值序列的型。它是一個具有 *named tuple* 介面的物件：值可以通過索引和屬性名稱存取。包含以下值：

<sup>1</sup> 現在 %Z 已被用，%z 藉由擴展偏好的小時/分鐘偏移而逃離了被用的命運，但其不是被所有 ANSI C 函式庫支援。此外，嚴格按照 1982 年的 RFC 822 標準，應該使用兩位數年份 (%y 而不是 %Y)，但實作中在 2000 年之前就已經轉向使用四位數年份。之後，RFC 822 被淘汰，四位數年份首先由 RFC 1123 推薦，然後由 RFC 2822 正式批准。

索引	屬性	值
0	<code>tm_year</code>	(例如 1993)
1	<code>tm_mon</code>	範圍 [1, 12]
2	<code>tm_mday</code>	範圍 [1, 31]
3	<code>tm_hour</code>	範圍 [0, 23]
4	<code>tm_min</code>	範圍 [0, 59]
5	<code>tm_sec</code>	範圍 [0, 61]; 參見 <code>strftime()</code> 中的釋 (2)
6	<code>tm_wday</code>	範圍 [0, 6]; 星期一是 0
7	<code>tm_yday</code>	範圍 [1, 366]
8	<code>tm_isdst</code>	0、1 或 -1; 見下文
N/A	<code>tm_zone</code>	時區名稱的縮寫
N/A	<code>tm_gmtoff</code>	UTC 向東的偏移量 (以秒單位)

請注意，與 C 結構不同，月份值的範圍是 [1, 12]，而不是 [0, 11]。

在呼叫 `mktime()` 時，當日光節約時間生效的時候，`tm_isdst` 可以設定 1，不生效時設定 0。值 -1 表示未知是否生效，通常結果會填入正確的狀態。

當一個長度不正確的元組被傳遞給預期得到 `struct_time` 的函式時，或者其中有元素型錯誤時，將引發 `TypeError`。

`time.time()` → *float*

回傳自 *epoch* 起的時間 (秒) 至今的浮點數。對 *leap seconds* 的處理是與平台有關的。在 Windows 和大多數 Unix 系統上，閏秒不計入自 *epoch* 起的秒數中。這通常被稱 Unix 時間。

請注意，即使時間始終作浮點數回傳，但非所有系統都提供比 1 秒還更精確的時間。雖然此函式通常回傳非遞進的值，但如果在兩次呼叫之間系統時鐘被回調，則它可能回傳比之前呼叫更小的值。

由 `time()` 回傳的數字可以通過傳遞給 `gmtime()` 函式轉 UTC 更常見的時間格式 (即年、月、日、小時等) 或通過傳遞給 `localtime()` 函式轉當地時間。在這兩種情況下都會回傳一個 `struct_time` 物件，從中可以作屬性存取日期的組成部分。

時鐘：

- 在 Windows 上，呼叫 `GetSystemTimeAsFileTime()`。
- 如果可以的話，呼叫 `clock_gettime(CLOCK_REALTIME)`。
- 否則，呼叫 `gettimeofday()`。

使用 `time_ns()` 以避免 `float` 型造成的精確度損失。

`time.time_ns()` → `int`

類似於 `time()`，但回傳自 `epoch` 起的以奈秒單位的整數。

在 3.7 版被加入。

`time.thread_time()` → `float`

回傳當前執行緒的系統和用 CPU 時間之和（以帶有小數的秒數表示）。它不包括睡眠期間經過的時間。根據定義，這是執行緒特定（thread-specific）的。回傳值的參照點未定義，因此只有同一執行緒中兩次呼叫結果之間的差才是有效的。

使用 `thread_time_ns()` 以避免 `float` 型造成的精確度損失。

適用：Linux, Unix, Windows.

有支援 `CLOCK_THREAD_CPUTIME_ID` 的 Unix 系統。

在 3.7 版被加入。

`time.thread_time_ns()` → `int`

類似於 `thread_time()`，但回傳以奈秒單位的時間。

在 3.7 版被加入。

`time.tzset()`

重置函式庫常式 (routine) 使用的時間轉規則。環境變數 `TZ` 指定了這一過程的實施方式。它還會設定變數 `tzname`（來自 `TZ` 環境變數）、`timezone`（非日光節約時間的 UTC 以西的時間偏移，單位秒）、`altzone`（日光節約時間的 UTC 以西的時間偏移，單位秒）和 `daylight`（如果該時區有日光節約時間規則，則設定 0；如果在過去、現在或未來的某個時間有日光節約時間規則，則設置非零的值）。

適用：Unix.

### 備

雖然在許多情況下，更改 `TZ` 環境變數可能會在呼叫 `tzset()` 的情況下影響 `localtime()` 等函式的輸出，但是這種行是不該被依賴的。

`TZ` 環境變數不應包含空格字元。

`TZ` 環境變數的標準格式（了清楚表達，中間增加了空格字元）：

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

其中各個組成部分：

#### std 和 dst

三個或更多字母與數字 (alphanumerics) 組成的時區縮寫。這些縮寫會被傳播到 `time.tzname` 中。

#### offset

偏移量的格式：± hh[:mm[:ss]]。這表示達到 UTC 而增加到當地時間的值。如果以 '-' 開頭，則表示該時區位於本初子午以東；否則，位於其西。如果 `dst` 之後有偏移量，則假定日光時間比標準時間快一小時。

#### start[/time], end[/time]

表示何時切至日光節約時間及何時切回來。開始和結束日期的格式如以下其一：

#### Jn

儒略日 (Julian day)  $n^*$  ( $1 \leq n \leq 365$ )。閏日不計算，因此在所有年份中，2 月 28 日是第 59 天，3 月 1 日是第 60 天。

#### n

從 0 開始的儒略日 ( $0 \leq n \leq 365$ )。閏日會計算，因此可以適用至 2 月 29 日。

**Mm.n.d**

一年中第  $m$  月的第  $n$  的  $d$  天 ( $0 \leq d \leq 6$ ,  $1 \leq n \leq 5$ ,  $1 \leq m \leq 12$ , 其中  $n \leq 5$  表示「該月的最後一個第  $d$  天」, 這可能出現在第四或第五)。第 1 是  $d$  天首次出現的那一。第零天 星期天。

`time` 的格式與 `offset` 相同, 但不允許出現前導符號 ('-' 或 '+')。如果未指定時間, 則預設 02:00:00。

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

在許多 Unix 系統 (包括 \*BSD、Linux、Solaris 和 Darwin) 上, 使用系統的 `zoneinfo` (`tzfile(5)`) 資料庫來指定時區規則會更加方便。要這樣做, 請將 `TZ` 環境變數設定所需時區資料檔案的路徑, 相對於系統 'zoneinfo' 時區資料庫的根目, 通常位於 `/usr/share/zoneinfo`。例如, 'US/Eastern'、'Australia/Melbourne'、'Egypt' 或 'Europe/Amsterdam'。

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

### 16.3.2 時鐘 ID 常數

這些常數用作 `clock_getres()` 和 `clock_gettime()` 的參數。

#### `time.CLOCK_BOOTTIME`

與 `CLOCK_MONOTONIC` 基本相同, 不同之處在於它還包括系統暫停的任何時間。

這允許應用程式獲取一個能感知暫停的單調時鐘, 而無需處理 `CLOCK_REALTIME` 的雜情, 後者在使用 `settimeofday()` 或類似函式更改時間時可能會出現不連續的情。

適用: Linux  $\geq$  2.6.39.

在 3.7 版被加入。

#### `time.CLOCK_HIGHRES`

Solaris 作業系統具有 `CLOCK_HIGHRES` 計時器, 它嘗試使用最佳的硬體資源, 可能提供接近奈秒的解析度。 `CLOCK_HIGHRES` 是不可調整且高解析度的時鐘。

適用: Solaris.

在 3.3 版被加入。

#### `time.CLOCK_MONOTONIC`

該時鐘無法被設定, 其表示自某個未指定起點以來的單調時間。

適用: Unix.

在 3.3 版被加入。

#### `time.CLOCK_MONOTONIC_RAW`

類似於 `CLOCK_MONOTONIC`, 但提供對基於硬體的原始時間的存取, 此時間不受 NTP 調整的影響。

適用: Linux  $\geq$  2.6.28, macOS  $\geq$  10.12.

在 3.3 版被加入。

`time.CLOCK_MONOTONIC_RAW_APPROX`

類似於 `CLOCK_MONOTONIC_RAW`，但讀取的是系統在情境切時快取的值，因此精確度較低。

適用: macOS >= 10.12.

在 3.13 版被加入。

`time.CLOCK_PROCESS_CPUTIME_ID`

來自 CPU 的高解析度每個行程的計時器。

適用: Unix.

在 3.3 版被加入。

`time.CLOCK_PROF`

來自 CPU 的高解析度每個行程的計時器。

適用: FreeBSD, NetBSD >= 7, OpenBSD.

在 3.7 版被加入。

`time.CLOCK_TAI`

國際原子時間

系統必須擁有當前的閏秒表才能給出正確答案。PTP 或 NTP 軟體可以維護閏秒表。

適用: Linux.

在 3.9 版被加入。

`time.CLOCK_THREAD_CPUTIME_ID`

執行緒相關的 CPU 時間時鐘。

適用: Unix.

在 3.3 版被加入。

`time.CLOCK_UPTIME`

表示系統運作且無暫停的對時間，提供包括對時間 (absolute) 和時間區間 (interval) 的精確的正常上時間 (uptime) 測量。

適用: FreeBSD, OpenBSD >= 5.5.

在 3.7 版被加入。

`time.CLOCK_UPTIME_RAW`

單調增量的時鐘，從某個任意點開始計時，不受頻率或時間調整影響，且在系統休眠時不增量。

適用: macOS >= 10.12.

在 3.8 版被加入。

`time.CLOCK_UPTIME_RAW_APPROX`

類似於 `CLOCK_UPTIME_RAW`，但該值在情境切時由系統快取，因此精確度較低。

適用: macOS >= 10.12.

在 3.13 版被加入。

以下常數是唯一可以傳遞給 `clock_settime()` 的參數。

`time.CLOCK_REALTIME`

涵蓋整個系統的即時時鐘。設定此時鐘需要適當的權限。

適用: Unix.

在 3.3 版被加入。

### 16.3.3 時區常數

`time.altzone`

如果本地 DST 時區有被定義，則此值本地 DST 時區相對於 UTC 以西的偏移量（以秒單位）。若本地 DST 時區位於 UTC 以東（例如包括英國在西歐），則此值負值。僅在 daylight 非零時使用此值。詳情請參見下方釋。

`time.daylight`

如果定義了 DST 時區，則非零值。詳情請參見下方釋。

`time.timezone`

本地（非 DST）時區相對於 UTC 以西的偏移量（以秒單位），西歐大多數地區負，美國正，英國零。詳情請參見下方釋。

`time.tzname`

一個包含兩個字串的元組：第一個是本地非 DST 時區的名稱，第二個是本地 DST 時區的名稱。如果有定義 DST 時區，則不應使用第二個字串。詳情請參見下方釋。

#### 備

對於上述時區常數 (`altzone`、`daylight`、`timezone` 和 `tzname`)，其值由模組載入時或 `tzset()` 最後一次被呼叫時的時區規則定，且過去的時間可能會不準確。建議使用 `localtime()` 回傳的 `tm_gmtoff` 和 `tm_zone` 來獲取時區資訊。

#### 也參考

##### `datetime` 模組

更多物件導向的日期和時間介面。

##### `locale` 模組

國際化服務。區域設定會影響 `strftime()` 和 `strptime()` 中許多格式指定符號 (format specifiers) 的解譯。

##### `calendar` 模組

通用的日相關函式。`timegm()` 是本模組中 `gmtime()` 的反函式。

解

## 16.4 logging --- Python 的日記工具

原始碼: `Lib/logging/__init__.py`

#### Important

此頁面包含 API 參考訊息。有關教學流程和更進階的主題討論，請參

- 基礎教學
- 進階教學
- 日記手

這個模組定義了函式與類 (class)，應用程式和函式庫實作彈性的日管理系統。

由標準函式庫模組提供的日記 API 的主要好處是，所有的 Python 模組都能參與日記，因此你的應用程式日可以包含你自己的訊息，與來自第三方模組的訊息整合在一起。

Here's a simple example of idiomatic usage:

```
# myapp.py
import logging
import mylib
logger = logging.getLogger(__name__)

def main():
    logging.basicConfig(filename='myapp.log', level=logging.INFO)
    logger.info('Started')
    mylib.do_something()
    logger.info('Finished')

if __name__ == '__main__':
    main()
```

```
# mylib.py
import logging
logger = logging.getLogger(__name__)

def do_something():
    logger.info('Doing something')
```

If you run *myapp.py*, you should see this in *myapp.log*:

```
INFO:__main__:Started
INFO:mylib:Doing something
INFO:__main__:Finished
```

The key feature of this idiomatic usage is that the majority of code is simply creating a module level logger with `getLogger(__name__)`, and using that logger to do any needed logging. This is concise, while allowing downstream code fine-grained control if needed. Logged messages to the module-level logger get forwarded to handlers of loggers in higher-level modules, all the way up to the highest-level logger known as the root logger; this approach is known as hierarchical logging.

For logging to be useful, it needs to be configured: setting the levels and destinations for each logger, potentially changing how specific modules log, often based on command-line arguments or application configuration. In most cases, like the one above, only the root logger needs to be so configured, since all the lower level loggers at module level eventually forward their messages to its handlers. `basicConfig()` provides a quick way to configure the root logger that handles many use cases.

這個模組提供了很多的功能性以及彈性。如果你對於 logging 不熟悉，熟悉它最好的方法就是去看教學（請看右上方的連結）。

The basic classes defined by the module, together with their attributes and methods, are listed in the sections below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- 格式器指定日誌記錄在最終輸出中的格式。

### 16.4.1 Logger 物件

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to `getLogger()` with the same name will always return a reference to the same Logger object.

The name is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. In addition, all loggers are descendants of the root logger. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis

using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

```
class logging.Logger
```

#### name

This is the logger's name, and is the value that was passed to `getLogger()` to obtain the logger.

#### 備註

This attribute should be treated as read-only.

#### level

The threshold of this logger, as set by the `setLevel()` method.

#### 備註

Do not set this attribute directly - always use `setLevel()`, which has checks for the level passed to it.

#### parent

The parent logger of this logger. It may change based on later instantiation of loggers which are higher up in the namespace hierarchy.

#### 備註

This value should be treated as read-only.

#### propagate

如果此屬性評估 `true`，則在此日誌器被記的事件會被傳到更高階（上代）日誌器的處理函式和所有附加在此日誌器的任何處理器。訊息會直接傳到上代 loggers 的處理器 - 在問題中上代日誌器的層級或是篩選器都不會被考慮。

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

Spelling it out with an example: If the `propagate` attribute of the logger named `A.B.C` evaluates to true, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to false, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

此建構函式將該屬性設 `True`。

#### 備註

If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their `propagate` setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

#### handlers

The list of handlers directly attached to this logger instance.

**備註**

This attribute should be treated as read-only; it is normally changed via the `addHandler()` and `removeHandler()` methods, which use locks to ensure thread-safe operation.

**disabled**

This attribute disables handling of any events. It is set to `False` in the initializer, and only changed by logging configuration code.

**備註**

This attribute should be treated as read-only.

**setLevel (level)**

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

當一個日誌器被建立時，日誌層級會被設定成 `NOTSET`（當此日誌器是根日誌器，或是代表父日誌器的非根日誌器時，會使所有訊息被處理）。請注意根日誌器會以日誌等級 `WARNING` 被建立。

The term 'delegation to the parent' means that if a logger has a level of `NOTSET`, its chain of ancestor loggers is traversed until either an ancestor with a level other than `NOTSET` is found, or the root is reached.

If an ancestor is found with a level other than `NOTSET`, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of `NOTSET`, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

層級清單請見 [Logging Levels](#)。

在 3.2 版的變更: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as `INFO`. Note, however, that levels are internally stored as integers, and methods such as e.g. `getEffectiveLevel()` and `isEnabledFor()` will return/expect to be passed integers.

**isEnabledFor (level)**

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger's effective level as determined by `getEffectiveLevel()`.

**getEffectiveLevel ()**

Indicates the effective level for this logger. If a value other than `NOTSET` has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than `NOTSET` is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

**getChild (suffix)**

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

在 3.2 版被加入。

**getChildren()**

Returns a set of loggers which are immediate children of this logger. So for example `logging.getLogger().getChildren()` might return a set containing loggers named `foo` and `bar`, but a logger named `foo.bar` wouldn't be included in the set. Likewise, `logging.getLogger('foo').getChildren()` might return a set including a logger named `foo.bar`, but it wouldn't include one named `foo.bar.baz`.

在 3.12 版被加入。

**debug(msg, \*args, \*\*kwargs)**

Logs a message with level `DEBUG` on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No `%` formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc\_info*, *stack\_info*, *stacklevel* and *extra*.

If *exc\_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) or an exception instance is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The second optional keyword argument is *stack\_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc\_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack\_info* independently of *exc\_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to `1`. If greater than `1`, the corresponding number of stack frames are skipped when computing the line number and function name set in the `LogRecord` created for the logging event. This can be used in logging helpers so that the function name, filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the `warnings` module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the section on `LogRecord` 屬性 for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the `Formatter` has been set up with a format string which expects 'clientip' and

'user' in the attribute dictionary of the *LogRecord*. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatters* would be used with particular *Handlers*.

If no handler is attached to this logger (or any of its ancestors, taking into account the relevant *Logger.propagate* attributes), the message will be sent to the handler set on *lastResort*.

在 3.2 版的變更: 新增 *stack\_info* 參數。

在 3.5 版的變更: The *exc\_info* parameter can now accept exception instances.

在 3.8 版的變更: 新增 *stacklevel* 參數。

**info** (*msg*, \**args*, \*\**kwargs*)

Logs a message with level *INFO* on this logger. The arguments are interpreted as for *debug()*.

**warning** (*msg*, \**args*, \*\**kwargs*)

在此記 器上記 一條層級 *WARNING* 的訊息。這些引數被直譯的方式與 *debug()* 相同。

There is an obsolete method *warn* which is functionally identical to *warning*. As *warn* is deprecated, please do not use it - use *warning* instead.

**error** (*msg*, \**args*, \*\**kwargs*)

Logs a message with level *ERROR* on this logger. The arguments are interpreted as for *debug()*.

**critical** (*msg*, \**args*, \*\**kwargs*)

Logs a message with level *CRITICAL* on this logger. The arguments are interpreted as for *debug()*.

**log** (*level*, *msg*, \**args*, \*\**kwargs*)

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for *debug()*.

**exception** (*msg*, \**args*, \*\**kwargs*)

Logs a message with level *ERROR* on this logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This method should only be called from an exception handler.

**addFilter** (*filter*)

在該 logger 增加指定的 filter *filter*。

**removeFilter** (*filter*)

在該 logger 移除指定的 filter *filter*。

**filter** (*record*)

Apply this logger's filters to the record and return *True* if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

**addHandler** (*hdlr*)

Adds the specified handler *hdlr* to this logger.

**removeHandler** (*hdlr*)

Removes the specified handler *hdlr* from this logger.

**findCaller** (*stack\_info=False, stacklevel=1*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack\_info* is `True`.

The *stacklevel* parameter is passed from code calling the `debug()` and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

**handle** (*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using `filter()`.

**makeRecord** (*name, level, fn, lno, msg, args, exc\_info, func=None, extra=None, sinfo=None*)

This is a factory method which can be overridden in subclasses to create specialized `LogRecord` instances.

**hasHandlers** ()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

在 3.2 版被加入。

在 3.7 版的變更: Loggers can now be pickled and unpickled.

## 16.4.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

Level	Numeric value	What it means / When to use it
<code>logging.NOTSET</code>	0	When set on a logger, indicates that ancestor loggers are to be consulted to determine the effective level. If that still resolves to <code>NOTSET</code> , then all events are logged. When set on a handler, all events are handled.
<code>logging.DEBUG</code>	10	Detailed information, typically only of interest to a developer trying to diagnose a problem.
<code>logging.INFO</code>	20	Confirmation that things are working as expected.
<code>logging.WARNING</code>	30	An indication that something unexpected happened, or that a problem might occur in the near future (e.g. 'disk space low'). The software is still working as expected.
<code>logging.ERROR</code>	40	Due to a more serious problem, the software has not been able to perform some function.
<code>logging.CRITICAL</code>	50	A serious error, indicating that the program itself may be unable to continue running.

### 16.4.3 Handler Objects

Handlers have the following attributes and methods. Note that *Handler* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler*.  
`__init__()`.

**class** logging.**Handler**

**\_\_init\_\_**(*level=NOTSET*)

Initializes the *Handler* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

**createLock**()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

**acquire**()

Acquires the thread lock created with *createLock()*.

**release**()

Releases the thread lock acquired with *acquire()*.

**setLevel**(*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to *NOTSET* (which causes all messages to be processed).

層級清單請見 *Logging Levels*。

在 3.2 版的變更: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as *INFO*.

**setFormatter**(*fmt*)

Sets the formatter for this handler to *fmt*. The *fmt* argument must be a *Formatter* instance or None.

**addFilter**(*filter*)

Adds the specified filter *filter* to this handler.

**removeFilter**(*filter*)

Removes the specified filter *filter* from this handler.

**filter**(*record*)

Apply this handler's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

**flush**()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

**close**()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal map of handlers, which is used for handler lookup by name.

Subclasses should ensure that this gets called from overridden *close()* methods.

**handle**(*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

**handleError**(*record*)

This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute *raiseExceptions* is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you

wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

**format** (*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

**emit** (*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

#### 警告

This method is called after a handler-level lock is acquired, which is released after this method returns. When you override this method, note that you should be careful when calling anything that invokes other parts of the logging API which might do locking, because that might result in a deadlock. Specifically:

- Logging configuration APIs acquire the module-level lock, and then individual handler-level locks as those handlers are configured.
- Many logging APIs lock the module-level lock. If such an API is called from this method, it could cause a deadlock if a configuration call is made on another thread, because that thread will try to acquire the module-level lock *before* the handler-level lock, whereas this thread tries to acquire the module-level lock *after* the handler-level lock (because in this method, the handler-level lock has already been acquired).

For a list of handlers included as standard, see `logging.handlers`.

## 16.4.4 Formatter Objects

**class** `logging.Formatter` (*fmt=None, datefmt=None, style='%', validate=True, \*, defaults=None*)

Responsible for converting a `LogRecord` to an output string to be interpreted by a human or external system.

#### 參數

- **fmt** (*str*) -- A format string in the given *style* for the logged output as a whole. The possible mapping keys are drawn from the `LogRecord` object's `LogRecord` 屬性. If not specified, `'%(message)s'` is used, which is just the logged message.
- **datefmt** (*str*) -- A format string in the given *style* for the date/time portion of the logged output. If not specified, the default described in `formatTime()` is used.
- **style** (*str*) -- Can be one of `'%'`, `'{'` or `'$'` and determines how the format string will be merged with its data: using one of `printf-style String Formatting` (`%`), `str.format()` (`{}`) or `string.Template` (`$`). This only applies to *fmt* and *datefmt* (e.g. `'%(message)s'` versus `'{message}'`), not to the actual log messages passed to the logging methods. However, there are other ways to use `{}`- and `$`-formatting for log messages.
- **validate** (*bool*) -- If `True` (the default), incorrect or mismatched *fmt* and *style* will raise a `ValueError`; for example, `logging.Formatter('%(asctime)s - %(message)s', style='{')`.
- **defaults** (*dict[str, Any]*) -- A dictionary with default values to use in custom fields. For example, `logging.Formatter('%(ip)s %(message)s', defaults={"ip": None})`

在 3.2 版的變更: 新增 *style* 參數。

在 3.8 版的變更: 新增 *validate* 參數。

在 3.10 版的變更: 新增 *defaults* 參數。

**format** (*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using *msg % args*. If the formatting string contains '(asctime)', *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc\_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value (by setting the *exc\_text* attribute to *None*) after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value, but recalculates it afresh.

If stack information is available, it's appended after the exception information, using *formatStack()* to transform it if necessary.

**formatTime** (*record*, *datefmt=None*)

This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format '%Y-%m-%d %H:%M:%S,uuu' is used, where the uuu part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is 2003-01-23 00:29:50,411. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the *converter* attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the *converter* attribute in the *Formatter* class.

在 3.3 版的變更: Previously, the default format was hard-coded as in this example: 2010-09-06 22:38:15,292 where the part before the comma is handled by a strftime format string ('%Y-%m-%d %H:%M:%S'), and the part after the comma is a millisecond value. Because strftime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, '%s, %03d' --- and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are *default\_time\_format* (for the strftime format string) and *default\_msec\_format* (for appending the millisecond value).

在 3.9 版的變更: The *default\_msec\_format* can be *None*.

**formatException** (*exc\_info*)

Formats the specified exception information (a standard exception tuple as returned by *sys.exc\_info()*) as a string. This default implementation just uses *traceback.print\_exception()*. The resulting string is returned.

**formatStack** (*stack\_info*)

Formats the specified stack information (a string as returned by *traceback.print\_stack()*, but with the last newline removed) as a string. This default implementation just returns the input value.

**class** logging.**BufferingFormatter** (*linefmt=None*)

A base formatter class suitable for subclassing when you want to format a number of records. You can pass a *Formatter* instance which you want to use to format each line (that corresponds to a single record). If not specified, the default formatter (which just outputs the event message) is used as the line formatter.

**formatHeader** (*records*)

Return a header for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records, a title or a separator line.

**formatFooter** (*records*)

Return a footer for a list of *records*. The base implementation just returns the empty string. You will need

to override this method if you want specific behaviour, e.g. to show the count of records or a separator line.

**format** (*records*)

Return formatted text for a list of *records*. The base implementation just returns the empty string if there are no records; otherwise, it returns the concatenation of the header, each record formatted with the line formatter, and the footer.

## 16.4.5 Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all events are passed.

**class** `logging.Filter` (*name=""*)

Returns an instance of the `Filter` class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

**filter** (*record*)

Is the specified record to be logged? Returns false for no, true for yes. Filters can either modify log records in-place or return a completely different record instance which will replace the original log record in any future processing of the event.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using `debug()`, `info()`, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

在 3.2 版的變更: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its `filter()` method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by `filter()`.

在 3.12 版的變更: You can now return a `LogRecord` instance from filters to replace the log record rather than modifying it in place. This allows filters attached to a `Handler` to modify the log record before it is emitted, without having side effects on other handlers.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the `LogRecord` being processed. Obviously changing the `LogRecord` needs to be done with some care, but it does allow the injection of contextual information into logs (see `filters-contextual`).

## 16.4.6 LogRecord 物件

`LogRecord` instances are created automatically by the `Logger` every time something is logged, and can be created manually via `makeLogRecord()` (for example, from a pickled event received over the wire).

**class** `logging.LogRecord` (*name, level, pathname, lineno, msg, args, exc\_info, func=None, sinfo=None*)

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the message attribute of the record.

### 參數

- **name** (*str*) -- The name of the logger used to log the event represented by this `LogRecord`. Note that the logger name in the `LogRecord` will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.

