>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()

```

### ⚠ 警示

If an `AttributeError` is raised by `PropertyMock`, it will be interpreted as a missing descriptor and `__getattr__()` will be called on the parent mock:

```

>>> m = MagicMock()
>>> no_attribute = PropertyMock(side_effect=AttributeError)
>>> type(m).my_property = no_attribute
>>> m.my_property
<MagicMock name='mock.my_property' id='140165240345424'>

```

詳情請見 `__getattr__()`。

**class** `unittest.mock.AsyncMock` (*spec=None, side\_effect=None, return\_value=DEFAULT, wraps=None, name=None, spec\_set=None, unsafe=False, \*\*kwargs*)

`MagicMock` 的非同步版本。`AsyncMock` 物件的表現將被視作非同步函式，且呼叫的結果是一個可等待物件。

```

>>> mock = AsyncMock()
>>> asyncio.iscoroutinefunction(mock)
True
>>> inspect.isawaitable(mock())
True

```

`mock()` 的結果是一個非同步函式，在它被等待後將具有 `side_effect` 或 `return_value` 的結果：

- 如果 `side_effect` 是一個函式，非同步函式將回傳該函式的結果，
- 如果 `side_effect` 是一個例外，則非同步函式將引發該例外，
- 如果 `side_effect` 是一個可迭代物件，非同步函式將回傳可迭代物件的下一個值，但如果結果序列耗盡，將立即引發 `StopAsyncIteration`，
- 如果 `side_effect` 有被定義，非同步函式將回傳由 `return_value` 定義的值，因此在預設情況下，非同步函式回傳一個新的 `AsyncMock` 物件。

將 `Mock` 或 `MagicMock` 的 `spec` 設定為非同步函式將導致在呼叫後回傳一個協程物件。

```

>>> async def async_func(): pass
...
>>> mock = MagicMock(async_func)
>>> mock
<MagicMock spec='function' id='...'>

```

(繼續下一頁)

(繼續上一頁)

```
>>> mock()
<coroutine object AsyncMockMixin._mock_call at ...>
```

將 `Mock`、`MagicMock` 或 `AsyncMock` 的 `spec` 設定為具有同步和非同步函式的類，會自動檢測同步函式將其設定為 `MagicMock` (如果上代 `mock` 為 `AsyncMock` 或 `MagicMock`) 或 `Mock` (如果上代 `mock` 為 `Mock`)。所有非同步函式將被設定為 `AsyncMock`。

```
>>> class ExampleClass:
...     def sync_foo():
...         pass
...     async def async_foo():
...         pass
...
>>> a_mock = AsyncMock(ExampleClass)
>>> a_mock.sync_foo
<MagicMock name='mock.sync_foo' id='... '>
>>> a_mock.async_foo
<AsyncMock name='mock.async_foo' id='... '>
>>> mock = Mock(ExampleClass)
>>> mock.sync_foo
<Mock name='mock.sync_foo' id='... '>
>>> mock.async_foo
<AsyncMock name='mock.async_foo' id='... '>
```

在 3.8 版被加入。

#### `assert_awaited()`

斷言 `mock` 至少被等待過一次。請注意這與物件是否被呼叫是分開的，`await` 關鍵字必須被使用：

```
>>> mock = AsyncMock()
>>> async def main(coroutine_mock):
...     await coroutine_mock
...
>>> coroutine_mock = mock()
>>> mock.called
True
>>> mock.assert_awaited()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited.
>>> asyncio.run(main(coroutine_mock))
>>> mock.assert_awaited()
```

#### `assert_awaited_once()`

斷言 `mock` 正好被等待了一次。

```
>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.assert_awaited_once()
>>> asyncio.run(main())
>>> mock.assert_awaited_once()
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once. Awaited 2 times.
```

#### `assert_awaited_with(*args, **kwargs)`

斷言最後一次等待使用了指定的引數。

```

>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_with('foo', bar='bar')
>>> mock.assert_awaited_with('other')
Traceback (most recent call last):
...
AssertionError: expected await not found.
Expected: mock('other')
Actual: mock('foo', bar='bar')

```

#### `assert_awaited_once_with(*args, **kwargs)`

斷言 `mock` 只被等待了一次<sup>[1]</sup>使用了指定的引數。

```

>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
>>> asyncio.run(main('foo', bar='bar'))
>>> mock.assert_awaited_once_with('foo', bar='bar')
Traceback (most recent call last):
...
AssertionError: Expected mock to have been awaited once. Awaited 2 times.

```

#### `assert_any_await(*args, **kwargs)`

斷言 `mock` 曾經被使用指定的引數等待過。

```

>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> asyncio.run(main('foo', bar='bar'))
>>> asyncio.run(main('hello'))
>>> mock.assert_any_await('foo', bar='bar')
>>> mock.assert_any_await('other')
Traceback (most recent call last):
...
AssertionError: mock('other') await not found

```

#### `assert_has_awaits(calls, any_order=False)`

斷言 `mock` 已被使用指定的呼叫進行等待。`await_args_list` 串列將被檢查以確認等待的<sup>[1]</sup>內容。

如果 `any_order` <sup>[1]</sup> `false`，則等待必須按照順序。指定的等待之前或之後可以有額外的呼叫。

如果 `any_order` <sup>[1]</sup> `true`，則等待可以以任何順序出現，但它們必須全部出現在`await_args_list` 中。

```

>>> mock = AsyncMock()
>>> async def main(*args, **kwargs):
...     await mock(*args, **kwargs)
...
>>> calls = [call("foo"), call("bar")]
>>> mock.assert_has_awaits(calls)
Traceback (most recent call last):
...
AssertionError: Awaits not found.

```

(繼續下一頁)

(繼續上一頁)

```

Expected: [call('foo'), call('bar')]
Actual: []
>>> asyncio.run(main('foo'))
>>> asyncio.run(main('bar'))
>>> mock.assert_has_awaits(calls)

```

**assert\_not\_awaited()**

斷言 `mock` 從未被等待。

```

>>> mock = AsyncMock()
>>> mock.assert_not_awaited()

```

**reset\_mock(\*args, \*\*kwargs)**

參見 `Mock.reset_mock()`。同時將 `await_count` 設定為 0，`await_args` 設定為 `None`，清除 `await_args_list`。

**await\_count**

一個整數，用來記 `mock` 物件已被等待的次數。

```

>>> mock = AsyncMock()
>>> async def main():
...     await mock()
...
>>> asyncio.run(main())
>>> mock.await_count
1
>>> asyncio.run(main())
>>> mock.await_count
2

```

**await\_args**

這可能是 `None`（如果 `mock` 尚未被等待），或者是上次等待 `mock` 時使用的引數。與 `Mock.call_args` 的功能相同。

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args
>>> asyncio.run(main('foo'))
>>> mock.await_args
call('foo')
>>> asyncio.run(main('bar'))
>>> mock.await_args
call('bar')

```

**await\_args\_list**

這是一個按照順序記 `mock` 物件所有等待的串列（因此串列的長度表示該物件已被等待的次數）。在進行任何等待之前，此串列為空。

```

>>> mock = AsyncMock()
>>> async def main(*args):
...     await mock(*args)
...
>>> mock.await_args_list
[]
>>> asyncio.run(main('foo'))
>>> mock.await_args_list
[call('foo')]

```

(繼續下一頁)

(繼續上一頁)

```
>>> asyncio.run(main('bar'))
>>> mock.await_args_list
[call('foo'), call('bar')]
```

**class** `unittest.mock.ThreadingMock` (*spec=None, side\_effect=None, return\_value=DEFAULT, wraps=None, name=None, spec\_set=None, unsafe=False, \*, timeout=UNSET, \*\*kwargs*)

A version of *MagicMock* for multithreading tests. The *ThreadingMock* object provides extra methods to wait for a call to be invoked, rather than assert on it immediately.

The default timeout is specified by the `timeout` argument, or if unset by the *ThreadingMock*.`DEFAULT_TIMEOUT` attribute, which defaults to blocking (`None`).

You can configure the global default timeout by setting *ThreadingMock*.`DEFAULT_TIMEOUT`.

**wait\_until\_called** (*\*, timeout=UNSET*)

等待直到 mock 被呼叫。

If a timeout was passed at the creation of the mock or if a timeout argument is passed to this function, the function raises an *AssertionError* if the call is not performed in time.

```
>>> mock = ThreadingMock()
>>> thread = threading.Thread(target=mock)
>>> thread.start()
>>> mock.wait_until_called(timeout=1)
>>> thread.join()
```

**wait\_until\_any\_call\_with** (*\*args, \*\*kwargs*)

等到直到 mock 被以特定引數呼叫。

If a timeout was passed at the creation of the mock the function raises an *AssertionError* if the call is not performed in time.

```
>>> mock = ThreadingMock()
>>> thread = threading.Thread(target=mock, args=("arg1", "arg2",), kwargs={"arg":
↪ "thing"})
>>> thread.start()
>>> mock.wait_until_any_call_with("arg1", "arg2", arg="thing")
>>> thread.join()
```

#### DEFAULT\_TIMEOUT

Global default timeout in seconds to create instances of *ThreadingMock*.

在 3.13 版被加入。

## 呼叫

Mock 物件可被呼叫。呼叫將回傳設定 `return_value` 屬性的值。預設的回傳值是一個新的 Mock 物件；它會在第一次存取回傳值時（無論是顯式存取還是透過呼叫 Mock）被建立，但是這個回傳值會被儲存，之後每次都回傳同一個值。

對物件的呼叫會被記在如 `call_args` 和 `call_args_list` 等屬性中。

如果 `side_effect` 被設定，那在呼叫被記後它才會被呼叫，所以如果 `side_effect` 引發例外，呼叫仍然會被記。

呼叫 mock 時引發例外的最簡單方式是將 `side_effect` 設定例外類或實例：

```
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
...

```

(繼續下一頁)

(繼續上一頁)

```

IndexError
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
...
KeyError: 'Bang!'
>>> m.mock_calls
[call(1, 2, 3), call('two', 'three', 'four')]

```

如果 `side_effect` 是一個函式，則該函式回傳的東西就是對 `mock` 的呼叫所回傳的值。`side_effect` 函式會使用與 `mock` 相同的引數被呼叫。這讓你可以根據輸入動態地變更呼叫的回傳值：

```

>>> def side_effect(value):
...     return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
>>> m.mock_calls
[call(1), call(2)]

```

如果你希望 `mock` 仍然回傳預設的回傳值（一個新的 `mock`），或者是任何已設定的回傳值，有兩種方法可以實現。從 `side_effect` 內部回傳 `return_value`，或回傳 `DEFAULT`：

```

>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
>>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> m.side_effect = side_effect
>>> m()
3

```

要刪除 `side_effect`，恢復預設行，將 `side_effect` 設為 `None`：

```

>>> m = MagicMock(return_value=6)
>>> def side_effect(*args, **kwargs):
...     return 3
...
>>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
6

```

`side_effect` 也可以是任何可迭代的物件。對 `mock` 的重複呼叫將從可迭代物件中回傳值（直到可迭代物件耗盡引發 `StopIteration` 為止）：

```

>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()

```

(繼續下一頁)

(繼續上一頁)

```

1
>>> m()
2
>>> m()
3
>>> m()
Traceback (most recent call last):
...
StopIteration

```

如果可迭代物件中的任何成員是例外，則它們將被引發而不是被回傳：

```

>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()
Traceback (most recent call last):
...
ValueError
>>> m()
66

```

## 刪除屬性

Mock 物件會在需要時建立屬性。這使得它們可以假裝成任何種類的物件。

你可能希望一個 mock 物件在 `hasattr()` 呼叫時回傳 `False`，或者在屬性被提取時引發 `AttributeError`。你可以通過將物件提供 mock 的 `spec` 來實現這一點，但這不總是那好用。

你可以通過刪除屬性來「阻擋」它們。一旦刪除，再次存取該屬性將會引發 `AttributeError`。

```

>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
...
AttributeError: f

```

## Mock 名稱與名稱屬性

由於 `name` 是傳遞給 `Mock` 建構函式的引數，如果你想讓你的 mock 物件擁有 `name` 屬性，你不能在建立時直接傳遞它。有兩種替代方法。其中一個選擇是使用 `configure_mock()`：

```

>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'

```

更簡單的方法是在 mock 建立後直接設定 `name` 屬性：

```

>>> mock = MagicMock()
>>> mock.name = "foo"

```

### 如同屬性一般附加 mock

當你將一個 mock 附加到另一個 mock 的屬性（或作回傳值），它將成該 mock 的「子代 (child)」。對子代的呼叫將被記在上代的 `method_calls` 和 `mock_calls` 屬性中。這對於配置子代將它們附加到上代，或將 mock 附加到記所有對子代的呼叫的上代允許你對 mock 間的呼叫順序進行斷言非常有用：

```
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

如果 mock 有 `name` 引數，則上述規則會有例外。這使你可以防止「親屬關 (parenting)」的建立，假設因某些原因你不希望這種狀況發生。

```
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
>>> mock.mock_calls
[]
```

由 `patch()` 你建立的 mock 會自動被賦予名稱。若要將具有名稱的 mock 附加到上代，你可以使用 `attach_mock()` 方法：

```
>>> thing1 = object()
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None) as child1:
...     with patch('__main__.thing2', return_value=None) as child2:
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')
...
>>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

## 27.6.3 Patchers

`patch` 裝飾器僅用於在裝飾的函式範圍對物件進行 `patch`。它們會自動你處理 `patch` 的中止，即使有常被引發也是如此。所有這些函式也可以在 `with` 陳述式中使用，或者作類裝飾器使用。

### patch

#### 備

關鍵是要在正確的命名空間進行 `patch`。請參 `where to patch` 一節。

`unittest.mock.patch` (*target*, *new=DEFAULT*, *spec=None*, *create=False*, *spec\_set=None*, *autospec=None*, *new\_callable=None*, *\*\*kwargs*)

`patch()` 充當函式裝飾器、類裝飾器或情境管理器。在函式或 `with` 陳述式的部，目標會被 `patch` 成一個新的物件。當函式或 `with` 陳述式結束時，`patch` 就會被解除。

如果 `new` 被省略，則如果被 `patch` 的物件是非同步函式，目標會被替換為 `AsyncMock`，反之則替換為 `MagicMock`。如果 `patch()` 做裝飾器使用且省略了 `new`，則所建立的 `mock` 會作額外的引數傳遞給被裝飾的函式。如果 `patch()` 作情境管理器使用，則所建立的 `mock` 將由情境管理器回傳。

`target` 應該是以 `'package.module.ClassName'` 形式出現的字串。`target` 會被引入用 `new` 物件替換指定的物件，因此 `target` 必須可從你呼叫 `patch()` 的環境中引入。`target` 在執行被裝飾的函式時被引入，而不是在裝飾器作用時 (decoration time)。

`spec` 和 `spec_set` 關鍵字引數會傳遞給 `MagicMock`，如果 `patch` 正在你建立一個。

此外，你還可以傳遞 `spec=True` 或 `spec_set=True`，這將導致 `patch` 將被 `mock` 的物件作 `spec/spec_set` 物件傳遞。

`new_callable` 允許你指定一個不同的類或可呼叫的物件，用於被呼叫建立 `new` 物件。預設情況下，對於非同步函式使用 `AsyncMock`，而對於其他情況則使用 `MagicMock`。

`spec` 的一種更大的形式是 `autospec`。如果你設定 `autospec=True`，則該 `mock` 將使用被替換物件的規格來建立。該 `mock` 的所有屬性也將具有被替換物件的對應屬性的規格。被 `mock` 的方法和函式將檢查其引數，如果呼叫時引數與規格不符 (被使用錯誤的簽名 (signature) 呼叫)，將引發 `TypeError`。對於替換類的 `mock`，它們的回傳值 (即 `'instance'`) 將具有與類相同的規格。請參閱 `create_autospec()` 函式和 `Autospeccing` (自動規格)。

你可以用 `autospec=some_object` 替代 `autospec=True`，以使用任意物件作規格，而不是被替換的物件。

預設情況下，`patch()` 將無法取代不存在的屬性。如果你傳入 `create=True`，且屬性不存在，則當被 `patch` 的函式被呼叫時，`patch` 將為你建立該屬性，在被 `patch` 的函式結束後再次刪除它。這對於撰寫針對你的生程序碼在執行環境建立的屬性的測試時非常有用。此功能預設關閉，因為這可能會相當危險。開這個功能後，你可以對於實際上不存在的 API 撰寫會通過的測試！

### 備註

在 3.5 版的變更: 如果你正在 `patch` 模組中的函式，那你不需要傳遞 `create=True`，它預設會被加入。

`patch` 可以做 `TestCase` 類的裝飾器使用。它透過裝飾類中的每個測試方法來運作。當你的測試方法共享一組常見的 `patch` 時，這會減少繁冗的代碼。`patch()` 通過搜尋以 `patch.TEST_PREFIX` 開頭的方法名來尋找測試。預設情況下會是 `'test'`，這與 `unittest` 尋找測試的方式相匹配。你可以通過設定 `patch.TEST_PREFIX` 來指定它的前綴。

透過 `with` 陳述式，`Patch` 可以做情境管理器使用。`patch` 適用於 `with` 陳述式之後的縮排區塊。如果你使用 `as`，則被 `patch` 的物件將被綁定到 `as` 後面的名稱；如果 `patch()` 正在你建立一個 `mock` 物件，這會非常有用。

`patch()` 接受任意的關鍵字引數。如果被 `patch` 的物件是非同步的，這些將會被傳遞給 `AsyncMock`，如果是同步的則會傳遞給 `MagicMock`，或如果指定了 `new_callable`，則傳遞給它。

`patch.dict(...)`、`patch.multiple(...)` 和 `patch.object(...)` 可用於其余的使用情境。

`patch()` 作函式裝飾器，你建立 `mock` 將其傳遞給被裝飾的函式：

```
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
...
>>> function(None)
True
```

`Patch` 一個類會以 `MagicMock` 實例取代該類。如果該類在被測試的程式碼中實例化，那它將是會被使用的 `mock` 的 `return_value`。

如果該類被實例化多次，你可以使用 `side_effect` 來每次回傳一個新的 `mock`。或者你可以將 `return_value` 設定成你想要的任何值。

若要配置被 `patch` 的類 `Class` 的實例方法的回傳值，你必須在 `return_value` 上進行配置。例如：

```
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
...
...