- **level** (*int*) -- The *numeric level* of the logging event (such as 10 for DEBUG, 20 for INFO, etc). Note that this is converted to *two* attributes of the `LogRecord`: `levelno` for the numeric value and `levelname` for the corresponding level name.
- **pathname** (*str*) -- The full string path of the source file where the logging call was made.
- **lineno** (*int*) -- The line number in the source file where the logging call was made.
- **msg** (*Any*) -- The event description message, which can be a %-format string with placeholders for variable data, or an arbitrary object (see arbitrary-object-messages).
- **args** (*tuple* / *dict* [*str*, *Any*]) -- Variable data to merge into the `msg` argument to obtain the event description.
- **exc\_info** (*tuple* [*type* [`BaseException`], `BaseException`, *types.TracebackType*] / *None*) -- An exception tuple with the current exception information, as returned by `sys.exc_info()`, or *None* if no exception information is available.
- **func** (*str* / *None*) -- The name of the function or method from which the logging call was invoked.
- **sinfo** (*str* / *None*) -- A text string representing stack information from the base of the stack in the current thread, up to the logging call.

**getMessage()**

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

在 3.2 版的變更: The creation of a `LogRecord` has been made more configurable by providing a factory which is used to create the record. The factory can be set using `getLogRecordFactory()` and `setLogRecordFactory()` (see this for the factory's signature).

This functionality can be used to inject your own values into a `LogRecord` at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

## 16.4.7 LogRecord 屬性

The `LogRecord` has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the `LogRecord` constructor parameters and the `LogRecord` attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (`str.format()`), you can use `{attrname}` as the placeholder in the format string. If you are using \$-formatting (`string.Template`), use the form `${attrname}`. In both cases, of course, replace `attrname` with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of `{msecs:03.0f}` would format a millisecond value of 4 as `004`. Refer to the `str.format()` documentation for full details on the options available to you.

屬性名	格式	描述
args	你不應該需要自己格式化它。	The tuple of arguments merged into <code>msg</code> to produce <code>message</code> , or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	<code>%(asctime)s</code>	Human-readable time when the <code>LogRecord</code> was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).
created	<code>%(created)f</code>	Time when the <code>LogRecord</code> was created (as returned by <code>time.time_ns() / 1e9</code> ).
exc_info	你不應該需要自己格式化它。	Exception tuple (à la <code>sys.exc_info</code> ) or, if no exception has occurred, <code>None</code> .
filename	<code>%(filename)s</code>	<code>pathname</code> 的檔案名稱部分。
funcName	<code>%(funcName)s</code>	Name of function containing the logging call.
levelname	<code>%(levelname)s</code>	Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL').
levelno	<code>%(levelno)s</code>	Numeric logging level for the message ( <code>DEBUG</code> , <code>INFO</code> , <code>WARNING</code> , <code>ERROR</code> , <code>CRITICAL</code> ).
lineno	<code>%(lineno)d</code>	Source line number where the logging call was issued (if available).
message	<code>%(message)s</code>	The logged message, computed as <code>msg % args</code> . This is set when <code>Formatter.format()</code> is invoked.
模組	<code>%(module)s</code>	模組 ( <code>filename</code> 的名稱部分)。
msecs	<code>%(msecs)d</code>	Millisecond portion of the time when the <code>LogRecord</code> was created.
msg	你不應該需要自己格式化它。	The format string passed in the original logging call. Merged with <code>args</code> to produce <code>message</code> , or an arbitrary object (see arbitrary-object-messages).
name	<code>%(name)s</code>	Name of the logger used to log the call.
pathname	<code>%(pathname)s</code>	Full pathname of the source file where the logging call was issued (if available).
process	<code>%(process)d</code>	行程 ID (如果可用)。
processName	<code>%(processName)s</code>	行程名稱 (如果可用)。
relativeCreated	<code>%(relativeCreated)s</code>	Time in milliseconds when the <code>LogRecord</code> was created, relative to the time the logging module was loaded.
stack_info	你不應該需要自己格式化它。	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	<code>%(thread)d</code>	執行緒 ID (如果可用)。
threadName	<code>%(threadName)s</code>	Thread name (if available).
taskName	<code>%(taskName)s</code>	<code>asyncio.Task</code> name (if available).

在 3.1 版的變更: 新增 `processName`。

在 3.12 版的變更: 新增 `taskName`。

## 16.4.8 LoggerAdapter 物件

`LoggerAdapter` instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

**class** `logging.LoggerAdapter` (*logger*, *extra*, *merge\_extra=False*)

Returns an instance of `LoggerAdapter` initialized with an underlying `Logger` instance, a dict-like object (*extra*), and a boolean (*merge\_extra*) indicating whether or not the *extra* argument of individual log calls should be merged with the `LoggerAdapter` *extra*. The default behavior is to ignore the *extra* argument of individual log calls and only use the one of the `LoggerAdapter` instance

**process** (*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

**manager**

Delegates to the underlying manager on *logger*.

**\_log**

Delegates to the underlying `_log()` method on *logger*.

In addition to the above, `LoggerAdapter` supports the following methods of `Logger`: `debug()`, `info()`, `warning()`, `error()`, `exception()`, `critical()`, `log()`, `isEnabledFor()`, `getEffectiveLevel()`, `setLevel()` and `hasHandlers()`. These methods have the same signatures as their counterparts in `Logger`, so you can use the two types of instances interchangeably.

在 3.2 版的變更: The `isEnabledFor()`, `getEffectiveLevel()`, `setLevel()` and `hasHandlers()` methods were added to `LoggerAdapter`. These methods delegate to the underlying logger.

在 3.6 版的變更: Attribute `manager` and method `_log()` were added, which delegate to the underlying logger and allow adapters to be nested.

在 3.13 版的變更: 新增 `merge_extra` 引數。

## 16.4.9 執行緒安全

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the `signal` module, you may not be able to use logging from within such handlers. This is because lock implementations in the `threading` module are not always re-entrant, and so cannot be invoked from such signal handlers.

### 16.4.10 模組層級函式

In addition to the classes described above, there are a number of module-level functions.

`logging.getLogger` (*name=None*)

Return a logger with the specified name or, if *name* is `None`, return the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like 'a', 'a.b' or 'a.b.c.d'. Choice of these names is entirely up to the developer who is using logging, though it is recommended that `__name__` be used unless you have a specific reason for not doing that, as mentioned in `Logger` 物件.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

`logging.getLoggerClass` ()

Return either the standard `Logger` class, or the last class passed to `setLoggerClass()`. This function may be called from within a new class definition, to ensure that installing a customized `Logger` class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... 在這 覆 蓋 其 行
```

`logging.getLoggerFactory()`

Return a callable which is used to create a *LogRecord*.

在 3.2 版被加入: This function has been provided, along with `setLogRecordFactory()`, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See `setLogRecordFactory()` for more information about the how the factory is called.

`logging.debug(msg, *args, **kwargs)`

This is a convenience function that calls `Logger.debug()`, on the root logger. The handling of the arguments is in every way identical to what is described in that method.

The only difference is that if the root logger has no handlers, then `basicConfig()` is called, prior to calling `debug` on the root logger.

For very short scripts or quick demonstrations of logging facilities, `debug` and the other module-level functions may be convenient. However, most programs will want to carefully and explicitly control the logging configuration, and should therefore prefer creating a module-level logger and calling `Logger.debug()` (or other level-specific methods) on it, as described at the beginning of this documentation.

`logging.info(msg, *args, **kwargs)`

Logs a message with level *INFO* on the root logger. The arguments and behavior are otherwise the same as for `debug()`.

`logging.warning(msg, *args, **kwargs)`

Logs a message with level *WARNING* on the root logger. The arguments and behavior are otherwise the same as for `debug()`.

#### 備

There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

`logging.error(msg, *args, **kwargs)`

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for `debug()`.

`logging.critical(msg, *args, **kwargs)`

Logs a message with level *CRITICAL* on the root logger. The arguments and behavior are otherwise the same as for `debug()`.

`logging.exception(msg, *args, **kwargs)`

Logs a message with level *ERROR* on the root logger. The arguments and behavior are otherwise the same as for `debug()`. Exception info is added to the logging message. This function should only be called from an exception handler.

`logging.log(level, msg, *args, **kwargs)`

Logs a message with level *level* on the root logger. The arguments and behavior are otherwise the same as for `debug()`.

`logging.disable(level=CRITICAL)`

Provides an overriding level *level* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *level* and below, so that if you call it with a value of *INFO*, then all *INFO* and *DEBUG* events would be discarded, whereas those of severity *WARNING* and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is

called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the `level` parameter, but will have to explicitly supply a suitable value.

在 3.7 版的變更: The `level` parameter was defaulted to level `CRITICAL`. See [bpo-28524](#) for more information about this change.

`logging.addLevelName` (*level*, *levelName*)

Associates level *level* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a *Formatter* formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

**備 F**

If you are thinking of defining your own levels, please see the section on custom-levels.

`logging.getLevelNamesMapping` ()

Returns a mapping from level names to their corresponding logging levels. For example, the string "CRITICAL" maps to `CRITICAL`. The returned mapping is copied from an internal mapping on each call to this function.

在 3.11 版被加入.

`logging.getLevelName` (*level*)

Returns the textual or numeric representation of logging level *level*.

If *level* is one of the predefined levels `CRITICAL`, `ERROR`, `WARNING`, `INFO` or `DEBUG` then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with *level* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The *level* parameter also accepts a string representation of the level such as 'INFO'. In such cases, this function returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string 'Level %s' % level is returned.

**備 F**

Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see *LogRecord* 屬性), and vice versa.

在 3.4 版的變更: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

`logging.getHandlerByName` (*name*)

Returns a handler with the specified *name*, or `None` if there is no handler with that name.

在 3.12 版被加入.

`logging.getHandlerNames` ()

Returns an immutable set of all known handler names.

在 3.12 版被加入.

`logging.makeLogRecord (attrdict)`

Creates and returns a new `LogRecord` instance whose attributes are defined by `attrdict`. This function is useful for taking a pickled `LogRecord` attribute dictionary, sent over a socket, and reconstituting it as a `LogRecord` instance at the receiving end.

`logging.basicConfig (**kwargs)`

Does basic configuration for the logging system by creating a `StreamHandler` with a default `Formatter` and adding it to the root logger. The functions `debug()`, `info()`, `warning()`, `error()` and `critical()` will call `basicConfig()` automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured, unless the keyword argument `force` is set to `True`.

#### 備 F

This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

支援以下的關鍵字引數。

格式	描述
<code>filename</code>	Specifies that a <code>FileHandler</code> be created, using the specified filename, rather than a <code>StreamHandler</code> .
<code>filemode</code>	If <code>filename</code> is specified, open the file in this <code>mode</code> . Defaults to 'a'.
<code>format</code>	Use the specified format string for the handler. Defaults to attributes <code>levelname</code> , <code>name</code> and <code>message</code> separated by colons.
<code>datefmt</code>	Use the specified date/time format, as accepted by <code>time.strftime()</code> .
<code>style</code>	If <code>format</code> is specified, use this style for the format string. One of '%', '{' or '\$' for <code>printf-style</code> , <code>str.format()</code> or <code>string.Template</code> respectively. Defaults to '%'. Note that this argument is incompatible with <code>filename</code> or <code>stream</code> - if both are present, a <code>ValueError</code> is raised.
<code>level</code>	Set the root logger level to the specified <code>level</code> .
<code>stream</code>	Use the specified stream to initialize the <code>StreamHandler</code> . Note that this argument is incompatible with <code>filename</code> - if both are present, a <code>ValueError</code> is raised.
<code>handlers</code>	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with <code>filename</code> or <code>stream</code> - if both are present, a <code>ValueError</code> is raised.
<code>force</code>	If this keyword argument is specified as <code>true</code> , any existing handlers attached to the root logger are removed and closed, before carrying out the configuration as specified by the other arguments.
<code>encoding</code>	If this keyword argument is specified along with <code>filename</code> , its value is used when the <code>FileHandler</code> is created, and thus used when opening the output file.
<code>errors</code>	If this keyword argument is specified along with <code>filename</code> , its value is used when the <code>FileHandler</code> is created, and thus used when opening the output file. If not specified, the value 'backslashreplace' is used. Note that if <code>None</code> is specified, it will be passed as such to <code>open()</code> , which means that it will be treated the same as passing 'errors'.

在 3.2 版的變更: 新增 `style` 引數。

在 3.3 版的變更: The `handlers` argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. `handlers` together with `stream` or `filename`, or `stream` together with `filename`).

在 3.8 版的變更: 新增 `force` 引數。

在 3.9 版的變更: 新增 `encoding` 與 `errors` 引數。

`logging.shutdown()`

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

When the logging module is imported, it registers this function as an exit handler (see *atexit*), so normally there's no need to do that manually.

`logging.setLoggerClass(klass)`

Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the `logging.getLogger()` API to get your loggers.

`logging.setLogRecordFactory(factory)`

Set a callable which is used to create a *LogRecord*.

#### 參數

**factory** -- The factory callable to be used to instantiate a log record.

在 3.2 版被加入: This function has been provided, along with `getLogRecordFactory()`, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None,
**kwargs)
```

#### name

The logger name.

#### level

The logging level (numeric).

#### fn

The full pathname of the file where the logging call was made.

#### lno

The line number in the file where the logging call was made.

#### msg

The logging message.

#### args

The arguments for the logging message.

#### exc\_info

An exception tuple, or `None`.

#### func

The name of the function or method which invoked the logging call.

#### sinfo

A stack traceback such as is provided by `traceback.print_stack()`, showing the call hierarchy.

#### kwargs

額外的關鍵字引數。

### 16.4.11 模組層級屬性

`logging.lastResort`

A "handler of last resort" is available through this attribute. This is a *StreamHandler* writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that "no

handlers could be found for logger XYZ”. If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

在 3.2 版被加入。

`logging.raiseExceptions`

Used to see if exceptions during handling should be propagated.

Default: `True`.

If `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors.

## 16.4.12 Integration with the warnings module

The `captureWarnings()` function can be used to integrate `logging` with the `warnings` module.

`logging.captureWarnings(capture)`

This function is used to turn the capture of warnings by logging on and off.

If `capture` is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named `'py.warnings'` with a severity of `WARNING`.

If `capture` is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- Logging Cookbook

This section describes the API for configuring the logging module.

## 16.5.1 Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional --- you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An `id` which does not have a corresponding destination.
- A non-existent handler `id` found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

`dictConfig()` calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then `dictConfig()` could be called exactly as in the default, uncustomized state.

在 3.2 版被加入。

`logging.config.fileConfig(fname, defaults=None, disable_existing_loggers=True, encoding=None)`

Reads the logging configuration from a `configparser`-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

It will raise `FileNotFoundError` if the file doesn't exist and `RuntimeError` if the file is invalid or empty.

### 參數

- **fname** -- A filename, or a file-like object, or an instance derived from `RawConfigParser`. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a `ConfigParser` is instantiated, and the configuration read by it from the object passed in `fname`. If that has a `readline()` method, it is assumed to be a file-like object and read using `read_file()`; otherwise, it is assumed to be a filename and passed to `read()`.
- **defaults** -- Defaults to be passed to the `ConfigParser` can be specified in this argument.
- **disable\_existing\_loggers** -- If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in

a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.

- **encoding** -- The encoding used to open file when *fname* is filename.

在 3.4 版的變更: An instance of a subclass of `RawConfigParser` is now accepted as a value for *fname*. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

在 3.10 版的變更: Added the *encoding* parameter.

在 3.12 版的變更: An exception will be thrown if the provided file doesn't exist or is invalid or empty.

`logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT, verify=None)`

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `dictConfig()` or `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

#### 備 F

Because portions of the configuration are passed through `eval()`, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls `listen()`. Specifically, if the process calling `listen()` runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's `listen()` socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to `listen()` to prevent unrecognised configurations from being applied.

在 3.4 版的變更: 新增 `verify` 引數。

#### 備 F

If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use `dictConfig()` for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

`logging.config.stopListening()`

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.

## 16.5.2 Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in *User-defined objects*. However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

## 16.5.3 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

### Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special '()' key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding `Formatter` instance.

The configuring dict is searched for the following optional keys which correspond to the arguments passed to create a `Formatter` object:

- `format`
- `datefmt`
- `style`
- `validate` (since version >=3.8)
- `defaults` (since version >=3.12)

An optional `class` key indicates the name of the formatter's class (as a dotted module and class name). The instantiation arguments are as for `Formatter`, thus this key is most useful for instantiating a customised subclass of `Formatter`. For example, the alternative class might present exception tracebacks in an expanded or condensed format. If your formatter requires different or extra configuration keys, you should use *User-defined objects*.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding `Filter` instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a `logging.Filter` instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding `Handler` instance.

The configuring dict is searched for the following keys:

- `class` (mandatory). This is the fully qualified name of the handler class.
- `level` (optional). The level of the handler.
- `formatter` (optional). The id of the formatter for this handler.

- `filters` (optional). A list of ids of the filters for this handler.

在 3.11 版的變更: `filters` can take filter instances in addition to ids.

All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level : INFO
    filters: [allow_foo]
    stream : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

the handler with id `console` is instantiated as a `logging.StreamHandler`, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a `logging.handlers.RotatingFileHandler` with the keyword arguments `filename='logconfig.log'`, `maxBytes=1024`, `backupCount=3`.

- `loggers` - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

The configuring dict is searched for the following keys:

- `level` (optional). The level of the logger.
- `propagate` (optional). The propagation setting of the logger.
- `filters` (optional). A list of ids of the filters for this logger.  
在 3.11 版的變更: `filters` can take filter instances in addition to ids.
- `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- `root` - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- `incremental` - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing `fileConfig()` API.

If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.

- `disable_existing_loggers` - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if `incremental` is `True`.

## Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is

problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

## Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
    # configuration of handler with id 'h1' goes here
    formatter: brief
  h2: #This is another id
    # configuration of handler with id 'h2' goes here
    formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

## User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a 'factory' - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here's a concrete example:

```

formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
    (): my.package.customFormatterFactory
    bar: baz
    spam: 99.9
    answer: 42

```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

和:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key `()`, the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key `()`, which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

### 警告

The values for keys such as `bar`, `spam` and `answer` in the above example should not be configuration dictionaries or references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but passed to the callable as-is.

The key `()` has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The `()` also serves as a mnemonic that the corresponding value is a callable.

在 3.11 版的變更: The `filters` member of `handlers` and `loggers` can take filter instances in addition to ids.

You can also specify a special key `'.'` whose value is a dictionary is a mapping of attribute names to values. If found, the specified attributes will be set on the user-defined object before it is returned. Thus, with the following configuration:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42,
  '.' : {
    'foo': 'bar',
    'baz': 'bozz'
  }
}
```

the returned formatter will have attribute `foo` set to `'bar'` and attribute `baz` set to `'bozz'`.

### 警告

The values for attributes such as `foo` and `baz` in the above example should not be configuration dictionaries or references such as `cfg://foo` or `ext://bar`, because they will not be processed by the configuration machinery, but set as attribute values as-is.

## Handler configuration order

Handlers are configured in alphabetical order of their keys, and a configured handler replaces the configuration dictionary in (a working copy of) the `handlers` dictionary in the schema. If you use a construct such as `cfg://handlers.foo`, then initially `handlers['foo']` points to the configuration dictionary for the handler named `foo`, and later (once that handler has been configured) it points to the configured handler instance. Thus, `cfg://handlers.foo` could resolve to either a dictionary or a handler instance. In general, it is wise to name handlers in a way such that dependent handlers are configured `_after_` any handlers they depend on; that allows something like `cfg://handlers.foo` to be used in configuring a handler that depends on handler `foo`. If that dependent handler were named `bar`, problems would result, because the configuration of `bar` would be attempted before that of `foo`, and `foo` would not yet have been configured. However, if the dependent handler were named `foobar`, it would be configured after `foo`, with the result that `cfg://handlers.foo` would resolve to configured handler `foo`, and not its configuration dictionary.

## Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://(?P<suffix>.*)*$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

## Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a level in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the `logging` module. For example, consider `logging.handlers.MemoryHandler`, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email'` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]'` would resolve to `'dev_team@domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. Please note that the characters `[` and `]` are not allowed in the keys. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

### Import resolution and custom importers

Import resolution, by default, uses the builtin `__import__()` function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the `importer` attribute of the `DictConfigurator` or its superclass, the `BaseConfigurator` class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with `staticmethod()`. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with `staticmethod()` if you're setting the import callable on a configurator *instance*.

## Configuring QueueHandler and QueueListener

If you want to configure a `QueueHandler`, noting that this is normally used in conjunction with a `QueueListener`, you can configure both together. After the configuration, the `QueueListener` instance will be available as the `listener` attribute of the created handler, and that in turn will be available to you using `getHandlerByName()` and passing the name you have used for the `QueueHandler` in your configuration. The dictionary schema for configuring the pair is shown in the example YAML snippet below.

```
handlers:
  qhand:
    class: logging.handlers.QueueHandler
    queue: my.module.queue_factory
    listener: my.package.CustomListener
    handlers:
      - hand_name_1
      - hand_name_2
      ...
```

The `queue` and `listener` keys are optional.

If the `queue` key is present, the corresponding value can be one of the following:

- An object implementing the `Queue.put_nowait` and `Queue.get` public API. For instance, this may be an actual instance of `queue.Queue` or a subclass thereof, or a proxy obtained by `multiprocessing.managers.SyncManager.Queue()`.

This is of course only possible if you are constructing or modifying the configuration dictionary in code.

- A string that resolves to a callable which, when called with no arguments, returns the queue instance to use. That callable could be a `queue.Queue` subclass or a function which returns a suitable queue instance, such as `my.module.queue_factory()`.
- A dict with a `()` key which is constructed in the usual way as discussed in *User-defined objects*. The result of this construction should be a `queue.Queue` instance.

If the `queue` key is absent, a standard unbounded `queue.Queue` instance is created and used.

If the `listener` key is present, the corresponding value can be one of the following:

- A subclass of `logging.handlers.QueueListener`. This is of course only possible if you are constructing or modifying the configuration dictionary in code.
- A string which resolves to a class which is a subclass of `QueueListener`, such as `'my.package.CustomListener'`.
- A dict with a `()` key which is constructed in the usual way as discussed in *User-defined objects*. The result of this construction should be a callable with the same signature as the `QueueListener` initializer.

If the `listener` key is absent, `logging.handlers.QueueListener` is used.

The values under the `handlers` key are the names of other handlers in the configuration (not shown in the above snippet) which will be passed to the queue listener.

Any custom queue handler and listener classes will need to be defined with the same initialization signatures as `QueueHandler` and `QueueListener`.

在 3.12 版被加入。

## 16.5.4 Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]`

section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

**i 備F**

The `fileConfig()` API is older than the `dictConfig()` API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure `Filter` objects, which provide for filtering of messages beyond simple integer levels, using `fileConfig()`. If you need to have instances of `Filter` in your logging configuration, you will need to use `dictConfig()`. Note that future enhancements to configuration functionality will be added to `dictConfig()`, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *evaluated* in the context of the logging package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by `eval()` in the logging package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when *evaluated* in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when *evaluated* in the context of the `logging` package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to `{}`.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args=('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')
kwargs={'timeout': 10.0}

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s %(customfield)s
datefmt=
style=%
validate=True
defaults={'customfield': 'defaultvalue'}
class=logging.Formatter
```

The arguments for the formatter configuration are the same as the keys in the dictionary schema *formatters section*.

The `defaults` entry, when *evaluated* in the context of the `logging` package's namespace, is a dictionary of default values for custom formatting fields. If not provided, it defaults to `None`.

### 備

Due to the use of `eval()` as described above, there are potential security risks which result from using the `listen()` to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the `listen()` documentation for more information.

Useful handlers included with the logging module.

## 16.6 logging.handlers --- 日 紀 處理器

原始碼: `Lib/logging/handlers.py`

### Important

This page contains only reference information. For tutorials, please see

- 基礎教學
- 進階教學
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (`StreamHandler`, `FileHandler` and `NullHandler`) are actually defined in the `logging` module itself, but have been documented here along with the other handlers.

### 16.6.1 StreamHandler

The `StreamHandler` class, located in the core `logging` package, sends logging output to streams such as `sys.stdout`, `sys.stderr` or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

**class** `logging.StreamHandler` (*stream=None*)

Returns a new instance of the `StreamHandler` class. If *stream* is specified, the instance will use it for logging output; otherwise, `sys.stderr` will be used.

**emit** (*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream followed by *terminator*. If exception information is present, it is formatted using *traceback.print\_exception()* and appended to the stream.

**flush** ()

Flushes the stream by calling its *flush()* method. Note that the *close()* method is inherited from *Handler* and so does no output, so an explicit *flush()* call may be needed at times.

**setStream** (*stream*)

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

參數

**stream** -- The stream that the handler should use.

回傳

the old stream, if the stream was changed, or *None* if it wasn't.

在 3.7 版被加入。

**terminator**

String used as the terminator when writing a formatted record to a stream. Default value is '\n'.

If you don't want a newline termination, you can set the handler instance's *terminator* attribute to the empty string.

In earlier versions, the terminator was hardcoded as '\n'.

在 3.2 版被加入。

## 16.6.2 FileHandler

The *FileHandler* class, located in the core *logging* package, sends logging output to a disk file. It inherits the output functionality from *StreamHandler*.

**class** logging.**FileHandler** (*filename, mode='a', encoding=None, delay=False, errors=None*)

Returns a new instance of the *FileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, 'a' is used. If *encoding* is not *None*, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely. If *errors* is specified, it's used to determine how encoding errors are handled.

在 3.6 版的變更: As well as string values, *Path* objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

**close** ()

Closes the file.

**emit** (*record*)

Outputs the record to the file.

Note that if the file was closed due to logging shutdown at exit and the file mode is 'w', the record will not be emitted (see [bpo-42378](#)).

## 16.6.3 NullHandler

在 3.1 版被加入。

The *NullHandler* class, located in the core *logging* package, does not do any formatting or output. It is essentially a 'no-op' handler for use by library developers.

**class** logging.**NullHandler**

Returns a new instance of the *NullHandler* class.

**emit** (*record*)

This method does nothing.

**handle** (*record*)

This method does nothing.

**createLock** ()

This method returns `None` for the lock, since there is no underlying I/O to which access needs to be serialized.

See `library-config` for more information on how to use `NullHandler`.

## 16.6.4 WatchedFileHandler

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

```
class logging.handlers.WatchedFileHandler (filename, mode='a', encoding=None, delay=False,
                                           errors=None)
```

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If `errors` is provided, it determines how encoding errors are handled.

在 3.6 版的變更: As well as string values, `Path` objects are also accepted for the `filename` argument.

在 3.9 版的變更: 新增 `errors` 參數。

**reopenIfNeeded** ()

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

在 3.6 版被加入。

**emit** (*record*)

Outputs the record to the file, but first calls `reopenIfNeeded()` to reopen the file if it has changed.

## 16.6.5 BaseRotatingHandler

The `BaseRotatingHandler` class, located in the `logging.handlers` module, is the base class for the rotating file handlers, `RotatingFileHandler` and `TimedRotatingFileHandler`. You should not need to instantiate this class, but it has attributes and methods you may need to override.

```
class logging.handlers.BaseRotatingHandler (filename, mode, encoding=None, delay=False,
                                           errors=None)
```

The parameters are as for `FileHandler`. The attributes are:

**namer**

If this attribute is set to a callable, the `rotation_filename()` method delegates to this callable. The parameters passed to the callable are those passed to `rotation_filename()`.

**i** 備 F

The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

It's also worth noting that care should be taken when using a namer to preserve certain attributes in the filename which are used during rotation. For example, `RotatingFileHandler` expects to have a set of log files whose names contain successive integers, so that rotation works as expected, and `TimedRotatingFileHandler` deletes old log files (based on the `backupCount` parameter passed to the handler's initializer) by determining the oldest files to delete. For this to happen, the filenames should be sortable using the date/time portion of the filename, and a namer needs to respect this. (If a namer is wanted that doesn't respect this scheme, it will need to be used in a subclass of `TimedRotatingFileHandler` which overrides the `getFilesToDelete()` method to fit in with the custom naming scheme.)

在 3.3 版被加入.

**rotator**

If this attribute is set to a callable, the `rotate()` method delegates to this callable. The parameters passed to the callable are those passed to `rotate()`.

在 3.3 版被加入.

**rotation\_filename** (*default\_name*)

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the 'namer' attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is `None`), the name is returned unchanged.

**參數**

**default\_name** -- The default name for the log file.

在 3.3 版被加入.

**rotate** (*source*, *dest*)

When rotating, rotate the current log.

The default implementation calls the 'rotator' attribute of the handler, if it's callable, passing the source and dest arguments to it. If the attribute isn't callable (the default is `None`), the source is simply renamed to the destination.

**參數**

- **source** -- The source filename. This is normally the base filename, e.g. 'test.log'.
- **dest** -- The destination filename. This is normally what the source is rotated to, e.g. 'test.log.1'.

在 3.3 版被加入.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of `RotatingFileHandler` and `TimedRotatingFileHandler`. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an `emit()` call, i.e. via the `handleError()` method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see `cookbook-rotator-namer`.

## 16.6.6 RotatingFileHandler

The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

```
class logging.handlers.RotatingFileHandler (filename, mode='a', maxBytes=0, backupCount=0,
                                             encoding=None, delay=False, errors=None)
```

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely. If `errors` is provided, it determines how encoding errors are handled.

You can use the `maxBytes` and `backupCount` values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly `maxBytes` in length; but if either of `maxBytes` or `backupCount` is zero, rollover never occurs, so you generally want to set `backupCount` to at least 1, and have a non-zero `maxBytes`. When `backupCount` is non-zero, the system will save old log files by appending the extensions '.1', '.2' etc., to the filename. For example, with a `backupCount` of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

在 3.6 版的變更: As well as string values, `Path` objects are also accepted for the `filename` argument.

在 3.9 版的變更: 新增 `errors` 參數。

**doRollover()**

Does a rollover, as described above.

**emit(record)**

Outputs the record to the file, catering for rollover as described previously.

## 16.6.7 TimedRotatingFileHandler

The `TimedRotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files at certain timed intervals.

```
class logging.handlers.TimedRotatingFileHandler (filename, when='h', interval=1, backupCount=0,
                                             encoding=None, delay=False, utc=False,
                                             atTime=None, errors=None)
```

Returns a new instance of the `TimedRotatingFileHandler` class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of `when` and `interval`.

You can use the `when` to specify the type of `interval`. The list of possible values is below. Note that they are not case sensitive.

Value	Type of interval	If/how <code>atTime</code> is used
'S'	Seconds	Ignored
'M'	Minutes	Ignored
'H'	Hours	Ignored
'D'	Days	Ignored
'W0'-'W6'	Weekday (0=Monday)	Used to compute initial rollover time
'midnight'	Roll over at midnight, if <code>atTime</code> not specified, else at time <code>atTime</code>	Used to compute initial rollover time

When using weekday-based rotation, specify 'W0' for Monday, 'W1' for Tuesday, and so on up to 'W6' for Sunday. In this case, the value passed for `interval` isn't used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to *emit()*.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen "at midnight" or "on a particular weekday". Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal interval calculation.

If *errors* is specified, it's used to determine how encoding errors are handled.

#### 備F

Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of "every minute" is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

在 3.4 版的變更: 新增 *atTime* 參數。

在 3.6 版的變更: As well as string values, *Path* objects are also accepted for the *filename* argument.

在 3.9 版的變更: 新增 *errors* 參數。

**doRollover()**

Does a rollover, as described above.

**emit(record)**

Outputs the record to the file, catering for rollover as described above.

**getFilesToDelete()**

Returns a list of filenames which should be deleted as part of rollover. These are the absolute paths of the oldest backup log files written by the handler.

## 16.6.8 SocketHandler

The *SocketHandler* class, located in the *logging.handlers* module, sends logging output to a network socket. The base class uses a TCP socket.

**class** `logging.handlers.SocketHandler(host, port)`

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

在 3.4 版的變更: If *port* is specified as `None`, a Unix domain socket is created using the value in *host* - otherwise, a TCP socket is created.

**close()**

Closes the socket.

**emit()**

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

**handleError()**

Handles an error which has occurred during *emit()*. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

**makeSocket()**

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (*socket.SOCK\_STREAM*).

**makePickle(record)**

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket. The details of this operation are equivalent to:

```
data = pickle.dumps(record_attr_dict, 1)
datalen = struct.pack('>L', len(data))
return datalen + data
```

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

**send(packet)**

Send a pickled byte-string *packet* to the socket. The format of the sent byte-string is as described in the documentation for *makePickle()*.

This function allows for partial sends, which can happen when the network is busy.

**createSocket()**

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- *retryStart* (initial delay, defaulting to 1.0 seconds).
- *retryFactor* (multiplier, defaulting to 2.0).
- *retryMax* (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

## 16.6.9 DatagramHandler

The *DatagramHandler* class, located in the *logging.handlers* module, inherits from *SocketHandler* to support sending logging messages over UDP sockets.

**class logging.handlers.DatagramHandler(host, port)**

Returns a new instance of the *DatagramHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

**備**

As UDP is not a streaming protocol, there is no persistent connection between an instance of this handler and *host*. For this reason, when using a network socket, a DNS lookup might have to be made each time an event is logged, which can introduce some latency into the system. If this affects you, you can do a lookup yourself and initialize this handler using the looked-up IP address rather than the hostname.

在 3.4 版的變更: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a UDP socket is created.

**emit()**

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

**makeSocket()**

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK\_DGRAM*).

**send(s)**

Send a pickled byte-string to a socket. The format of the sent byte-string is as described in the documentation for *SocketHandler.makePickle()*.

## 16.6.10 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

```
class logging.handlers.SysLogHandler (address=('localhost', SYSLOG_UDP_PORT),
                                       facility=LOG_USER, socktype=socket.SOCK_DGRAM)
```

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a (*host*, *port*) tuple. If *address* is not specified, ('localhost', 514) is used. The address is used to open a socket. An alternative to providing a (*host*, *port*) tuple is providing an address as a string, for example '/dev/log'. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, LOG\_USER is used. The type of socket opened depends on the *socktype* argument, which defaults to *socket.SOCK\_DGRAM* and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of *socket.SOCK\_STREAM*.

Note that if your server is not listening on UDP port 514, *SysLogHandler* may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually '/dev/log' but on OS/X it's '/var/run/syslog'. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

**備**

On macOS 12.x (Monterey), Apple has changed the behaviour of their syslog daemon - it no longer listens on a domain socket. Therefore, you cannot expect *SysLogHandler* to work on this system.

See [gh-91070](https://github.com/python/cpython/issues/91070) for more information.

在 3.2 版的變更: 新增 *socktype*。

**close()**

Closes the socket to the remote host.

**createSocket ()**

Tries to create a socket and, if it's not a datagram socket, connect it to the other end. This method is called during handler initialization, but it's not regarded as an error if the other end isn't listening at this point - the method will be called again when emitting an event, if there is no socket at that point.

在 3.11 版被加入。

**emit (record)**

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

在 3.2.1 版的變更: (See: [bpo-12168](#).) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification ([RFC 5424](#)). More recent versions of these daemons don't expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

在 3.3 版的變更: (See: [bpo-12419](#).) In earlier versions, there was no facility for an "ident" or "tag" prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to "" to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident must be text, not bytes, and is prepended to the message exactly as is.

**encodePriority (facility, priority)**

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in `SysLogHandler` and mirror the values defined in the `sys/syslog.h` header file.

**Priorities**

Name (string)	Symbolic value
alert	LOG_ALERT
crit 或 critical	LOG_CRIT
debug	LOG_DEBUG
emerg 或 panic	LOG_EMERG
err 或 error	LOG_ERR
info	LOG_INFO
notice	LOG_NOTICE
warn 或 warning	LOG_WARNING

**Facilities**

Name (string)	Symbolic value
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP
local0	LOG_LOCAL0
local1	LOG_LOCAL1
local2	LOG_LOCAL2
local3	LOG_LOCAL3
local4	LOG_LOCAL4
local5	LOG_LOCAL5
local6	LOG_LOCAL6
local7	LOG_LOCAL7

#### **mapPriority** (*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to 'warning'.

### 16.6.11 NTEventLogHandler

The `NTEventLogHandler` class, located in the `logging.handlers` module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

**class** `logging.handlers.NTEventLogHandler` (*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the `NTEventLogHandler` class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

**close** ()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

**emit** (*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

**getEventCategory** (*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

**getEventType** (*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's `typemap` attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's `typemap` attribute.

**getMessageID** (*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the `msg` passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

## 16.6.12 SMTPHandler

The `SMTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

```
class logging.handlers.SMTPHandler (mailhost, fromaddr, toaddrs, subject, credentials=None,
                                     secure=None, timeout=1.0)
```

Returns a new instance of the `SMTPHandler` class. The instance is initialized with the from and to addresses and subject line of the email. The `toaddrs` should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the `mailhost` argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the `credentials` argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the `secure` argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the `smtpplib.SMTP.starttls()` method.)

A timeout can be specified for communication with the SMTP server using the `timeout` argument.

在 3.3 版的變更: 新增 `timeout` 參數。

**emit** (*record*)

Formats the record and sends it to the specified addressees.

**getSubject** (*record*)

If you want to specify a subject line which is record-dependent, override this method.

## 16.6.13 MemoryHandler

The `MemoryHandler` class, located in the `logging.handlers` module, supports buffering of logging records in memory, periodically flushing them to a `target` handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

`MemoryHandler` is a subclass of the more general `BufferingHandler`, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

```
class logging.handlers.BufferingHandler (capacity)
```

Initializes the handler with a buffer of the specified capacity. Here, `capacity` means the number of logging records buffered.

**emit** (*record*)

Append the record to the buffer. If `shouldFlush()` returns true, call `flush()` to process the buffer.

**flush** ()

For a `BufferingHandler` instance, flushing means that it sets the buffer to an empty list. This method can be overwritten to implement more useful flushing behavior.

**shouldFlush** (*record*)

Return `True` if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

**class** `logging.handlers.MemoryHandler` (*capacity*, *flushLevel=ERROR*, *target=None*, *flushOnClose=True*)

Returns a new instance of the `MemoryHandler` class. The instance is initialized with a buffer size of *capacity* (number of records buffered). If *flushLevel* is not specified, `ERROR` is used. If no *target* is specified, the target will need to be set using `setTarget()` before this handler does anything useful. If *flushOnClose* is specified as `False`, then the buffer is *not* flushed when the handler is closed. If not specified or specified as `True`, the previous behaviour of flushing the buffer will occur when the handler is closed.

在 3.6 版的變更: 新增 *flushOnClose* 參數。

**close** ()

Calls `flush()`, sets the target to `None` and clears the buffer.

**flush** ()

For a `MemoryHandler` instance, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when buffered records are sent to the target. Override if you want different behavior.

**setTarget** (*target*)

Sets the target handler for this handler.

**shouldFlush** (*record*)

Checks for buffer full or a record at the *flushLevel* or higher.

## 16.6.14 HTTPHandler

The `HTTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to a web server, using either GET or POST semantics.

**class** `logging.handlers.HTTPHandler` (*host*, *url*, *method='GET'*, *secure=False*, *credentials=None*, *context=None*)

Returns a new instance of the `HTTPHandler` class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, `GET` is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a `ssl.SSLContext` instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify credentials, you should also specify *secure=True* so that your userid and password are not passed in cleartext across the wire.

在 3.5 版的變更: 新增 *context* 參數。

**mapLogRecord** (*record*)

Provides a dictionary, based on *record*, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of `LogRecord` is to be sent to the web server, or if more specific customization of what's sent to the server is required.

**emit** (*record*)

Sends the record to the web server as a URL-encoded dictionary. The `mapLogRecord()` method is used to convert the record to the dictionary to be sent.

### 備 F

Since preparing a record for sending it to a web server is not the same as a generic formatting operation, using `setFormatter()` to specify a `Formatter` for a `HTTPHandler` has no effect. Instead of calling `format()`, this handler calls `mapLogRecord()` and then `urllib.parse.urlencode()` to encode the dictionary in a form suitable for sending to a web server.

### 16.6.15 QueueHandler

在 3.2 版被加入。

The `QueueHandler` class, located in the `logging.handlers` module, supports sending logging messages to a queue, such as those implemented in the `queue` or `multiprocessing` modules.

Along with the `QueueListener` class, `QueueHandler` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

**class** `logging.handlers.QueueHandler(queue)`

Returns a new instance of the `QueueHandler` class. The instance is initialized with the queue to send messages to. The `queue` can be any queue-like object; it's used as-is by the `enqueue()` method, which needs to know how to send messages to it. The queue is not *required* to have the task tracking API, which means that you can use `SimpleQueue` instances for `queue`.

#### 備 F

If you are using `multiprocessing`, you should avoid using `SimpleQueue` and instead use `multiprocessing.Queue`.

**emit(record)**

Enqueues the result of preparing the `LogRecord`. Should an exception occur (e.g. because a bounded queue has filled up), the `handleError()` method is called to handle the error. This can result in the record silently being dropped (if `logging.raiseExceptions` is `False`) or a message printed to `sys.stderr` (if `logging.raiseExceptions` is `True`).

**prepare(record)**

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message, arguments, exception and stack information, if present. It also removes unpickleable items from the record in-place. Specifically, it overwrites the record's `msg` and `message` attributes with the merged message (obtained by calling the handler's `format()` method), and sets the `args`, `exc_info` and `exc_text` attributes to `None`.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

#### 備 F

The base implementation formats the message with arguments, sets the `message` and `msg` attributes to the formatted message and sets the `args` and `exc_text` attributes to `None` to allow pickling and to prevent further attempts at formatting. This means that a handler on the `QueueListener` side won't have the information to do custom formatting, e.g. of exceptions. You may wish to subclass `QueueHandler` and override this method to e.g. avoid setting `exc_text` to `None`. Note that the `message / msg / args` changes are related to ensuring the record is pickleable, and you might or might not be able to avoid doing that depending on whether your `args` are pickleable. (Note that you may have to consider not only your own code but also code in any libraries that you use.)

**enqueue(record)**

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

**listener**

When created via configuration using `dictConfig()`, this attribute will contain a `QueueListener` instance for use with this handler. Otherwise, it will be `None`.

在 3.12 版被加入。

## 16.6.16 QueueListener

在 3.2 版被加入。

The `QueueListener` class, located in the `logging.handlers` module, supports receiving logging messages from a queue, such as those implemented in the `queue` or `multiprocessing` modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While `QueueListener` is not itself a handler, it is documented here because it works hand-in-hand with `QueueHandler`.

Along with the `QueueHandler` class, `QueueListener` can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via `SMTPHandler`) are done on a separate thread.

**class** `logging.handlers.QueueListener` (*queue*, *\*handlers*, *respect\_handler\_level=False*)

Returns a new instance of the `QueueListener` class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the `dequeue()` method, which needs to know how to get messages from it. The queue is not *required* to have the task tracking API (though it's used if available), which means that you can use `SimpleQueue` instances for *queue*.

### 備 F

If you are using `multiprocessing`, you should avoid using `SimpleQueue` and instead use `multiprocessing.Queue`.

If `respect_handler_level` is `True`, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

在 3.5 版的變更: 新增 `respect_handler_level` 引數。

**dequeue** (*block*)

Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

**prepare** (*record*)

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

**handle** (*record*)

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from `prepare()`.

**start** ()

Starts the listener.

This starts up a background thread to monitor the queue for `LogRecords` to process.

**stop** ()

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

`enqueue_sentinel()`

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

在 3.3 版被加入。

Configuration API for the logging module.

## 16.7 platform --- 對底層平台識 資料的存取

原始碼: `Lib/platform.py`

### 備

特定平臺清單按字母順序排列，Linux 包括在 Unix 小節之中。

### 16.7.1 跨平台

`platform.architecture(executable=sys.executable, bits="", linkage="")`

查詢給定的可執行檔案（預設 Python 直譯器二進位制檔案）來獲取各種架構資訊。

回傳一個 tuple（元組）(bits, linkage)，其中包含可執行檔案所使用的位元架構和連結格式資訊。這兩個值均以字串形式回傳。

無法確定的值將回傳參數所給定之預先設置值。如果給定的位元 `''`，則會使用 `sizeof(pointer)`（或者當 Python 版本 `< 1.5.2` 時 `sizeof(long)`）作所支援指標大小的指示器 (indicator)。

此函式依賴於系統的 `file` 命令來執行實際的操作。這在幾乎所有 Unix 平臺和某些非 Unix 平臺上，只有當可執行檔案指向 Python 直譯器時才可使用。當以上要求不滿足時將會使用合理的預設值。

### 備

在 macOS（也許還有其他平臺）上，可執行檔案可能是包含多種架構的通用檔案。

要獲取當前直譯器的“64 位元性 (64-bitness)”，更可靠的做法是查詢 `sys.maxsize` 屬性：

```
is_64bits = sys.maxsize > 2**32
```

`platform.machine()`

回傳機器種類，例如 `'AMD64'`。如果該值無法確定則會回傳一個空字串。

`platform.node()`

回傳電腦的網路名稱（可能不是完整名稱!）。如果該值無法確定則會回傳一個空字串。

`platform.platform(aliased=False, terse=False)`

會可能附帶有用資訊地回傳一個標識底層平臺的字串。

輸出應人類易讀的 (human readable)，而非機器易剖析的 (machine parseable)。它在不同平臺上看起來可能不一致，這是有意之的。

如果 `aliased` 為真值，此函式將使用各種不同於平臺通用名稱之名稱來回報系統名稱，例如 SunOS 將被回報為 Solaris。`system_alias()` 函式被用於實作此功能。

將 `terse` 設為真值將導致此函式只回傳標識平臺所需的最小量資訊。

在 3.8 版的變更：在 macOS 上，如果 `mac_ver()` 回傳的釋出版字串非空字串，此函式現在會使用它以獲取 macOS 版本而非 darwin 版本。

`platform.processor()`

回傳（真實的）處理器名稱，例如 'amd64'。

如果該值無法確定則將回傳空字串。請注意，許多平臺都不提供此資訊或是簡單地回傳與 `machine()` 相同的值。NetBSD 則會提供此資訊。

`platform.python_build()`

回傳一個 tuple (buildno, builddate)，表示字串形式的 Python 建置編號和日期。

`platform.python_compiler()`

回傳一個標識用於編譯 Python 的編譯器的字串。

`platform.python_branch()`

回傳一個標識 Python 實作 SCM 分支的字串。

`platform.python_implementation()`

回傳一個標識 Python 實作的字串。可能的回傳值有：'CPython'、'IronPython'、'Jython'、'PyPy'。

`platform.python_revision()`

回傳一個標識 Python 實作 SCM 修訂版的字串。

`platform.python_version()`

將 Python 版本以字串 'major.minor.patchlevel' 形式回傳。

請注意此回傳值不同於 Python `sys.version`，它總是會包括 patchlevel（預設為 '0'）。

`platform.python_version_tuple()`

將 Python 版本以字串 tuple (major, minor, patchlevel) 形式回傳。

請注意此回傳值不同於 Python `sys.version`，它總是會包括 patchlevel（預設為 '0'）。

`platform.release()`

回傳系統的釋出版本，例如 '2.2.0' 或 'NT'，如果該值無法確定則將回傳一個空字串。

`platform.system()`

回傳系統/OS 的名稱，例如 'Linux'、'Darwin'、'Java'、'Windows'。如果該值無法確定則回傳一個空字串。

On iOS and Android, this returns the user-facing OS name (i.e. 'iOS', 'iPadOS' or 'Android'). To obtain the kernel name ('Darwin' or 'Linux'), use `os.uname()`.

`platform.system_alias(system, release, version)`

回傳做某些系統所使用的常見行銷名稱之名稱的 (system, release, version)。它還會在可能導致混淆的情況下對資訊進行一些重新排序。

`platform.version()`

回傳系統的釋出版本資訊，例如 '#3 on degas'。如果該值無法確定則將回傳一個空字串。

On iOS and Android, this is the user-facing OS version. To obtain the Darwin or Linux kernel version, use `os.uname()`.

`platform.uname()`

具有高可攜性 (portable) 的 `uname` 介面。回傳包含六個屬性的 `namedtuple()`：system、node、release、version、machine 和 processor。

`processor` 會延遲解析，有需求時才會解析

注意：前兩個屬性名稱與 `os.uname()` 提供的名稱不同，它們分別命名為 `sysname` 和 `nodename`。

無法確定的條目會被設 `''`。

在 3.3 版的變更: 將結果從 `tuple` 改 `namedtuple()`。

在 3.9 版的變更: `processor` 會延遲解析, 非立即解析。

## 16.7.2 Java 平台

```
platform.java_ver (release=", vendor=", vminfo=(", ", ), osinfo=(", ", ))
```

Jython 的版本介面。

回傳一個 `tuple` (`release`, `vendor`, `vminfo`, `osinfo`), 其中 `vminfo` 是 `tuple` (`vm_name`, `vm_release`, `vm_vendor`) 而 `osinfo` 是 `tuple` (`os_name`, `os_version`, `os_arch`)。無法確定的值將被設由參數所給定的預設值 (預設均 `''`)。

Deprecated since version 3.13, will be removed in version 3.15: It was largely untested, had a confusing API, and was only useful for Jython support.

## 16.7.3 Windows 平台

```
platform.win32_ver (release=", version=", csd=", ptype=")
```

從 Windows 登錄檔 (Window Registry) 獲取額外的版本資訊回傳一個 `tuple` (`release`, `version`, `csd`, `ptype`), 它代表 OS 發行版、版本號、CSD 級 (service pack) 和 OS 類型 (多個/單個處理器)。

一點提示: `ptype` 在單個處理器的 NT 機器上 `'Uniprocessor Free'`, 而在多個處理器的機器上 `'Multiprocessor Free'`。'Free' 是指該 OS 版本有除錯程式。它也可能以 `'Checked'` 表示, 代表該 OS 版本使用了除錯程式, 即檢查引數、範圍等的程式。

```
platform.win32_edition()
```

回傳一個代表當前 Windows 版本的字串。可能的值包括但不限於 `'Enterprise'`、`'IoTUAP'`、`'ServerStandard'` 和 `'nanoserver'`。

在 3.8 版被加入。

```
platform.win32_is_iot()
```

如果 `win32_edition()` 回傳的 Windows 版本被識 IoT 版則回傳 `True`。

在 3.8 版被加入。

## 16.7.4 macOS 平台

```
platform.mac_ver (release=", versioninfo=(", ", ), machine=")
```

獲取 Mac OS 版本資訊將其回傳 `tuple` (`release`, `versioninfo`, `machine`), 其中 `versioninfo` 是一個 `tuple` (`version`, `dev_stage`, `non_release_version`)。

無法確定的條目會被設 `''`。所有 `tuple` 條目均 `''` 字串。

## 16.7.5 iOS 平台

```
platform.ios_ver (system=", release=", model=", is_simulator=False)
```

Get iOS version information and return it as a `namedtuple()` with the following attributes:

- `system` is the OS name; either `'iOS'` or `'iPadOS'`.
- `release` is the iOS version number as a string (e.g., `'17.2'`).
- `model` is the device model identifier; this will be a string like `'iPhone13,2'` for a physical device, or `'iPhone'` on a simulator.
- `is_simulator` is a boolean describing if the app is running on a simulator or a physical device.

Entries which cannot be determined are set to the defaults given as parameters.

## 16.7.6 Unix 平台

`platform.libc_ver` (*executable=sys.executable, lib="", version="", chunksize=16384*)

嘗試確認可執行檔案（預設 Python 直譯器）所連結到的 libc 版本。回傳一個字串 tuple (lib, version)，當查詢失敗時其預設值將被設給定的參數值。

請注意，此函式對於不同 libc 版本如何可執行檔案新增符號的方式有深層的關聯，可能僅適用於以 gcc 編譯出來的可執行檔案。

檔案會以 *chunksize* 位元組大小的分塊 (chunk) 來讀取和掃描。

## 16.7.7 Linux 平台

`platform.freedesktop_os_release` ()

從 os-release 檔案獲取作業系統標識，將其作一個字典回傳。os-release 檔案 freedesktop.org 標準，在大多數 Linux 發行版上可用。一個重要的例外是 Android 和基於 Android 的發行版。

當 /etc/os-release 與 /usr/lib/os-release 均無法被讀取時將引發 `OSError` 或其子類。

成功時，該函式將回傳一個字典，其中鍵和值均字串。值當中的特殊字元例如 " 和 \$ 會被移除引號 (unquoted)。欄位 NAME、ID 和 PRETTY\_NAME 總會按照標準來定義。所有其他欄位都是可選的。根據不同廠商可能會包括額外的欄位。

請注意 NAME、VERSION 和 VARIANT 等欄位是適用於向使用者展示的字串。程式應當使用 ID、ID\_LIKE、VERSION\_ID 或 VARIANT\_ID 等欄位來標識 Linux 發行版。

範例：

```
def get_like_distro():
    info = platform.freedesktop_os_release()
    ids = [info["ID"]]
    if "ID_LIKE" in info:
        # ids are space separated and ordered by precedence
        ids.extend(info["ID_LIKE"].split())
    return ids
```

在 3.10 版被加入。

## 16.7.8 Android 平台

`platform.android_ver` (*release="", api\_level=0, manufacturer="", model="", device="", is\_emulator=False*)

Get Android device information. Returns a `namedtuple()` with the following attributes. Values which cannot be determined are set to the defaults given as parameters.

- `release` - Android version, as a string (e.g. "14").
- `api_level` - API level of the running device, as an integer (e.g. 34 for Android 14). To get the API level which Python was built against, see `sys.getandroidapilevel()`.
- `manufacturer` - Manufacturer name.
- `model` - Model name – typically the marketing name or model number.
- `device` - Device name – typically the model number or a codename.
- `is_emulator` - True if the device is an emulator; False if it's a physical device.

Google maintains a list of known model and device names.

在 3.13 版被加入。

## 16.8 `errno` --- 標準 `errno` 系統符號

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be all-inclusive.

`errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`

Operation not permitted. This error is mapped to the exception `PermissionError`.

`errno.ENOENT`

No such file or directory. This error is mapped to the exception `FileNotFoundError`.

`errno.ESRCH`

No such process. This error is mapped to the exception `ProcessLookupError`.

`errno.EINTR`

Interrupted system call. This error is mapped to the exception `InterruptedError`.

`errno.EIO`

I/O error

`errno.ENXIO`

No such device or address

`errno.E2BIG`

Arg list too long

`errno.ENOEXEC`

Exec format error

`errno.EBADF`

Bad file number

`errno.ECHILD`

No child processes. This error is mapped to the exception `ChildProcessError`.

`errno.EAGAIN`

Try again. This error is mapped to the exception `BlockingIOError`.

`errno.ENOMEM`

Out of memory

`errno.EACCES`

Permission denied. This error is mapped to the exception `PermissionError`.

`errno.EFAULT`

Bad address

`errno.ENOTBLK`

Block device required

`errno.EBUSY`

Device or resource busy

`errno.EEXIST`

File exists. This error is mapped to the exception *FileExistsError*.

`errno.EXDEV`

Cross-device link

`errno.ENODEV`

No such device

`errno.ENOTDIR`

Not a directory. This error is mapped to the exception *NotADirectoryError*.

`errno.EISDIR`

Is a directory. This error is mapped to the exception *IsADirectoryError*.

`errno.EINVAL`

Invalid argument

`errno.ENFILE`

File table overflow

`errno.EMFILE`

Too many open files

`errno.ENOTTY`

Not a typewriter

`errno.ETXTBSY`

Text file busy

`errno.EFBIG`

File too large

`errno.ENOSPC`

No space left on device

`errno.ESPIPE`

Illegal seek

`errno.EROFS`

Read-only file system

`errno.EMLINK`

Too many links

`errno.EPIPE`

Broken pipe. This error is mapped to the exception *BrokenPipeError*.

`errno.EDOM`

Math argument out of domain of func

`errno.ERANGE`

Math result not representable

`errno.EDEADLK`

Resource deadlock would occur

`errno.ENAMETOOLONG`

File name too long

`errno.ENOLCK`

No record locks available

---

<code>errno.ENOSYS</code>	Function not implemented
<code>errno.ENOTEMPTY</code>	Directory not empty
<code>errno.ELOOP</code>	Too many symbolic links encountered
<code>errno.EWOULDBLOCK</code>	Operation would block. This error is mapped to the exception <i>BlockingIOError</i> .
<code>errno.ENOMSG</code>	No message of desired type
<code>errno.EIDRM</code>	Identifier removed
<code>errno.ECHRNG</code>	Channel number out of range
<code>errno.EL2NSYNC</code>	Level 2 not synchronized
<code>errno.EL3HLT</code>	Level 3 halted
<code>errno.EL3RST</code>	Level 3 reset
<code>errno.ELNRNG</code>	Link number out of range
<code>errno.EUNATCH</code>	Protocol driver not attached
<code>errno.ENOCSI</code>	No CSI structure available
<code>errno.EL2HLT</code>	Level 2 halted
<code>errno.EBADE</code>	Invalid exchange
<code>errno.EBADR</code>	Invalid request descriptor
<code>errno.EXFULL</code>	Exchange full
<code>errno.ENOANO</code>	No anode
<code>errno.EBADRQC</code>	Invalid request code
<code>errno.EBADSLT</code>	Invalid slot
<code>errno.EDEADLOCK</code>	File locking deadlock error

`errno.EBFONT`  
Bad font file format

`errno.ENOSTR`  
Device not a stream

`errno.ENODATA`  
No data available

`errno.ETIME`  
Timer expired

`errno.ENOSR`  
Out of streams resources

`errno.ENONET`  
Machine is not on the network

`errno.ENOPKG`  
Package not installed

`errno.EREMOTE`  
Object is remote

`errno.ENOLINK`

## 16.9 ctypes --- 用於 Python 的外部函式庫

原始碼: [Lib/ctypes](#)

`ctypes` is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

### 16.9.1 ctypes 教學

Note: The code samples in this tutorial use `doctest` to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or macOS, they contain `doctest` directives in comments.

Note: Some code samples reference the ctypes `c_int` type. On platforms where `sizeof(long) == sizeof(int)` it is an alias to `c_long`. So, you should not be confused if `c_long` is printed if you would expect `c_int` --- they are actually the same type.

#### Loading dynamic link libraries

`ctypes` exports the `cdll`, and on Windows `windll` and `oledll` objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. `cdll` loads libraries which export functions using the standard `cdecl` calling convention, while `windll` libraries call functions using the `stdcall` calling convention. `oledll` also uses the `stdcall` calling convention, and assumes the functions return a Windows `HRESULT` error code. The error code is used to automatically raise an `OSError` exception when the function call fails.

在 3.3 版的變更: Windows errors used to raise `WindowsError`, which is now an alias of `OSError`.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the `cdecl` calling convention:

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

#### 備<sup>F</sup>

Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

### Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with a `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI 版本 */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE 版本 */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

`windll` does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use `getattr()` to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

## 呼叫函式

You can call these functions like any other Python callable. This example uses the `rand()` function, which takes no arguments and returns a pseudo-random integer:

```
>>> print(libc.rand())
1804289383
```

On Windows, you can call the `GetModuleHandleA()` function, which returns a win32 module handle (passing `None` as single argument to call it with a `NULL` pointer):

```
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

`ValueError` is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>>

>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, `ctypes` uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with `ctypes`, so you should be careful anyway. The `faulthandler` module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

`None`, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. `None` is passed as a C `NULL` pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (`char*` or `wchar_t*`). Python integers are passed as the platform's default C `int` type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about `ctypes` data types.

## Fundamental data types

`ctypes` defines a number of primitive C compatible data types:

ctypes 型	C 型	Python 型
<code>c_bool</code>	<code>_Bool</code>	bool (1)
<code>c_char</code>	<code>char</code>	1-character bytes object
<code>c_wchar</code>	<code>wchar_t</code>	1-character string
<code>c_byte</code>	<code>char</code>	int
<code>c_ubyte</code>	unsigned char	int
<code>c_short</code>	<code>short</code>	int
<code>c_ushort</code>	unsigned short	int
<code>c_int</code>	<code>int</code>	int
<code>c_uint</code>	unsigned int	int
<code>c_long</code>	<code>long</code>	int
<code>c_ulong</code>	unsigned long	int
<code>c_longlong</code>	<code>__int64</code> 或 <code>long long</code>	int
<code>c_ulonglong</code>	unsigned <code>__int64</code> 或 unsigned long long	int
<code>c_size_t</code>	<code>size_t</code>	int
<code>c_ssize_t</code>	<code>ssize_t</code> 或 <code>Py_ssize_t</code>	int
<code>c_time_t</code>	<code>time_t</code>	int
<code>c_float</code>	<code>float</code>	float
<code>c_double</code>	<code>double</code>	float
<code>c_longdouble</code>	long double	float
<code>c_char_p</code>	<code>char*</code> (NUL terminated)	bytes object or None
<code>c_wchar_p</code>	<code>wchar_t*</code> (NUL terminated)	字串或 None
<code>c_void_p</code>	<code>void*</code>	int or None

(1) The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
>>>
```

Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python string objects are immutable):

```
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
```

(繼續下一頁)

(繼續上一頁)

```

>>> print(c_s)                # the memory location has changed
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)                  # first object is unchanged
Hello, World
>>>

```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, `ctypes` has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```

>>> from ctypes import *
>>> p = create_string_buffer(3)          # create a 3 byte buffer, initialized to NUL bytes
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")   # create a buffer containing a NUL terminated_
↪string
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10 byte buffer
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00\x00'
>>>

```

The `create_string_buffer()` function replaces the old `c_buffer()` function (which is still available as an alias). To create a mutable memory block containing unicode characters of the C type `wchar_t`, use the `create_unicode_buffer()` function.

### Calling functions, continued

Note that `printf` prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```

>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ctypes.ArgumentError: argument 2: TypeError: Don't know how to convert parameter 2
>>>

```

As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding `ctypes` type, so that they can be converted to the required C data type:

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

### Calling variadic functions

On a lot of platforms calling variadic functions through `ctypes` is exactly the same as calling functions with a fixed number of parameters. On some platforms, and in particular ARM64 for Apple Platforms, the calling convention for variadic functions is different than that for regular functions.

On those platforms it is required to specify the `argtypes` attribute for the regular, non-variadic, function arguments:

```
libc.printf.argtypes = [ctypes.c_char_p]
```

Because specifying the attribute does not inhibit portability it is advised to always specify `argtypes` for all variadic functions.

### Calling functions with your own custom data types

You can also customize `ctypes` argument conversion to allow instances of your own classes be used as function arguments. `ctypes` looks for an `_as_parameter_` attribute and uses this as the function argument. The attribute must be an integer, string, bytes, a `ctypes` instance, or an object with an `_as_parameter_` attribute:

```
>>> class Bottles:
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a `property` which makes the attribute available on request.

### Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf()` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ctypes.ArgumentError: argument 2: TypeError: 'int' object cannot be interpreted as ctypes.c_
↳char_p
>>> printf(b"%s %d %f\n", b"X", 2, 3)
```

(繼續下一頁)

(繼續上一頁)

```
X 2 3.000000
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a `ctypes` instance, or an object with an `_as_parameter_` attribute.

## Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

The C prototype of `time()` is `time_t time(time_t *)`. Because `time_t` might be of a different type than the default return type `int`, you should specify the `restype` attribute:

```
>>> libc.time.restype = c_time_t
```

The argument types can be specified using `argtypes`:

```
>>> libc.time.argtypes = (POINTER(c_time_t),)
```

To call the function with a NULL pointer as first argument, use `None`:

```
>>> print(libc.time(None))
1150640792
```

Here is a more advanced example, it uses the `strchr()` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p # c_char_p is a pointer to a string
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr(b"abcdef", b"d")
b'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
ctypes.ArgumentError: argument 2: TypeError: one character bytes, bytearray or integer_
↳expected
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
b'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):

  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be found.
>>>
```

`WinError` is a function which will call `Windows FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

### Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the `byref()` function which is used to pass parameters by reference. The same effect can be achieved with the `pointer()` function, although `pointer()` does a lot more work since it constructs a real pointer object, so it is faster to use `byref()` if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>
```

### Structures and unions

Structures and unions must derive from the `Structure` and `Union` base classes which are defined in the `ctypes` module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of 2-tuples, containing a *field name* and a *field type*.

The field type must be a `ctypes` type like `c_int`, or any other derived `ctypes` type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named `x` and `y`, and also shows how to initialize a structure in the constructor:

```

>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: too many initializers
>>>

```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```

>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>

```

Nested structures can also be initialized in the constructor in several ways:

```

>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))

```

Field *descriptors* can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```

>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>

```

### 警告

`ctypes` does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

## Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC. It is also possible to set a minimum alignment for how the subclass itself is packed in the same way `#pragma align(n)` works in MSVC. This can be achieved by specifying a `_align_` class attribute in the subclass definition.

`ctypes` uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the `BigEndianStructure`, `LittleEndianStructure`, `BigEndianUnion`, and `LittleEndianUnion` base classes. These classes cannot contain pointer fields.

### Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

### Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = ("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

## Pointers

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another `c_int` instance to the pointer's `contents` attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_int'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_int instead of int
```

(繼續下一頁)

(繼續上一頁)

```
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a NULL pointer. NULL pointers have a False boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

*ctypes* checks for NULL when dereferencing pointers (but dereferencing invalid non-NULL pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
....
ValueError: NULL pointer access
>>>
```

## Type conversions

Usually, *ctypes* does strict type checking. This means, if you have `POINTER(c_int)` in the *argtypes* list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where *ctypes* accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, *ctypes* accepts an array of `c_int`:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in *argtypes*, an object of the pointed type (`c_int` in this case) can be passed to the function. *ctypes* will apply the required *byref()* conversion in this case automatically.

To set a `POINTER` type field to NULL, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. *ctypes* provides a *cast()* function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or `c_int` arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the `cast()` function is handy.

The `cast()` function can be used to cast a ctypes instance into a pointer to a different ctypes data type. `cast()` takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, `cast()` can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

## Incomplete Types

*Incomplete Types* are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new class `cell` is not available in the class statement itself. In *ctypes*, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Let's try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```

>>> c1 = cell()
>>> c1.name = b"foo"
>>> c2 = cell()
>>> c2.name = b"bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>

```

## 回呼函式

`ctypes` allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The `CFUNCTYPE()` factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the `WINFUNCTYPE()` factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, that is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```

>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>

```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```

>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>

```

To get started, here is a simple callback that shows the values it gets passed:

```

>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>

```

結果:

```

>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1

```

(繼續下一頁)

(繼續上一頁)

```

py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>

```

Now we can actually compare the two items and return a useful result:

```

>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>

```

As we can easily check, our array is sorted now:

```

>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>

```

The function factories can be used as decorator factories, so we may as well write:

```

>>> @CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
... def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), py_cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>

```

### 備註

Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), `ctypes` creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will *not* survive across different callbacks, even when those calls are made from the same C thread.

## Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_Version`, Python runtime version number encoded in a single constant integer.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api:

```
>>> version = ctypes.c_int.in_dll(ctypes.pythonapi, "Py_Version")
>>> print(hex(version.value))
0x30c00a0
```

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the docs for that value:

This pointer is initialized to point to an array of `_frozen` records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with `ctypes`:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int),
...                 ("get_code", POINTER(c_ubyte)), # 函式指標
...                 ]
...
>>>
```

We have defined the `_frozen` data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "_PyImport_FrozenBootstrap")
>>>
```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the `NULL` entry:

```
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
zipimport 12345
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative `size` member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

## Surprises

There are some edges in `ctypes` where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
```

(繼續下一頁)

(繼續上一頁)

```

...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>

```

Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```

>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>

```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`'s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave differently from what one would expect is this:

```

>>> s = c_char_p()
>>> s.value = b"abc def ghi"
>>> s.value
b'abc def ghi'
>>> s.value is s.value
False
>>>

```

### 備註

Objects instantiated from `c_char_p` can only have their value set to bytes or integers.

Why is it printing `False`? `ctypes` instances are objects containing a memory block plus some *descriptors* accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the contents of the object is stored. Accessing the contents again constructs a new Python object each time!

## Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing `ctypes` object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the object's type, a `ValueError` is raised if this is tried:

```

>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
Traceback (most recent call last):
...

```

(繼續下一頁)

(繼續上一頁)

```

ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>

```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```

>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
...
IndexError: invalid index
>>>

```

Another way to use variable-sized data types with *ctypes* is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

## 16.9.2 ctypes reference

### Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the *find\_library()* function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The *ctypes.util* module provides a function which can help to determine the library to load.

*ctypes.util.find\_library(name)*

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like *.so*, *.dylib* or version number (this is the form used for the posix linker option *-l*). If no library can be found, returns *None*.

The exact functionality is system dependent.

On Linux, *find\_library()* tries to run external programs (*/sbin/ldconfig*, *gcc*, *objdump* and *ld*) to find the library file. It returns the filename of the library file.

在 3.6 版的變更: On Linux, the value of the environment variable *LD\_LIBRARY\_PATH* is used when searching for libraries, if a library cannot be found by any other means.

以下是一些範例:

```

>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>

```

On macOS and Android, *find\_library()* uses the system's standard naming schemes and paths to locate the library, and returns a full pathname if successful:

```

>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>

```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

### Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

```
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False, winmode=None)
```

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

On Windows creating a `CDLL` instance may fail even if the DLL name exists. When a dependent DLL of the loaded DLL is not found, a `OSError` error is raised with the message "[WinError 126] The specified module could not be found". This error message does not contain the name of the missing DLL because the Windows API does not return this information making this error hard to diagnose. To resolve this error and determine which DLL is not found, you need to find the list of dependent DLLs and determine which one is not found using Windows debugging and tracing tools.

在 3.12 版的變更: The `name` parameter can now be a *path-like object*.

#### 也參考

Microsoft DUMPBIN tool -- A tool to find DLL dependents.

```
class ctypes.OleDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False, winmode=None)
```

Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific `HRESULT` code. `HRESULT` values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an `OSError` is automatically raised.

適用: Windows

在 3.3 版的變更: `WindowsError` used to be raised, which is now an alias of `OSError`.

在 3.12 版的變更: The `name` parameter can now be a *path-like object*.

```
class ctypes.WinDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False, winmode=None)
```

Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

適用: Windows

在 3.12 版的變更: The `name` parameter can now be a *path-like object*.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

**class** `ctypes.PyDLL` (*name*, *mode*=`DEFAULT_MODE`, *handle*=`None`)

Instances of this class behave like `CDLL` instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

在 3.12 版的變更: The *name* parameter can now be a *path-like object*.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platform's `dlopen()` or `LoadLibrary()` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage. On Windows, *mode* is ignored. On posix systems, `RTLD_NOW` is always added, and is not configurable.

The *use\_errno* parameter, when set to true, enables a `ctypes` mechanism that allows accessing the system *errno* error number in a safe way. `ctypes` maintains a thread-local copy of the system's *errno* variable; if you call foreign functions created with `use_errno=True` then the *errno* value before the function call is swapped with the `ctypes` private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the `ctypes` private copy, and the function `ctypes.set_errno()` changes the `ctypes` private copy to a new value and returns the former value.

The *use\_last\_error* parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the `ctypes` private copy of the windows error code.

The *winmode* parameter is used on Windows to specify how the library is loaded (since *mode* is ignored). It takes any value that is valid for the Win32 API `LoadLibraryEx` flags parameter. When omitted, the default is to use the flags that result in the most secure DLL load, which avoids issues such as DLL hijacking. Passing the full path to the DLL is the safest way to ensure the correct library and dependencies are loaded.

在 3.8 版的變更: 新增 *winmode* 參數。

`ctypes.RTLD_GLOBAL`

Flag to use as *mode* parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`

Flag to use as *mode* parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

`ctypes.DEFAULT_MODE`

The default mode which is used to load shared libraries. On OSX 10.3, this is `RTLD_GLOBAL`, otherwise it is the same as `RTLD_LOCAL`.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6") # 於 Linux
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

`PyDLL._handle`

The system handle used to access the library.

`PyDLL._name`

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the `LibraryLoader` class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

**class** `ctypes.LibraryLoader(dlltype)`

Class which loads shared libraries. `dlltype` should be one of the `CDLL`, `PyDLL`, `WinDLL`, or `OleDLL` types.

`__getattr__()` has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

**LoadLibrary(name)**

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

`ctypes.cdll`

Creates `CDLL` instances.

`ctypes.windll`

Creates `WinDLL` instances.

適用: Windows

`ctypes.oledll`

Creates `OleDLL` instances.

適用: Windows

`ctypes.pydll`

Creates `PyDLL` instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

`ctypes.pythonapi`

An instance of `PyDLL` that exposes Python C API functions as attributes. Note that all these functions are assumed to return C `int`, which is of course not always the truth, so you have to assign the correct `restype` attribute to use these functions.

Loading a library through any of these objects raises an *auditing event* `ctypes.dlopen` with string argument `name`, the name used to load the library.

Accessing a function on a loaded library raises an auditing event `ctypes.dlsym` with arguments `library` (the library object) and `name` (the symbol's name as a string or integer).

In cases when only the library handle is available rather than the object, accessing a function raises an auditing event `ctypes.dlsym/handle` with arguments `handle` (the raw library handle) and `name`.

## Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any `ctypes` data instances as arguments, and return the default result type specified by the library loader.

They are instances of a private local class `_FuncPtr` (not exposed in `ctypes`) which inherits from the private `_CFuncPtr` class:

```
>>> import ctypes
>>> lib = ctypes.CDLL(None)
>>> issubclass(lib._FuncPtr, ctypes._CFuncPtr)
True
>>> lib._FuncPtr is ctypes._CFuncPtr
False
```

#### **class** `ctypes._CFuncPtr`

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

#### **restype**

Assign a `ctypes` type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a `ctypes` type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a `ctypes` data type as `restype` and assign a callable to the `errcheck` attribute.

#### **argtypes**

Assign a tuple of `ctypes` types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the `argtypes` tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a `c_char_p` item in the `argtypes` tuple will convert a string passed as argument into a bytes object using `ctypes` conversion rules.

New: It is now possible to put items in `argtypes` which are not `ctypes` types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, `ctypes` instance). This allows defining adapters that can adapt custom objects as function parameters.

#### **errcheck**

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

**callable** (*result*, *func*, *arguments*)

*result* is what the foreign function returns, as specified by the `restype` attribute.

*func* is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

*arguments* is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

#### **exception** `ctypes.ArgumentError`

This exception is raised when a foreign function call cannot convert one of the passed arguments.

On Windows, when a foreign function call raises a system exception (for example, due to an access violation), it will be captured and replaced with a suitable Python exception. Further, an auditing event `ctypes.set_exception` with argument `code` will be raised, allowing an audit hook to replace the exception with its own.

Some ways to invoke foreign function calls may raise an auditing event `ctypes.call_function` with arguments `function pointer` and `arguments`.

## Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function, and can be used as decorator factories, and as such, be applied to functions through the `@wrapper` syntax. See [回呼函式](#) for examples.

`ctypes.CFUNCTYPE` (*restype*, \**argtypes*, *use\_errno=False*, *use\_last\_error=False*)

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use\_errno* is set to true, the `ctypes` private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; *use\_last\_error* does the same for the Windows error code.

`ctypes.WINFUNCTYPE` (*restype*, \**argtypes*, *use\_errno=False*, *use\_last\_error=False*)

The returned function prototype creates functions that use the `stdcall` calling convention. The function will release the GIL during the call. *use\_errno* and *use\_last\_error* have the same meaning as above.

適用: Windows

`ctypes.PYFUNCTYPE` (*restype*, \**argtypes*)

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

**prototype** (*address*)

Returns a foreign function at the specified address which must be an integer.

**prototype** (*callable*)

Create a C callable function (a callback function) from a Python *callable*.

**prototype** (*func\_spec*[, *paramflags* ])

Returns a foreign function exported by a shared library. *func\_spec* must be a 2-tuple (*name\_or\_ordinal*, *library*). The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

**prototype** (*vtbl\_index*, *name*[, *paramflags*[, *iid* ] ])

Returns a foreign function that will call a COM method. *vtbl\_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the *argtypes* tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

*paramflags* must be a tuple of the same length as *argtypes*.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1

Specifies an input parameter to the function.

- 2 Output parameter. The foreign function fills in a value.
- 4 Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

The following example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", "Hello from ctypes"), (1,
↳ "flags", 0)
>>> MessageBox = prototype(("MessageBoxW", windll.user32), paramflags)
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam", spam, spam)
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with `ctypes`:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the `GetWindowRect` function now returns a `RECT` instance, when called.

Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
```

(繼續下一頁)

(繼續上一頁)

```

...     raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>

```

If the `errcheck` function returns the argument tuple it receives unchanged, `ctypes` continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```

>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>

```

## Utility functions

`ctypes.addressof(obj)`

Returns the address of the memory buffer as integer. *obj* must be an instance of a `ctypes` type.

引發一個附帶引數 *obj* 的稽核事件 `ctypes.addressof`。

`ctypes.alignment(obj_or_type)`

Returns the alignment requirements of a `ctypes` type. *obj\_or\_type* must be a `ctypes` type or instance.

`ctypes.byref(obj[, offset])`

Returns a light-weight pointer to *obj*, which must be an instance of a `ctypes` type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

`ctypes.cast(obj, type)`

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(init_or_size, size=None)`

This function creates a mutable character buffer. The returned object is a `ctypes` array of `c_char`.

*init\_or\_size* must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

引發一個附帶引數 *init* 與 *size* 的稽核事件 `ctypes.create_string_buffer`。

`ctypes.create_unicode_buffer(init_or_size, size=None)`

This function creates a mutable unicode character buffer. The returned object is a `ctypes` array of `c_wchar`.

*init\_or\_size* must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

引發一個附帶引數 `init` 與 `size` 的稽核事件 `ctypes.create_unicode_buffer`。

`ctypes.DllCanUnloadNow()`

This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllCanUnloadNow` function that the `_ctypes` extension dll exports.

適用: Windows

`ctypes.DllGetClassObject()`

This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the `DllGetClassObject` function that the `_ctypes` extension dll exports.

適用: Windows

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

`ctypes.util.find_msvcrt()`

Returns the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

適用: Windows

`ctypes.FormatError([code])`

Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

適用: Windows

`ctypes.GetLastError()`

Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

適用: Windows

`ctypes.get_errno()`

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.

引發一個不附帶引數的稽核事件 `ctypes.get_errno`。

`ctypes.get_last_error()`

Returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

適用: Windows

引發一個不附帶引數的稽核事件 `ctypes.get_last_error`。

`ctypes.memmove(dst, src, count)`

Same as the standard C `memmove` library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

`ctypes.memset(dst, c, count)`

Same as the standard C `memset` library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

`ctypes.POINTER` (*type*, /)

Create and return a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

`ctypes.pointer` (*obj*, /)

Create a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize` (*obj*, *size*)

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

`ctypes.set_errno` (*value*)

Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

引發一個附帶引數 *errno* 的稽核事件 `ctypes.set_errno`。

`ctypes.set_last_error` (*value*)

Sets the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

適用: Windows

引發一個附帶引數 *error* 的稽核事件 `ctypes.set_last_error`。

`ctypes.sizeof` (*obj\_or\_type*)

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

`ctypes.string_at` (*ptr*, *size=-1*)

Return the byte string at *void \*ptr*. If *size* is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

引發一個附帶引數 *ptr*、*size* 的稽核事件 `ctypes.string_at`。

`ctypes.WinError` (*code=None*, *descr=None*)

This function is probably the worst-named thing in ctypes. It creates an instance of `OSError`. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, `FormatError()` is called to get a textual description of the error.

適用: Windows

在 3.3 版的變更: An instance of `WindowsError` used to be created, which is now an alias of `OSError`.

`ctypes.wstring_at` (*ptr*, *size=-1*)

Return the wide-character string at *void \*ptr*. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

引發一個附帶引數 *ptr*、*size* 的稽核事件 `ctypes.wstring_at`。

## Data types

**class** `ctypes._CData`

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects`; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

**from\_buffer** (*source* [, *offset* ])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

引發一個附帶引數 *pointer*、*size*、*offset* 的稽核事件 `ctypes.cdata/buffer`。

**from\_buffer\_copy** (*source* [, *offset* ])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

引發一個附帶引數 *pointer*、*size*、*offset* 的稽核事件 `ctypes.cdata/buffer`。

**from\_address** (*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

This method, and others that indirectly call this method, raises an *auditing event* `ctypes.cdata` with argument *address*.

**from\_param** (*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's *argtypes* tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

**in\_dll** (*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

**`_b_base_`**

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The `_b_base_` read-only member is the root ctypes object that owns the memory block.

**`_b_needsfree_`**

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

**`_objects`**

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

## Fundamental data types

**class** `ctypes._SimpleCData`

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. `_SimpleCData` is a subclass of `_CData`, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

**value**

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a `ctypes` instance, usually a new object is returned each time. `ctypes` does *not* implement original object return, always a new object is constructed. The same is true for all other `ctypes` object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a `restype` of `c_char_p`, you will always receive a Python bytes object, *not* a `c_char_p` instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of `c_void_p`, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental `ctypes` data types:

**class** `ctypes.c_byte`

Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_char`

Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

**class** `ctypes.c_char_p`

Represents the C `char*` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

**class** `ctypes.c_double`

Represents the C `double` datatype. The constructor accepts an optional float initializer.

**class** `ctypes.c_longdouble`

Represents the C `long double` datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

**class** `ctypes.c_float`

Represents the C `float` datatype. The constructor accepts an optional float initializer.

**class** `ctypes.c_int`

Represents the C `signed int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

**class** `ctypes.c_int8`

Represents the C 8-bit `signed int` datatype. Usually an alias for `c_byte`.

**class** `ctypes.c_int16`

Represents the C 16-bit `signed int` datatype. Usually an alias for `c_short`.

**class** `ctypes.c_int32`

Represents the C 32-bit `signed int` datatype. Usually an alias for `c_int`.

**class** `ctypes.c_int64`

Represents the C 64-bit `signed int` datatype. Usually an alias for `c_longlong`.

**class** `ctypes.c_long`

Represents the C `signed long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_longlong`

Represents the C `signed long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_short`

Represents the C `signed short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_size_t`

Represents the C `size_t` datatype.

**class** `ctypes.c_ssize_t`

Represents the C `ssize_t` datatype.

在 3.2 版被加入。

**class** `ctypes.c_time_t`

Represents the C `time_t` datatype.

在 3.12 版被加入。

**class** `ctypes.c_ubyte`

Represents the C `unsigned char` datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_uint`

Represents the C `unsigned int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for `c_ulong`.

**class** `ctypes.c_uint8`

Represents the C 8-bit `unsigned int` datatype. Usually an alias for `c_ubyte`.

**class** `ctypes.c_uint16`

Represents the C 16-bit `unsigned int` datatype. Usually an alias for `c_ushort`.

**class** `ctypes.c_uint32`

Represents the C 32-bit `unsigned int` datatype. Usually an alias for `c_uint`.

**class** `ctypes.c_uint64`

Represents the C 64-bit `unsigned int` datatype. Usually an alias for `c_ulonglong`.

**class** `ctypes.c_ulong`

Represents the C `unsigned long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_ulonglong`

Represents the C `unsigned long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_ushort`

Represents the C `unsigned short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

**class** `ctypes.c_void_p`

Represents the C `void*` type. The value is represented as integer. The constructor accepts an optional integer initializer.

**class** `ctypes.c_wchar`

Represents the C `wchar_t` datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

**class** `ctypes.c_wchar_p`

Represents the C `wchar_t*` datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

**class** `ctypes.c_bool`

Represent the C `bool` datatype (more accurately, `_Bool` from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

**class** `ctypes.HRESULT`

Represents a `HRESULT` value, which contains success or error information for a function or method call.

適用: Windows

**class** `ctypes.py_object`

Represents the C `PyObject*` datatype. Calling this without an argument creates a `NULL PyObject*` pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

## Structured data types

**class** `ctypes.Union(*args, **kw)`

Abstract base class for unions in native byte order.

**class** `ctypes.BigEndianUnion(*args, **kw)`

Abstract base class for unions in *big endian* byte order.

在 3.11 版被加入。

**class** `ctypes.LittleEndianUnion(*args, **kw)`

Abstract base class for unions in *little endian* byte order.

在 3.11 版被加入。

**class** `ctypes.BigEndianStructure(*args, **kw)`

Abstract base class for structures in *big endian* byte order.

**class** `ctypes.LittleEndianStructure(*args, **kw)`

Abstract base class for structures in *little endian* byte order.

Structures and unions with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

**class** `ctypes.Structure(*args, **kw)`

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `_fields_` class variable. `ctypes` will create *descriptors* which allow reading and writing the fields by direct attribute accesses. These are the

### `_fields_`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any `ctypes` data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `_fields_` class variable *after* the class statement that defines the `Structure` subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List._fields_ = [("pNext", POINTER(List)),
                 ...
                ]
```