```

如果你使用 `spec` 或 `spec_set` 且 `patch()` 正在取代一個類 `Class`，那 `Class` 被建立的 `mock` 的回傳值將具有相同的規格：

```
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()

```

當你想要 `Class` 被建立的 `mock` 使用一個替代的類 `MockClass` 取代預設的 `MagicMock` 時，`new_callable` 引數非常有用。例如，如果你想要一個 `NonCallableMock` 被使用：

```
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock) as mock_thing:
...     assert thing is mock_thing
...     thing()
...
Traceback (most recent call last):
...
TypeError: 'NonCallableMock' object is not callable

```

另一個用法是用一個 `io.StringIO` 實例替 `sys.stdout` 一個物件：

```
>>> from io import StringIO
>>> def foo():
...     print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...     foo()
...     assert mock_stdout.getvalue() == 'Something\n'
...
>>> test()

```

當 `patch()` 你建立 `mock` 時，通常你需要做的第一件事就是配置 `mock`。其中一些配置可以在對 `patch` 的呼叫中完成。你傳遞到呼叫中的任何關鍵字都將用於在被建立的 `mock` 上設定屬性：

```
>>> patcher = patch('__main__.thing', first='one', second='two')
>>> mock_thing = patcher.start()
>>> mock_thing.first
'one'
>>> mock_thing.second
'two'

```

除了被建立的 `mock` 上的屬性外，還可以配置 `child mock` 的 `return_value` 和 `side_effect`。它們在語法上不能直接作 `patch()` 關鍵字引數傳入，但是以它們作 `kwargs` 的字典仍然可以使用 `**` 擴充 `patch()` 呼叫：

```
>>> config = {'method.return_value': 3, 'other.side_effect': KeyError}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
...
KeyError
```

預設情況下，嘗試 `patch` 模組中不存在的函式（或類中的方法或屬性）將會失敗，引發 `AttributeError`：

```
>>> @patch('sys.non_existing_attribute', 42)
... def test():
...     assert sys.non_existing_attribute == 42
...
>>> test()
Traceback (most recent call last):
...
AttributeError: <module 'sys' (built-in)> does not have the attribute 'non_existing_attribute
↪'
```

但是在對 `patch()` 的呼叫中增加 `create=True` 將使前面的範例按照預期運作：

```
>>> @patch('sys.non_existing_attribute', 42, create=True)
... def test(mock_stdout):
...     assert sys.non_existing_attribute == 42
...
>>> test()
```

在 3.8 版的變更：如果目標是一個非同步函式，`patch()` 現在會回傳一個 `AsyncMock`。

## patch.object

`patch.object` (*target, attribute, new=DEFAULT, spec=None, create=False, spec\_set=None, autospec=None, new\_callable=None, \*\*kwargs*)

使用一個 mock 物件 `patch` 一個物件（目標）上的命名成員（屬性）。

`patch.object()` 可以做裝飾器、類裝飾器或情境管理器使用。引數 `new`、`spec`、`create`、`spec_set`、`autospec` 和 `new_callable` 與在 `patch()` 中的引數具有相同的意義。與 `patch()` 一樣，`patch.object()` 接受任意關鍵字引數來配置它所建立的 mock 物件。

當作類裝飾器使用時，`patch.object()` 會遵循 `patch.TEST_PREFIX` 來選擇要包裝的方法。

你可以使用三個引數或兩個引數來呼叫 `patch.object()`。三個引數的形式接受要被 `patch` 的物件、屬性名稱和要替換掉屬性的物件。

當使用兩個引數的形式呼叫時，你會省略要替換的物件，一個 mock 會替你建立將其作額外的引數傳遞給被裝飾的函式：

```
>>> @patch.object(SomeClass, 'class_method')
... def test(mock_method):
...     SomeClass.class_method(3)
...     mock_method.assert_called_with(3)
...
>>> test()
```

`spec`、`create` 和 `patch.object()` 的其他引數與在 `patch()` 中的引數具有相同的意義。

## patch.dict

`patch.dict` (*in\_dict*, *values=()*, *clear=False*, *\*\*kwargs*)

Patch 字典或類字典的物件，在測試後將字典回復到其原本的狀態。

*in\_dict* 可以是一個字典或一個類對映的容器。如果它是一個對映，那它至少必須支援獲取、設定、刪除項目以及對鍵的代。

*in\_dict* 也可以是指定字典名稱的字串，然後透過 `import` 來取得該字典。

*values* 可以是要設定的值的字典。*values* 也可以是 (key, value) 對 (pairs) 的可代物件。

如果 *clear* 為 `true`，則在設定新值之前字典將被清除。

也可以使用任意關鍵字引數呼叫 `patch.dict()` 以在字典中設定值。

在 3.8 版的變更: `patch.dict()` 現在在做情境管理器使用時回傳被 `patch` 的字典。

`patch.dict()` 可以做情境管理器、裝飾器或類裝飾器使用：

```
>>> foo = {}
>>> @patch.dict(foo, {'newkey': 'newvalue'})
... def test():
...     assert foo == {'newkey': 'newvalue'}
...
>>> test()
>>> assert foo == {}
```

當作類裝飾器使用時，`patch.dict()` 會遵循 `patch.TEST_PREFIX` (預設為 'test') 來選擇要包裝的方法：

```
>>> import os
>>> import unittest
>>> from unittest.mock import patch
>>> @patch.dict('os.environ', {'newkey': 'newvalue'})
... class TestSample(unittest.TestCase):
...     def test_sample(self):
...         self.assertEqual(os.environ['newkey'], 'newvalue')
```

如果你想在測試中使用不同的前綴，你可以透過設定 `patch.TEST_PREFIX` 來告知 `patcher` 使用不同的前綴。請參閱 `TEST_PREFIX` 以得知如何修改前綴的更多內容。

`patch.dict()` 可用於在字典中新增成員，或單純地讓測試更改字典，確保在測試結束時將字典回復原狀。

```
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}) as patched_foo:
...     assert foo == {'newkey': 'newvalue'}
...     assert patched_foo == {'newkey': 'newvalue'}
...     # You can add, update or delete keys of foo (or patched_foo, it's the same dict)
...     patched_foo['spam'] = 'eggs'
...
>>> assert foo == {}
>>> assert patched_foo == {}
```

```
>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newvalue'}):
...     print(os.environ['newkey'])
...
newvalue
>>> assert 'newkey' not in os.environ
```

可以在 `patch.dict()` 呼叫中使用關鍵字來設定字典中的值：

```

>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
...     import mymodule
...     mymodule.function('some', 'args')
...
'fish'

```

`patch.dict()` 可以與實際上不是字典的類字典物件一起使用。最低限度它們必須支援項目的獲取、設定、刪除以及迭代或隸屬資格檢測。這對應到魔術方法中的 `__getitem__()`、`__setitem__()`、`__delitem__()` 以及 `__iter__()` 或 `__contains__()`。

```

>>> class Container:
...     def __init__(self):
...         self.values = {}
...     def __getitem__(self, name):
...         return self.values[name]
...     def __setitem__(self, name, value):
...         self.values[name] = value
...     def __delitem__(self, name):
...         del self.values[name]
...     def __iter__(self):
...         return iter(self.values)
...
>>> thing = Container()
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']

```

## patch.multiple

`patch.multiple(target, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

在一次呼叫中執行多個 `patch`。它接受被 `patch` 的物件（作物件或透過 `import` 取得物件的字串）和 `patch` 的關鍵字引數：

```

with patch.multiple(settings, FIRST_PATCH='one', SECOND_PATCH='two'):
...

```

如果你想要 `patch.multiple()` 為你建立 `mock`，請使用 `DEFAULT` 作值。在這種情況下，被建立的 `mock` 會透過關鍵字傳遞到被裝飾的函式中，且當 `patch.multiple()` 作情境管理器時會回傳字典。

`patch.multiple()` 可以做裝飾器、類裝飾器或情境管理器使用。引數 `spec`、`spec_set`、`create`、`autospec` 和 `new_callable` 與在 `patch()` 中的引數具有相同的意義。這些引數將應用於由 `patch.multiple()` 完成的所有 `patch`。

當作類裝飾器使用時，`patch.multiple()` 遵循 `patch.TEST_PREFIX` 來選擇要包裝的方法。

如果你想要 `patch.multiple()` 為你建立 `mock`，那你也可以使用 `DEFAULT` 作值。如果你使用 `patch.multiple()` 作裝飾器，那你被建立的 `mock` 將透過關鍵字傳遞到被裝飾的函式中。

```

>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other=DEFAULT)
... def test_function(thing, other):

```

(繼續下一頁)

(繼續上一頁)

```
...     assert isinstance(thing, MagicMock)
...     assert isinstance(other, MagicMock)
...
>>> test_function()
```

`patch.multiple()` 可以與其他 `patch` 裝飾器巢狀使用，但需要將透過關鍵字傳遞的引數放在 `patch()` 建立的任何標準引數之後：

```
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other=DEFAULT)
... def test_function(mock_exit, other, thing):
...     assert 'other' in repr(other)
...     assert 'thing' in repr(thing)
...     assert 'exit' in repr(mock_exit)
...
>>> test_function()
```

如果 `patch.multiple()` 作情境管理器使用，則情境管理器回傳的值是一個字典，其中被建立的 `mock` 會按名稱作其鍵值：

```
>>> with patch.multiple('__main__', thing=DEFAULT, other=DEFAULT) as values:
...     assert 'other' in repr(values['other'])
...     assert 'thing' in repr(values['thing'])
...     assert values['thing'] is thing
...     assert values['other'] is other
...
>>>
```

### patch 方法：啟動與停止

所有的 `patcher` 都有 `start()` 與 `stop()` 方法。這使得在 `setUp` 方法中進行 `patch` 或在你想要在巢狀使用裝飾器或 `with` 陳述式的情境下進行多個 `patch` 時變得更簡單。

要使用它們，請像平常一樣呼叫 `patch()`、`patch.object()` 或 `patch.dict()`，保留對回傳的 `patcher` 物件的參照。之後你就可以呼叫 `start()` 將 `patch` 準備就緒，呼叫 `stop()` 來取消 `patch`。

如果你使用 `patch()` 你建立 `mock`，那它將透過呼叫 `patcher.start` 回傳。：

```
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName is not original
>>> assert module.ClassName is new_mock
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

一個典型的用法是在一個 `TestCase` 的 `setUp` 方法中執行多個 `patch`：

```
>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher1 = patch('package.module.Class1')
...         self.patcher2 = patch('package.module.Class2')
...         self.MockClass1 = self.patcher1.start()
...         self.MockClass2 = self.patcher2.start()
...
...     def tearDown(self):
...         self.patcher1.stop()
...         self.patcher2.stop()
...
...     def test_something(self):
```

(繼續下一頁)

(繼續上一頁)

```

...     assert package.module.Class1 is self.MockClass1
...     assert package.module.Class2 is self.MockClass2
...
>>> MyTest('test_something').run()

```

**警告**

如果你使用這個技巧，你必須確保透過呼叫 `stop` 來“取消” `patch`。這可能會比你想像的還要複雜一點，因為如果有例外在 `setUp` 中被引發，則 `tearDown` 就不會被呼叫。`unittest.TestCase.addCleanup()` 會讓這稍微簡單一點：

```

>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('package.module.Class')
...         self.MockClass = patcher.start()
...         self.addCleanup(patcher.stop)
...
...     def test_something(self):
...         assert package.module.Class is self.MockClass
...

```

作額外的好處，你不再需要保留對 `patcher` 物件的參照。

也可以使用 `patch.stopall()` 來停止所有已啟動的 `patch`。

```
patch.stopall()
```

停止所有運作的 `patch`。只停止以 `start` 啟動的 `patch`。

**patch 建構函式**

你可以 `patch` 模組的任何建構函式。以下範例 `patch` 建構函式 `ord()`：

```

>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101

```

**TEST\_PREFIX**

所有 `patcher` 都可以作類裝飾器使用。以這種方式使用時，它們包裝了類上的每個測試方法。`Patcher` 將 'test' 開頭的方法認定為測試方法。這與 `unittest.TestLoader` 預設尋找測試方法的方式相同。

你可能會想你的測試使用不同的前綴。你可以透過設定 `patch.TEST_PREFIX` 來告知 `patcher` 使用不同的前綴：

```

>>> patch.TEST_PREFIX = 'foo'
>>> value = 3
>>>
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print(value)
...     def foo_two(self):
...         print(value)
...
>>>

```

(繼續下一頁)

```
>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3
```

### 巢狀使用 Patch 裝飾器

如果你想執行多個 `patch`，那麼你可以簡單地堆疊裝飾器。

你可以使用這個模式來堆疊多個 `patch` 裝飾器：

```
>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
...     SomeClass.class_method('bar')
...     return mock1, mock2
...
>>> mock1, mock2 = test()
>>> mock1.assert_called_once_with('foo')
>>> mock2.assert_called_once_with('bar')
```

請注意，裝飾器是從底部向上應用的。這是 Python 應用裝飾器的標準方式。被建立的 `mock` 傳遞到測試函式中的順序與此順序相同。

### 該 patch 何處

`patch()` 的工作原理是（暫時）將 `name` 指向的物件變更到另一個物件。可以有許多 `name` 指向任何單一物件，因此為了使 `patch` 起作用，你必須確保你 `patch` 了被測試系統使用的 `name`。

基本原則是在物件被查找的位置進行 `patch`，該位置不一定與其被定義的位置相同。幾個範例將有助於闡明這一點。

想像一下，我們想要測試一個專案，其結構如下：

```
a.py
-> Defines SomeClass

b.py
-> from a import SomeClass
-> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using `patch()`. The problem is that when we import module `b`, which we will have to do when it imports `SomeClass` from module `a`. If we use `patch()` to mock out `a.SomeClass` then it will have no effect on our test; module `b` already has a reference to the *real* `SomeClass` and it looks like our patching had no effect.

關鍵是在使用（或查找它）的地方 `patch` `SomeClass`。在這個情況下，`some_function` 實際上會在我們 `import` 它的模組 `b` 中查找 `SomeClass`。這時的 `patch` 應該長得像這樣：

```
@patch('b.SomeClass')
```

然而，考慮另一種情況，其中模組 `b` 不是使用 `from a import SomeClass`，而是 `import a`，然後 `some_function` 使用 `a.SomeClass`。這兩種 `import` 形式都很常見。在這種情況下，我們想要 `patch` 的類正在其模組中被查找，因此我們必須 `patch a.SomeClass`：

```
@patch('a.SomeClass')
```

## Patch 描述器與代理物件 (Proxy Objects)

`patch` 和 `patch.object` 都正確地 `patch` 和還原描述器：類方法、態方法以及屬性。你應該在類而不是實例上 `patch` 它們。它們還可以使用代理屬性存取的一些物件，例如 `django` 設定物件。

### 27.6.4 MagicMock 以及魔術方法支援

#### Mock 魔術方法

`Mock` 支援 `mock` Python 協定方法，其也被稱作“魔術方法”。這允許 `mock` 物件替換容器或實作 Python 協定的其他物件。

由於魔術方法被查找的方式與一般的方法<sup>2</sup> 不同，因此專門實作了此支援方式。這代表著僅有特定的魔術方法被此方式支援。現在已支援清單中已經幾乎包含了所有魔術方法。如果你需要 `mock` 任何魔術方法而其尚未被支援，請讓我們知道。

你可以透過將你感興趣的方法設定函式或 `mock` 實例來 `mock` 魔術方法。如果你使用函式，那它必須將 `self` 作第一個引數<sup>3</sup>。

```
>>> def __str__(self):
...     return 'fooble'
...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'
```

```
>>> mock = Mock()
>>> mock.__iter__ = Mock(return_value=iter([]))
>>> list(mock)
[]
```