The `_fields_` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `_fields_` class variable will raise an `AttributeError`.

It is possible to define sub-subclasses of structure types, they inherit the fields of the base class plus the `_fields_` defined in the sub-subclass, if any.

#### `_pack_`

An optional small integer that allows overriding the alignment of structure fields in the instance. `_pack_` must already be defined when `_fields_` is assigned, otherwise it will have no effect. Setting this attribute to 0 is the same as not setting it at all.

#### `_align_`

An optional small integer that allows overriding the alignment of the structure when being packed or unpacked to/from memory. Setting this attribute to 0 is the same as not setting it at all.

在 3.13 版被加入。

#### `_anonymous_`

An optional sequence that lists the names of unnamed (anonymous) fields. `_anonymous_` must be already defined when `_fields_` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    _fields_ = [("lptdesc", POINTER(TYPEDESC)),
               ("lpadesc", POINTER(ARRAYDESC)),
               ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    _anonymous_ = ("u",)
    _fields_ = [("u", _U),
               ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the `TYPEDESC` instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to define sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `_fields_` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they appear in `_fields_`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `_fields_` with the same name, or create new attributes for names not present in `_fields_`.

## Arrays and pointers

**class** `ctypes.Array` (\*args)

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any *ctypes* data type with a non-negative integer. Alternatively, you can subclass this type and define `_length_` and `_type_` class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an *Array*.

`_length_`

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an *IndexError*. Will be returned by `len()`.

`_type_`

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

`ctypes.ARRAY` (*type*, *length*)

Create an array. Equivalent to `type * length`, where *type* is a *ctypes* data type and *length* an integer.

This function is *soft deprecated* in favor of multiplication. There are no plans to remove it.

**class** `ctypes._Pointer`

Private, abstract base class for pointers.

Concrete pointer types are created by calling `POINTER()` with the type that will be pointed to; this is done automatically by `pointer()`.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so `len()` will raise *TypeError*. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

`_type_`

Specifies the type pointed to.

**contents**

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

本章節所描述的模組協助實作應用程式的命令列與終端介面。

## 17.1 `argparse` --- 命令列選項、引數和子命令的剖析器

在 3.2 版被加入。

原始碼：[Lib/argparse.py](#)

### 備註

While `argparse` is the default recommended standard library module for implementing basic command line applications, authors with more exacting requirements for exactly how their command line applications behave may find it doesn't provide the necessary level of control. Refer to [選擇一個命令列參數剖析函式庫](#) for alternatives to consider when `argparse` doesn't support behaviors that the application requires (such as entirely disabling support for interspersed options and positional arguments, or accepting option parameter values that start with `-` even when they correspond to another defined option).

### 教學

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the [argparse tutorial](#).

The `argparse` module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and `argparse` will figure out how to parse those out of `sys.argv`. The `argparse` module also automatically generates help and usage messages. The module will also issue errors when users give the program invalid arguments.

The `argparse` module's support for command-line interfaces is built around an instance of `argparse.ArgumentParser`. It is a container for argument specifications and has options that apply to the parser as whole:

```
parser = argparse.ArgumentParser(
    prog='ProgramName',
    description='What the program does',
    epilog='Text at the bottom of help')
```

The `ArgumentParser.add_argument()` method attaches individual argument specifications to the parser. It supports positional arguments, options that accept values, and on/off flags:

```
parser.add_argument('filename')           # 位置引數
parser.add_argument('-c', '--count')     # 接收一個值的選項
parser.add_argument('-v', '--verbose',
                    action='store_true') # 開關旗標
```

The `ArgumentParser.parse_args()` method runs the parser and places the extracted data in a `argparse.Namespace` object:

```
args = parser.parse_args()
print(args.filename, args.count, args.verbose)
```

### 備註

If you're looking for a guide about how to upgrade `optparse` code to `argparse`, see [Upgrading Optparse Code](#).

## 17.1.1 ArgumentParser 物件

```
class argparse.ArgumentParser(prog=None, usage=None, description=None, epilog=None, parents=[],
                              formatter_class=argparse.HelpFormatter, prefix_chars='-',
                              fromfile_prefix_chars=None, argument_default=None,
                              conflict_handler='error', add_help=True, allow_abbrev=True,
                              exit_on_error=True)
```

Create a new `ArgumentParser` object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- `prog` - 程式的名稱 (預設值: `os.path.basename(sys.argv[0])`)
- `usage` - 描述程式用法的字串 (預設值: 從新增到剖析器的引數生成)
- `description` - 引數說明之前要顯示的文字 (預設值: 無文字)
- `epilog` - 引數說明之後要顯示的文字 (預設值: 無文字)
- `parents` - 一個 `ArgumentParser` 物件的串列, 其引數也應該被包含
- `formatter_class` - 用於自訂說明輸出的類
- `prefix_chars` - 前綴可選引數的字元集合 (預設值: '-')
- `fromfile_prefix_chars` - The set of characters that prefix files from which additional arguments should be read (default: None)
- `argument_default` - The global default value for arguments (default: None)
- `conflict_handler` - The strategy for resolving conflicting optionals (usually unnecessary)
- `add_help` - Add a `-h/--help` option to the parser (default: True)
- `allow_abbrev` - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: True)
- `exit_on_error` - Determines whether or not `ArgumentParser` exits with error info when an error occurs. (default: True)

在 3.5 版的變更: 新增 `allow_abbrev` 參數。

在 3.8 版的變更: In previous versions, *allow\_abbrev* also disabled grouping of short flags such as `-vv` to mean `-v -v`.

在 3.9 版的變更: 新增 *exit\_on\_error* 參數。

The following sections describe how each of these are used.

## prog

By default, *ArgumentParser* calculates the name of the program to display in help messages depending on the way the Python interpreter was run:

- The *base name* of `sys.argv[0]` if a file was passed as argument.
- The Python interpreter name followed by `sys.argv[0]` if a directory or a zipfile was passed as argument.
- The Python interpreter name followed by `-m` followed by the module or package name if the `-m` option was used.

This default is almost always desirable because it will make the help messages match the string that was used to invoke the program on the command line. However, to change this default behavior, another value can be supplied using the `prog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

options:
  -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

options:
  -h, --help  show this help message and exit
  --foo FOO   foo of the myprogram program
```

## usage

By default, *ArgumentParser* calculates the usage message from the arguments it contains. The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
  bar                bar help

options:
  -h, --help  show this help message and exit
  --foo [FOO] foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

## description

Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments.

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the `formatter_class` argument.

## epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

options:
  -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the `description` argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the `formatter_class` argument to `ArgumentParser`.

## parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to `ArgumentParser` can be used. The `parents=` argument takes a list of `ArgumentParser` objects, collects all the positional and optional actions from them, and adds these actions to the `ArgumentParser` object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the `ArgumentParser` will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

### 備F

You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

## formatter\_class

*ArgumentParser* objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

```
class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter
```

*RawDescriptionHelpFormatter* and *RawTextHelpFormatter* give more control over how textual descriptions are displayed. By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...         but that is okay''',
...     epilog='''
...         likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

options:
  -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines
```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         -----
...         I have indented it
...         exactly the way
...         I want it
...         '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
-----

I have indented it
exactly the way
I want it

options:
  -h, --help  show this help message and exit
```

*RawTextHelpFormatter* maintains whitespace for all sorts of help text, including argument descriptions. However, multiple newlines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

*ArgumentDefaultsHelpFormatter* automatically adds information about default values to each of the argument help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar ...]

positional arguments:
  bar          BAR! (default: [1, 2, 3])

options:
  -h, --help  show this help message and exit
  --foo FOO   FOO! (default: 42)
```

*MetavarTypeHelpFormatter* uses the name of the *type* argument for each argument as the display name for its values (rather than using the *dest* as the regular formatter does):

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

options:
  -h, --help  show this help message and exit
  --foo int
```

## prefix\_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the *ArgumentParser* constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+')
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

## fromfile\_prefix\_chars

Sometimes, when dealing with a particularly long argument list, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the *ArgumentParser* constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w', encoding=sys.getfilesystemencoding()) as fp:
...     fp.write('-f\nbar')
... 
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also *convert\_arg\_line\_to\_args()*) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

*ArgumentParser* uses *filesystem encoding and error handler* to read the file containing arguments.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

在 3.12 版的變更: *ArgumentParser* changed encoding and errors to read arguments files from default (e.g. *locale.getpreferredencoding(False)* and "strict") to the *filesystem encoding and error handler*. Arguments file should be encoded in UTF-8 instead of ANSI Codepage on Windows.

### argument\_default

Generally, argument defaults are specified either by passing a default to *add\_argument()* or by calling the *set\_defaults()* methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to *ArgumentParser*. For example, to globally suppress attribute creation on *parse\_args()* calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

### allow\_abbrev

Normally, when you pass an argument list to the *parse\_args()* method of an *ArgumentParser*, it *recognizes abbreviations* of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

在 3.5 版被加入。

### conflict\_handler

*ArgumentParser* objects do not allow two actions with the same option string. By default, *ArgumentParser* objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
```

(繼續下一頁)

(繼續上一頁)

```
..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value 'resolve' can be supplied to the `conflict_handler=` argument of `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

options:
  -h, --help  show this help message and exit
  -f FOO      old foo help
  --foo FOO   new foo help
```

Note that `ArgumentParser` objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

### add\_help

By default, `ArgumentParser` objects add an option which simply displays the parser's help message. If `-h` or `--help` is supplied at the command line, the `ArgumentParser` help will be printed.

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to `ArgumentParser`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

options:
  --foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

options:
  +h, ++help  show this help message and exit
```

### exit\_on\_error

Normally, when you pass an invalid argument list to the `parse_args()` method of an `ArgumentParser`, it will print a message to `sys.stderr` and exit with a status code of 2.

If the user would like to catch errors manually, the feature can be enabled by setting `exit_on_error` to `False`:

```
>>> parser = argparse.ArgumentParser(exit_on_error=False)
>>> parser.add_argument('--integers', type=int)
_StoreAction(option_strings=['--integers'], dest='integers', nargs=None, const=None,
↪ default=None, type=<class 'int'>, choices=None, help=None, metavar=None)
```

(繼續下一頁)

(繼續上一頁)

```
>>> try:
...     parser.parse_args('--integers a'.split())
... except argparse.ArgumentError:
...     print('Catching an argumentError')
...
Catching an argumentError
```

在 3.9 版被加入。

### 17.1.2 add\_argument() 方法

`ArgumentParser.add_argument` (*name or flags...*, \**[[ action ]* *[[ nargs ]* *[[ const ]* *[[ default ]* *[[ type ]* *[[ choices ]* *[[ required ]* *[[ help ]* *[[ metavar ]* *[[ dest ]* *[[ deprecated ]*)

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- *name or flags* - Either a name or a list of option strings, e.g. 'foo' or '-f', '--foo'.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line and if it is absent from the namespace object.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A sequence of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by `parse_args()`.
- *deprecated* - Whether or not use of the argument is deprecated.

The following sections describe how each of these are used.

#### name or flags

The `add_argument()` method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to `add_argument()` must therefore be either a series of flags, or a simple argument name.

For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
```

(繼續下一頁)

```

Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar

```

## action

`ArgumentParser` objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by `parse_args()`. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action.
- `'store_const'` - This stores the value specified by the `const` keyword argument; note that the `const` keyword argument defaults to `None`. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_const', const=42)
>>> parser.parse_args(['--foo'])
Namespace(foo=42)

```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` used for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('--bar', action='store_false')
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)

```

- `'append'` - This stores a list, and appends each argument value to the list. It is useful to allow an option to be specified multiple times. If the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values. Example usage:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])

```

- `'append_const'` - This stores a list, and appends the value specified by the `const` keyword argument to the list; note that the `const` keyword argument defaults to `None`. The `'append_const'` action is typically useful when multiple arguments need to store constants to the same list. For example:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])

```

- `'extend'` - This stores a list and appends each item from the multi-value argument list to it. The `'extend'` action is typically used with the `nargs` keyword argument value `'+'` or `'*'`. Note that when `nargs` is `None` (the default) or `'?'`, each character of the argument string will be appended to the list. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument("--foo", action="extend", nargs="+", type=str)
>>> parser.parse_args(["--foo", "f1", "--foo", "f2", "f3", "f4"])
Namespace(foo=['f1', 'f2', 'f3', 'f4'])
```

在 3.8 版被加入。

- 'count' - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count', default=0)
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

Note, the *default* will be `None` unless explicitly set to `0`.

- 'help' - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See [ArgumentParser](#) for details of how the output is created.
- 'version' - This expects a `version=` keyword argument in the `add_argument()` call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='% (prog)s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

Only actions that consume command-line arguments (e.g. 'store', 'append' or 'extend') can be used with positional arguments.

#### class argparse.BooleanOptionalAction

You may also specify an arbitrary action by passing an [Action](#) subclass or other object that implements the same interface. The `BooleanOptionalAction` is available in `argparse` and adds support for boolean actions such as `--foo` and `--no-foo`:

```
>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=argparse.BooleanOptionalAction)
>>> parser.parse_args(['--no-foo'])
Namespace(foo=False)
```

在 3.9 版被加入。

The recommended way to create a custom action is to extend [Action](#), overriding the `__call__()` method and optionally the `__init__()` and `format_usage()` methods. You can also register custom actions using the `register()` method and reference them by their registered name.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super().__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

更多詳情請見 *Action*。

## nargs

*ArgumentParser* objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. See also 指定不明確的引數. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar='c', foo=['a', 'b'])
```

Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from *default* will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from *const* will be produced. Some examples to illustrate this:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.add_argument('bar', nargs='?', default='d')
>>> parser.parse_args(['XX', '--foo', 'YY'])
Namespace(bar='XX', foo='YY')
>>> parser.parse_args(['XX', '--foo'])
Namespace(bar='XX', foo='c')
>>> parser.parse_args([])
Namespace(bar='d', foo='d')
```

One of the more common uses of `nargs='?'` is to allow optional input and output files:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
...                   default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
...                   default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='output.txt' encoding='UTF-8'>)
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' encoding='UTF-8'>)
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- '+'. Just like '\*', all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the *action*. Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced. Actions that do not consume command-line arguments (e.g. 'store\_const') set `nargs=0`.

### const

The `const` argument of `add_argument()` is used to hold constant values that are not read from the command line but are required for the various *ArgumentParser* actions. The two most common uses of it are:

- When `add_argument()` is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by `parse_args()`. See the *action* description for examples. If `const` is not provided to `add_argument()`, it will receive a default value of `None`.
- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed to be `None` instead. See the *nargs* description for examples.

在 3.11 版的變更: `const=None` by default, including when `action='append_const'` or `action='store_const'`.

### default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the target namespace already has an attribute set, the action *default* will not overwrite it:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args([], namespace=argparse.Namespace(foo=101))
Namespace(foo=101)
```

If the `default` value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *Namespace* return

value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the default value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

For *required* arguments, the default value is ignored. For example, this applies to positional arguments with *nargs* values other than `?` or `*`, or optional arguments marked as `required=True`.

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

## type

By default, the parser reads command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, such as a *float* or *int*. The `type` keyword for `add_argument()` allows any necessary type-checking and type conversions to be performed.

If the `type` keyword is used with the `default` keyword, the type converter is only applied if the default is a string.

The argument to `type` can be a callable that accepts a single string or the name of a registered type (see `register()`). If the function raises `ArgumentTypeError`, `TypeError`, or `ValueError`, the exception is caught and a nicely formatted error message is displayed. Other exception types are not handled.

Common built-in types and functions can be used as type converters:

```
import argparse
import pathlib

parser = argparse.ArgumentParser()
parser.add_argument('count', type=int)
parser.add_argument('distance', type=float)
parser.add_argument('street', type=ascii)
parser.add_argument('code_point', type=ord)
parser.add_argument('dest_file', type=argparse.FileType('w', encoding='latin-1'))
parser.add_argument('datapath', type=pathlib.Path)
```

User defined functions can be used as well:

```
>>> def hyphenated(string):
...     return '-'.join([word[:4] for word in string.casefold().split()])
...
>>> parser = argparse.ArgumentParser()
>>> _ = parser.add_argument('short_title', type=hyphenated)
```

(繼續下一頁)

(繼續上一頁)

```
>>> parser.parse_args(['The Tale of Two Cities'])
Namespace(short_title='the-tale-of-two-citi')
```

The `bool()` function is not recommended as a type converter. All it does is convert empty strings to `False` and non-empty strings to `True`. This is usually not what is desired.

In general, the `type` keyword is a convenience that should only be used for simple conversions that can only raise one of the three supported exceptions. Anything with more interesting error-handling or resource management should be done downstream after the arguments are parsed.

For example, JSON or YAML conversions have complex error cases that require better reporting than can be given by the `type` keyword. A `JSONDecodeError` would not be well formatted and a `FileNotFoundError` exception would not be handled at all.

Even `FileType` has its limitations for use with the `type` keyword. If one argument uses `FileType` and then a subsequent argument fails, an error is reported but the file is not automatically closed. In this case, it would be better to wait until after the parser has run and then use the `with`-statement to manage the files.

For type checkers that simply check against a fixed set of values, consider using the `choices` keyword instead.

### choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a sequence object as the `choices` keyword argument to `add_argument()`. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the `choices` sequence is checked after any `type` conversions have been performed, so the type of the objects in the `choices` sequence should match the `type` specified.

Any sequence can be passed as the `choices` value, so `list` objects, `tuple` objects, and custom sequences are all supported.

Use of `enum.Enum` is not recommended because it is difficult to control its appearance in usage, help, and error messages.

Formatted choices override the default `metavar` which is normally derived from `dest`. This is usually what you want because the user never sees the `dest` parameter. If this display isn't desirable (perhaps because there are many choices), just specify an explicit `metavar`.

### required

In general, the `argparse` module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: [-h] --foo FOO
: error: the following arguments are required: --foo
```

As the example shows, if an option is marked as `required`, `parse_args()` will report an error if that option is not present at the command line.

### 備F

Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

## help

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these `help` descriptions will be displayed with each argument.

The `help` strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, `%(prog)s` and most keyword arguments to `add_argument()`, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                    help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
  bar      the bar to frobble (default: 42)

options:
  -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal % to appear in the help string, you must escape it as %%.

`argparse` supports silencing the help entry for certain options, by setting the `help` value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

options:
  -h, --help  show this help message and exit
```

## metavar

When `ArgumentParser` generates help messages, it needs some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the "name" of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo FOO] bar

positional arguments:
  bar
```

(繼續下一頁)

(繼續上一頁)

```
options:
-h, --help  show this help message and exit
--foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo YYY] XXX

positional arguments:
  XXX

options:
-h, --help  show this help message and exit
--foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the *dest* value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

options:
-h, --help      show this help message and exit
-x X X
--foo bar baz
```

## dest

Most `ArgumentParser` actions add some value as an attribute of the object returned by `parse_args()`. The name of this attribute is determined by the `dest` keyword argument of `add_argument()`. For positional argument actions, `dest` is normally supplied as the first argument to `add_argument()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. `ArgumentParser` generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
```

(繼續下一頁)

(繼續上一頁)

```
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

## deprecated

During a project's lifetime, some arguments may need to be removed from the command line. Before removing them, you should inform your users that the arguments are deprecated and will be removed. The `deprecated` keyword argument of `add_argument()`, which defaults to `False`, specifies if the argument is deprecated and will be removed in the future. For arguments, if `deprecated` is `True`, then a warning will be printed to `sys.stderr` when the argument is used:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='snake.py')
>>> parser.add_argument('--legs', default=0, type=int, deprecated=True)
>>> parser.parse_args([])
Namespace(legs=0)
>>> parser.parse_args(['--legs', '4'])
snake.py: warning: option '--legs' is deprecated
Namespace(legs=4)
```

在 3.13 版被加入。

## Action 類 F

`Action` classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to `add_argument()`.

```
class argparse.Action(option_strings, dest, nargs=None, const=None, default=None, type=None,
                      choices=None, required=False, help=None, metavar=None)
```

`Action` objects are used by an `ArgumentParser` to represent the information needed to parse a single argument from one or more strings from the command line. The `Action` class must accept the two positional arguments plus any keyword arguments passed to `ArgumentParser.add_argument()` except for the action itself.

Instances of `Action` (or return value of any callable to the `action` parameter) should have attributes `dest`, `option_strings`, `default`, `type`, `required`, `help`, etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__()`.

```
__call__(parser, namespace, values, option_string=None)
```

`Action` instances should be callable, so subclasses must override the `__call__()` method, which should accept four parameters:

- `parser` - The `ArgumentParser` object which contains this action.
- `namespace` - The `Namespace` object that will be returned by `parse_args()`. Most actions add an attribute to this object using `setattr()`.
- `values` - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the `type` keyword argument to `add_argument()`.
- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

The `__call__()` method may perform arbitrary actions, but will typically set attributes on the namespace based on `dest` and `values`.

#### `format_usage()`

Action subclasses can define a `format_usage()` method that takes no argument and return a string which will be used when printing the usage of the program. If such method is not provided, a sensible default will be used.

### 17.1.3 `parse_args()` 方法

`ArgumentParser.parse_args(args=None, namespace=None)`

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to `add_argument()` determine exactly what objects are created and how they are assigned. See the documentation for `add_argument()` for details.

- `args` - List of strings to parse. The default is taken from `sys.argv`.
- `namespace` - An object to take the attributes. The default is a new empty `Namespace` object.

#### Option value syntax

The `parse_args()` method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using `=` to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

#### 無效引數

While parsing the command line, `parse_args()` checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # 無效型
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # 無效選項
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # 錯誤引數數量
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger

```

### 包含 - 的引數

The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument

```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `--` which tells `parse_args()` that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

See also *the argparse howto on ambiguous arguments* for more details.

### 引數縮寫 (前綴匹配)

The `parse_args()` method *by default* allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args(['-bac MMM'].split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args(['-bad WOOD'].split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args(['-ba BA'].split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting `allow_abbrev` to `False`.

### Beyond `sys.argv`

Sometimes it may be useful to have an `ArgumentParser` parse arguments other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

### 命名空間物件

#### `class` `argparse.Namespace`

Simple class used by default by `parse_args()` to create an object holding attributes and return it.