一個用法是在 `with` 陳述式中 `mock` 作情境管理器使用的物件：

```
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
...     assert m == 'foo'
...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

對魔術方法的呼叫不會出現在 `method_calls` 中，它們會被記在 `mock_calls` 。

#### 備

如果你使用 `spec` 關鍵字引數來建立一個 `mock`，則嘗試設定規格中未包含的魔術方法將引發一個 `AttributeError`。

已支援的魔術方法的完整列表是：

<sup>2</sup> 魔術方法應該在類而不是實例上被查找。不同版本的 Python 對於這條規則的適用不一致。支援的協定方法應適用於所有支援的 Python 版本。

<sup>3</sup> 該函式基本上與類，但每個 `Mock` 實例都與其他實例保持隔離。

- `__hash__`、`__sizeof__`、`__repr__` 和 `__str__`
- `__dir__`、`__format__` 和 `__subclasses__`
- `__round__`、`__floor__`、`__trunc__` 和 `__ceil__`
- 比較方法: `__lt__`、`__gt__`、`__le__`、`__ge__`、`__eq__` 和 `__ne__`
- 容器方法: `__getitem__`、`__setitem__`、`__delitem__`、`__contains__`、`__len__`、`__iter__`、`__reversed__` 和 `__missing__`
- 情境管理器: `__enter__`、`__exit__`、`__aenter__` 和 `__aexit__`
- 一元數值方法: `__neg__`、`__pos__` 和 `__invert__`
- 數值方法 (包括右側 (right hand) 和原地 (in-place) 變體) : `__add__`、`__sub__`、`__mul__`、`__matmul__`、`__truediv__`、`__floordiv__`、`__mod__`、`__divmod__`、`__lshift__`、`__rshift__`、`__and__`、`__xor__`、`__or__` 和 `__pow__`
- 數值轉方法: `__complex__`、`__int__`、`__float__` 和 `__index__`
- 描述器方法: `__get__`、`__set__` 和 `__delete__`
- Pickling: `__reduce__`、`__reduce_ex__`、`__getinitargs__`、`__getnewargs__`、`__getstate__` 和 `__setstate__`
- 檔案系統路徑表示法: `__fspath__`
- 非同步迭代方法: `__aiter__` 和 `__anext__`

在 3.8 版的變更: 新增對於 `os.PathLike.__fspath__()` 的支援。

在 3.8 版的變更: 新增對於 `__aenter__`、`__aexit__`、`__aiter__` 和 `__anext__` 的支援。

以下方法存在, 但「不」被支援, 因為它們在被 mock 使用時, 會無法動態設定, 或可能導致問題:

- `__getattr__`、`__setattr__`、`__init__` 和 `__new__`
- `__prepare__`、`__instancecheck__`、`__subclasscheck__`、`__del__`

## Magic Mock

MagicMock 有兩個變體: `MagicMock` 和 `NonCallableMagicMock`。

**class** `unittest.mock.MagicMock(*args, **kw)`

`MagicMock` 是 `Mock` 的子類, 其預設具有大多數魔術方法的實作。你可以使用 `MagicMock`, 而無需自行配置魔術方法。

建構函式參數的意義與 `Mock` 中的參數相同。

如果你使用 `spec` 或 `spec_set` 引數, 那麼只有規格中存在的魔術方法會被建立。

**class** `unittest.mock.NonCallableMagicMock(*args, **kw)`

`MagicMock` 的不可呼叫版本。

建構函式參數的意義與 `MagicMock` 中的參數相同, 但 `return_value` 和 `side_effect` 除外, 它們對不可呼叫的 mock 來沒有任何意義。

魔術方法是使用 `MagicMock` 物件設定的, 因此你可以配置它們以一般的方法來使用它們:

```
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

預設情況下, 許多協定方法都需要回傳特定種類的物件。這些方法預先配置了預設回傳值, 因此如果你對回傳值不感興趣, 則無需執行任何操作即可使用它們。如果你想更改預設值, 你仍然可以手動設定回傳值。

方法及其預設值：

- `__lt__`: *NotImplemented*
- `__gt__`: *NotImplemented*
- `__le__`: *NotImplemented*
- `__ge__`: *NotImplemented*
- `__int__`: 1
- `__contains__`: False
- `__len__`: 0
- `__iter__`: `iter([])`
- `__exit__`: False
- `__aexit__`: False
- `__complex__`: `1j`
- `__float__`: `1.0`
- `__bool__`: True
- `__index__`: 1
- `__hash__`: mock 的預設雜
- `__str__`: mock 的預設字串
- `__sizeof__`: mock 的預設 `sizeof`

舉例來：

```
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

`__eq__()` 和 `__ne__()` 這兩個相等的方法是特異的。它們使用 `side_effect` 屬性對識性 (identity) 進行預設的相等比較，除非你變更它們的回傳值以回傳其他：

```
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
>>> mock.__eq__.return_value = True
>>> mock == 3
True
```

`MagicMock.__iter__()` 的回傳值可以是任何可代物件，且不需是一個代器：

```
>>> mock = MagicMock()
>>> mock.__iter__.return_value = ['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
['a', 'b', 'c']
```

如果回傳值是一個代器，那對其進行一次代將消耗它，且後續代將生一個空串列：

```
>>> mock.__iter__.return_value = iter(['a', 'b', 'c'])
>>> list(mock)
['a', 'b', 'c']
>>> list(mock)
[]
```

MagicMock 配置了所有支援的魔術方法，除了一些少見和過時的方法。如果你想要，你仍然可以設定這些魔術方法。

MagicMock 中支援但預設未設置的魔術方法包含：

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`、`__set__` 和 `__delete__`
- `__reversed__` 和 `__missing__`
- `__reduce__`、`__reduce_ex__`、`__getinitargs__`、`__getnewargs__`、`__getstate__` 和 `__setstate__`
- `__getformat__`

## 27.6.5 輔助函式

### sentinel (哨兵)

`unittest.mock.sentinel`

哨兵物件提供了一種你的測試提供獨特物件的便利方式。

當你使用名稱存取屬性時，屬性會根據需要被建立。存取相同的屬性將始終回傳相同的物件。回傳的物件會具有合適的 `repr`，讓測試失敗的訊息是可讀的。

在 3.7 版的變更：哨兵屬性現在當被 `repr` 或序列化時會保留其識別性。

在測試時，有時你需要測試特定物件是否作引數被傳遞給另一個方法或回傳。建立命名的哨兵物件來測試這一點是常見的。`sentinel` 提供了一種此類建立和測試物件識別性的便利方式。

在這個例子中，我們 monkey patch method 以回傳 `sentinel.some_object`：

```
>>> real = ProductionClass()
>>> real.method = Mock(name="method")
>>> real.method.return_value = sentinel.some_object
>>> result = real.method()
>>> assert result is sentinel.some_object
>>> result
sentinel.some_object
```

### DEFAULT

`unittest.mock.DEFAULT`

`DEFAULT` 物件是一個預先建立的哨兵（實際上是 `sentinel.DEFAULT`）。它可以被 `side_effect` 函式使用來表示正常的回傳值應該被使用。

### call

`unittest.mock.call(*args, **kwargs)`

與 `call_args`、`call_args_list`、`mock_calls` 和 `method_calls` 相比，`call()` 是一個用於進行更簡單的斷言的輔助物件。`call()` 也可以與 `assert_has_calls()` 一起使用。

```

>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar'), call()]
True

```

`call.call_list()`

對於表示多個呼叫的 `call` 物件，`call_list()` 回傳所有中間呼叫以及最終呼叫的串列。

`call_list` 在對「鏈接呼叫 (chained calls)」進行斷言時特別有用。鏈接呼叫是在單行程式碼進行的多次呼叫。這會導致 `mock` 上的 `mock_calls` 中出現多個項目。手動建構呼叫序列會相當單調乏味。

`call_list()` 可以從同一個鏈接呼叫建構呼叫序列：

```

>>> m = MagicMock()
>>> m(1).method(arg='foo').other('bar')(2.0)
<MagicMock name='mock().method().other()' id='...'>
>>> kall = call(1).method(arg='foo').other('bar')(2.0)
>>> kall.call_list()
[call(1),
 call().method(arg='foo'),
 call().method().other('bar'),
 call().method().other()(2.0)]
>>> m.mock_calls == kall.call_list()
True

```

取於它的建構方式，一個 `call` 物件會是 (位置引數, 關鍵字引數) 的元組，或是 (名稱, 位置引數, 關鍵字引數) 的元組。當你自己建構它們時，這不是那有趣，但是 `Mock.call_args`、`Mock.call_args_list` 和 `Mock.mock_calls` 屬性中的 `call` 物件可以被省以取得它們包含的各個引數。

`Mock.call_args` 和 `Mock.call_args_list` 中的 `call` 物件是 (位置引數, 關鍵字引數) 的二元組，而 `Mock.mock_calls` 中的 `call` 物件以及你自己建立的 `call` 物件是 (名稱, 位置引數, 關鍵字引數) 的三元組。

你可以利用它們作元組的特性來提取單個引數，以進行更複雜的省和斷言。位置引數是一個元組 (如果有位置引數則空元組)，關鍵字引數是一個字典：

```

>>> m = MagicMock(return_value=None)
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> kall.args
(1, 2, 3)
>>> kall.kwargs
{'arg': 'one', 'arg2': 'two'}
>>> kall.args is kall[0]
True
>>> kall.kwargs is kall[1]
True

```

```

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
<MagicMock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg': 'two', 'arg2': 'three'}
>>> name is m.mock_calls[0][0]
True

```

## create\_autospec

`unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)`

使用另一個物件作規格建立一個 mock 物件。Mock 上的屬性將使用 `spec` 物件上的對應屬性作其規格。

被 mock 的函式或方法將檢查其引數，以確保他們被使用正確的簽名來呼叫。

如果 `spec_set` 為 `True`，則嘗試設定規格物件上不存在的屬性將引發 `AttributeError`。

如果一個類作規格使用，則 mock（該類的實例）的回傳值將具有相同的規格。你可以透過傳遞 `instance=True` 來使用一個類作一個實例物件的規格。只有當 mock 的實例是可呼叫物件時，回傳的 mock 才會是可呼叫物件。

`create_autospec()` 也接受任意的關鍵字引數，這些引數會傳遞給已建立的 mock 的建構函式。

請參閱 [Autospecing \(自動規格\)](#) 以得知如何以 `create_autospec()` 使用自動規格以及如何在 `patch()` 中使用 `autospec` 引數的範例。

在 3.8 版的變更: 如果目標是一個非同步函式，`create_autospec()` 現在會回傳一個 `AsyncMock`。

## ANY

`unittest.mock.ANY`

有時你可能需要對 mock 的呼叫中的某些引數進行斷言，但你不介意其他的某些引數，或想將它們單獨從 `call_args` 中取出進行更加複雜的斷言。

要忽略某些引數，你可以傳入對所有物件來都相等的物件。那無論傳入什麼內容，對 `assert_used_with()` 和 `assert_used_once_with()` 的呼叫都會成功。

```
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=object())
>>> mock.assert_called_once_with('foo', bar=ANY)
```

`ANY` 也可以用來與呼叫串列進行比較，例如 `mock_calls`:

```
>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True
```

`ANY` 不只能與呼叫物件比較，其也可以在測試斷言中使用:

```
class TestStringMethods(unittest.TestCase):

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', ANY])
```

## FILTER\_DIR

`unittest.mock.FILTER_DIR`

`FILTER_DIR` 是一個模組級的變數，用於控制 mock 物件回應 `dir()` 的方式。其預設值為 `True`，它使用以下描述的過濾方式來只顯示有用的成員。如果你不喜歡這個過濾方式，或由於診斷意圖而需要將其關閉，請設定 `mock.FILTER_DIR = False`。

當過濾方式關閉時，`dir(some_mock)` 僅會顯示有用的屬性，並將包括通常不會顯示的任何動態建立的屬性。如果 mock 是使用 `spec` (或 `autospec`) 來建立的，那源頭的所有屬性都會顯示，即使它們尚未被存取:

```
>>> dir(Mock())
['assert_any_call',
 'assert_called',
 'assert_called_once',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'assert_not_called',
 'attach_mock',
 ...
>>> from urllib import request
>>> dir(Mock(spec=request))
['AbstractBasicAuthHandler',
 'AbstractDigestAuthHandler',
 'AbstractHTTPHandler',
 'BaseHandler',
 ...
```

許多不是很有用的（對 `Mock` 來是私有的，而不是被 `mock` 的東西）底和雙底前綴屬性已從在 `Mock` 上呼叫 `dir()` 的結果中濾除。如果你不喜歡這種特性，可以透過設定模組級開關 `FILTER_DIR` 來將其關閉：

```
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
['_NonCallableMock__get_return_value',
 '_NonCallableMock__get_side_effect',
 '_NonCallableMock__return_value_doc',
 '_NonCallableMock__set_return_value',
 '_NonCallableMock__set_side_effect',
 '__call__',
 '__class__',
 ...
```

或者，你可以只使用 `vars(my_mock)`（實例成員）和 `dir(type(my_mock))`（型成員）來略過過濾，而不考慮 `FILTER_DIR`。

## mock\_open

`unittest.mock.mock_open(mock=None, read_data=None)`

用於建立取代 `open()` 用途的 `mock` 的輔助函式。它適用於直接呼叫或用作情境管理器的 `open()`。

`mock` 引數是要配置的 `mock` 物件。如果其是 `None`（預設值），那它就會為你建立一個 `MagicMock`，其 API 限制在標準檔案處理上可用的方法或屬性。

`read_data` 是檔案處理方法 `read()`、`readline()` 和 `readlines()` 的回傳字串。對這些方法的呼叫將從 `read_data` 取得資料，直到資料耗盡。對這些方法的 `mock` 非常單純：每次呼叫 `mock` 時，`read_data` 都會倒回到起點。如果你需要對提供給測試程式碼的資料進行更多控制，你會需要自行客制化這個 `mock`。如果這樣還不，PyPI 上的其中一個記憶體檔案系統 (in-memory filesystem) 套件可以提供用於測試的真實檔案系統。

在 3.4 版的變更：新增對 `readline()` 和 `readlines()` 的支援。`read()` 的 `mock` 更改消耗 `read_data` 而不是在每次呼叫時回傳它。

在 3.5 版的變更：現在，每次呼叫 `mock` 時都會重置 `read_data`。

在 3.8 版的變更：新增 `__iter__()` 到實作中，以便使它（例如在 `for` 圈中）正確地消耗 `read_data`。

使用 `open()` 作情境管理器是確保檔案處理正確關閉的好方式，且這種方式正在變得普遍：

```
with open('/some/path', 'w') as f:
    f.write('something')
```

問題是，即使你 mock 了對 `open()` 的呼叫，它也是作情境管理器使用的回傳物件（且其 `__enter__()` 和 `__exit__()` 已被呼叫）。

使用 `MagicMock` mock 情境管理器相當常見且精細，因此輔助函式就非常有用：

```
>>> m = mock_open()
>>> with patch('__main__.open', m):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
 call().write('some stuff'),
 call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')
```

以及讀取檔案：

```
>>> with patch('__main__.open', mock_open(read_data='bibble')) as m:
...     with open('foo') as h:
...         result = h.read()
...
>>> m.assert_called_once_with('foo')
>>> assert result == 'bibble'
```

### Autospeccing (自動規格)

自動規格以 mock 現有的 spec 功能作基礎。它將 mock 的 api 限制原始物件（規格）的 api，但它是遞性的（惰性 lazily）實現，因此 mock 的屬性僅具有與規格的屬性相同的 api。此外，被 mock 的函式/方法具有與原始的函式/方法相同的呼叫簽名，因此如果它們被不正確地呼叫，就會引發 `TypeError`。

在解釋自動規格如何運作之前，我們先解釋什麼需要它。

`Mock` 是一個非常大且靈活的物件，但它有一個常見的 mock 缺陷。如果你重構某些程式碼或重新命名成員等，則任何仍然使用舊 api 但使用 mock 而非真實物件的程式碼測試仍然會通過。這意味著即使你的程式碼壞了，但測試仍可以全部通過。

在 3.5 版的變更：在 3.5 之前，當測試應該引發錯誤時，斷言單字中存在拼字錯誤的測驗會默默地通過。你仍可以透過將 `unsafe=True` 傳遞給 `Mock` 來實作此行。

謹記這是你需要整合測試和單元測試的另一個原因。單獨測試所有內容都很好，但如果你不測試你的單元是如何「連接在一起」的，那麼測試還是有機會發現很多錯誤。

`unittest.mock` 已經提供了一個功能來幫助解決這個問題，其稱作 `speccing`。如果你使用類或實例作 mock 的 spec，那麼你在 mock 上只能存取真實類中存在的屬性：

```
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assert_called_with # Intentional typo!
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
```

該規格僅適用於 mock 本身，因此在 mock 上的任何方法仍然有相同的問題：

```
>>> mock.has_data()
<mock.Mock object at 0x...>
>>> mock.has_data.assert_called_with() # 故意的錯字！
```

自動規格解決了這個問題。你可以將 `autospec=True` 傳遞給 `patch()` / `patch.object()` 或使用 `create_autospec()` 函式建立帶有規格的 mock。如果你對 `patch()` 使用 `autospec=True` 引數，則被

取代的物件將作規格物件使用。因規格是「惰性」完成的（規格是在 mock 被存取時作屬性被建立的），所以你可以將它與非常雜或深度巢狀使用的物件（例如連續引用的模組）一起使用，而不會過於影響性能。

這是一個正在使用的例子：

```
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='... '>
```

你可以看到 `request.Request` 有一個規格。`request.Request` 在建構函式中接受兩個引數（其中之一是 `self`）。如果我們錯誤地呼叫它，會發生以下情況：

```
>>> req = request.Request()
Traceback (most recent call last):
...
TypeError: <lambda>() takes at least 2 arguments (1 given)
```

此規格也適用於實例化的類（即有規格的 mock 的回傳值）：

```
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Request' id='... '>
```

`Request` 物件不是可呼叫物件，因此實例化我們 mock out 的 `request.Request` 的回傳值是不可呼叫的 mock。規格到位後，斷言中的任何拼字錯誤都會引發正確的錯誤：

```
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='... '>
>>> req.add_header.assert_called_with # Intentional typo!
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'assert_called_with'
>>> req.add_header.assert_called_with('spam', 'eggs')
```

在許多情況下，你只需要將 `autospec=True` 新增至現有的 `patch()` 呼叫中，然後就可以防止因拼字錯誤和 api 變更而導致的錯誤。

除了透過 `patch()` 使用 `autospec` 之外，還有一個 `create_autospec()` 用於直接建立有自動規格的 mock：

```
>>> from urllib import request
>>> mock_request = create_autospec(request)
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request' id='... '>
```

然而，這並非完全有限制，這就是它不是預設的。為了理解規格物件上有哪些可用屬性，`autospec` 必須省（存取屬性）規格。當你遍歷 mock 上的屬性時，原始物件的對應遍歷正在默默發生。如果你的規格物件具有可以觸發程式碼執行的屬性或描述器，那你可能無法使用 `autospec`。句話，設計你的物件讓省是安全的<sup>4</sup> 會比較好。

一個更嚴重的問題是，在 `__init__()` 方法中建立實例屬性是常見的，而其根本不存在於類中。`autospec` 無法知道任何動態建立的屬性，將 api 限制可見的屬性：

```
>>> class Something:
...     def __init__(self):
...         self.a = 33
```

(繼續下一頁)

<sup>4</sup> 這只適用於類或已經實例化的物件。呼叫一個被 mock 的類來建立一個 mock 實例不會建立真的實例。它僅查找屬性及對 `dir()` 的呼叫。

(繼續上一頁)

```

...
>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'

```

有幾種不同的方法可以解這個問題。最簡單但可能有點煩人的方法是在建立後簡單地在 `mock` 上設定所需的屬性。因雖然 `autospec` 不允許你取得規格中不存在的屬性，但是它不會阻止你設定它們：

```

>>> with patch('__main__.Something', autospec=True):
...     thing = Something()
...     thing.a = 33
...

```

`spec` 和 `autospec` 有一個更激進的版本，它會確實地阻止你設定不存在的屬性。如果你想確保你的程式碼僅能設定有效的屬性，那這會很有用，但顯然它也順便阻止了這個特殊情：

```

>>> with patch('__main__.Something', autospec=True, spec_set=True):
...     thing = Something()
...     thing.a = 33
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'

```

解問題的最佳方法可能是新增類屬性作在 `__init__()` 中初始化的實例成員的預設值。請注意，如果你僅在 `__init__()` 中設定預設屬性，那透過類屬性（當然在實例之間共用）提供它們也會更快。例如：

```

class Something:
    a = 33

```

這就帶來了另一個問題。稍後將成不同型的物件的成員提供預設值 `None` 是相對常見的。`None` 作規格是無用的，因它不允許你存取其上的任何屬性或方法。由於 `None` 作規格永遠不會有用，且可能表示通常屬於其他型的成員，因此自動規格不會對設定 `None` 的成員使用規格。這些會只是普通的 `mock`（通常是 `MagicMocks`）：

```

>>> class Something:
...     member = None
...
>>> mock = create_autospec(Something)
>>> mock.member.foo.bar.baz()
<MagicMock name='mock.member.foo.bar.baz()' id='...'>

```

如果修改正式生 (production) 類以新增預設值不符合你的喜好，那還有更多選擇。其中之一就是簡單地使用實例作規格而不是使用類。另一種是建立一個正式生類的子類，將預設值新增至子類中，而不影響正式生類。這兩個都需要你使用替代物件作規格。值得慶幸的是 `patch()` 支援這一點 - 你可以簡單地將替代物件作 `autospec` 引數傳遞：

```

>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> class SomethingForTest(Something):
...     a = 33
...
>>> p = patch('__main__.Something', autospec=SomethingForTest)

```

(繼續下一頁)

(繼續上一頁)

```
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int' id='... '>
```

## 密封 mock

`unittest.mock.seal(mock)`

當存取被密封的 `mock` 的屬性或其任何已經遞回 `mock` 的屬性時，`seal` 將停用 `mock` 的自動建立。

如果將具有名稱或規格的 `mock` 實例指派給屬性，則不會出現在密封鏈中。這表示可藉由固定 `mock` 物件的一部分來防止密封：

```
>>> mock = Mock()
>>> mock.submock.attribute1 = 2
>>> mock.not_submock = mock.Mock(name="sample_name")
>>> seal(mock)
>>> mock.new_attribute # This will raise AttributeError.
>>> mock.submock.attribute2 # This will raise AttributeError.
>>> mock.not_submock.attribute2 # This won't raise.
```

在 3.7 版被加入。

## 27.6.6 `side_effect`、`return_value` 和 `wraps` 的優先順序

它們的優先順序是：

1. `side_effect`
2. `return_value`
3. `wraps`

如果這三個都有設定，`mock` 將會回傳來自 `side_effect` 的值，忽略 `return_value` 和被包裝物件。如果設定了任兩項，則優先順序較高的一項將回傳該值。無論先設定哪個順序，優先順序都保持不變。

```
>>> from unittest.mock import Mock
>>> class Order:
...     @staticmethod
...     def get_value():
...         return "third"
...
>>> order_mock = Mock(spec=Order, wraps=Order)
>>> order_mock.get_value.side_effect = ["first"]
>>> order_mock.get_value.return_value = "second"
>>> order_mock.get_value()
'first'
```

由於 `None` 是 `side_effect` 的預設值，如果將其值重新賦值回 `None`，則會檢查 `return_value` 和被包裝物件之間的優先順序，忽略 `side_effect`。

```
>>> order_mock.get_value.side_effect = None
>>> order_mock.get_value()
'second'
```

如果 `side_effect` 回傳的值是 `DEFAULT`，它將被忽略，且優先順序被移動到後面一個以獲得要回傳的值。

```
>>> from unittest.mock import DEFAULT
>>> order_mock.get_value.side_effect = [DEFAULT]
>>> order_mock.get_value()
'second'
```

當 `Mock` 包裝一個物件時，`return_value` 的預設值將 `DEFAULT`。

```
>>> order_mock = Mock(spec=Order, wraps=Order)
>>> order_mock.return_value
sentinel.DEFAULT
>>> order_mock.get_value.return_value
sentinel.DEFAULT
```

優先順序將忽略該值，`DEFAULT` 將移動到最後一個，即被包裝物件。

當對被包裝物件進行真正的呼叫時，建立此 `mock` 的實例將回傳該類 `DEFAULT` 的真實實例。必須傳遞被包裝物件所需的位置引數（如果存在）。

```
>>> order_mock_instance = order_mock()
>>> isinstance(order_mock_instance, Order)
True
>>> order_mock_instance.get_value()
'third'
```

```
>>> order_mock.get_value.return_value = DEFAULT
>>> order_mock.get_value()
'third'
```

```
>>> order_mock.get_value.return_value = "second"
>>> order_mock.get_value()
'second'
```

但如果你 `DEFAULT` 其賦予 `None` 則不會被忽略，因為它是明確賦值。因此，優先順序不會移至被包裝物件。

```
>>> order_mock.get_value.return_value = None
>>> order_mock.get_value() is None
True
```

即使你在初始化 `mock` 時同時設定所有三個，優先順序也保持不變：

```
>>> order_mock = Mock(spec=Order, wraps=Order,
...                   **{"get_value.side_effect": ["first"],
...                      "get_value.return_value": "second"}
...                   )
...
>>> order_mock.get_value()
'first'
>>> order_mock.get_value.side_effect = None
>>> order_mock.get_value()
'second'
>>> order_mock.get_value.return_value = DEFAULT
>>> order_mock.get_value()
'third'
```

如果 `side_effect` 已耗盡，則優先順序將不會使值由後面取得。相反地這會引發 `StopIteration` 例外。

```
>>> order_mock = Mock(spec=Order, wraps=Order)
>>> order_mock.get_value.side_effect = ["first side effect value",
...                                    "another side effect value"]
...
>>> order_mock.get_value.return_value = "second"
```

```
>>> order_mock.get_value()
'first side effect value'
>>> order_mock.get_value()
'another side effect value'
```

```
>>> order_mock.get_value()
Traceback (most recent call last):
...
StopIteration
```

## 27.7 unittest.mock --- 入門指南

在 3.3 版被加入。

### 27.7.1 使用 Mock 的方式

#### 使用 Mock 來 patching 方法

Mock 物件的常見用法包含：

- Patching 方法
- 記在物件上的方法呼叫

你可能會想要取代一個物件上的方法，以便檢查系統的另一部分是否使用正確的引數呼叫它：

```
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

一旦我們的 mock 已經被使用（例如在這個範例中的 `real.method`），它就有了方法和屬性，允許你對其使用方式進行斷言 (assertions)。

#### 備

在大多數的範例中，`Mock` 和 `MagicMock` 類是可以互的。不過由於 `MagicMock` 是功能更大的類，因此通常它是一個更好的選擇。

一旦 mock 被呼叫，它的 `called` 屬性將被設定為 `True`。更重要的是，我們可以使用 `assert_called_with()` 或 `assert_called_once_with()` 方法來檢查它是否被使用正確的引數來呼叫。

這個範例測試呼叫 `ProductionClass().method` 是否導致對 `something` 方法的呼叫：

```
>>> class ProductionClass:
...     def method(self):
...         self.something(1, 2, 3)
...     def something(self, a, b, c):
...         pass
...
>>> real = ProductionClass()
>>> real.something = MagicMock()
>>> real.method()
>>> real.something.assert_called_once_with(1, 2, 3)
```

#### 對物件的方法呼叫使用 mock

在上一個範例中，我們直接對物件上的方法進行 patch，以檢查它是否被正確呼叫。另一個常見的用法是將一個物件傳遞給一個方法（或受測系統的某一部分），然後檢查它是否以正確的方式被使用。

下面是一個單純的 `ProductionClass`，含有一個 `closer` 方法。如果它被傳入一個物件，它就會呼叫此物件中的 `close`。

```
>>> class ProductionClass:
...     def closer(self, something):
...         something.close()
... 
```

因此，為了對此進行測試，我們需要傳遞一個具有 `close` 方法的物件，檢查它是否被正確的呼叫。

```
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```

我們不必做任何額外的事情來讓 `mock` 提供 `'close'` 方法，存取 `close` 會建立它。因此，如果 `'close'` 未被呼叫過，在測試中存取 `'close'` 就會建立它，但 `assert_called_with()` 就會引發一個失敗的例外。

## Mock 類

一個常見的使用案例是在測試的時候 `mock` 被程式碼實例化的類。當你 `patch` 一個類時，該類就會被替換 `mock`。實例是透過呼叫類建立的。這代表你可以透過查看被 `mock` 的類的回傳值來存取「`mock` 實例」。

在下面的範例中，我們有一個函式 `some_function`，它實例化 `Foo` 呼叫它的方法。對 `patch()` 的呼叫將類 `Foo` 替換一個 `mock`。`Foo` 實例是呼叫 `mock` 的結果，因此它是透過修改 `mock return_value` 來配置的。：

```
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

## 命名你的 mock

你的 `mock` 命名可能會很有用。這個名稱會顯示在 `mock` 的 `repr` 中，且當 `mock` 出現在測試的失敗訊息中時，名稱會很有幫助。該名稱也會傳播到 `mock` 的屬性或方法：

```
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
<MagicMock name='foo.method' id='...'>
```

## 追蹤所有呼叫

通常你會想要追蹤對一個方法的多個呼叫。`mock_calls` 屬性記錄對 `mock` 的子屬性以及其子屬性的所有呼叫。

```
>>> mock = MagicMock()
>>> mock.method()
<MagicMock name='mock.method()' id='...'>
>>> mock.attribute.method(10, x=53)
<MagicMock name='mock.attribute.method()' id='...'>
>>> mock.mock_calls
[call.method(), call.attribute.method(10, x=53)]
```

如果你對 `mock_calls` 做出斷言且有任何不預期的方法被呼叫，則斷言將失敗。這很有用，因為除了斷言你期望的呼叫已經進行之外，你還可以檢查它們是否按正確的順序進行，且有多餘的呼叫：

你可以使用 `call` 物件來建構串列以與 `mock_calls` 進行比較：

```
>>> expected = [call.method(), call.attribute.method(10, x=53)]
>>> mock.mock_calls == expected
True
```

然而，回傳 `mock` 的呼叫的參數不會被記，這代表在巢狀呼叫中，無法追用於建立上代的參數 `important` 的值：

```
>>> m = Mock()
>>> m.factory(important=True).deliver()
<Mock name='mock.factory().deliver()' id='... '>
>>> m.mock_calls[-1] == call.factory(important=False).deliver()
True
```

### 設定回傳值和屬性

在 `mock` 物件上設定回傳值非常簡單：

```
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

當然，你可以對 `mock` 上的方法執行相同的操作：

```
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

回傳值也可以在建構函式中設定：

```
>>> mock = Mock(return_value=3)
>>> mock()
3
```

如果你需要在 `mock` 上進行屬性設置，只需執行以下操作：

```
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

有時你想要 `mock` 更複雜的情，例如 `mock.connection.cursor().execute("SELECT 1")`。如果我們希望此呼叫回傳一個串列，那我們就必須配置巢狀呼叫的結果。

如下所示，我們可以使用 `call` 在「接呼叫 (chained call)」中建構呼叫的集合，以便在之後輕鬆的進行斷言：

```
>>> mock = Mock()
>>> cursor = mock.connection.cursor.return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT 1").call_list()
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().execute('SELECT 1')]
>>> mock.mock_calls == expected
True
```

正是對 `.call_list()` 的呼叫將我們的呼叫物件轉代表接呼叫的呼叫串列。

### 透過 mock 引發例外

一個有用的屬性是 `side_effect`。如果將其設定成例外類或實例，則當 mock 被呼叫時將引發例外。

```
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
...
Exception: Boom!
```

### Side effect 函式以及可代物件

`side_effect` 也可以設定成函式或可代物件。`side_effect` 作為可代物件的使用案例是：當你的 mock 將會被多次呼叫，且你希望每次呼叫回傳不同的值。當你將 `side_effect` 設定成可代物件時，對 mock 的每次呼叫都會傳回可代物件中的下一個值：

```
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

對於更進階的使用案例，例如根據 mock 被呼叫的內容動態變更回傳值，可以將 `side_effect` 設成一個函式。該函式會使用與 mock 相同的引數被呼叫。函式回傳的內容就會是呼叫回傳的內容：

```
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2
```

### Mock 非同步可代物件

從 Python 3.8 開始，`AsyncMock` 和 `MagicMock` 支援透過 `__aiter__` 來 mock async-iterators。`__aiter__` 的 `return_value` 屬性可用來設定用於代的回傳值。

```
>>> mock = MagicMock() # AsyncMock also works here
>>> mock.__aiter__.return_value = [1, 2, 3]
>>> async def main():
...     return [i async for i in mock]
...
>>> asyncio.run(main())
[1, 2, 3]
```

### Mock 非同步情境管理器

從 Python 3.8 開始，`AsyncMock` 和 `MagicMock` 支援透過 `__aenter__` 和 `__aexit__` 來 mock async-context-managers。預設情況下，`__aenter__` 和 `__aexit__` 是回傳非同步函式的 `AsyncMock` 實例。

```
>>> class AsyncContextManager:
...     async def __aenter__(self):
...         return self
...     async def __aexit__(self, exc_type, exc, tb):
...         pass
...
```

(繼續下一頁)

(繼續上一頁)

```

>>> mock_instance = MagicMock(AsyncContextManager()) # AsyncMock also works here
>>> async def main():
...     async with mock_instance as result:
...         pass
...
>>> asyncio.run(main())
>>> mock_instance.__aenter__.assert_awaited_once()
>>> mock_instance.__aexit__.assert_awaited_once()

```

### 從現有物件建立 mock

過度使用 mock 的一個問題是，它將你的測試與 mock 的實作結合在一起，而不是與真實的程式碼結合。假設你有一個實作 `some_method` 的類，在另一個類的測試中，你提供了一個 mock 的物件，其也提供了 `some_method`。如果之後你重構第一個類，使其不再具有 `some_method` - 那即使你的程式碼已經損壞，你的測試也將繼續通過！

`Mock` 允許你使用 `spec` 關鍵字引數提供一個物件作 mock 的規格。對 mock 存取規格物件上不存在的方法或屬性將立即引發一個屬性錯誤。如果你更改規格的實作，那使用該類的測試將立即失敗，而無需在這這些測試中實例化該類。

```

>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'old_method'. Did you mean: 'class_method'?