This class is deliberately simple, just an `object` subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, `vars()`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an `ArgumentParser` assign attributes to an already existing object, rather than a new `Namespace` object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
... 
```

(繼續下一頁)

```

>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'

```

## 17.1.4 Other utilities

### 子命令

`ArgumentParser.add_subparsers` (\*[, *title*][[, *description*][[, *prog*][[, *parser\_class*][[, *action*][[, *dest*][[, *required*][[, *help*][[, *metavar* ]])

Many programs split up their functionality into a number of subcommands, for example, the `svn` program can invoke subcommands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. `ArgumentParser` supports the creation of such subcommands with the `add_subparsers()` method. The `add_subparsers()` method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any `ArgumentParser` constructor arguments, and returns an `ArgumentParser` object that can be modified as usual.

參數的解釋：

- *title* - title for the sub-parser group in help output; by default "subcommands" if description is provided, otherwise uses title for positional arguments
- *description* - description for the sub-parser group in help output, by default `None`
- *prog* - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- *parser\_class* - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. `ArgumentParser`)
- *action* - the basic type of action to be taken when this argument is encountered at the command line
- *dest* - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- *required* - Whether or not a subcommand must be provided, by default `False` (added in 3.7)
- *help* - help for sub-parser group in help output, by default `None`
- *metavar* - string presenting available subcommands in help; by default it is `None` and presents subcommands in form `{cmd1, cmd2, ..}`

一些使用範例：

```

>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='subcommand help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices=('X', 'Y', 'Z'), help='baz help')
>>>
>>> # parse some argument lists

```

(繼續上一頁)

```
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}  subcommand help
  a      a help
  b      b help

options:
  -h, --help  show this help message and exit
  --foo       foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar      bar help

options:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

options:
  -h, --help      show this help message and exit
  --baz {X,Y,Z}  baz help
```

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                  description='valid subcommands',
...                                  help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage: [-h] {foo,bar} ...

options:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}  additional help
```

Furthermore, `add_parser()` supports an additional *aliases* argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', aliases=['co'])
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

`add_parser()` supports also an additional *deprecated* argument, which allows to deprecate the subparser.

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='chicken.py')
>>> subparsers = parser.add_subparsers()
>>> run = subparsers.add_parser('run')
>>> fly = subparsers.add_parser('fly', deprecated=True)
>>> parser.parse_args(['fly'])
chicken.py: warning: command 'fly' is deprecated
Namespace()
```

在 3.13 版被加入。

One particularly effective way of handling subcommands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```
>>> # subcommand functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('({%s})' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(required=True)
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the `add_subparsers()` call will work:

```

>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')

```

在 3.7 版的變更: New *required* keyword-only parameter.

## FileType 物件

**class** `argparse.FileType` (*mode='r', bufsize=-1, encoding=None, errors=None*)

The `FileType` factory creates objects that can be passed to the type argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the `open()` function for more details):

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType('wb', 0))
>>> parser.add_argument('out', type=argparse.FileType('w', encoding='UTF-8'))
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='w' encoding='UTF-8'>, raw=<_io.
↳FileIO name='raw.dat' mode='wb'>)

```

`FileType` objects understand the pseudo-argument '-' and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>)

```

在 3.4 版的變更: Added the *encodings* and *errors* parameters.

## Argument groups

`ArgumentParser.add_argument_group` (*title=None, description=None, \*[, argument\_default][, conflict\_handler]*)

By default, `ArgumentParser` groups command-line arguments into "positional arguments" and "options" when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```

>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar      bar help
  --foo FOO  foo help

```

The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts *title* and *description* arguments which can be used to customize this display:

```

>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo    foo help

group2:
  group2 description

  --bar BAR  bar help

```

The optional, keyword-only parameters *argument\_default* and *conflict\_handler* allow for finer-grained control of the behavior of the argument group. These parameters have the same meaning as in the *ArgumentParser* constructor, but apply specifically to the argument group rather than the entire parser.

Note that any arguments not in your user-defined groups will end up back in the usual "positional arguments" and "optional arguments" sections.

在 3.11 版的變更: Calling *add\_argument\_group()* on an argument group is deprecated. This feature was never supported and does not always work correctly. The function exists on the API by accident through inheritance and will be removed in the future.

## Mutual exclusion

*ArgumentParser.add\_mutually\_exclusive\_group(required=False)*

Create a mutually exclusive group. *argparse* will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo

```

The *add\_mutually\_exclusive\_group()* method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required

```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of *add\_argument\_group()*. However, a mutually exclusive group can be added to an argument group that has a title and description. For example:

```

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_argument_group('Group title', 'Group description')
>>> exclusive_group = group.add_mutually_exclusive_group(required=True)
>>> exclusive_group.add_argument('--foo', help='foo help')
>>> exclusive_group.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [-h] (--foo FOO | --bar BAR)

options:
  -h, --help  show this help message and exit

Group title:
  Group description

  --foo FOO    foo help
  --bar BAR    bar help

```

在 3.11 版的變更: Calling `add_argument_group()` or `add_mutually_exclusive_group()` on a mutually exclusive group is deprecated. These features were never supported and do not always work correctly. The functions exist on the API by accident through inheritance and will be removed in the future.

## Parser defaults

`ArgumentParser.set_defaults(**kwargs)`

Most of the time, the attributes of the object returned by `parse_args()` will be fully determined by inspecting the command-line arguments and the argument actions. `set_defaults()` allows some additional attributes that are determined without any inspection of the command line to be added:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)

```

Note that parser-level defaults always override argument-level defaults:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')

```

Parser-level defaults can be particularly useful when working with multiple parsers. See the `add_subparsers()` method for an example of this type.

`ArgumentParser.get_default(dest)`

Get the default value for a namespace attribute, as set by either `add_argument()` or by `set_defaults()`:

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'

```

## 印出幫助訊息

In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

## Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

警告

*Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

## Customizing file parsing

`ArgumentParser.convert_arg_line_to_args(arg_line)`

Arguments that are read from a file (see the `fromfile_prefix_chars` keyword argument to the `ArgumentParser` constructor) are read one argument per line. `convert_arg_line_to_args()` can be overridden for fancier reading.

This method takes a single argument `arg_line` which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

## Exiting methods

`ArgumentParser.exit(status=0, message=None)`

This method terminates the program, exiting with the specified `status` and, if given, it prints a `message` to `sys.stderr` before that. The user can override this method to handle these steps differently:

```
class ErrorCatchingArgumentParser(argparse.ArgumentParser):
    def exit(self, status=0, message=None):
```

(繼續下一頁)

(繼續上一頁)

```

if status:
    raise Exception(f'Exiting because of an error: {message}')
exit(status)

```

`ArgumentParser.error(message)`

This method prints a usage message, including the *message*, to `sys.stderr` and terminates the program with a status code of 2.

## Intermixed parsing

`ArgumentParser.parse_intermixed_args(args=None, namespace=None)`

`ArgumentParser.parse_known_intermixed_args(args=None, namespace=None)`

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The `parse_intermixed_args()` and `parse_known_intermixed_args()` methods support this parsing style.

These parsers do not support all the `argparse` features, and will raise exceptions if unsupported features are used. In particular, subparsers, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between `parse_known_args()` and `parse_intermixed_args()`: the former returns `['2', '3']` as unparsed arguments, while the latter collects all the positionals into `rest`.

```

>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split())
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3'])
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.split())
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])

```

`parse_known_intermixed_args()` returns a two item tuple containing the populated namespace and the list of remaining argument strings. `parse_intermixed_args()` raises an error if there are any remaining unparsed argument strings.

在 3.7 版被加入。

## Registering custom types or actions

`ArgumentParser.register(registry_name, value, object)`

Sometimes it's desirable to use a custom string in error messages to provide more user-friendly output. In these cases, `register()` can be used to register custom actions or types with a parser and allow you to reference the type by their registered name instead of their callable name.

The `register()` method accepts three arguments - a *registry\_name*, specifying the internal registry where the object will be stored (e.g., `action`, `type`), *value*, which is the key under which the object will be registered, and *object*, the callable to be registered.

The following example shows how to register a custom type with a parser:

```

>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.register('type', 'hexadecimal integer', lambda s: int(s, 16))
>>> parser.add_argument('--foo', type='hexadecimal integer')
_StoreAction(option_strings=['--foo'], dest='foo', nargs=None, const=None, default=None,
↳ type='hexadecimal integer', choices=None, required=False, help=None, metavar=None,
↳ deprecated=False)
>>> parser.parse_args(['--foo', '0xFA'])

```

(繼續下一頁)

```

Namespace(foo=250)
>>> parser.parse_args(['--foo', '1.2'])
usage: PROG [-h] [--foo FOO]
PROG: error: argument --foo: invalid 'hexadecimal integer' value: '1.2'

```

## 17.1.5 例外

### exception `argparse.ArgumentError`

An error from creating or using an argument (optional or positional).

The string value of this exception is the message, augmented with information about the argument that caused it.

### exception `argparse.ArgumentTypeError`

Raised when something goes wrong converting a command line string to a type.

## Guides and Tutorials

### Argparse 教學

#### 作者

Tshepang Mbambo

本教學旨在簡要介紹 `argparse` 這個 Python 標準函式庫中推薦的命令列剖析模組。

#### 備

標準函式庫包含另外兩個與命令列參數處理直接相關的函式庫：較低階的 `optparse` 模組（可能需要更多程式碼來給定應用程式設定，但也允許應用程式要求 `argparse` 不支援的行），以及非常低階的 `getopt`（專門用作 C 程式設計師可用的 `getopt()` 函式系列的等價）。雖然這個指南未直接涵蓋這些模組，但 `argparse` 的許多核心概念最初來自於 `optparse`，因此本教學的某些部分也適用於 `optparse` 使用者。

## 概念

讓我們透過使用 `ls` 指令來展示我們將在本介紹教學中探索的功能類型：

```

$ ls
cpython devguide prog.py pypy rm-unused-function.patch
$ ls pypy
ctypes_configure demo dotviewer include lib_pypy lib-python ...
$ ls -l
total 20
drwxr-xr-x 19 wena wena 4096 Feb 18 18:51 cpython
drwxr-xr-x  4 wena wena 4096 Feb  8 12:04 devguide
-rwxr-xr-x  1 wena wena  535 Feb 19 00:05 prog.py
drwxr-xr-x 14 wena wena 4096 Feb  7 00:59 pypy
-rw-r--r--  1 wena wena  741 Feb 18 01:01 rm-unused-function.patch
$ ls --help
Usage: ls [OPTION]... [FILE]...
List information about the FILES (the current directory by default).
Sort entries alphabetically if none of -cftuvSUX nor --sort is specified.
...

```

我們可以從這四個命令中學到一些概念：

- `ls` 命令即便在有任何選項的情況下執行仍非常有用。它預設顯示目前目錄的內容。
- 如果我們想要看到比它預設提供更多的內容，我們也需要多告訴它一點。在本例中，我們希望它顯示不同的目錄 `pypy`，我們做的是指定所謂的位置引數。之所以如此命名是因程式應該只根據該

值在命令列中出現的位置來知道如何處理該值。這個概念與 `cp` 這樣的指令更相關，其最基本的用法是 `cp SRC DEST`。第一個是你想要的位置，第二個是你想要過去的位置。

- 現在假設我們想要改變程式的行。在我們的範例中，我們顯示每個檔案的更多資訊，而不僅是顯示檔案名稱。在這種情況下，`-l` 被稱可選引數。
- 這是幫助文字的片段。它非常有用，因當你遇到以前從未使用過的程式時，只需讀其幫助文字即可了解它的工作原理。

## 基本用法

讓我們從一個非常簡單的例子開始，它（幾乎）什麼都不做：

```
import argparse
parser = argparse.ArgumentParser()
parser.parse_args()
```

程式碼執行結果如下：

```
$ python prog.py
$ python prog.py --help
usage: prog.py [-h]

options:
  -h, --help  show this help message and exit
$ python prog.py --verbose
usage: prog.py [-h]
prog.py: error: unrecognized arguments: --verbose
$ python prog.py foo
usage: prog.py [-h]
prog.py: error: unrecognized arguments: foo
```

這是發生的事情：

- 執行不帶任何選項的本不會在標準輸出中顯示任何內容。不太有用。
- 第二個開始能顯現 `argparse` 模組的有用之處。我們幾乎什麼也做，但我們已經收到了一個很好的幫助訊息。
- `--help` 選項也可以縮寫 `-h`，是我們能隨意獲得的唯一選項（即無需指定它）。指定任何其他內容都會導致錯誤。但即便如此，我們也還是輕鬆地獲得了有用的使用資訊。

## 位置引數的介紹

例如：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("echo")
args = parser.parse_args()
print(args.echo)
```

執行這段程式碼：

```
$ python prog.py
usage: prog.py [-h] echo
prog.py: error: the following arguments are required: echo
$ python prog.py --help
usage: prog.py [-h] echo

positional arguments:
  echo
```

(繼續下一頁)

(繼續上一頁)

```
options:
  -h, --help  show this help message and exit
$ python prog.py foo
foo
```

這是會發生的事情：

- 我們新增了 `add_argument()` 方法，我們用它來指定程式願意接受哪些命令列選項。在本例中，我將其命名為 `echo`，以便與其功能一致。
- 現在呼叫我們的程式時需要指定一個選項。
- `parse_args()` 方法實際上從指定的選項中回傳一些資料，在本例中為 `echo`。
- 該變數是某種形式的「魔法」，`argparse` 可以自由執行（即無需指定該值儲存在哪個變數中）。你還會注意到，它的名稱與提供給方法 `echo` 的字串引數相符。

但請注意，儘管幫助顯示看起來不錯，但它目前還沒有發揮出應有的用處。例如，我們看到 `echo` 作為位置引數，但除了猜測或讀原始程式碼之外，我們不知道它的作用。那麼，我們來讓它變得更有用一點：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("echo", help="echo the string you use here")
args = parser.parse_args()
print(args.echo)
```

然後我們得到：

```
$ python prog.py -h
usage: prog.py [-h] echo

positional arguments:
  echo          echo the string you use here

options:
  -h, --help  show this help message and exit
```

現在來做一些更有用處的事情：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", help="display a square of a given number")
args = parser.parse_args()
print(args.square**2)
```

程式碼執行結果如下：

```
$ python prog.py 4
Traceback (most recent call last):
  File "prog.py", line 5, in <module>
    print(args.square**2)
TypeError: unsupported operand type(s) for ** or pow(): 'str' and 'int'
```

進展不太順利。這是因為，除非我們另有說明，`argparse` 會將我們給它的選項視為字串。因此，讓我們告訴 `argparse` 將該輸入視為整數：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", help="display a square of a given number",
                    type=int)
args = parser.parse_args()
print(args.square**2)
```

程式碼執行結果如下：

```
$ python prog.py 4
16
$ python prog.py four
usage: prog.py [-h] square
prog.py: error: argument square: invalid int value: 'four'
```

順利進展。現在該程式甚至可以在繼續操作之前因錯誤的非法輸入而退出。

## 可選引數的介紹

到目前為止，我們一直在討論位置引數。我們來看看如何新增可選引數：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("--verbosity", help="increase output verbosity")
args = parser.parse_args()
if args.verbosity:
    print("verbosity turned on")
```

接者是結果：

```
$ python prog.py --verbosity 1
verbosity turned on
$ python prog.py
$ python prog.py --help
usage: prog.py [-h] [--verbosity VERBOSITY]

options:
  -h, --help            show this help message and exit
  --verbosity VERBOSITY
                        increase output verbosity
$ python prog.py --verbosity
usage: prog.py [-h] [--verbosity VERBOSITY]
prog.py: error: argument --verbosity: expected one argument
```

這是發生的事情：

- 程式被編寫在指定 `--verbosity` 時顯示一些內容，在未指定時不顯示任何內容。
- 為了表示該選項實際上是可選的，使用它來執行程式不會出現錯誤。請注意，預設情況下，如果未使用可選引數，則相關變數（在本例中 `args.verbosity`）將被賦予 `None` 作值，這就是它未能通過 `if` 陳述式真值測試的原因。
- 幫助訊息有點不同。
- 當使用 `--verbosity` 選項時必須要指定一些值，任何值都可以。

在上面的例子中，`--verbosity` 接受任意的整數，但對我們的程式來只接受兩個輸入值，`True` 或 `False`。所以我們來修改一下程式碼使其符合：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("--verbose", help="increase output verbosity",
                    action="store_true")
args = parser.parse_args()
if args.verbose:
    print("verbosity turned on")
```

接者是結果：

```
$ python prog.py --verbose
verbosity turned on
$ python prog.py --verbose 1
usage: prog.py [-h] [--verbose]
prog.py: error: unrecognized arguments: 1
$ python prog.py --help
usage: prog.py [-h] [--verbose]

options:
  -h, --help  show this help message and exit
  --verbose  increase output verbosity
```

這是發生的事情：

- 這個選項現在更像是一個旗標，而不是需要值的東西。我們甚至更改了選項的名稱以符合這個想法。請注意，我們現在指定一個新的關鍵字 `action`，其指定值 `"store_true"`。這意味著，如果指定了該選項，則將值 `True` 指派給 `args.verbose`。不指定它代表 `False`。
- 當你指定一個值時，它會本著旗標的實際精神來抱怨。
- 請注意不同的幫助文字。

### 短選項

如果你熟悉命令列用法，你會注意到我尚未提及選項的簡短版本。這很簡單：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("-v", "--verbose", help="increase output verbosity",
                    action="store_true")
args = parser.parse_args()
if args.verbose:
    print("verbosity turned on")
```

而這：

```
$ python prog.py -v
verbosity turned on
$ python prog.py --help
usage: prog.py [-h] [-v]

options:
  -h, --help  show this help message and exit
  -v, --verbose  increase output verbosity
```

請注意，新功能也反映在幫助文字中。

### 組合位置引數和可選引數

我們的程式的複雜性不斷增加：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display a square of a given number")
parser.add_argument("-v", "--verbose", action="store_true",
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbose:
    print(f"the square of {args.square} equals {answer}")
```

(繼續下一頁)

(繼續上一頁)

```
else:
    print(answer)
```

然後現在的輸出結果：

```
$ python prog.py
usage: prog.py [-h] [-v] square
prog.py: error: the following arguments are required: square
$ python prog.py 4
16
$ python prog.py 4 --verbose
the square of 4 equals 16
$ python prog.py --verbose 4
the square of 4 equals 16
```

- 我們帶回了位置引數，因而被抱怨。
- 請注意，順序 **F** 不重要。

我們讓這個程式擁有多個訊息詳細級 **F** (verbosity) 之值的能力，**F** 實際使用它們：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display a square of a given number")
parser.add_argument("-v", "--verbosity", type=int,
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
    print(f"the square of {args.square} equals {answer}")
elif args.verbosity == 1:
    print(f"{args.square}^2 == {answer}")
else:
    print(answer)
```

接者是結果：

```
$ python prog.py 4
16
$ python prog.py 4 -v
usage: prog.py [-h] [-v VERBOSITY] square
prog.py: error: argument -v/--verbosity: expected one argument
$ python prog.py 4 -v 1
4^2 == 16
$ python prog.py 4 -v 2
the square of 4 equals 16
$ python prog.py 4 -v 3
16
```

除了最後一個外都看起來正常，它透露了我們程式中的一個錯誤。我們可透過限制 `--verbosity` 選項可以接受的值來修復它：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display a square of a given number")
parser.add_argument("-v", "--verbosity", type=int, choices=[0, 1, 2],
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
```

(繼續下一頁)

(繼續上一頁)

```

    print(f"the square of {args.square} equals {answer}")
elif args.verbosity == 1:
    print(f"{args.square}^2 == {answer}")
else:
    print(answer)

```

接者是結果：

```

$ python prog.py 4 -v 3
usage: prog.py [-h] [-v {0,1,2}] square
prog.py: error: argument -v/--verbosity: invalid choice: 3 (choose from 0, 1, 2)
$ python prog.py 4 -h
usage: prog.py [-h] [-v {0,1,2}] square

positional arguments:
  square                display a square of a given number

options:
  -h, --help            show this help message and exit
  -v, --verbosity {0,1,2}
                        increase output verbosity

```

請注意，更改也會反映在錯誤訊息和幫助字串中。

現在，讓我們使用另一種常見方法來玩玩訊息詳細級。它也與 CPython 執行檔處理其自身訊息詳細級引數的方式相符（請見 `python --help` 的輸出）：

```

import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display the square of a given number")
parser.add_argument("-v", "--verbosity", action="count",
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity == 2:
    print(f"the square of {args.square} equals {answer}")
elif args.verbosity == 1:
    print(f"{args.square}^2 == {answer}")
else:
    print(answer)

```

我們已經介紹過另一個操作“count”用來計算指定的選項出現的次數。

```

$ python prog.py 4
16
$ python prog.py 4 -v
4^2 == 16
$ python prog.py 4 -vv
the square of 4 equals 16
$ python prog.py 4 --verbosity --verbosity
the square of 4 equals 16
$ python prog.py 4 -v 1
usage: prog.py [-h] [-v] square
prog.py: error: unrecognized arguments: 1
$ python prog.py 4 -h
usage: prog.py [-h] [-v] square

positional arguments:
  square                display a square of a given number

```

(繼續下一頁)

(繼續上一頁)

```
options:
  -h, --help      show this help message and exit
  -v, --verbosity increase output verbosity
$ python prog.py 4 -vvv
16
```

- 是的，現在它更像是我們上一版本中的旗標（類似於 `action="store_true"`），這應該可以解釋抱怨的原因。
- 它的行也類似“store\_true”操作。
- 現在這示範了“count”動作的作用。你可能以前見過這種用法。
- 如果你不指定 `-v` 旗標，則該旗標被視具有 `None` 值。
- 正如預期的那樣，指定長形式旗標，我們應該得到相同的輸出。
- 遺憾的是，我們的幫助輸出對於我們本獲得的新功能有提供太多資訊，但我們都可以透過改進本的文件來解這個問題（例如：透過 `help` 關鍵字引數）。
- 最後的輸出透露了我們程式中的一個錯誤。

讓我們來解問題：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display a square of a given number")
parser.add_argument("-v", "--verbosity", action="count",
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2

# bugfix: replace == with >=
if args.verbosity >= 2:
    print(f"the square of {args.square} equals {answer}")
elif args.verbosity >= 1:
    print(f"{args.square}^2 == {answer}")
else:
    print(answer)
```

這就是它給出的：

```
$ python prog.py 4 -vvv
the square of 4 equals 16
$ python prog.py 4 -vvvv
the square of 4 equals 16
$ python prog.py 4
Traceback (most recent call last):
  File "prog.py", line 11, in <module>
    if args.verbosity >= 2:
TypeError: '>=' not supported between instances of 'NoneType' and 'int'
```

- 第一次輸出順利進行，修復了我們之前遇到的錯誤。也就是，我們希望任何 `>= 2` 的值都盡可能詳細。
- 第三個輸出不太好。

我們來修復這個錯誤：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("square", type=int,
                    help="display a square of a given number")
```

(繼續下一頁)

(繼續上一頁)

```

parser.add_argument("-v", "--verbosity", action="count", default=0,
                    help="increase output verbosity")
args = parser.parse_args()
answer = args.square**2
if args.verbosity >= 2:
    print(f"the square of {args.square} equals {answer}")
elif args.verbosity >= 1:
    print(f"{args.square}^2 == {answer}")
else:
    print(answer)

```

我們剛剛引入了另一個關鍵字 `default`。我們將其設 0，以便使其與其他 `int` 值進行比較。請記住，預設情況下，如果未指定可選引數，它將獲得 `None` 值，且不能與 `int` 值進行比較（因此會出現 `TypeError` 例外）。

而且：

```

$ python prog.py 4
16

```

僅憑我們迄今為止所學到的知識就可以做到很多事情了，不過其實這樣只有學到一點皮毛而已。`argparse` 模組非常強大，在結束本教學之前我們會對它進行更多探索。

### 更進階一點

如果我們想擴充我們的小程式來執行其他次方的運算，而不僅是平方：

```

import argparse
parser = argparse.ArgumentParser()
parser.add_argument("x", type=int, help="the base")
parser.add_argument("y", type=int, help="the exponent")
parser.add_argument("-v", "--verbosity", action="count", default=0)
args = parser.parse_args()
answer = args.x**args.y
if args.verbosity >= 2:
    print(f"{args.x} to the power {args.y} equals {answer}")
elif args.verbosity >= 1:
    print(f"{args.x}^{args.y} == {answer}")
else:
    print(answer)

```

結果：

```

$ python prog.py
usage: prog.py [-h] [-v] x y
prog.py: error: the following arguments are required: x, y
$ python prog.py -h
usage: prog.py [-h] [-v] x y

positional arguments:
  x                the base
  y                the exponent

options:
  -h, --help      show this help message and exit
  -v, --verbosity

$ python prog.py 4 2 -v
4^2 == 16

```

請注意，到目前為止，我們一直在使用詳細級來更改顯示的文字。以下範例使用詳細級來顯示更多文字：

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument("x", type=int, help="the base")
parser.add_argument("y", type=int, help="the exponent")
parser.add_argument("-v", "--verbosity", action="count", default=0)
args = parser.parse_args()
answer = args.x**args.y
if args.verbosity >= 2:
    print(f"Running '{__file__}'")
if args.verbosity >= 1:
    print(f"{args.x}^{args.y} == ", end="")
print(answer)
```

結果:

```
$ python prog.py 4 2
16
$ python prog.py 4 2 -v
4^2 == 16
$ python prog.py 4 2 -vv
Running 'prog.py'
4^2 == 16
```

### 指定不明確的引數

當指定一個引數是位置引數還是引數會有歧義，可以使用 `--` 來告訴 `parse_args()` 之後的所有內容都是位置引數：

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-n', nargs='+')
>>> parser.add_argument('args', nargs='*')

>>> # ambiguous, so parse_args assumes it's an option
>>> parser.parse_args(['-f'])
usage: PROG [-h] [-n N [N ...]] [args ...]
PROG: error: unrecognized arguments: -f

>>> parser.parse_args(['--', '-f'])
Namespace(args=['-f'], n=None)

>>> # ambiguous, so the -n option greedily accepts arguments
>>> parser.parse_args(['-n', '1', '2', '3'])
Namespace(args=[], n=['1', '2', '3'])

>>> parser.parse_args(['-n', '1', '--', '2', '3'])
Namespace(args=['2', '3'], n=['1'])
```

### 相互衝突的選項

到目前為止，我們一直在使用 `argparse.ArgumentParser` 實例的兩種方法。讓我們介紹第三個，`add_mutually_exclusive_group()`，它允許我們指定彼此衝突的選項。我們還可以更改程式的其余部分，以使得新功能更有意義：我們將引入 `--quiet` 選項，該選項與 `--verbose` 選項相反：

```
import argparse

parser = argparse.ArgumentParser()
group = parser.add_mutually_exclusive_group()
group.add_argument("-v", "--verbose", action="store_true")
group.add_argument("-q", "--quiet", action="store_true")
parser.add_argument("x", type=int, help="the base")
```

(繼續下一頁)

(繼續上一頁)

```

parser.add_argument("y", type=int, help="the exponent")
args = parser.parse_args()
answer = args.x**args.y

if args.quiet:
    print(answer)
elif args.verbose:
    print(f"{args.x} to the power {args.y} equals {answer}")
else:
    print(f"{args.x}^{args.y} == {answer}")

```

我們的程式現在更簡單了，我們因功能展示失去了一些功能，但無論如何，以下這是輸出：

```

$ python prog.py 4 2
4^2 == 16
$ python prog.py 4 2 -q
16
$ python prog.py 4 2 -v
4 to the power 2 equals 16
$ python prog.py 4 2 -vq
usage: prog.py [-h] [-v | -q] x y
prog.py: error: argument -q/--quiet: not allowed with argument -v/--verbose
$ python prog.py 4 2 -v --quiet
usage: prog.py [-h] [-v | -q] x y
prog.py: error: argument -q/--quiet: not allowed with argument -v/--verbose

```

這應該很容易理解。我新增了最後一個輸出，以便看到所獲得的靈活性，即可以混合長形式與短形式選項。

在我們結束之前，你可能想告訴使用者你的程式的主要目的，以防他們不知道：