```

使用規格還可以更聰明地匹配對 mock 的呼叫，無論引數是作位置引數還是命名引數傳遞：

```

>>> def f(a, b, c): pass
...
>>> mock = Mock(spec=f)
>>> mock(1, 2, 3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(a=1, b=2, c=3)

```

如果你希望這種更聰明的匹配也可以應用於 mock 上的方法呼叫，你可以使用自動規格。

如果你想要一種更大的規格形式來防止設定任意屬性以及取得它們，那你可以使用 `spec_set` 而不是 `spec`。

### 使用 side\_effect 回傳各檔案內容

`mock_open()` 是用於 patch `open()` 方法。`side_effect` 可以用來在每次呼叫回傳一個新的 mock 物件。這可以用於回傳儲存在字典中的各檔案的不同內容：

```

DEFAULT = "default"
data_dict = {"file1": "data1",
             "file2": "data2"}

def open_side_effect(name):
    return mock_open(read_data=data_dict.get(name, DEFAULT))()

with patch("builtins.open", side_effect=open_side_effect):
    with open("file1") as file1:
        assert file1.read() == "data1"

    with open("file2") as file2:
        assert file2.read() == "data2"

    with open("file3") as file2:
        assert file2.read() == "default"

```

## 27.7.2 Patch 裝飾器

## 備

使用 `patch()` 時，需注意的是你得在被查找物件的命名空間中（in the namespace where they are looked up）patch 物件。這通常很直接，但若需要快速導引，請參該 `patch` 何處。

測試中的常見需求是 patch 類屬性或模組屬性，例如 patch 一個建函式（built-in）或 patch 模組中的類以測試它是否已實例化。模組和類實際上是全域的，因此在測試後必須撤銷它們的 patch，否則 patch 將延續到其他測試中導致難以診斷問題。

mock 此提供了三個方便的裝飾器：`patch()`、`patch.object()` 和 `patch.dict()`。`patch` 接受單一字串，格式 `package.module.Class.attribute`，用來指定要 patch 的屬性。同時它也可以接受你想要替的屬性（或類或其他）的值。`patch.object` 接受一個物件和你想要 patch 的屬性的名稱，同時也可以接受要 patch 的值。

`patch.object`:

```
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
... def test():
...     assert SomeClass.attribute == sentinel.attribute
...
>>> test()
>>> assert SomeClass.attribute == original

>>> @patch('package.module.attribute', sentinel.attribute)
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
...
>>> test()
```

如果你要 patch 一個模組（包括 `builtins`），請使用 `patch()` 而非 `patch.object()`：

```
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
...
>>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle returned"
```

如有需要，模組名稱可以含有 `.`，形式 `package.module`：

```
>>> @patch('package.module.ClassName.attribute', sentinel.attribute)
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.attribute
...
>>> test()
```

一個好的模式是實際裝飾測試方法本身：

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel.attribute)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel.attribute)
...
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

如果你想使用一個 `mock` 進行 `patch`，你可以使用僅帶有一個引數的 `patch()`（或帶有兩個引數的 `patch.object()`）。`Mock` 將被建立並被傳遞到測試函式 / 方法中：

```
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'static_method')
...     def test_something(self, mock_method):
...         SomeClass.static_method()
...         mock_method.assert_called_with()
...
>>> MyTest('test_something').test_something()
```

你可以使用這個模式堆多個 `patch` 裝飾器：

```
>>> class MyTest(unittest.TestCase):
...     @patch('package.module.ClassName1')
...     @patch('package.module.ClassName2')
...     def test_something(self, MockClass2, MockClass1):
...         self.assertIs(package.module.ClassName1, MockClass1)
...         self.assertIs(package.module.ClassName2, MockClass2)
...
>>> MyTest('test_something').test_something()
```

當你巢狀使用 `patch` 裝飾器時，`mock` 傳遞到被裝飾函式的順序會跟其被應用的順序相同（一般 *Python* 應用裝飾器的順序）。這意味著由下而上，因此在上面的範例中，`package.ClassName2` 的 `mock` 會先被傳入。

也有 `patch.dict()`，用於在測試範圍中設定字典的值，並在測試結束時將其恢復原始狀態：

```
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

`patch`、`patch.object` 和 `patch.dict` 都可以用來作情境管理器。

當你使用 `patch()` 你建立一個 `mock` 時，你可以使用 `with` 陳述式的“`as`”形式來取得 `mock` 的參照：

```
>>> class ProductionClass:
...     def method(self):
...         pass
...
>>> with patch.object(ProductionClass, 'method') as mock_method:
...     mock_method.return_value = None
...     real = ProductionClass()
...     real.method(1, 2, 3)
...
>>> mock_method.assert_called_with(1, 2, 3)
```

另外，“`patch`”、“`patch.object`”和“`patch.dict`”也可以用來作類裝飾器。以這種方式使用時，與將裝飾器單獨應用於每個名稱以“`test`”開頭的方法相同。

### 27.7.3 更多范例

以下是一些更進階一點的情境的範例。

#### Mock 接呼叫

一旦你了解了 `return_value` 屬性，`mock` 接呼叫其實就很簡單了。當一個 `mock` 第一次被呼叫，或者你在它被呼叫之前取得其 `return_value` 時，一個新的 `Mock` 就會被建立。

這代表你可以透過查問 `return_value` `mock` 來了解一個對被 `mock` 的物件的呼叫回傳的物件是如何被使用的：

```
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

這只需一個簡單的步驟即可進行配置對接呼叫進行斷言。當然，另一種選擇是先以更容易被測試的方式撰寫程式碼...

所以，假設我們有一些程式碼，看起來大概像這樣：

```
>>> class Something:
...     def __init__(self):
...         self.backend = BackendProvider()
...     def method(self):
...         response = self.backend.get_endpoint('foobar').create_call('spam', 'eggs').start_
↳call()
...         # more code
```

假設 `BackendProvider` 已經經過充分測試，那我們該如何測試 `method()`？具體來，我們要測試程式碼部分 `# more code` 是否以正確的方式使用 `response` 物件。

由於此呼叫是從實例屬性進行的，因此我們可以在 `Something` 實例上 monkey patch `backend` 屬性。在這種特定的情況下，我們只對最終呼叫 `start_call` 的回傳值感興趣，因此我們不需要做太多配置。我們假設它傳回的物件是類檔案物件 (file-like)，因此我們會確保我們的 `response` 物件使用 `open()` 作其 spec。

此，我們建立一個 `mock` 實例作我們的 `mock backend`，其建立一個 `mock response` 物件。要將 `response` 設定最後的 `start_call` 的回傳值，我們可以這樣做：

```
mock_backend.get_endpoint.return_value.create_call.return_value.start_call.return_value =
↳mock_response
```

我們可以使用 `configure_mock()` 方法來以稍微好一點的方式我們直接設定回傳值：

```
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value.start_call.return_value':
↳mock_response}
>>> mock_backend.configure_mock(**config)
```

有了這些，我們就可以原地 (in place) monkey patch “mock backend”，且可以進行真正的呼叫：

```
>>> something.backend = mock_backend
>>> something.method()
```

藉由使用 `mock_calls`，我們可以使用單一個斷言來檢查接呼叫。一個接呼叫是一行程式碼中的多個呼叫，因此 `mock_calls` 中會有多個項目。我們可以使用 `call.call_list()` 來我們建立這個呼叫串列：

```
>>> chained = call.get_endpoint('foobar').create_call('spam', 'eggs').start_call()
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

## 部分 mocking

在某些測試中，我們會想 `mock` 對 `datetime.date.today()` 的呼叫以回傳一個已知日期，但我不想阻止測試中的程式碼建立新的日期物件。不幸的是 `datetime.date` 是用 C 語言寫的，所以我們不能 monkey patch 態的 `datetime.date.today()` 方法。

我們找到了一種簡單的方法來做到這一點，其用 `mock` 有效地包裝日期類，但將對建構函式的呼叫傳遞給真實的類（返回真實的實例）。

這使用 `patch` 裝飾器來 mock 被測模組中的 `date` 類。然後，mock 日期類上的 `side_effect` 屬性會被設定回傳真實日期的 `lambda` 函式。當 mock 日期類被呼叫時，將透過 `side_effect` 建構回傳真實日期：

```
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10, 8)
...     mock_date.side_effect = lambda *args, **kw: date(*args, **kw)
...
...     assert mymodule.date.today() == date(2010, 10, 8)
...     assert mymodule.date(2009, 6, 8) == date(2009, 6, 8)
```

注意，我們有全域 `patch datetime.date`，而是在使用它的模組中 `patch date`。請參該 `patch` 何處。

當 `date.today()` 被呼叫時，一個已知日期會被回傳，但對 `date(...)` 建構函式的呼叫仍然會回傳正常日期。如果不這樣使用，你可能會發現自己必須使用與被測程式碼完全相同的演算法來計算預期結果，這是一個典型的測試的反面模式 (anti-pattern)。

對日期建構函式的呼叫被記在 `mock_date` 屬性 (`call_count` 及其相關屬性) 中，這對你的測試也可能有用處。

處理 mock 日期或其他建類的另一種方法在 這個 blog 中討論。

## Mock 生成器方法

Python 生成器是一個函式或方法，它使用 `yield` 陳述式在迭代時回傳一系列的數值。

生成器方法 / 函式會被呼叫以回傳生成器物件。之後此生成器會進行迭代。迭代的協定方法是 `__iter__()`，所以我們可以使用 `MagicMock` 來 mock 它。

下面是一個範例類，其包含實作生成器的一個 "iter" 方法：

```
>>> class Foo:
...     def iter(self):
...         for i in [1, 2, 3]:
...             yield i
...
>>> foo = Foo()
>>> list(foo.iter())
[1, 2, 3]
```

我們該如何 mock 這個類，特別是它的 "iter" 方法呢？

要配置從迭代回傳的數值 (隱含在對 `list` 的呼叫中)，我們需要配置呼叫 `foo.iter()` 所回傳的物件。

```
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

## 對每個測試方法應用相同的 patch

如果你希望 `patch` 能用在多個測試方法上，顯而易見的方式是將 `patch` 裝飾器應用於每個方法。這感覺是不必要的重行，因此你可以使用 `patch()` (及其他 `patch` 的變體) 作類裝飾器。這會將 `patch` 應用在該類的所有測試方法上。測試方法由名稱以 `test` 開頭來識：

```
>>> @patch('mymodule.SomeClass')
... class MyTest(unittest.TestCase):
...
...     def test_one(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
```

(繼續下一頁)

<sup>1</sup> 還有關於生成器運算式及生成器的更多 進階用法，但我們在這不考慮它們。一個關於生成器及其大功能的優良 是：Generator Tricks for Systems Programmers。

(繼續上一頁)

```

...
...     def test_two(self, MockSomeClass):
...         self.assertIs(mymodule.SomeClass, MockSomeClass)
...
...     def not_a_test(self):
...         return 'something'
...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'

```

管理 patch 的另一種方式是使用 `patch` 方法：`patch` 動與停止。這允許你將 patch 移到你的 `setUp` 與 `tearDown` 方法中。:

```

>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         self.patcher = patch('mymodule.foo')
...         self.mock_foo = self.patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
...     def tearDown(self):
...         self.patcher.stop()
...
>>> MyTest('test_foo').run()

```

如果你使用這個技巧，你必須確保透過呼叫 `stop` 來“取消”patch。這可能會比你想像的還要複雜一點，因為如果有例外在 `setUp` 中被引發，則 `tearDown` 就不會被呼叫。`unittest.TestCase.addCleanup()` 會讓這稍微簡單一點:

```

>>> class MyTest(unittest.TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
>>> MyTest('test_foo').run()

```

### Mock Unbound Methods (未綁定方法)

在撰寫測試時，當我們需要 patch 一個未綁定方法 (patch 類別上的方法而不是實例上的方法)。我們需要將 `self` 作第一個引數傳入，因為我們想斷言哪些物件正在呼叫這個特定方法。問題是你無法使用 mock 進行 patch，因為就算你用一個 mock 替換未綁定方法，從實例取得它時它也不會成一個綁定方法，因此 `self` 不會被傳遞。解法是使用真實的函式來 patch 未綁定方法。`patch()` 裝飾器使得用 mock 來 patch out 方法是如此的簡單，以至於建立一個真正的函式相對變得很麻煩。

如果你將 `autospec=True` 傳遞給 `patch`，那麼它會使用真的函式物件來進行 patch。此函式物件與它所替換的函式物件具有相同的簽名，但實際上委給 mock。你仍然會以與之前完全相同的方式自動建立 mock。但這意味著，如果你使用它來 patch 類別上的未綁定方法，則從實例取得的 mock 函式將轉為綁定方法。`self` 會作其第一個引數傳入，而這正是我們想要的:

```

>>> class Foo:
...     def foo(self):
...         pass
...

```

(繼續下一頁)

(繼續上一頁)

```
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...     mock_foo.return_value = 'foo'
...     foo = Foo()
...     foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with(foo)
```

如果我們不使用 `autospec=True`，那麼未連結方法將使用一個 `Mock` 實例 `patch out`，且不被使用 `self` 進行呼叫。

### 使用 `mock` 檢查多個呼叫

`mock` 有很好的 API，用於對 `mock` 物件的使用方式做出斷言。

```
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```

如果你的 `mock` 只被呼叫一次，你可以使用 `assert_called_once_with()` 方法，其也斷言 `call_count` 是 1。

```
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam='eggs')
Traceback (most recent call last):
...
AssertionError: Expected 'foo_bar' to be called once. Called 2 times.
Calls: [call('baz', spam='eggs'), call()]
```

`assert_called_with` 和 `assert_called_once_with` 都對最近一次的呼叫做出斷言。如果你的 `mock` 將被多次呼叫，且你想要對所有這些呼叫進行斷言，你可以使用 `call_args_list`：

```
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

`call` 輔助函式可以輕鬆地對這些呼叫做出斷言。你可以建立預期呼叫的清單，將其與 `call_args_list` 進行比較。這看起來與 `call_args_list` 的 `repr` 非常相似：

```
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```

### 應對可變引數

另一種情況很少見，但可能會困擾你，那就是當你的 `mock` 被使用可變引數呼叫。`call_args` 和 `call_args_list` 儲存對引數的參照。如果引數被測試中的程式碼改變，那麼你將無法再對 `mock` 被呼叫時的值進行斷言。

這是一些秀出問題的程式碼範例。想像 `'mymodule'` 中定義以下函式：

```
def frob(val):
    pass

def grob(val):
```

(繼續下一頁)

```
"First frob and then clear val"
frob(val)
val.clear()
```

當我們嘗試測試 `grob` 使用正確的引數呼叫 `frob` 時，看看會發生什麼：

```
>>> with patch('mymodule.frob') as mock_frob:
...     val = {6}
...     mymodule.grob(val)
...
>>> val
set()
>>> mock_frob.assert_called_with({6})
Traceback (most recent call last):
...
AssertionError: Expected: (({6},), {})
Called with: ((set(),), {})
```

一種可能是讓 `mock` 你傳入的引數。如果你進行的斷言依賴於物件識性來確定相等性，這就可能導致問題。

以下是一種使用 `side_effect` 功能的解法。如果你 `mock` 提供一個 `side_effect` 函式，則 `side_effect` 將被使用與 `mock` 相同的引數呼叫。這使我們有機會引數將其儲存以供之後的斷言。在這個範例中，我們使用另一個 `mock` 來儲存引數，以便我們可以使用 `mock` 方法來執行斷言。同樣的，有一個輔助函式我們設定了這些。：

```
>>> from copy import deepcopy
>>> from unittest.mock import Mock, patch, DEFAULT
>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         new_mock(*args, **kwargs)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock
...
>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = {6}
...     mymodule.grob(val)
...
>>> new_mock.assert_called_with({6})
>>> new_mock.call_args
call({6})
```

`copy_call_args` 與將要被呼叫的 `mock` 一起被呼叫。它回傳一個我們會對其進行斷言的新的 `mock`。`side_effect` 函式建立引數們的副本，用該副本呼叫我們的 `new_mock`。

### 備

如果你的 `mock` 只會被使用一次，則有一種更簡單的方法可以在呼叫引數時檢查它們。你可以簡單地在 `side_effect` 函式進行檢查。

```
>>> def side_effect(arg):
...     assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
```

```
Traceback (most recent call last):
...
AssertionError
```

另一種方法是建立 `Mock` 或 `MagicMock` 的子類來 (使用 `copy.deepcopy()`) 引數。這是一個實作的例子：

```
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...     def __call__(self, /, *args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         return super().__call__(*args, **kwargs)
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
...
AssertionError: expected call not found.
Expected: mock({1})
Actual: mock(set())
>>> c.foo
<CopyingMock name='mock.foo' id='...'>
```

當你將 `Mock` 或 `MagicMock` 子類化時，所有屬性會被動態建立，且 `return_value` 會自動使用你的子類。這代表著 `CopyingMock` 的所有子代 (child) 也會具有 `CopyingMock` 型。

## 巢狀使用 Patch

將 `patch` 作情境管理器使用很好，但是如果你使用數個 `patch`，你最終可能會得到巢狀的 `with` 陳述式，且越來越向右縮排：

```
>>> class MyTest(unittest.TestCase):
...
...     def test_foo(self):
...         with patch('mymodule.Foo') as mock_foo:
...             with patch('mymodule.Bar') as mock_bar:
...                 with patch('mymodule.Spam') as mock_spam:
...                     assert mymodule.Foo is mock_foo
...                     assert mymodule.Bar is mock_bar
...                     assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original
```

我們可以使用 `unittest` 的 `cleanup` 函式以及 `patch` 方法：動與停止 來達到相同的效果，而不會出現因巢狀導致的縮排。一個簡單的輔助方法 `create_patch` 會將 `patch` 放置到我們回傳被建立的 `mock`：

```
>>> class MyTest(unittest.TestCase):
...
...     def create_patch(self, name):
...         patcher = patch(name)
...         thing = patcher.start()
...         self.addCleanup(patcher.stop)
...         return thing
```

(繼續下一頁)

(繼續上一頁)

```

...
...     def test_foo(self):
...         mock_foo = self.create_patch('mymodule.Foo')
...         mock_bar = self.create_patch('mymodule.Bar')
...         mock_spam = self.create_patch('mymodule.Spam')
...
...         assert mymodule.Foo is mock_foo
...         assert mymodule.Bar is mock_bar
...         assert mymodule.Spam is mock_spam
...
>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original

```

### 使用 MagicMock 來 mock 字典

你可能會想要 mock 字典或其他容器物件，記對它的所有存取，同時讓它仍然像字典一樣運作。

我們可以使用 *MagicMock* 來做到這一點，它的行會與字典一致，使用 *side\_effect* 將字典存取委給我們控制下的真實底層字典。

當 *MagicMock* 的 `__getitem__()` 和 `__setitem__()` 方法被呼叫時（一般的字典存取），*side\_effect* 會被使用鍵 (key) 來呼叫（在 `__setitem__` 的情也會使用值 (value)）。我們也可以控制回傳的。

使用 *MagicMock* 後，我們可以使用諸如 *call\_args\_list* 之類的屬性來斷言字典被使用的方式：

```

>>> my_dict = {'a': 1, 'b': 2, 'c': 3}
>>> def getitem(name):
...     return my_dict[name]
...
>>> def setitem(name, val):
...     my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem

```

#### 備

不使用 *MagicMock* 的替代方案是使用 *Mock* 且只提供你特想要的魔術方法：

```

>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)

```

第三個選擇是使用 *MagicMock*，但傳入 *dict* 作 *spec*（或 *spec\_set*）引數，以使被建立的 *MagicMock* 僅具有字典可用的魔術方法：

```

>>> mock = MagicMock(spec_set=dict)
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem

```

有了這些 *side effect* 函式，*mock* 會像一般的字典一樣運作，但會記存取。如果你嘗試存取不存在的鍵，它甚至會引發一個 *KeyError*。

```

>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']

```

(繼續下一頁)

(繼續上一頁)

```
Traceback (most recent call last):
...
KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
>>> mock['d']
'eggs'
```

在上述方式被使用後，你就可以使用普通的 `mock` 方法和屬性對存取進行斷言：

```
>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'b': 'fish', 'c': 3, 'd': 'eggs'}
```

## Mock 子類及其屬性

你會想子類化 `Mock` 的原因可能有很多種。其中之一是增加輔助方法。以下是一個有點笨的例子：

```
>>> class MyMock(MagicMock):
...     def has_been_called(self):
...         return self.called
...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has_been_called()
False
>>> mymock()
>>> mymock.has_been_called()
True
```

`Mock` 實例的標準行是屬性 `mock` 和回傳值 `mock` 會與存取它們的 `mock` 具有相同的型。這確保了 `Mock` 屬性是 `Mocks`，`MagicMock` 屬性是 `MagicMocks`<sup>2</sup>。因此，如果你要子類化以新增輔助方法，那麼它們也可用於子類實例的屬性 `mock` 和回傳值 `mock`。

```
>>> mymock.foo
<MyMock name='mock.foo' id='...'>
>>> mymock.foo.has_been_called()
False
>>> mymock.foo()
<MyMock name='mock.foo()' id='...'>
>>> mymock.foo.has_been_called()
True
```

有時候這很不方便。例如，有一個使用者正在子類化 `mock` 以建立 `Twisted adaptor`。將其應用於屬性實際上會導致錯誤。

`Mock`（及其各種形式）使用名 `_get_child_mock` 的方法來屬性和回傳值建立這些“子 `mock`”。你可以透過置因此方法來防止你的子類被用屬性。其簽名是取用任意的關鍵字引數 (`**kwargs`)，然後將其傳遞給 `mock` 建構函式：

```
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, /, **kwargs):
...         return MagicMock(**kwargs)
```

(繼續下一頁)

<sup>2</sup> 此規則的例外是非可呼叫物件的 `mock`。屬性使用可呼叫物件的變體，否則非可呼叫物件的 `mock` 無法具有可呼叫的方法。

```

...
>>> mymock = Subclass()
>>> mymock.foo
<MagicMock name='mock.foo' id='...'>
>>> assert isinstance(mymock, Subclass)
>>> assert not isinstance(mymock.foo, Subclass)
>>> assert not isinstance(mymock(), Subclass)

```

### 使用 `patch.dict` 來 mock import

可能會讓 mock 很困難的一種情況是在函式內部進行區域 import。這些狀況會更難進行 mock，因為它們有使用我們可以 patch out 的模組命名空間中的物件。

一般來說，我們應該避免區域 import 的發生。有時這樣做是為了防止循環相依 (circular dependencies)，此通常有更好的方式來解決問題 (例如重構程式碼) 或透過延遲 import 來防止「前期成本 (up front costs)」。這也可以透過比無條件的區域 import 更好的方式來解決 (例如將模組儲存類或模組屬性，且僅在第一次使用時進行 import)。

除此之外，還有一種方法可以使用 mock 來影響 import 的結果。Import 會從 `sys.modules` 字典中取得一個物件。請注意，它會取得一個物件，而該物件不需要是一個模組。初次 import 模組會導致模組物件被放入 `sys.modules` 中，因此通常當你 import 某些東西時，你會得到一個模組。但非一定要如此。

這代表你可以使用 `patch.dict()` 來暫時在 `sys.modules` 中原地放置 mock。在這個 patch 作用時的任何 import 都會取得這個 mock。當 patch 完成時 (被裝飾的函式結束、with 陳述式主體完成或 `patcher.stop()` 被呼叫)，那之前 `sys.modules` 中的任何內容都會被安全地復原。

下面是一個 mock out 'fooble' 模組的例子。

```

>>> import sys
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     import fooble
...     fooble.blob()
...
<Mock name='mock.blob()' id='...'>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()

```

如你所見，import fooble 成功了，但在離開之後，`sys.modules` 中就沒有 'fooble' 了。

這也適用於 from module import name 形式：

```

>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock}):
...     from fooble import blob
...     blob.blip()
...
<Mock name='mock.blob.blip()' id='...'>
>>> mock.blob.blip.assert_called_once_with()

```

透過稍微多一點的處理，你也可以 mock 套件的引入：

```

>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock.module}
>>> with patch.dict('sys.modules', modules):
...     from package.module import fooble
...     fooble()
...
<Mock name='mock.module.fooble()' id='...'>
>>> mock.module.fooble.assert_called_once_with()

```

## 追蹤呼叫順序與更簡潔的呼叫斷言

`Mock` 類可以讓你透過 `method_calls` 屬性追蹤 `mock` 物件上方法呼叫的順序。這不會讓你可以追蹤不同的 `mock` 物件之間的呼叫順序，然而我們可以使用 `mock_calls` 來達到相同的效果。

因為 `mock` 會在 `mock_calls` 中追蹤對子 `mock` 的呼叫，且存取 `mock` 的任意屬性會建立一個子 `mock`，所以我們可以從父 `mock` 建立不同的 `mock`。之後對這些子 `mock` 的呼叫將依序全部記錄在父 `mock` 的 `mock_calls` 中：

```
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar
```

```
>>> mock_foo.something()
<Mock name='mock.foo.something()' id='... '>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='... '>
```

```
>>> manager.mock_calls
[call.foo.something(), call.bar.other.thing()]
```

之後我們可以透過與管理器 (`manager`) `mock` 上的 `mock_calls` 屬性進行比較來斷言呼叫及其順序：

```
>>> expected_calls = [call.foo.something(), call.bar.other.thing()]
>>> manager.mock_calls == expected_calls
True
```

如果 `patch` 正在被建立或放置你的 `mock`，那麼你可以使用 `attach_mock()` 方法將它們附加到管理器 `mock`。附加之後，呼叫將被記錄在管理器的 `mock_calls` 中：

```
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
...         manager.attach_mock(MockClass1, 'MockClass1')
...         manager.attach_mock(MockClass2, 'MockClass2')
...         MockClass1().foo()
...         MockClass2().bar()
<MagicMock name='mock.MockClass1().foo()' id='... '>
<MagicMock name='mock.MockClass2().bar()' id='... '>
>>> manager.mock_calls
[call.MockClass1(),
call.MockClass1().foo(),
call.MockClass2(),
call.MockClass2().bar()]
```

如果進行了多次呼叫，但你只對其中特定呼叫的序列感興趣，則可以使用 `assert_has_calls()` 方法。這需要一個呼叫串列（使用 `call` 物件建構）。如果該呼叫序列位於 `mock_calls` 中，則斷言成功。

```
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='... '>
>>> m.one().two().three()
<MagicMock name='mock.one().two().three()' id='... '>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)
```

儘管你接呼叫 `m.one().two().three()` 不是對 `mock` 進行的唯一呼叫，斷言仍會成功。

有時可能會對一個 `mock` 進行多次呼叫，而你只對斷言其中某些呼叫感興趣。你甚至可能不關心順序。在這種情況下，你可以將 `any_order=True` 傳遞給 `assert_has_calls`：

```
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)]
>>> m.assert_has_calls(calls, any_order=True)
```

### 更複雜的引數匹配

使用與 *ANY* 相同的基本概念，我們可以實作匹配器 (*matcher*)，對用來作 *mock* 引數的物件進行更複雜的斷言。

假設我們預期某個物件會被傳進 *mock*，預設情況下，該 *mock* 會根據物件識別性進行相等比較（對使用者定義類型的 Python 預設行徑）。要使用 *assert\_called\_with()*，我們需要傳入完全相同的物件。如果我們只對該物件的某些屬性感興趣，那麼我們可以建立一個匹配器來讓我們檢查這些屬性。

你可以在這個範例中看到對 *assert\_called\_with* 的一個「標準」呼叫是不行的：

```
>>> class Foo:
...     def __init__(self, a, b):
...         self.a, self.b = a, b
...
>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
...
AssertionError: expected call not found.
Expected: mock(<__main__.Foo object at 0x...>)
Actual: mock(<__main__.Foo object at 0x...>)
```

對我們的 *Foo* 類型的比較函式看起來可能會像這樣：

```
>>> def compare(self, other):
...     if not type(self) == type(other):
...         return False
...     if self.a != other.a:
...         return False
...     if self.b != other.b:
...         return False
...     return True
...
```

而可以使用像這樣的比較函式進行其相等性運算的匹配器物件會長得像這樣：

```
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
...
```

把這些都放在一起：

```
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

*Matcher* 是用我們想要比較的 *Foo* 物件和比較函式實例化的。在 *assert\_called\_with* 中，*Matcher* 相等方法將被呼叫，它將呼叫 *mock* 時傳入的物件與我們建立匹配器時傳入的物件進行比較。如果它們匹配，則 *assert\_called\_with* 會通過，如果它們不匹配，則會引發 *AssertionError*：

```
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
...
AssertionError: Expected: ((<Matcher object at 0x...>), {})
Called with: ((<Foo object at 0x...>), {})
```

透過一些調整，你可以讓比較函式直接引發 `AssertionError` 提供更有用的失敗訊息。

從版本 1.5 開始，Python 測試函式庫 `PyHamcrest` 以其相等匹配器的形式，提供了類似的功能，在這可能是有用的 (`hamcrest.library.integration.match_equality`)。

## 27.8 test --- Python 的回歸測試 (regression tests) 套件

### 備

The `test` package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python's standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The `test` package contains all regression tests for Python as well as the modules `test.support` and `test.regrtest`. `test.support` is used to enhance your tests while `test.regrtest` drives the testing suite.

Each module in the `test` package whose name starts with `test_` is a testing suite for a specific module or feature. All new tests should be written using the `unittest` or `doctest` module. Some older tests are written using a "traditional" testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

### 也參考

#### `unittest` 模組

撰寫 PyUnit 回歸測試。

#### `doctest` 模組

鑲嵌在文件字串中的測試。

### 27.8.1 撰寫 test 套件的單元測試

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```
import unittest
from test import support

class MyTestCase(unittest.TestCase):

    # Only use setUp() and tearDown() if necessary

    def setUp(self):
```

(繼續下一頁)

(繼續上一頁)

```

... code to execute in preparation for tests ...

def tearDown(self):
    ... code to execute to clean up after tests ...

def test_feature_one(self):
    # Test feature one.
    ... testing code ...

def test_feature_two(self):
    # Test feature two.
    ... testing code ...

... more test methods ...

class MyTestCase2(unittest.TestCase):
    ... same structure as MyTestCase1 ...

... more test classes ...

if __name__ == '__main__':
    unittest.main()

```

This code pattern allows the testing suite to be run by `test.regrtest`, on its own as a script that supports the `unittest` CLI, or via the `python -m unittest` CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also "private" code.
- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.
- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
- Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.
- Make sure to clean up after your tests (such as close and remove all temporary files).
- If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.
- Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.
- Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```

class TestFuncAcceptsSequencesMixin:

    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = [1, 2, 3]

```

(繼續下一頁)

(繼續上一頁)

```
class AcceptStrings(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequencesMixin, unittest.TestCase):
    arg = (1, 2, 3)
```

When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The `TestFuncAcceptsSequencesMixin` class in the example above does not have any data and so can't be run by itself, thus it does not inherit from `unittest.TestCase`.

由 Kent Beck 所著，關於先寫測試再寫程式的書籍。

## 27.8.2 使用命令列介面執行測試

The `test` package can be run as a script to drive Python's regression test suite, thanks to the `-m` option: `python -m test`. Under the hood, it uses `test.regrtest`; the call `python -m test.regrtest` used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present or loading the tests via `unittest.TestLoader.loadTestsFromModule` if `test_main` does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (`python -m test test_spam`) will minimize output and only print whether the test passed or failed.

Running `test` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources: `python -m test -uall`. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command `python -m test -uall,-audio,-largefile` will run `test` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run `python -m test -h`.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run `make test` at the top-level directory where Python was built. On Windows, executing `rt.bat` from your `PCbuild` directory will run all regression tests.

## 27.9 test.support --- Python 測試套件的工具

`test.support` 模組提供 Python 回歸測試套件的支援。

### 備 F

`test.support` is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

此模組定義了以下例外：

#### exception test.support.TestFailed

Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

#### exception test.support.ResourceDenied

Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

`test.support` 模組定義了以下常數：

`test.support.verbose`

True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`.

`test.support.is_jython`

如果執行的直譯器是 Jython，則 True。

`test.support.is_android`

如果系統是 Android，則 True。

`test.support.unix_shell`

Path for shell if not on Windows; otherwise None.

`test.support.LOOPBACK_TIMEOUT`

Timeout in seconds for tests using a network server listening on the network local loopback interface like 127.0.0.1.

The timeout is long enough to prevent test failure: it takes into account that the client and the server can run in different threads or even different processes.

The timeout should be long enough for `connect()`, `recv()` and `send()` methods of `socket.socket`.

預設值 5 秒。

另請參 `INTERNET_TIMEOUT`。

`test.support.INTERNET_TIMEOUT`

Timeout in seconds for network requests going to the internet.

The timeout is short enough to prevent a test to wait for too long if the internet request is blocked for whatever reason.

Usually, a timeout using `INTERNET_TIMEOUT` should not mark a test as failed, but skip the test instead: see `transient_internet()`.

預設值 1 分鐘。

另請參 `LOOPBACK_TIMEOUT`。

`test.support.SHORT_TIMEOUT`

Timeout in seconds to mark a test as failed if the test takes "too long".

The timeout value depends on the `regrtest --timeout` command line option.

If a test using `SHORT_TIMEOUT` starts to fail randomly on slow buildbots, use `LONG_TIMEOUT` instead.

預設值 30 秒。

`test.support.LONG_TIMEOUT`

Timeout in seconds to detect when a test hangs.

It is long enough to reduce the risk of test failure on the slowest Python buildbots. It should not be used to mark a test as failed if the test takes "too long". The timeout value depends on the `regrtest --timeout` command line option.

預設值 5 分鐘。

請參 `LOOPBACK_TIMEOUT`、`INTERNET_TIMEOUT` 和 `SHORT_TIMEOUT`。

`test.support.PGO`

Set when tests can be skipped when they are not useful for PGO.

`test.support.PIPE_MAX_SIZE`

A constant that is likely larger than the underlying OS pipe buffer size, to make writes blocking.

`test.support.Py_DEBUG`

True if Python was built with the `Py_DEBUG` macro defined, that is, if Python was built in debug mode.  
在 3.12 版被加入。

`test.support.SOCK_MAX_SIZE`

A constant that is likely larger than the underlying OS socket buffer size, to make writes blocking.

`test.support.TEST_SUPPORT_DIR`

設定包含 `test.support` 的頂層目錄。

`test.support.TEST_HOME_DIR`

設定測試套件的頂層目錄。

`test.support.TEST_DATA_DIR`

設定測試套件中的 `data` 目錄。

`test.support.MAX_Py_ssize_t`

設定 `sys.maxsize` 以進行大記憶體測試。

`test.support.max_memuse`

Set by `set_memlimit()` as the memory limit for big memory tests. Limited by `MAX_Py_ssize_t`.

`test.support.real_max_memuse`

Set by `set_memlimit()` as the memory limit for big memory tests. Not limited by `MAX_Py_ssize_t`.

`test.support.MISSING_C_DOCSTRINGS`

Set to True if Python is built without docstrings (the `WITH_DOC_STRINGS` macro is not defined). See the configure `--without-doc-strings` option.

See also the `HAVE_DOCSTRINGS` variable.

`test.support.HAVE_DOCSTRINGS`

Set to True if function docstrings are available. See the `python -OO` option, which strips docstrings of functions implemented in Python.

請參閱 `MISSING_C_DOCSTRINGS` 變數。

`test.support.TEST_HTTP_URL`

Define the URL of a dedicated HTTP server for the network tests.

`test.support.ALWAYS_EQ`

Object that is equal to anything. Used to test mixed type comparison.

`test.support.NEVER_EQ`

Object that is not equal to anything (even to `ALWAYS_EQ`). Used to test mixed type comparison.

`test.support.LARGEST`

Object that is greater than anything (except itself). Used to test mixed type comparison.

`test.support.SMALLEST`

Object that is less than anything (except itself). Used to test mixed type comparison.

`test.support` 模組定義了以下函式：

`test.support.busy_retry(timeout, err_msg=None, /, *, error=True)`

執行圈主體直到 `break` 停止圈。

After `timeout` seconds, raise an `AssertionError` if `error` is true, or just stop the loop if `error` is false.

範例：

```
for _ in support.busy_retry(support.SHORT_TIMEOUT):
    if check():
        break
```

`error=False` 用法範例:

```
for _ in support.busy_retry(support.SHORT_TIMEOUT, error=False):
    if check():
        break
else:
    raise RuntimeError('my custom error')
```

`test.support.sleeping_retry(timeout, err_msg=None, /, *, init_delay=0.010, max_delay=1.0, error=True)`

Wait strategy that applies exponential backoff.

Run the loop body until `break` stops the loop. Sleep at each loop iteration, but not at the first iteration. The sleep delay is doubled at each iteration (up to `max_delay` seconds).

請見 `busy_retry()` 文件以解參數用法。

在 `SHORT_TIMEOUT` 秒後引發例外的範例:

```
for _ in support.sleeping_retry(support.SHORT_TIMEOUT):
    if check():
        break
```

`error=False` 用法範例:

```
for _ in support.sleeping_retry(support.SHORT_TIMEOUT, error=False):
    if check():
        break
else:
    raise RuntimeError('my custom error')
```

`test.support.is_resource_enabled(resource)`

Return True if *resource* is enabled and available. The list of available resources is only set when `test.regrtest` is executing the tests.

`test.support.python_is_optimized()`

如果 Python 不是使用 `-O0` 或 `-Og` 建置則回傳 True。

`test.support.with_pymalloc()`

回傳 `_testcapi.WITH_PYMALLOC`。

`test.support.requires(resource, msg=None)`

Raise `ResourceDenied` if *resource* is not available. *msg* is the argument to `ResourceDenied` if it is raised. Always returns True if called by a function whose `__name__` is `'__main__'`. Used when tests are executed by `test.regrtest`.