```

import argparse

parser = argparse.ArgumentParser(description="calculate X to the power of Y")
group = parser.add_mutually_exclusive_group()
group.add_argument("-v", "--verbose", action="store_true")
group.add_argument("-q", "--quiet", action="store_true")
parser.add_argument("x", type=int, help="the base")
parser.add_argument("y", type=int, help="the exponent")
args = parser.parse_args()
answer = args.x**args.y

if args.quiet:
    print(answer)
elif args.verbose:
    print(f"{args.x} to the power {args.y} equals {answer}")
else:
    print(f"{args.x}^{args.y} == {answer}")

```

請注意用法文字中的細微差別。注意 `[-v | -q]`，它告訴我們可以使用 `-v` 或 `-q`，但不能同時使用：

```

$ python prog.py --help
usage: prog.py [-h] [-v | -q] x y

calculate X to the power of Y

positional arguments:
  x          the base
  y          the exponent

options:

```

(繼續下一頁)

(繼續上一頁)

```
-h, --help      show this help message and exit
-v, --verbose
-q, --quiet
```

## 如何翻譯 `argparse` 輸出

`argparse` 模組的輸出，例如幫助文字和錯誤訊息，都可以透過使用 `gettext` 模組進行翻譯。這允許應用程式能輕鬆本地化 `argparse` 生成的訊息。另請參閱 [Internationalizing your programs and modules](#)。

例如，在此 `argparse` 輸出中：

```
$ python prog.py --help
usage: prog.py [-h] [-v | -q] x y

calculate X to the power of Y

positional arguments:
  x                the base
  y                the exponent

options:
  -h, --help      show this help message and exit
  -v, --verbose
  -q, --quiet
```

字串 `usage:`、`positional arguments:`、`options:` 和 `show this help message and exit` 都是可被翻譯的。

為了翻譯這些字串，必須先將它們提取到 `.po` 檔案中。例如，使用 `Babel` 執行下列命令：

```
$ pybabel extract -o messages.po /usr/lib/python3.12/argparse.py
```

此命令將從 `argparse` 模組中提取出所有可翻譯的字串，並將它們輸出到名 `messages.po` 的檔案中。這個指令假設你的 Python 是安裝在 `/usr/lib` 中。

你可以使用以下方法找到 `argparse` 模組在系統上的位置：

```
import argparse
print(argparse.__file__)
```

一旦翻譯了 `.po` 檔案中的訊息，使用 `gettext` 安裝了翻譯，`argparse` 將能顯示翻譯後的訊息。

若要在 `argparse` 輸出中翻譯你自己的字串，請使用 `gettext`。

## Custom type converters

The `argparse` module allows you to specify custom type converters for your command-line arguments. This allows you to modify user input before it's stored in the `argparse.Namespace`. This can be useful when you need to pre-process the input before it is used in your program.

When using a custom type converter, you can use any callable that takes a single string argument (the argument value) and returns the converted value. However, if you need to handle more complex scenarios, you can use a custom action class with the `action` parameter instead.

For example, let's say you want to handle arguments with different prefixes and process them accordingly:

```
import argparse

parser = argparse.ArgumentParser(prefix_chars='-+')

parser.add_argument('-a', metavar='<value>', action='append',
```

(繼續下一頁)

(繼續上一頁)

```

        type=lambda x: ('-', x)
parser.add_argument('+a', metavar='<value>', action='append',
                    type=lambda x: ('+', x))

args = parser.parse_args()
print(args)

```

結果:

```

$ python prog.py -a value1 +a value2
Namespace(a=[('-', 'value1'), ('+', 'value2')])

```

在這個範例當中，我們：

- Created a parser with custom prefix characters using the `prefix_chars` parameter.
- Defined two arguments, `-a` and `+a`, which used the `type` parameter to create custom type converters to store the value in a tuple with the prefix.

Without the custom type converters, the arguments would have treated the `-a` and `+a` as the same argument, which would have been undesirable. By using custom type converters, we were able to differentiate between the two arguments.

## 結論

`argparse` 模組提供的功能比此篇內容的要多得多。它的文件非常詳細與透徹有很多範例。讀完本教學後，你應該可以輕鬆消化它們，而不會感到不知所措。

## 將 `optparse` 程式碼遷移到 `argparse`

`argparse` 模組提供了一些高階功能，這些功能在 `optparse` 模組中未原生提供，包括：

- 處理位置引數。
- 支援子命令。
- 允許替代選項前綴，如 `+` 和 `/`。
- 處理零或多個 (zero-or-more) 和一個或多個 (and one-or-more) 樣式的引數。
- 產生更多資訊的使用訊息。
- 自訂 `type` 和 `action` 提供了一個更簡單的介面。

最初 `argparse` 模組試圖保持與 `optparse` 的相容性，但在基礎設計上的存在差異 -- 支援宣告式 (declarative) 命令列選項處理 (同時將位置引數處理留給應用程式的程式碼) 和在宣告式介面中支援命名選項 (named options) 和位置引數 -- 代表 API 隨著時間的推移已經與 `optparse` API 分歧。

如選擇一個命令列參數剖析函式庫 中所述，目前使用 `optparse` 對其運作方式滿意的應用程式可以繼續使用 `optparse`。

在決定是否遷移之前，應用程式開發人員應該先檢閱該段落中描述的在行差清單，來決定是否值得遷移。

對於選擇從 `optparse` 遷移到 `argparse` 的應用程式，以下建議應會有所幫助：

- 將所有 `optparse.OptionParser.add_option()` 呼叫替換 `ArgumentParser.add_argument()` 呼叫。
- 將 `(options, args) = parser.parse_args()` 替換 `args = parser.parse_args()`，位置引數新增額外的 `ArgumentParser.add_argument()` 呼叫。請記住，以前稱 `options` 的東西，在 `argparse` 情境中現在稱 `args`。
- 使用 `parse_intermixed_args()` 來替換掉 `optparse.OptionParser.disable_interspersed_args()`，而不是使用 `parse_args()`。

- 將回呼動作和 `callback_*` 關鍵字引數替 `type` 或 `action` 引數。
- 將 `type` 關鍵字引數的字串名稱替相應的類型物件 (例如 `int`、`float`、`complex` 等)。
- 將 `optparse.Values` 替 `Namespace`，將 `optparse.OptionError` 和 `optparse.OptionValueError` 替 `ArgumentError`。
- 將隱式引數的字串，如 `%default` 或 `%prog` 替使用字典來格式化字串的標準 Python 語法，即 `%(default)s` 和 `%(prog)s`。
- 將 `OptionParser` 建構函式的 `version` 引數替呼叫 `parser.add_argument('--version', action='version', version='<the version>')`。

## 17.2 optparse --- 命令列選項剖析器

原始碼: `Lib/optparse.py`

### 17.2.1 選擇一個命令列參數剖析函式庫

標準函式庫包含三個命令列引數剖析函式庫：

- `getopt`: a module that closely mirrors the procedural C `getopt` API. Included in the standard library since before the initial Python 1.0 release.
- `optparse`: a declarative replacement for `getopt` that provides equivalent functionality without requiring each application to implement its own procedural option parsing logic. Included in the standard library since the Python 2.3 release.
- `argparse`: a more opinionated alternative to `optparse` that provides more functionality by default, at the expense of reduced application flexibility in controlling exactly how arguments are processed. Included in the standard library since the Python 2.7 and Python 3.2 releases.

In the absence of more specific argument parsing design constraints, `argparse` is the recommended choice for implementing command line applications, as it offers the highest level of baseline functionality with the least application level code.

`getopt` is retained almost entirely for backwards compatibility reasons. However, it also serves a niche use case as a tool for prototyping and testing command line argument handling in `getopt`-based C applications.

`optparse` should be considered as an alternative to `argparse` in the following cases:

- an application is already using `optparse` and doesn't want to risk the subtle behavioural changes that may arise when migrating to `argparse`
- the application requires additional control over the way options and positional parameters are interleaved on the command line (including the ability to disable the interleaving feature completely)
- the application requires additional control over the incremental parsing of command line elements (while `argparse` does support this, the exact way it works in practice is undesirable for some use cases)
- the application requires additional control over the handling of options which accept parameter values that may start with `-` (such as delegated options to be passed to invoked subprocesses)
- the application requires some other command line parameter processing behavior which `argparse` does not support, but which can be implemented in terms of the lower level interface offered by `optparse`

These considerations also mean that `optparse` is likely to provide a better foundation for library authors writing third party command line argument processing libraries.

As a concrete example, consider the following two command line argument parsing configurations, the first using `optparse`, and the second using `argparse`:

```
import optparse

if __name__ == '__main__':
    parser = optparse.OptionParser()
    parser.add_option('-o', '--output')
    parser.add_option('-v', dest='verbose', action='store_true')
    opts, args = parser.parse_args()
    process(args, output=opts.output, verbose=opts.verbose)
```

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    parser.add_argument('rest', nargs='*')
    args = parser.parse_args()
    process(args.rest, output=args.output, verbose=args.verbose)
```

The most obvious difference is that in the `optparse` version, the non-option arguments are processed separately by the application after the option processing is complete. In the `argparse` version, positional arguments are declared and processed in the same way as the named options.

However, the `argparse` version will also handle some parameter combination differently from the way the `optparse` version would handle them. For example (amongst other differences):

- supplying `-o -v` gives `output="-v"` and `verbose=False` when using `optparse`, but a usage error with `argparse` (complaining that no value has been supplied for `-o/--output`, since `-v` is interpreted as meaning the verbosity flag)
- similarly, supplying `-o --` gives `output="--"` and `args=()` when using `optparse`, but a usage error with `argparse` (also complaining that no value has been supplied for `-o/--output`, since `--` is interpreted as terminating the option processing and treating all remaining values as positional arguments)
- supplying `-o=foo` gives `output="=foo"` when using `optparse`, but gives `output="foo"` with `argparse` (since `=` is special cased as an alternative separator for option parameter values)

Whether these differing behaviors in the `argparse` version are considered desirable or a problem will depend on the specific command line application use case.

### 👉 也參考

`click` is a third party argument processing library (originally based on `optparse`), which allows command line applications to be developed as a set of decorated command implementation functions.

Other third party libraries, such as `typer` or `msgspec-click`, allow command line interfaces to be specified in ways that more effectively integrate with static checking of Python type annotations.

## 17.2.2 Introduction

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the minimalist `getopt` module. `optparse` uses a more declarative style of command-line parsing: you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script:

```
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
```

(繼續下一頁)

(繼續上一頁)

```

        help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose", default=True,
                  help="don't print status messages to stdout")

(options, args) = parser.parse_args()

```

With these few lines of code, users of your script can now do the "usual thing" on the command-line, for example:

```
<yourscript> --file=outfile -q
```

As it parses the command line, *optparse* sets attributes of the *options* object returned by *parse\_args()* based on user-supplied command-line values. When *parse\_args()* returns from parsing this command line, *options.filename* will be "outfile" and *options.verbose* will be *False*. *optparse* supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```

<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -foutfile
<yourscript> -qfoutfile

```

Additionally, users can run one of the following

```

<yourscript> -h
<yourscript> --help

```

and *optparse* will print out a brief summary of your script's options:

```

Usage: <yourscript> [options]

Options:
  -h, --help            show this help message and exit
  -f FILE, --file=FILE  write report to FILE
  -q, --quiet           don't print status messages to stdout

```

where the value of *yourscript* is determined at runtime (normally from *sys.argv[0]*).

## 17.2.3 背景

*optparse* was explicitly designed to encourage the creation of programs with straightforward command-line interfaces that follow the conventions established by the *getopt()* family of functions available to C developers. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, reading this section will allow you to acquaint yourself with them.

### 術語

#### 引數

a string entered on the command-line, and passed by the shell to *execl()* or *execv()*. In Python, arguments are elements of *sys.argv[1:]* (*sys.argv[0]* is the name of the program being executed). Unix shells also use the term "word".

It is occasionally desirable to substitute an argument list other than *sys.argv[1:]*, so you should read "argument" as "an element of *sys.argv[1:]*", or of some other list provided as a substitute for *sys.argv[1:]*".

#### 選項

an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen ("-") followed by a single letter, e.g. *-x* or *-F*. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. *-x -F* is equivalent to *-xF*. The GNU project introduced *--* followed by a series of hyphen-separated words, e.g. *--file* or *--dry-run*. These are the only two option syntaxes provided by *optparse*.

Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is *not* the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren't usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by `optparse`, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you're exclusively targeting Windows or certain legacy platforms (e.g. VMS, MS-DOS).

### 選項引數

an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With `optparse`, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-ffoo
--file=foo
```

Typically, a given option either takes an argument or it doesn't. Lots of people want an "optional option arguments" feature, meaning that some options will take an argument if they see it, and won't if they don't. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and `-b` is another option entirely, how do we interpret `-ab`? Because of this ambiguity, `optparse` does not support this feature.

### 位置引數

something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

### required option

an option that must be supplied on the command-line; note that the phrase "required option" is self-contradictory in English. `optparse` doesn't prevent you from implementing required options, but doesn't give you much help at it either.

For example, consider this hypothetical command-line:

```
prog -v --report report.txt foo bar
```

`-v` and `--report` are both options. Assuming that `--report` takes one argument, `report.txt` is an option argument. `foo` and `bar` are positional arguments.

### What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn't clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are `find`, `tar`, and `dd`--all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have "required options". Think about it. If it's required, then it's *not optional*! If there is a piece of information that your program absolutely requires in order to run successfully, that's what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn't make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

### What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn't much matter *how* you get that information from the user---most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply---use sensible defaults whenever possible. Of course, you also want to make your programs reasonably flexible. That's what options are for. Again, it doesn't matter if they are entries in a config file, widgets in the "Preferences" dialog of a GUI, or command-line options---the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.

## 17.2.4 教學

While `optparse` is quite flexible and powerful, it's also straightforward to use in most cases. This section covers the code patterns that are common to any `optparse`-based program.

First, you need to import the `OptionParser` class; then, early in the main program, create an `OptionParser` instance:

```
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```
parser.add_option(opt_str, ...,
                 attr=value, ...)
```

Each option has one or more option strings, such as `-f` or `--file`, and several option attributes that tell `optparse` what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```
parser.add_option("-f", "--file", ...)
```

You're free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to `OptionParser.add_option()` are effectively labels for the option defined by that call. For brevity, we will frequently refer to *encountering an option* on the command line; in reality, `optparse` encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct `optparse` to parse your program's command line:

```
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` 回傳兩個值:

- `options`, an object containing values for all of your options---e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- `args`, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes: `action`, `type`, `dest` (destination), and `help`. Of these, `action` is the most fundamental.

## Understanding option actions

Actions tell `optparse` what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into `optparse`; adding new actions is an advanced topic covered in section [Extending optparse](#). Most actions tell `optparse` to store a value in some variable---for example, take a string from the command line and store it in an attribute of `options`.

If you don't specify an option action, `optparse` defaults to `store`.

## The store action

The most common option action is `store`, which tells `optparse` to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

舉例來:

```
parser.add_option("-f", "--file",
                  action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask `optparse` to parse it:

```
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When `optparse` sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is `"foo.txt"`.

Some other option types supported by `optparse` are `int` and `float`. Here's an option that expects an integer argument:

```
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code

```
(options, args) = parser.parse_args(["-n42"])
print(options.num)
```

會印出 42。

If you don't specify a type, `optparse` assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, `optparse` figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, `optparse` looks at the first short option string: the default destination for `-f` is `f`.

`optparse` also includes the built-in `complex` type. Adding types is covered in section [Extending optparse](#).

## Handling boolean (flag) options

Flag options---set a variable to true or false when a particular option is seen---are quite common. *optparse* supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values---see below.)

When *optparse* encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

## Other actions

Some other actions supported by *optparse* are:

- "store\_const"**  
store a constant value, pre-set via *Option.const*
- "append"**  
append this option's argument to a list
- "count"**  
increment a counter by one
- "callback"**  
call a specified function

These are covered in section *Reference Guide*, and section *Option Callbacks*.

## 預設值

All of the above examples involve setting some variable (the "destination") when certain command-line options are seen. What happens if those options are never seen? Since we didn't supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. *optparse* lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the verbose/quiet example. If we want *optparse* to set `verbose` to `True` unless `-q` is seen, then we can do this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=True)
parser.add_option("-q", action="store_false", dest="verbose")
```

Since default values apply to the *destination* rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Consider this:

```
parser.add_option("-v", action="store_true", dest="verbose", default=False)
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for `verbose` will be `True`: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the `set_defaults()` method of *OptionParser*, which you can call at any time before calling `parse_args()`:

```
parser.set_defaults(verbose=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

## Generating help

*optparse*'s ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a *help* value for each option, and optionally a short usage message for your whole program. Here's an *OptionParser* populated with user-friendly (documented) options:

```
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose", default=True,
                  help="make lots of noise [default]")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose",
                  help="be vewwy quiet (I'm hunting wabbits)")
parser.add_option("-f", "--filename",
                  metavar="FILE", help="write output to FILE")
parser.add_option("-m", "--mode",
                  default="intermediate",
                  help="interaction mode: novice, intermediate, "
                       "or expert [default: %default]")
```

If *optparse* encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output:

```
Usage: <yourscrip> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]
```

(If the help output is triggered by a help option, *optparse* exits after printing the help text.)

There's a lot going on here to help *optparse* generate the best possible help message:

- the script defines its own usage message:

```
usage = "usage: %prog [options] arg1 arg2"
```

*optparse* expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don't supply a usage string, *optparse* uses a bland but sensible default: `"Usage: %prog [options]"`, which is fine if your script doesn't take any positional arguments.

- every option defines a help string, and doesn't worry about line-wrapping---*optparse* takes care of wrapping lines and making the help output look good.
- options that take a value indicate this fact in their automatically generated help message, e.g. for the "mode" option:

```
-m MODE, --mode=MODE
```

Here, "MODE" is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that's not what you want---for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically generated option description:

```
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there's a connection between the semi-formal syntax `-f FILE` and the informal semantic description "write output to `FILE`". This is a simple but effective way to make your help text a lot clearer and more useful for end users.

- options that have a default value can include `%default` in the help string---`optparse` will replace it with `str()` of the option's default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

## Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup`:

```
class optparse.OptionGroup(parser, title, description=None)
```

where

- `parser` is the `OptionParser` instance the group will be inserted in to
- `title` is the group title
- `description`, optional, is a long description of the group

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an `OptionGroup` to a parser is easy:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet          be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, or
                        expert [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
```

(繼續下一頁)

(繼續上一頁)

```
of them bite.

-g                Group option.
```

A bit more complete example might involve using more than one group: still extending the previous example:

```
group = OptionGroup(parser, "Dangerous Options",
                    "Caution: use these options at your own risk. "
                    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.")
parser.add_option_group(group)

group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
                help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
                help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every action done")
parser.add_option_group(group)
```

that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet          be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
                        write output to FILE
  -m MODE, --mode=MODE interaction mode: novice, intermediate, or expert
                        [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk.  It is believed that some
  of them bite.

  -g                Group option.

Debug Options:
  -d, --debug        Print debug information
  -s, --sql          Print all SQL statements executed
  -e                Print every action done
```

Another interesting method, in particular when working programmatically with option groups is:

`OptionParser.get_option_group(opt_str)`

Return the `OptionGroup` to which the short or long option string *opt\_str* (e.g. '-o' or '--option') belongs. If there's no such `OptionGroup`, return `None`.

### Printing a version string

Similar to the brief usage string, `optparse` can also print a version string for your program. You have to supply the string as the `version` argument to `OptionParser`:

```
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")
```

`%prog` is expanded just like it is in usage. Apart from that, `version` can contain anything you like. When you supply it, `optparse` automatically adds a `--version` option to your parser. If it encounters this option on the command line, it expands your `version` string (by replacing `%prog`), prints it to `stdout`, and exits.

For example, if your script is called `/usr/bin/foo`:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the `version` string:

`OptionParser.print_version(file=None)`

Print the version message for the current program (`self.version`) to `file` (default `stdout`). As with `print_usage()`, any occurrence of `%prog` in `self.version` is replaced with the name of the current program. Does nothing if `self.version` is empty or undefined.

`OptionParser.get_version()`

Same as `print_version()` but returns the version string instead of printing it.

### How `optparse` handles errors

There are two broad classes of errors that `optparse` has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to `OptionParser.add_option()`, e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either `optparse.OptionError` or `TypeError`) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. `optparse` can automatically detect some user errors, such as bad option arguments (passing `-n 4x` where `-n` takes an integer argument), missing arguments (`-n` at the end of the command line, where `-n` takes an argument of any type). Also, you can call `OptionParser.error()` to signal an application-defined error condition:

```
(options, args) = parser.parse_args()
...
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
```

In either case, `optparse` handles the error the same way: it prints the program's usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes `4x` to an option that takes an integer:

```
$ /usr/bin/foo -n 4x
Usage: foo [options]

foo: error: option -n: invalid integer value: '4x'
```

Or, where the user fails to pass a value at all:

```
$ /usr/bin/foo -n
Usage: foo [options]

foo: error: -n option requires an argument
```

`optparse`-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling `OptionParser.error()` from your application code.

If `optparse`'s default error-handling behaviour does not suit your needs, you'll need to subclass `OptionParser` and override its `exit()` and/or `error()` methods.

### Putting it all together

Here's what `optparse`-based scripts usually look like:

```
from optparse import OptionParser
...
def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
```

(繼續下一頁)

```

parser.add_option("-f", "--file", dest="filename",
                  help="read data from FILENAME")
parser.add_option("-v", "--verbose",
                  action="store_true", dest="verbose")
parser.add_option("-q", "--quiet",
                  action="store_false", dest="verbose")
...
(options, args) = parser.parse_args()
if len(args) != 1:
    parser.error("incorrect number of arguments")
if options.verbose:
    print("reading %s..." % options.filename)
...

if __name__ == "__main__":
    main()

```

## 17.2.5 Reference Guide

### Creating the parser

The first step in using *optparse* is to create an `OptionParser` instance.

```
class optparse.OptionParser(...)
```

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

**usage (default: "%prog [options]")**

The usage summary to print when your program is run incorrectly or with a help option. When *optparse* prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

**option\_list (default: [])**

A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any version or help options. Deprecated; use `add_option()` after creating the parser instead.

**option\_class (default: optparse.Option)**

Class to use when adding options to the parser in `add_option()`.

**version (default: None)**

A version string to print when the user supplies a version option. If you supply a true value for `version`, *optparse* automatically adds a version option with the single option string `--version`. The substring `%prog` is expanded the same as for `usage`.

**conflict\_handler (default: "error")**

Specifies what to do when options with conflicting option strings are added to the parser; see section *Conflicts between options*.

**description (default: None)**

A paragraph of text giving a brief overview of your program. *optparse* reformats this paragraph to fit the current terminal width and prints it when the user requests help (after `usage`, but before the list of options).

**formatter (default: a new IndentedHelpFormatter)**

An instance of `optparse.HelpFormatter` that will be used for printing help text. *optparse* provides two concrete classes for this purpose: `IndentedHelpFormatter` and `TitledHelpFormatter`.

**add\_help\_option (default: True)**

If true, *optparse* will add a help option (with option strings `-h` and `--help`) to the parser.

**prog**

The string to use when expanding `%prog` in `usage` and `version` instead of `os.path.basename(sys.argv[0])`.

**epilog (default: None)**

A paragraph of help text to print after the option help.

**Populating the parser**

There are several ways to populate the parser with options. The preferred way is by using `OptionParser.add_option()`, as shown in section [教學](#). `add_option()` can be called in one of two ways:

- pass it an `Option` instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the `Option` constructor), and it will create the `Option` instance for you

The other alternative is to pass a list of pre-constructed `Option` instances to the `OptionParser` constructor, as in:

```
option_list = [
    make_option("-f", "--filename",
                action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
                action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating `Option` instances; currently it is an alias for the `Option` constructor. A future version of `optparse` may split `Option` into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate `Option` directly.)

**定義選項**

Each `Option` instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.

The canonical way to create an `Option` instance is with the `add_option()` method of `OptionParser`.

`OptionParser.add_option(option)`

`OptionParser.add_option(*opt_str, attr=value, ...)`

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new `Option` object. The most important option attribute is `action`, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, `optparse` raises an `OptionError` exception explaining your mistake.

An option's `action` determines what `optparse` does when it encounters this option on the command-line. The standard option actions hard-coded into `optparse` are:

**"store"**

store this option's argument (default)

**"store\_const"**

store a constant value, pre-set via `Option.const`

**"store\_true"**

store `True`

```

"store_false"
    store False

"append"
    append this option's argument to a list

"append_const"
    append a constant value to a list, pre-set via Option.const

"count"
    increment a counter by one

"callback"
    call a specified function

"help"
    print a usage message including all options and the documentation for them

```

(If you don't supply an action, the default is "store". For this action, you may also supply *type* and *dest* option attributes; see *Standard option actions*.)

As you can see, most actions involve storing or updating a value somewhere. *optparse* always creates a special object for this, conventionally called *options*, which is an instance of *optparse.Values*.

#### class *optparse.Values*

An object holding parsed argument names and values as attributes. Normally created by calling when calling *OptionParser.parse\_args()*, and can be overridden by a custom subclass passed to the *values* argument of *OptionParser.parse\_args()* (as described in 剖析引數).

Option arguments (and various other values) are stored as attributes of this object, according to the *dest* (destination) option attribute.