`test.support.sortedict(dict)`

Return a repr of *dict* with keys sorted.

`test.support.findfile(filename, subdir=None)`

Return the path to the file named *filename*. If no match is found *filename* is returned. This does not equal a failure since it could be the path to the file.

Setting *subdir* indicates a relative path to use to find the file rather than looking directly in the path directories.

`test.support.get_pagesize()`

Get size of a page in bytes.

在 3.12 版被加入。

`test.support.setswitchinterval(interval)`

Set the `sys.setswitchinterval()` to the given *interval*. Defines a minimum interval for Android systems to prevent the system from hanging.

`test.support.check_impl_detail (**guards)`

Use this check to guard CPython's implementation-specific tests or to run them only on the implementations guarded by the arguments. This function returns `True` or `False` depending on the host platform. Example usage:

```
check_impl_detail()           # Only on CPython (default).
check_impl_detail(jython=True) # Only on Jython.
check_impl_detail(cpython=False) # Everywhere except CPython.
```

`test.support.set_memlimit (limit)`

Set the values for `max_memuse` and `real_max_memuse` for big memory tests.

`test.support.record_original_stdout (stdout)`

Store the value from `stdout`. It is meant to hold the stdout at the time the regrtest began.

`test.support.get_original_stdout ()`

Return the original stdout set by `record_original_stdout ()` or `sys.stdout` if it's not set.

`test.support.args_from_interpreter_flags ()`

Return a list of command line arguments reproducing the current settings in `sys.flags` and `sys.warnoptions`.

`test.support.optim_args_from_interpreter_flags ()`

Return a list of command line arguments reproducing the current optimization settings in `sys.flags`.

`test.support.captured_stdin ()`

`test.support.captured_stdout ()`

`test.support.captured_stderr ()`

A context managers that temporarily replaces the named stream with `io.StringIO` object.

使用輸出串流的範例:

```
with captured_stdout() as stdout, captured_stderr() as stderr:
    print("hello")
    print("error", file=sys.stderr)
assert stdout.getvalue() == "hello\n"
assert stderr.getvalue() == "error\n"
```

使用輸入串流的範例:

```
with captured_stdin() as stdin:
    stdin.write('hello\n')
    stdin.seek(0)
    # call test code that consumes from sys.stdin
    captured = input()
self.assertEqual(captured, "hello")
```

`test.support.disable_faulthandler ()`

A context manager that temporary disables `faulthandler`.

`test.support.gc_collect ()`

Force as many objects as possible to be collected. This is needed because timely deallocation is not guaranteed by the garbage collector. This means that `__del__` methods may be called later than expected and weakrefs may remain alive for longer than expected.

`test.support.disable_gc ()`

A context manager that disables the garbage collector on entry. On exit, the garbage collector is restored to its prior state.

`test.support.swap_attr(obj, attr, new_val)`

Context manager to swap out an attribute with a new object.

用法:

```
with swap_attr(obj, "attr", 5):
    ...
```

This will set `obj.attr` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `attr` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.swap_item(obj, attr, new_val)`

Context manager to swap out an item with a new object.

用法:

```
with swap_item(obj, "item", 5):
    ...
```

This will set `obj["item"]` to 5 for the duration of the `with` block, restoring the old value at the end of the block. If `item` doesn't exist on `obj`, it will be created and then deleted at the end of the block.

The old value (or `None` if it doesn't exist) will be assigned to the target of the "as" clause, if there is one.

`test.support.flush_std_streams()`

Call the `flush()` method on `sys.stdout` and then on `sys.stderr`. It can be used to make sure that the logs order is consistent before writing into `stderr`.

在 3.11 版被加入。

`test.support.print_warning(msg)`

Print a warning into `sys.__stderr__`. Format the message as: `f"Warning -- {msg}"`. If `msg` is made of multiple lines, add `"Warning -- "` prefix to each line.

在 3.9 版被加入。

`test.support.wait_process(pid, *, exitcode, timeout=None)`

Wait until process `pid` completes and check that the process exit code is `exitcode`.

如果行程退出代號不等於 `exitcode` 則引發 `AssertionError`。

If the process runs longer than `timeout` seconds (`SHORT_TIMEOUT` by default), kill the process and raise an `AssertionError`. The timeout feature is not available on Windows.

在 3.9 版被加入。

`test.support.calcobjsize(fmt)`

Return the size of the `PyObject` whose structure members are defined by `fmt`. The returned value includes the size of the Python object header and alignment.

`test.support.calcvobjsize(fmt)`

Return the size of the `PyVarObject` whose structure members are defined by `fmt`. The returned value includes the size of the Python object header and alignment.

`test.support.checksizeof(test, o, size)`

For testcase `test`, assert that the `sys.getsizeof` for `o` plus the GC header size equals `size`.

`@test.support.anticipate_failure(condition)`

A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

`test.support.system_must_validate_cert(f)`

A decorator that skips the decorated test on TLS certification validation failures.

`@test.support.run_with_locale` (*catstr*, *\*locales*)

A decorator for running a function in a different locale, correctly resetting it after it has finished. *catstr* is the locale category as a string (for example "LC\_ALL"). The *locales* passed will be tried sequentially, and the first valid locale will be used.

`@test.support.run_with_tz` (*tz*)

A decorator for running a function in a specific timezone, correctly resetting it after it has finished.

`@test.support.requires_freebsd_version` (*\*min\_version*)

Decorator for the minimum version when running test on FreeBSD. If the FreeBSD version is less than the minimum, the test is skipped.

`@test.support.requires_linux_version` (*\*min\_version*)

Decorator for the minimum version when running test on Linux. If the Linux version is less than the minimum, the test is skipped.

`@test.support.requires_mac_version` (*\*min\_version*)

Decorator for the minimum version when running test on macOS. If the macOS version is less than the minimum, the test is skipped.

`@test.support.requires_gil_enabled`

Decorator for skipping tests on the free-threaded build. If the *GIL* is disabled, the test is skipped.

`@test.support.requires_ieee_754`

Decorator for skipping tests on non-IEEE 754 platforms.

`@test.support.requires_zlib`

如果 *zlib* 不存在則跳過測試的裝飾器。

`@test.support.requires_gzip`

如果 *gzip* 不存在則跳過測試的裝飾器。

`@test.support.requires_bz2`

如果 *bz2* 不存在則跳過測試的裝飾器。

`@test.support.requires_lzma`

如果 *lzma* 不存在則跳過測試的裝飾器。

`@test.support.requires_resource` (*resource*)

如果 *resource* 不可用則跳過測試的裝飾器。

`@test.support.requires_docstrings`

Decorator for only running the test if *HAVE\_DOCSTRINGS*.

`@test.support.requires_limited_api`

Decorator for only running the test if Limited C API is available.

`@test.support.cpython_only`

Decorator for tests only applicable to CPython.

`@test.support.impl_detail` (*msg=None*, *\*\*guards*)

Decorator for invoking `check_impl_detail()` on *guards*. If that returns `False`, then uses *msg* as the reason for skipping the test.

`@test.support.no_tracing`

Decorator to temporarily turn off tracing for the duration of the test.

`@test.support.refcount_test`

Decorator for tests which involve reference counting. The decorator does not run the test if it is not run by CPython. Any trace function is unset for the duration of the test to prevent unexpected refcounts caused by the trace function.

`@test.support.bigmemtest (size, memuse, dry_run=True)`

大記憶體測試的裝飾器。

*size* is a requested size for the test (in arbitrary, test-interpreted units.) *memuse* is the number of bytes per unit for the test, or a good estimate of it. For example, a test that needs two byte buffers, of 4 GiB each, could be decorated with `@bigmemtest (size=_4G, memuse=2)`.

The *size* argument is normally passed to the decorated test method as an extra argument. If *dry\_run* is `True`, the value passed to the test method may be less than the requested value. If *dry\_run* is `False`, it means the test doesn't support dummy runs when `-M` is not specified.

`@test.support.bigaddrspacetest`

Decorator for tests that fill the address space.

`test.support.check_syntax_error (testcase, statement, errtext="", *, lineno=None, offset=None)`

Test for syntax errors in *statement* by attempting to compile *statement*. *testcase* is the `unittest` instance for the test. *errtext* is the regular expression which should match the string representation of the raised `SyntaxError`. If *lineno* is not `None`, compares to the line of the exception. If *offset* is not `None`, compares to the offset of the exception.

`test.support.open_urlresource (url, *args, **kw)`

Open *url*. If open fails, raises `TestFailed`.

`test.support.reap_children ()`

Use this at the end of `test_main` whenever sub-processes are started. This will help ensure that no extra children (zombies) stick around to hog resources and create problems when looking for reflinks.

`test.support.get_attribute (obj, name)`

Get an attribute, raising `unittest.SkipTest` if `AttributeError` is raised.

`test.support.catch_unraisable_exception ()`

Context manager catching unraisable exception using `sys.unraisablehook ()`.

Storing the exception value (`cm.unraisable.exc_value`) creates a reference cycle. The reference cycle is broken explicitly when the context manager exits.

Storing the object (`cm.unraisable.object`) can resurrect it if it is set to an object which is being finalized. Exiting the context manager clears the stored object.

用法：

```
with support.catch_unraisable_exception() as cm:
    # code creating an "unraisable exception"
    ...

    # check the unraisable exception: use cm.unraisable
    ...

# cm.unraisable attribute no longer exists at this point
# (to break a reference cycle)
```

在 3.8 版被加入。

`test.support.load_package_tests (pkg_dir, loader, standard_tests, pattern)`

Generic implementation of the `unittest` `load_tests` protocol for use in test packages. *pkg\_dir* is the root directory of the package; *loader*, *standard\_tests*, and *pattern* are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__), *args)
```

```
test.support.detect_api_mismatch(ref_api, other_api, *, ignore=())
```

Returns the set of attributes, functions or methods of *ref\_api* not found on *other\_api*, except for a defined list of items to be ignored in this check specified in *ignore*.

這預設會跳過以 '\_' 開頭的私有屬性，但會包含所有魔術方法，即以 '\_\_' 開頭和結尾的方法。

在 3.5 版被加入。

```
test.support.patch(test_instance, object_to_patch, attr_name, new_value)
```

Override *object\_to\_patch.attr\_name* with *new\_value*. Also add cleanup procedure to *test\_instance* to restore *object\_to\_patch* for *attr\_name*. The *attr\_name* should be a valid attribute for *object\_to\_patch*.

```
test.support.run_in_subinterp(code)
```

Run *code* in subinterpreter. Raise `unittest.SkipTest` if `tracemalloc` is enabled.

```
test.support.check_free_after_iterating(test, iter, cls, args=())
```

Assert instances of *cls* are deallocated after iterating.

```
test.support.missing_compiler_executable(cmd_names=[])
```

Check for the existence of the compiler executables whose names are listed in *cmd\_names* or all the compiler executables when *cmd\_names* is empty and return the first missing executable or `None` when none is found missing.

```
test.support.check_all__(test_case, module, name_of_module=None, extra=(), not_exported=())
```

Assert that the `__all__` variable of *module* contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in *module*.

The *name\_of\_module* argument can specify (as a string or tuple thereof) what module(s) an API could be defined in order to be detected as a public API. One case for this is when *module* imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The *extra* argument can be a set of names that wouldn't otherwise be automatically detected as "public", like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The *not\_exported* argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

用法範例：

```
import bar
import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test_all__(self):
        support.check_all__(self, foo)

class OtherTestCase(unittest.TestCase):
    def test_all__(self):
        extra = {'BAR_CONST', 'FOO_CONST'}
        not_exported = {'baz'} # Undocumented name.
        # bar imports part of its API from _bar.
        support.check_all__(self, bar, ('bar', '_bar'),
                           extra=extra, not_exported=not_exported)
```

在 3.6 版被加入。

```
test.support.skip_if_broken_multiprocessing_synchronize()
```

Skip tests if the `multiprocessing.synchronize` module is missing, if there is no available semaphore implementation, or if creating a lock raises an `OSError`.

在 3.10 版被加入。

```
test.support.check_disallow_instantiation(test_case, tp, *args, **kwds)
```

Assert that type *tp* cannot be instantiated using *args* and *kwds*.

在 3.10 版被加入。

```
test.support.adjust_int_max_str_digits(max_digits)
```

This function returns a context manager that will change the global `sys.set_int_max_str_digits()` setting for the duration of the context to allow execution of test code that needs a different limit on the number of digits when converting between an integer and string.

在 3.11 版被加入。

`test.support` 模組定義了以下類：

```
class test.support.SuppressCrashReport
```

A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using `SetErrorMode`.

On UNIX, `resource.setrlimit()` is used to set `resource.RLIMIT_CORE`'s soft limit to 0 to prevent coredump file creation.

在兩個平台上，舊值會被 `__exit__()` 還原。

```
class test.support.SaveSignals
```

Class to save and restore signal handlers registered by the Python signal handler.

```
save(self)
```

Save the signal handlers to a dictionary mapping signal numbers to the current signal handler.

```
restore(self)
```

Set the signal numbers from the `save()` dictionary to the saved handler.

```
class test.support.Matcher
```

```
matches(self, d, **kwargs)
```

Try to match a single dict with the supplied arguments.

```
match_value(self, k, dv, v)
```

Try to match a single stored value (*dv*) with a supplied value (*v*).

## 27.10 test.support.socket\_helper --- 用於 socket 測試的工具

The `test.support.socket_helper` module provides support for socket tests.

在 3.9 版被加入。

```
test.support.socket_helper.IPV6_ENABLED
```

Set to `True` if IPv6 is enabled on this host, `False` otherwise.

```
test.support.socket_helper.find_unused_port(family=socket.AF_INET,
                                             socktype=socket.SOCK_STREAM)
```

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is `AF_INET`, `SOCK_STREAM`), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a Python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's `s_server` mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

`test.support.socket_helper.bind_port(sock, host=HOST)`

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is `AF_INET` and `sock.type` is `SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

`test.support.socket_helper.bind_unix_socket(sock, addr)`

Bind a Unix socket, raising `unittest.SkipTest` if `PermissionError` is raised.

`@test.support.socket_helper.skip_unless_bind_unix_socket`

A decorator for running tests that require a functional `bind()` for Unix sockets.

`test.support.socket_helper.transient_internet(resource_name, *, timeout=30.0, errnos=())`

A context manager that raises `ResourceDenied` when various issues with the internet connection manifest themselves as exceptions.

## 27.11 test.support.script\_helper --- 用於 Python 執行測試的工具

`test.support.script_helper` 模組提供 Python 的本機執行測試的支援。

`test.support.script_helper.interpreter_requires_environment()`

Return True if `sys.executable` interpreter requires environment variables in order to be able to run at all.

This is designed to be used with `@unittest.skipIf()` to annotate tests that need to use an `assert_python*()` function to launch an isolated mode (`-I`) or no environment mode (`-E`) sub-interpreter process.

A normal build & test does not run into this situation but it can happen when trying to run the standard library test suite from an interpreter that doesn't have an obvious home with Python's current home finding logic.

Setting `PYTHONHOME` is one way to get most of the testsuite to run in that situation. `PYTHONPATH` or `PYTHONUSERSITE` are other common environment variables that might impact whether or not the interpreter can start.

`test.support.script_helper.run_python_until_end(*args, **env_vars)`

Set up the environment based on `env_vars` for running the interpreter in a subprocess. The values can include `__isolated`, `__cleanenv`, `__cwd`, and `TERM`.

在 3.9 版的變更: 此函式不再從 `stderr` 中移除空白。

`test.support.script_helper.assert_python_ok(*args, **env_vars)`

Assert that running the interpreter with `args` and optional environment variables `env_vars` succeeds (`rc == 0`) and return a `(return code, stdout, stderr)` tuple.

If the `__cleanenv` keyword-only parameter is set, `env_vars` is used as a fresh environment.

Python is started in isolated mode (command line option `-I`), except if the `__isolated` keyword-only parameter is set to `False`.

在 3.9 版的變更: 此函式不再從 `stderr` 中移除空白。

`test.support.script_helper.assert_python_failure(*args, **env_vars)`

Assert that running the interpreter with `args` and optional environment variables `env_vars` fails (`rc != 0`) and return a `(return code, stdout, stderr)` tuple.

更多選項請見 `assert_python_ok()`。

在 3.9 版的變更: 此函式不再從 `stderr` 中移除空白。

```
test.support.script_helper.spawn_python(*args, stdout=subprocess.PIPE, stderr=subprocess.STDOUT,
**kw)
```

Run a Python subprocess with the given arguments.

*kw* is extra keyword args to pass to `subprocess.Popen()`. Returns a `subprocess.Popen` object.

```
test.support.script_helper.kill_python(p)
```

Run the given `subprocess.Popen` process until completion and return stdout.

```
test.support.script_helper.make_script(script_dir, script_basename, source, omit_suffix=False)
```

Create script containing *source* in path *script\_dir* and *script\_basename*. If *omit\_suffix* is `False`, append `.py` to the name. Return the full script path.

```
test.support.script_helper.make_zip_script(zip_dir, zip_basename, script_name,
name_in_zip=None)
```

Create zip file at *zip\_dir* and *zip\_basename* with extension `zip` which contains the files in *script\_name*. *name\_in\_zip* is the archive name. Return a tuple containing (full path, full path of archive name).

```
test.support.script_helper.make_pkg(pkg_dir, init_source="")
```

Create a directory named *pkg\_dir* containing an `__init__` file with *init\_source* as its contents.