例如，當你呼叫：

```
parser.parse_args()
```

one of the first things *optparse* does is create the *options* object:

```
options = Values()
```

If one of the options in this parser is defined with

```
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

and the command-line being parsed includes any of the following:

```
-ffoo
-f foo
--file=foo
--file foo
```

then *optparse*, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The *type* and *dest* option attributes are almost as important as *action*, but *action* is the only one that makes sense for *all* options.

#### 選項屬性

#### class *optparse.Option*

A single command line argument, with various attributes passed by keyword to the constructor. Normally created with *OptionParser.add\_option()* rather than directly, and can be overridden by a custom class via the *option\_class* argument to *OptionParser*.

The following option attributes may be passed as keyword arguments to `OptionParser.add_option()`. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, `optparse` raises `OptionError`.

**Option.action**

(預設值: "store")

Determines `optparse`'s behaviour when this option is seen on the command line; the available options are documented [here](#).

**Option.type**

(預設值: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented [here](#).

**Option.dest**

(default: derived from option strings)

If the option's action implies writing or modifying a value somewhere, this tells `optparse` where to write it: `dest` names an attribute of the `options` object that `optparse` builds as it parses the command line.

**Option.default**

The value to use for this option's destination if the option is not seen on the command line. See also `OptionParser.set_defaults()`.

**Option.nargs**

(預設值: 1)

How many arguments of type `type` should be consumed when this option is seen. If  $> 1$ , `optparse` will store a tuple of values to `dest`.

**Option.const**

For actions that store a constant value, the constant value to store.

**Option.choices**

For options of type "choice", the list of strings the user may choose from.

**Option.callback**

For options with action "callback", the callable to call when this option is seen. See section [Option Callbacks](#) for detail on the arguments passed to the callable.

**Option.callback\_args**

**Option.callback\_kwargs**

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.

**Option.help**

Help text to print for this option when listing all available options after the user supplies a `help` option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

**Option metavar**

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section [教學](#) for an example.

## Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide `optparse`'s behaviour; a few have required attributes, which you must specify for any option using that action.

- "store" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is converted to a value according to *type* and stored in *dest*. If *nargs* > 1, multiple arguments will be consumed from the command line; all will be converted according to *type* and stored to *dest* as a tuple. See the *Standard option types* section.

If *choices* is supplied (a list or tuple of strings), the type defaults to "choice".

If *type* is not supplied, it defaults to "string".

If *dest* is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there are no long option strings, *optparse* derives a destination from the first short option string (e.g., `-f` implies `f`).

範例：

```
parser.add_option("-f")
parser.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

*optparse* will set

```
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- "store\_const" [required: *const*; relevant: *dest*]

The value *const* is stored in *dest*.

範例：

```
parser.add_option("-q", "--quiet",
                 action="store_const", const=0, dest="verbose")
parser.add_option("-v", "--verbose",
                 action="store_const", const=1, dest="verbose")
parser.add_option("--noisy",
                 action="store_const", const=2, dest="verbose")
```

If `--noisy` is seen, *optparse* will set

```
options.verbose = 2
```

- "store\_true" [relevant: *dest*]

A special case of "store\_const" that stores True to *dest*.

- "store\_false" [relevant: *dest*]

Like "store\_true", but stores False.

範例：

```
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="clobber")
```

- "append" [relevant: *type*, *dest*, *nargs*, *choices*]

The option must be followed by an argument, which is appended to the list in *dest*. If no default value for *dest* is supplied, an empty list is automatically created when *optparse* first encounters this option on the command-line. If *nargs* > 1, multiple arguments are consumed, and a tuple of length *nargs* is appended to *dest*.

The defaults for *type* and *dest* are the same as for the "store" action.

範例：

```
parser.add_option("-t", "--tracks", action="append", type="int")
```

If `-t3` is seen on the command-line, `optparse` does the equivalent of:

```
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, `--tracks=4` is seen, it does:

```
options.tracks.append(int("4"))
```

The `append` action calls the `append` method on the current value of the option. This means that any default value specified must have an `append` method. It also means that if the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values:

```
>>> parser.add_option("--files", action="append", default=['~/mypkg/defaults'])
>>> opts, args = parser.parse_args(['--files', 'overrides.mypkg'])
>>> opts.files
['~/mypkg/defaults', 'overrides.mypkg']
```

- "append\_const" [required: *const*; relevant: *dest*]

Like "store\_const", but the value *const* is appended to *dest*; as with "append", *dest* defaults to None, and an empty list is automatically created the first time the option is encountered.

- "count" [relevant: *dest*]

Increment the integer stored at *dest*. If no default value is supplied, *dest* is set to zero before being incremented the first time.

範例：

```
parser.add_option("-v", action="count", dest="verbosity")
```

The first time `-v` is seen on the command line, `optparse` does the equivalent of:

```
options.verbosity = 0
options.verbosity += 1
```

Every subsequent occurrence of `-v` results in

```
options.verbosity += 1
```

- "callback" [required: *callback*; relevant: *type*, *nargs*, *callback\_args*, *callback\_kwargs*]

Call the function specified by *callback*, which is called as

```
func(option, opt_str, value, parser, *args, **kwargs)
```

更多細節請見 *Option Callbacks*。

- "help"

Prints a complete help message for all the options in the current option parser. The help message is constructed from the *usage* string passed to `OptionParser`'s constructor and the *help* string passed to every option.

If no *help* string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value `optparse.SUPPRESS_HELP`.

`optparse` automatically adds a *help* option to all `OptionParsers`, so you do not normally need to create one.

範例：

```

from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can
# be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                  help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                  help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)

```

If *optparse* sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is `"foo.py"`):

```

Usage: foo.py [options]

Options:
  -h, --help          Show this help message and exit
  -v                  Be moderately verbose
  --file=FILENAME    Input file to read data from

```

After printing the help message, *optparse* terminates your process with `sys.exit(0)`.

- "version"

Prints the version number supplied to the `OptionParser` to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of `OptionParser`. Generally only relevant if the `version` argument is supplied to the `OptionParser` constructor. As with *help* options, you will rarely create *version* options, since *optparse* automatically adds them when needed.

## Standard option types

*optparse* has five built-in option types: "string", "int", "choice", "float" and "complex". If you need to add new option types, see section *Extending optparse*.

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type "int") are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling `int()` with the appropriate base (2, 8, 10, or 16). If this fails, so will *optparse*, although with a more useful error message.

"float" and "complex" option arguments are converted directly with `float()` and `complex()`, with similar error-handling.

"choice" options are a subtype of "string" options. The *choices* option attribute (a sequence of strings) defines the set of allowed option arguments. `optparse.check_choice()` compares user-supplied option arguments against this master list and raises `OptionValueError` if an invalid string is given.

## 剖析引數

The whole point of creating and populating an `OptionParser` is to call its `parse_args()` method.

`OptionParser.parse_args(args=None, values=None)`

Parse the command-line options found in *args*.

The input parameters are

### **args**

the list of arguments to process (default: `sys.argv[1:]`)

### **values**

a `Values` object to store option arguments in (default: a new instance of `Values`) -- if you give an existing object, the option defaults will not be initialized on it

and the return value is a pair (`options, args`) where

### **options**

the same object that was passed in as *values*, or the `optparse.Values` instance created by `optparse`

### **args**

the leftover positional arguments after all options have been processed

The most common usage is to supply neither keyword argument. If you supply *values*, it will be modified with repeated `setattr()` calls (roughly one for every option argument stored to an option destination) and returned by `parse_args()`.

If `parse_args()` encounters any errors in the argument list, it calls the `OptionParser`'s `error()` method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

## Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. `OptionParser` provides several methods to help you out:

`OptionParser.disable_interspersed_args()`

Set parsing to stop on the first non-option. For example, if `-a` and `-b` are both simple options that take no arguments, `optparse` normally accepts this syntax:

```
prog -a arg1 -b arg2
```

and treats it as equivalent to

```
prog -a -b arg1 arg2
```

To disable this feature, call `disable_interspersed_args()`. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another command which has options of its own and you want to make sure these options don't get confused. For example, each command might have a different set of options.

`OptionParser.enable_interspersed_args()`

Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

`OptionParser.get_option(opt_str)`

Returns the `Option` instance with the option string *opt\_str*, or `None` if no options have that option string.

`OptionParser.has_option(opt_str)`

Return `True` if the `OptionParser` has an option with option string *opt\_str* (e.g., `-q` or `--verbose`).

`OptionParser.remove_option(opt_str)`

If the `OptionParser` has an option corresponding to `opt_str`, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If `opt_str` does not occur in any option belonging to this `OptionParser`, raises `ValueError`.

### Conflicts between options

If you're not careful, it's easy to define options with conflicting option strings:

```
parser.add_option("-n", "--dry-run", ...)
...
parser.add_option("-n", "--noisy", ...)
```

(This is particularly true if you've defined your own `OptionParser` subclass with some standard options.)

Every time you add an option, `optparse` checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

**"error" (default)**

assume option conflicts are a programming error and raise `OptionConflictError`

**"resolve"**

resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously added option is already using the `-n` option string. Since `conflict_handler` is `"resolve"`, it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```
Options:
  --dry-run      do no harm
  ...
  -n, --noisy   be noisy
```

It's possible to whittle away the option strings for a previously added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, `optparse` removes that option completely, so it doesn't show up in help text or anywhere else. Carrying on with our existing `OptionParser`:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/--dry-run` option is no longer accessible, so `optparse` removes it, leaving this help text:

```
Options:
  ...
  -n, --noisy   be noisy
  --dry-run     new dry-run option
```

## Cleanup

`OptionParser` instances have several cyclic references. This should not be a problem for Python's garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your `OptionParser` once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your `OptionParser`.

## 其他方法

`OptionParser` supports several other public methods:

`OptionParser.set_usage(usage)`

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a usage message.

`OptionParser.print_usage(file=None)`

Print the usage message for the current program (`self.usage`) to `file` (default `stdout`). Any occurrence of the string `%prog` in `self.usage` is replaced with the name of the current program. Does nothing if `self.usage` is empty or not defined.

`OptionParser.get_usage()`

Same as `print_usage()` but returns the usage string instead of printing it.

`OptionParser.set_defaults(dest=value, ...)`

Set default values for several option destinations at once. Using `set_defaults()` is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several "mode" options all set the same destination, any one of them can set the default, and the last one wins:

```
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced",
                  default="novice") # overridden below
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice",
                  default="advanced") # overrides above setting
```

To avoid this confusion, use `set_defaults()`:

```
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                  dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                  dest="mode", const="novice")
```

## 17.2.6 Option Callbacks

When `optparse`'s built-in actions and types aren't quite enough for your needs, you have two choices: extend `optparse` or define a callback option. Extending `optparse` is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

### Defining a callback option

As always, the easiest way to define a callback option is by using the `OptionParser.add_option()` method. Apart from `action`, the only option attribute you must specify is `callback`, the function to call:

```
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, `optparse` doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments---the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it's covered later in this section.

`optparse` always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via `callback_args` and `callback_kwargs`. Thus, the minimal callback function signature is:

```
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

#### *type*

has its usual meaning: as with the "store" or "append" actions, it instructs `optparse` to consume one argument and convert it to *type*. Rather than storing the converted value(s) anywhere, though, `optparse` passes it to your callback function.

#### *nargs*

also has its usual meaning: if it is supplied and  $> 1$ , `optparse` will consume *nargs* arguments, each of which must be convertible to *type*. It then passes a tuple of converted values to your callback.

#### *callback\_args*

a tuple of extra positional arguments to pass to the callback

#### *callback\_kwargs*

a dictionary of extra keyword arguments to pass to the callback

### How callbacks are called

All callbacks are called as follows:

```
func(option, opt_str, value, parser, *args, **kwargs)
```

where

#### **option**

is the Option instance that's calling the callback

#### **opt\_str**

is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, `opt_str` will be the full, canonical option string---e.g. if the user puts `--foo` on the command-line as an abbreviation for `--foobar`, then `opt_str` will be `--foobar`.)

#### **value**

is the argument to this option seen on the command-line. `optparse` will only expect an argument if *type* is set; the type of `value` will be the type implied by the option's type. If *type* for this option is `None` (no argument expected), then `value` will be `None`. If *nargs*  $> 1$ , `value` will be a tuple of values of the appropriate type.

#### **parser**

is the OptionParser instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

##### **parser.largs**

the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify `parser.largs`, e.g. by adding more arguments to it. (This list will become `args`, the second return value of `parse_args()`.)

##### **parser.rargs**

the current list of remaining arguments, ie. with `opt_str` and `value` (if applicable) removed, and only the arguments following them still there. Feel free to modify `parser.rargs`, e.g. by consuming more arguments.

**parser.values**

the object where option values are by default stored (an instance of `optparse.OptionValues`). This lets callbacks use the same mechanism as the rest of `optparse` for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

**args**

is a tuple of arbitrary positional arguments supplied via the `callback_args` option attribute.

**kwargs**

is a dictionary of arbitrary keyword arguments supplied via `callback_kwargs`.

**Raising errors in a callback**

The callback function should raise `OptionValueError` if there are any problems with the option or its argument(s). `optparse` catches this and terminates the program, printing the error message you supply to `stderr`. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what they did wrong.

**Callback example 1: trivial callback**

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True

parser.add_option("--foo", action="callback", callback=record_foo_seen)
```

Of course, you could do that with the "store\_true" action.

**Callback example 2: check option order**

Here's a slightly more interesting example: record the fact that `-a` is seen, but blow up if it comes after `-b` in the command-line.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1
    ...
parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

**Callback example 3: check option order (generalized)**

If you want to reuse this callback for several similar options (set a flag, but blow up if `-b` has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)
    ...
parser.add_option("-a", action="callback", callback=check_order, dest='a')
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order, dest='c')
```

### Callback example 4: check arbitrary condition

Of course, you could put any condition in there---you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```
def check_moon(option, opt_str, value, parser):
    if is_moon_full():
        raise OptionValueError("%s option invalid when moon is full"
                                % opt_str)
    setattr(parser.values, option.dest, 1)
...
parser.add_option("--foo",
                  action="callback", callback=check_moon, dest="foo")
```

(The definition of `is_moon_full()` is left as an exercise for the reader.)

### Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define `type`, then the option takes one argument that must be convertible to that type; if you further define `nargs`, then the option takes `nargs` arguments.

Here's an example that just emulates the standard "store" action:

```
def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)
...
parser.add_option("--foo",
                  action="callback", callback=store_value,
                  type="int", nargs=3, dest="foo")
```

Note that `optparse` takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don't need a callback for this example.)

### Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number of arguments. For this case, you must write a callback, as `optparse` doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that `optparse` normally handles for you. In particular, callbacks should implement the conventional rules for bare `--` and `-` arguments:

- either `--` or `-` can be option arguments
- bare `--` (if not the argument to some option): halt command-line processing and discard the `--`
- bare `-` (if not the argument to some option): halt command-line processing but keep the `-` (append it to `parser.largs`)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why `optparse` doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
```

(繼續下一頁)

(繼續上一頁)

```

        return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
        if arg[:1] == "-" and len(arg) > 1 and not floatable(arg):
            break
        value.append(arg)

    del parser.rargs[:len(value)]
    setattr(parser.values, option.dest, value)

...
parser.add_option("-c", "--callback", dest="vararg_attr",
                  action="callback", callback=vararg_callback)

```

## 17.2.7 Extending `optparse`

Since the two major controlling factors in how `optparse` interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

### Adding new types

To add new types, you need to define your own subclass of `optparse`'s `Option` class. This class has a couple of attributes that define `optparse`'s types: `TYPES` and `TYPE_CHECKER`.

#### `Option.TYPES`

A tuple of type names; in your subclass, simply define a new tuple `TYPES` that builds on the standard one.

#### `Option.TYPE_CHECKER`

A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```
def check_mytype(option, opt, value)
```

where `option` is an `Option` instance, `opt` is an option string (e.g., `-f`), and `value` is the string from the command line that must be checked and converted to your desired type. `check_mytype()` should return an object of the hypothetical type `mytype`. The value returned by a type-checking function will wind up in the `OptionValues` instance returned by `OptionParser.parse_args()`, or be passed to a callback as the `value` parameter.

Your type-checking function should raise `OptionValueError` if it encounters any problems. `OptionValueError` takes a single string argument, which is passed as-is to `OptionParser`'s `error()` method, which in turn prepends the program name and the string "error:" and prints everything to `stderr` before terminating the process.

Here's a silly example that demonstrates adding a "complex" option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because `optparse` 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the `TYPE_CHECKER` class attribute of your `Option` subclass):

```
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError(
            "option %s: invalid complex value: %r" % (opt, value))
```

Finally, the Option subclass:

```
class MyOption (Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a `copy()` of `Option.TYPE_CHECKER`, we would end up modifying the `TYPE_CHECKER` attribute of `optparse`'s Option class. This being Python, nothing stops you from doing that except good manners and common sense.)

That's it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to instruct your OptionParser to use MyOption instead of Option:

```
parser = OptionParser(option_class=MyOption)
parser.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to OptionParser; if you don't use `add_option()` in the above way, you don't need to tell OptionParser which option class to use:

```
option_list = [MyOption("-c", action="store", type="complex", dest="c")]
parser = OptionParser(option_list=option_list)
```

## Adding new actions

Adding new actions is a bit trickier, because you have to understand that `optparse` has a couple of classifications for actions:

### ”store” actions

actions that result in `optparse` storing a value to an attribute of the current OptionValues instance; these options require a `dest` attribute to be supplied to the Option constructor.

### ”typed” actions

actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a `type` attribute to the Option constructor.

These are overlapping sets: some default ”store” actions are "store", "store\_const", "append", and "count", while the default ”typed” actions are "store", "append", and "callback".

When you add an action, you need to categorize it by listing it in at least one of the following class attributes of Option (all are lists of strings):

#### Option.ACTIONS

All actions must be listed in ACTIONS.

#### Option.STORE\_ACTIONS

”store” actions are additionally listed here.

#### Option.TYPED\_ACTIONS

”typed” actions are additionally listed here.

#### Option.ALWAYS\_TYPED\_ACTIONS

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that `optparse` assigns the default type, "string", to options with no explicit type whose action is listed in `ALWAYS_TYPED_ACTIONS`.

In order to actually implement your new action, you must override `Option`'s `take_action()` method and add a case that recognizes your action.

For example, let's add an "extend" action. This is similar to the standard "append" action, but instead of taking a single value from the command-line and appending it to an existing list, "extend" will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if `--names` is an "extend" option of type "string", the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```

Again we define a subclass of `Option`:

```
class MyOption(Option):

    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
            Option.take_action(
                self, action, dest, opt, value, values, parser)
```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both `STORE_ACTIONS` and `TYPED_ACTIONS`.
- to ensure that `optparse` assigns the default type of "string" to "extend" actions, we put the "extend" action in `ALWAYS_TYPED_ACTIONS` as well.
- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard `optparse` actions.
- `values` is an instance of the `optparse_parser.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially `getattr()` with a safety valve; it is called as

```
values.ensure_value(attr, value)
```

If the `attr` attribute of `values` doesn't exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns `value`. This is very handy for actions like "extend", "append", and "count", all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don't have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it's needed.

## 17.2.8 例外

**exception** `optparse.OptionError`

Raised if an `Option` instance is created with invalid or inconsistent arguments.

**exception** `optparse.OptionConflictError`

Raised if conflicting options are added to an `OptionParser`.

**exception** `optparse.OptionValueError`

Raised if an invalid option value is encountered on the command line.

**exception** `optparse.BadOptionError`

Raised if an invalid option is passed on the command line.

**exception** `optparse.AmbiguousOptionError`

Raised if an ambiguous option is passed on the command line.

## 17.3 `getpass` --- 可式密碼輸入工具

原始碼: `Lib/getpass.py`

適用: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參 [WebAssembly](#) 平台。

`getpass` 模組 (module) 提供了兩個函式:

`getpass.getpass` (*prompt='Password: ', stream=None*)

提示使用者輸入一個密碼且不會有回音 (echo)。使用者會看到字串 *prompt* 作提示，其預設值 `'Password: '`。在 Unix 上，如有必要的話會使用替錯誤處理函式 (replace error handler) 寫入到類檔案物件 (file-like object) *stream* 中。*stream* 預設主控終端機 (controlling terminal) (`/dev/tty`)，如果不可用則 `sys.stderr` (此引數在 Windows 上會被忽略)。

如果無回音輸入 (echo-free input) 無法使用則 `getpass()` 將回退印出一條警告訊息到 *stream*，從 `sys.stdin` 讀取且同時發出 `GetPassWarning`。

### 備

如果你從 IDLE 部呼叫 `getpass`，輸入可能會在你動 IDLE 的終端機中完成，而非在 IDLE 視窗中。

**exception** `getpass.GetPassWarning`

當密碼輸入可能被回音時會發出的 `UserWarning` 子類。

`getpass.getuser` ()

回傳使用者的“登入名稱”。

This function checks the environment variables `LOGNAME`, `USER`, `LNAME` and `USERNAME`, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the `pwd` module, otherwise, an `OSError` is raised.

大部分情況下，此函式應該要比 `os.getlogin()` 優先使用。

在 3.13 版的變更: Previously, various exceptions beyond just `OSError` were raised.

## 17.4 `fileinput` --- 逐列代多個輸入串流

原始碼: `Lib/fileinput.py`

This module implements a helper class and functions to quickly write a loop over standard input or a list of files. If you just want to read or write one file see `open()`.

The typical use is:

```
import fileinput
for line in fileinput.input(encoding="utf-8"):
    process(line)
```

This iterates over the lines of all files listed in `sys.argv[1:]`, defaulting to `sys.stdin` if the list is empty. If a filename is `'-'`, it is also replaced by `sys.stdin` and the optional arguments `mode` and `openhook` are ignored. To specify an alternative list of filenames, pass it as the first argument to `input()`. A single file name is also allowed.

All files are opened in text mode by default, but you can override this by specifying the `mode` parameter in the call to `input()` or `FileInput`. If an I/O error occurs during opening or reading a file, `OSError` is raised.

在 3.3 版的變更: `IOError` used to be raised; it is now an alias of `OSError`.

If `sys.stdin` is used more than once, the second and further use will return no lines, except perhaps for interactive use, or if it has been explicitly reset (e.g. using `sys.stdin.seek(0)`).

Empty files are opened and immediately closed; the only time their presence in the list of filenames is noticeable at all is when the last file opened is empty.

Lines are returned with any newlines intact, which means that the last line in a file may not have one.

You can control how files are opened by providing an opening hook via the `openhook` parameter to `fileinput.input()` or `FileInput()`. The hook must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. If `encoding` and/or `errors` are specified, they will be passed to the hook as additional keyword arguments. This module provides a `hook_compressed()` to support compressed files.

The following function is the primary interface of this module:

```
fileinput.input(files=None, inplace=False, backup="", *, mode='r', openhook=None, encoding=None,
                errors=None)
```

Create an instance of the `FileInput` class. The instance will be used as global state for the functions of this module, and is also returned to use during iteration. The parameters to this function will be passed along to the constructor of the `FileInput` class.

The `FileInput` instance can be used as a context manager in the `with` statement. In this example, `input` is closed after the `with` statement is exited, even if an exception occurs:

```
with fileinput.input(files=('spam.txt', 'eggs.txt'), encoding="utf-8") as f:
    for line in f:
        process(line)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameters `mode` and `openhook` are now keyword-only.

在 3.10 版的變更: The keyword-only parameter `encoding` and `errors` are added.

The following functions use the global state created by `fileinput.input()`; if there is no active state, `RuntimeError` is raised.

```
fileinput.filename()
```

Return the name of the file currently being read. Before the first line has been read, returns `None`.

```
fileinput.fileeno()
```

Return the integer "file descriptor" for the current file. When no file is opened (before the first line and between files), returns `-1`.

```
fileinput.lineno()
```

Return the cumulative line number of the line that has just been read. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line.

```
fileinput.filelineno()
```

Return the line number in the current file. Before the first line has been read, returns `0`. After the last line of the last file has been read, returns the line number of that line within the file.

```
fileinput.isfirstline()
```

Return True if the line just read is the first line of its file, otherwise return False.

```
fileinput.isstdin()
```

Return True if the last line was read from `sys.stdin`, otherwise return False.

```
fileinput.nextfile()
```

Close the current file so that the next iteration will read the first line from the next file (if any); lines not read from the file will not count towards the cumulative line count. The filename is not changed until after the first line of the next file has been read. Before the first line has been read, this function has no effect; it cannot be used to skip the first file. After the last line of the last file has been read, this function has no effect.

```
fileinput.close()
```

Close the sequence.

The class which implements the sequence behavior provided by the module is available for subclassing as well:

```
class fileinput.FileInput (files=None, inplace=False, backup="", *, mode='r', openhook=None,
                          encoding=None, errors=None)
```

Class `FileInput` is the implementation; its methods `filename()`, `fileno()`, `lineno()`, `filelineno()`, `isfirstline()`, `isstdin()`, `nextfile()` and `close()` correspond to the functions of the same name in the module. In addition it is *iterable* and has a `readline()` method which returns the next input line. The sequence must be accessed in strictly sequential order; random access and `readline()` cannot be mixed.

With `mode` you can specify which file mode will be passed to `open()`. It must be one of 'r' and 'rb'.

The `openhook`, when given, must be a function that takes two arguments, `filename` and `mode`, and returns an accordingly opened file-like object. You cannot use `inplace` and `openhook` together.

You can specify `encoding` and `errors` that is passed to `open()` or `openhook`.

A `FileInput` instance can be used as a context manager in the `with` statement. In this example, `input` is closed after the `with` statement is exited, even if an exception occurs:

```
with FileInput(files=('spam.txt', 'eggs.txt')) as input:
    process(input)
```

在 3.2 版的變更: Can be used as a context manager.

在 3.8 版的變更: The keyword parameter `mode` and `openhook` are now keyword-only.

在 3.10 版的變更: The keyword-only parameter `encoding` and `errors` are added.

在 3.11 版的變更: The 'rU' and 'U' modes and the `__getitem__()` method have been removed.

**Optional in-place filtering:** if the keyword argument `inplace=True` is passed to `fileinput.input()` or to the `FileInput` constructor, the file is moved to a backup file and standard output is directed to the input file (if a file of the same name as the backup file already exists, it will be replaced silently). This makes it possible to write a filter that rewrites its input file in place. If the `backup` parameter is given (typically as `backup='.<some extension>'`), it specifies the extension for the backup file, and the backup file remains around; by default, the extension is `'.bak'` and it is deleted when the output file is closed. In-place filtering is disabled when standard input is read.

The two following opening hooks are provided by this module:

```
fileinput.hook_compressed(filename, mode, *, encoding=None, errors=None)
```

Transparently opens files compressed with `gzip` and `bzip2` (recognized by the extensions `'.gz'` and `'.bz2'`) using the `gzip` and `bz2` modules. If the filename extension is not `'.gz'` or `'.bz2'`, the file is opened normally (ie, using `open()` without any decompression).

The `encoding` and `errors` values are passed to `io.TextIOWrapper` for compressed files and open for normal files.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_compressed, encoding="utf-8")`

在 3.10 版的變更: The keyword-only parameter `encoding` and `errors` are added.

`fileinput.hook_encoded(encoding, errors=None)`

Returns a hook which opens each file with `open()`, using the given `encoding` and `errors` to read the file.

Usage example: `fi = fileinput.FileInput(openhook=fileinput.hook_encoded("utf-8", "surrogateescape"))`

在 3.6 版的變更: 新增可選參數 `errors`。

在 3.10 版之後被<sup>F</sup>用: This function is deprecated since `fileinput.input()` and `FileInput` now have `encoding` and `errors` parameters.

## 17.5 curses --- 字元儲存格顯示的終端處理

原始碼: [Lib/curses](#)

The `curses` module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

適用: not Android, not iOS, not WASI.

此模組在行動平台或 *WebAssembly* 平台上不支援。

### 備<sup>F</sup>

Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

### 17.5.1 函式

The module `curses` defines the following exception:

**exception** `curses.error`

Exception raised when a curses library function returns an error.

### 備<sup>F</sup>

Whenever `x` or `y` arguments to a function or a method are optional, they default to the current cursor location. Whenever `attr` is optional, it defaults to `A_NORMAL`.

The module `curses` defines the following functions:

`curses.baudrate()`

Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

`curses.beep()`

Emit a short attention sound.

`curses.can_change_color()`

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

`curses.cbreak()`

Enter `cbreak` mode. In `cbreak` mode (sometimes called "rare" mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first `raw()` then `cbreak()` leaves the terminal in `cbreak` mode.

`curses.color_content(color_number)`