```
test.support.script_helper.make_zip_pkg(zip_dir, zip_basename, pkg_name, script_basename, source,
depth=1, compiled=False)
```

Create a zip package directory with a path of *zip\_dir* and *zip\_basename* containing an empty `__init__` file and a file *script\_basename* containing the *source*. If *compiled* is `True`, both source files will be compiled and added to the zip package. Return a tuple of the full zip path and the archive name for the zip file.

## 27.12 test.support.bytecode\_helper --- 用於測試位元組碼能正確 生的支援工具

`test.support.bytecode_helper` 模組提供測試和檢查位元組碼 生的支援。

在 3.9 版被加入。

此模組定義了以下類：

```
class test.support.bytecode_helper.BytecodeTestCase(unittest.TestCase)
```

This class has custom assertion methods for inspecting bytecode.

```
BytecodeTestCase.get_disassembly_as_string(co)
```

Return the disassembly of *co* as string.

```
BytecodeTestCase.assertInBytecode(x, opname, argval=_UNSPECIFIED)
```

Return *instr* if *opname* is found, otherwise throws `AssertionError`.

```
BytecodeTestCase.assertNotInBytecode(x, opname, argval=_UNSPECIFIED)
```

Throws `AssertionError` if *opname* is found.

## 27.13 test.support.threading\_helper --- Utilities for threading tests

The `test.support.threading_helper` module provides support for threading tests.

在 3.10 版被加入。

```
test.support.threading_helper.join_thread(thread, timeout=None)
```

Join a *thread* within *timeout*. Raise an `AssertionError` if thread is still alive after *timeout* seconds.

`@test.support.threading_helper.reap_threads`

Decorator to ensure the threads are cleaned up even if the test fails.

`test.support.threading_helper.start_threads (threads, unlock=None)`

Context manager to start *threads*, which is a sequence of threads. *unlock* is a function called after the threads are started, even if an exception was raised; an example would be `threading.Event.set()`. `start_threads` will attempt to join the started threads upon exit.

`test.support.threading_helper.threading_cleanup (*original_values)`

Cleanup up threads not specified in *original\_values*. Designed to emit a warning if a test leaves running threads in the background.

`test.support.threading_helper.threading_setup()`

Return current thread count and copy of dangling threads.

`test.support.threading_helper.wait_threads_exit (timeout=None)`

Context manager to wait until all threads created in the `with` statement exit.

`test.support.threading_helper.catch_threading_exception()`

Context manager catching `threading.Thread` exception using `threading.excepthook()`.

當捕捉到例外時會設定的屬性：

- `exc_type`
- `exc_value`
- `exc_traceback`
- `thread`

參閱 `threading.excepthook()` 文件。

這些屬性會在離開情境管理器時被刪除。

用法：

```
with threading_helper.catch_threading_exception() as cm:
    # code spawning a thread which raises an exception
    ...

    # check the thread exception, use cm attributes:
    # exc_type, exc_value, exc_traceback, thread
    ...

# exc_type, exc_value, exc_traceback, thread attributes of cm no longer
# exists at this point
# (to avoid reference cycles)
```

在 3.8 版被加入。

## 27.14 test.support.os\_helper --- 用於 OS 測試的工具

`test.support.os_helper` 模組提供 OS 測試的支援。

在 3.10 版被加入。

`test.support.os_helper.FS_NONASCII`

A non-ASCII character encodable by `os.fsencode()`.

`test.support.os_helper.SAVEDCWD`

設定 `os.getcwd()`。

`test.support.os_helper.TESTFN`

Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

`test.support.os_helper.TESTFN_NONASCII`

Set to a filename containing the `FS_NONASCII` character, if it exists. This guarantees that if the filename exists, it can be encoded and decoded with the default filesystem encoding. This allows tests that require a non-ASCII filename to be easily skipped on platforms where they can't work.

`test.support.os_helper.TESTFN_UNENCODABLE`

Set to a filename (str type) that should not be able to be encoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNDECODABLE`

Set to a filename (bytes type) that should not be able to be decoded by file system encoding in strict mode. It may be `None` if it's not possible to generate such a filename.

`test.support.os_helper.TESTFN_UNICODE`

Set to a non-ASCII name for a temporary file.

**class** `test.support.os_helper.EnvironmentVarGuard`

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying `os.environ`. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

在 3.1 版的變更: 新增字典介面。

**class** `test.support.os_helper.FakePath(path)`

Simple *path-like object*. It implements the `__fspath__()` method which just returns the `path` argument. If `path` is an exception, it will be raised in `__fspath__()`.

`EnvironmentVarGuard.set(envvar, value)`

Temporarily set the environment variable `envvar` to the value of `value`.

`EnvironmentVarGuard.unset(envvar)`

暫時取消環境變數 `envvar`。

`test.support.os_helper.can_symlink()`

如果作業系統支援符號連結則回傳 `True`, 否則回傳 `False`。

`test.support.os_helper.can_xattr()`

如果作業系統支援 `xattr` 則回傳 `True`, 否則回傳 `False`。

`test.support.os_helper.change_cwd(path, quiet=False)`

A context manager that temporarily changes the current working directory to `path` and yields the directory.

If `quiet` is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

`test.support.os_helper.create_empty_file(filename)`

Create an empty file with `filename`. If it already exists, truncate it.

`test.support.os_helper.fd_count()`

Count the number of open file descriptors.

`test.support.os_helper.fs_is_case_insensitive(directory)`

Return `True` if the file system for `directory` is case-insensitive.

`test.support.os_helper.make_bad_fd()`

Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

`test.support.os_helper.rmtree(filename)`

Call `os.rmtree()` on *filename*. On Windows platforms, this is wrapped with a wait loop that checks for the existence of the file, which is needed due to antivirus programs that can hold files open and prevent deletion.

`test.support.os_helper.rmtree(path)`

Call `shutil.rmtree()` on *path* or call `os.lstat()` and `os.rmtree()` to remove a path and its contents. As with `rmdir()`, on Windows platforms this is wrapped with a wait loop that checks for the existence of the files.

`@test.support.os_helper.skip_unless_symlink`

A decorator for running tests that require support for symbolic links.

`@test.support.os_helper.skip_unless_xattr`

A decorator for running tests that require support for xattr.

`test.support.os_helper.temp_cwd(name='tempcwd', quiet=False)`

A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name *name* before temporarily changing the current working directory. If *name* is `None`, the temporary directory is created using `tempfile.mkdtemp()`.

If *quiet* is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

`test.support.os_helper.temp_dir(path=None, quiet=False)`

A context manager that creates a temporary directory at *path* and yields the directory.

If *path* is `None`, the temporary directory is created using `tempfile.mkdtemp()`. If *quiet* is `False`, the context manager raises an exception on error. Otherwise, if *path* is specified and cannot be created, only a warning is issued.

`test.support.os_helper.temp_umask(umask)`

A context manager that temporarily sets the process umask.

`test.support.os_helper.unlink(filename)`

Call `os.unlink()` on *filename*. As with `rmdir()`, on Windows platforms, this is wrapped with a wait loop that checks for the existence of the file.

## 27.15 test.support.import\_helper --- 用於 import 測試的工具

`test.support.import_helper` 模組提供 import 測試的支援。

在 3.10 版被加入。

`test.support.import_helper.forget(module_name)`

Remove the module named *module\_name* from `sys.modules` and delete any byte-compiled files of the module.

`test.support.import_helper.import_fresh_module(name, fresh=(), blocked=(), deprecated=False)`

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

*fresh* is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

*blocked* is an iterable of module names that are replaced with `None` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the *fresh* and *blocked* parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`.

如果無法引入指定的模組則此函式會引發 `ImportError`。

用法範例：

```
# Get copies of the warnings module for testing without affecting the
# version being used by the rest of the test suite. One copy uses the
# C implementation, the other is forced to use the pure Python fallback
# implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

在 3.1 版被加入。

`test.support.import_helper.import_module(name, deprecated=False, *, required_on=())`

This function imports and returns the named module. Unlike a normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if *deprecated* is `True`. If a module is required on a platform but optional for others, set *required\_on* to an iterable of platform prefixes which will be compared against `sys.platform`.

在 3.1 版被加入。

`test.support.import_helper.modules_setup()`

回傳 `sys.modules` 的副本。

`test.support.import_helper.modules_cleanup(oldmodules)`

Remove modules except for *oldmodules* and encodings in order to preserve internal cache.

`test.support.import_helper.unload(name)`

從 `sys.modules` 中刪除 *name*。

`test.support.import_helper.make_legacy_pyc(source)`

Move a [PEP 3147/PEP 488](#) pyc file to its legacy pyc location and return the file system path to the legacy pyc file. The *source* value is the file system path to the source file. It does not need to exist, however the PEP 3147/488 pyc file must exist.

`class test.support.import_helper.CleanImport(*module_names)`

A context manager to force import to return a new module reference. This is useful for testing module-level behaviors, such as the emission of a `DeprecationWarning` on import. Example usage:

```
with CleanImport('foo'):
    importlib.import_module('foo') # New reference.
```

`class test.support.import_helper.DirsOnSysPath(*paths)`

A context manager to temporarily add directories to `sys.path`.

This makes a copy of `sys.path`, appends any directories given as positional arguments, then reverts `sys.path` to the copied settings when the context ends.

Note that *all* `sys.path` modifications in the body of the context manager, including replacement of the object, will be reverted at the end of the block.

## 27.16 test.support.warnings\_helper --- 用於 warnings 測試的工具

`test.support.warnings_helper` 模組提供 warnings 測試的支援。

在 3.10 版被加入。

```
test.support.warnings_helper.ignore_warnings(*, category)
```

Suppress warnings that are instances of *category*, which must be *Warning* or a subclass. Roughly equivalent to `warnings.catch_warnings()` with `warnings.simplefilter('ignore', category=category)`. For example:

```
@warning_helper.ignore_warnings(category=DeprecationWarning)
def test_suppress_warning():
    # do something
```

在 3.8 版被加入。

```
test.support.warnings_helper.check_no_resource_warning(testcase)
```

Context manager to check that no *ResourceWarning* was raised. You must remove the object which may emit *ResourceWarning* before the end of the context manager.

```
test.support.warnings_helper.check_syntax_warning(testcase, statement, errtext="", *, lineno=1,
                                                  offset=None)
```

Test for syntax warning in *statement* by attempting to compile *statement*. Test also that the *SyntaxWarning* is emitted only once, and that it will be converted to a *SyntaxError* when turned into error. *testcase* is the *unittest* instance for the test. *errtext* is the regular expression which should match the string representation of the emitted *SyntaxWarning* and raised *SyntaxError*. If *lineno* is not *None*, compares to the line of the warning and exception. If *offset* is not *None*, compares to the offset of the exception.

在 3.8 版被加入。

```
test.support.warnings_helper.check_warnings(*filters, quiet=True)
```

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form `("message regexp", WarningCategory)` as positional arguments. If one or more *filters* are provided, or if the optional keyword argument *quiet* is *False*, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set *quiet* to *True*.

如果 有指定引數，預設：

```
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a *WarningRecorder* instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's *warnings* attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return *None*.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```
with check_warnings(("assertion is always true", SyntaxWarning),
                  ("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

在 3.2 版的變更: 新的可選引數 *filters* 和 *quiet*。

**class** test.support.warnings\_helper.**WarningsRecorder**

Class used to record warnings for unit tests. See documentation of `check_warnings()` above for more details.

---

 除錯與效能分析
 

---

這些函式庫幫助你進行 Python 程式開發：除錯器允許你在程式碼中單步 (step) 執行、分析堆棧框 (stack frames) 以及設置中斷點 (breakpoints) 等，效能分析工具執行程式碼提供關於執行時間的詳細分析，讓你找到程式中的瓶頸 (bottlenecks)。事件稽核 (auditing events) 提供執行時期行爲的可見性，否則的話可能需要更侵入性的除錯或修補。

## 28.1 稽核事件表

這張表包含了所有在 CPython 運行環境 (runtime) 與標準函式庫對於 `sys.audit()` 或 `PySys_Audit()` 的呼叫所觸發的事件。這些呼叫是在 3.8 或更新的版本中被新增 (請見 [PEP 578](#))。

請參考 `sys.addaudithook()` 及 `PySys_AddAuditHook()` 來了解如何處理這些事件。

這張表是從 CPython 文件生成的，可能不包含其它實作所觸發的事件。請參考你的運行環境 (runtime) 特定文件來了解實際會觸發的事件。

Audit event	Arguments
<code>_thread.start_new_thread</code>	<code>function, args, kwargs</code>
<code>array.__new__</code>	<code>typecode, initializer</code>

## 28.2 bdb --- 偵錯器框架

原始碼: [Lib/bdb.py](#)

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger. 有定義以下例外:

**exception** `bdb.BdbQuit`

由 `Bdb` 類所引發的例外，用來退出偵錯器。

`bdb` 模組也定義了兩個類:

**class** `bdb.Breakpoint` (*self, file, line, temporary=False, cond=None, funcname=None*)

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by (`file`, `line`) pairs through `bpplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated `file name` should be in canonical form. If a `funcname` is defined, a breakpoint `hit` will be counted when the first line of that function is executed. A `conditional` breakpoint always counts a `hit`.

`Breakpoint` 實例有以下方法:

**deleteMe** ()

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

**enable** ()

Mark the breakpoint as enabled.

**disable** ()

Mark the breakpoint as disabled.

**bpformat** ()

Return a string with all the information about the breakpoint, nicely formatted:

- Breakpoint number.
- Temporary status (del or keep).
- File/line position.
- Break condition.
- Number of times to ignore.
- Number of times hit.

在 3.2 版被加入。

**bpprint** (*out=None*)

Print the output of *bpformat()* to the file *out*, or if it is *None*, to standard output.

*Breakpoint* instances have the following attributes:

**file**

File name of the *Breakpoint*.

**line**

Line number of the *Breakpoint* within *file*.

**temporary**

True if a *Breakpoint* at (file, line) is temporary.

**cond**

Condition for evaluating a *Breakpoint* at (file, line).

**funcname**

Function name that defines whether a *Breakpoint* is hit upon entering the function.

**enabled**

如 *Breakpoint* 有被用則 True。

**bpbynumber**

Numeric index for a single instance of a *Breakpoint*.

**bpdict**

Dictionary of *Breakpoint* instances indexed by (file, line) tuples.

**ignore**

Number of times to ignore a *Breakpoint*.

**hits**

Count of the number of times a *Breakpoint* has been hit.

**class** `bdb.Bdb` (*skip=None*)

The *Bdb* class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (*pdb.Pdb*) is an example.

The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

在 3.1 版的變更: 新增 *skip* 引數。

The following methods of *Bdb* normally don't need to be overridden.

**canonic** (*filename*)

Return canonical form of *filename*.

For real file names, the canonical form is an operating-system-dependent, *case-normalized absolute path*. A *filename* with angle brackets, such as "`<stdin>`" generated in interactive mode, is returned unchanged.

**reset** ()

Set the `botframe`, `stopframe`, `returnframe` and *quitting* attributes with values ready to start debugging.

**trace\_dispatch** (*frame, event, arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c\_call": A C function is about to be called.
- "c\_return": A C function has returned.
- "c\_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The *arg* parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to types.

**dispatch\_line** (*frame*)

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch\_call** (*frame, arg*)

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch\_return** (*frame, arg*)

If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch\_exception** (*frame, arg*)

If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

**is\_skipped\_line** (*module\_name*)

Return `True` if *module\_name* matches any skip pattern.

**stop\_here** (*frame*)

Return `True` if *frame* is below the starting frame in the stack.

**break\_here** (*frame*)

Return `True` if there is an effective breakpoint for this line.

Check whether a line or function breakpoint exists and is in effect. Delete temporary breakpoints based on information from `effective()`.

**break\_anywhere** (*frame*)

Return `True` if any breakpoint exists for *frame*'s filename.

Derived classes should override these methods to gain control over debugger operation.

**user\_call** (*frame*, *argument\_list*)

Called from `dispatch_call()` if a break might stop inside the called function.

*argument\_list* is not used anymore and will always be `None`. The argument is kept for backwards compatibility.

**user\_line** (*frame*)

Called from `dispatch_line()` when either `stop_here()` or `break_here()` returns `True`.

**user\_return** (*frame*, *return\_value*)

Called from `dispatch_return()` when `stop_here()` returns `True`.

**user\_exception** (*frame*, *exc\_info*)

Called from `dispatch_exception()` when `stop_here()` returns `True`.

**do\_clear** (*arg*)

Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set\_step** ()

Stop after one line of code.

**set\_next** (*frame*)

Stop on the next line in or below the given frame.

**set\_return** (*frame*)

Stop when returning from the given frame.

**set\_until** (*frame*, *lineno=None*)

Stop when the line with the *lineno* greater than the current one is reached or when returning from current frame.

**set\_trace** ([*frame* ])

Start debugging from *frame*. If *frame* is not specified, debugging starts from caller's frame.

在 3.13 版的變更: `set_trace()` will enter the debugger immediately, rather than on the next line of code to be executed.

**set\_continue** ()

Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to `None`.

**set\_quit** ()

Set the `quitting` attribute to `True`. This raises `BdbQuit` in the next call to one of the `dispatch_*` () methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or `None` if all is well.

**set\_break** (*filename*, *lineno*, *temporary=False*, *cond=None*, *funcname=None*)

Set a new breakpoint. If the *lineno* line doesn't exist for the *filename* passed as argument, return an error message. The *filename* should be in canonical form, as described in the `canonic()` method.

**clear\_break** (*filename*, *lineno*)

Delete the breakpoints in *filename* and *lineno*. If none were set, return an error message.

**clear\_bpbynumber** (*arg*)

Delete the breakpoint which has the index *arg* in the `Breakpoint.bpbynumber`. If *arg* is not numeric or out of range, return an error message.

**clear\_all\_file\_breaks** (*filename*)

Delete all breakpoints in *filename*. If none were set, return an error message.

**clear\_all\_breaks** ()

Delete all existing breakpoints. If none were set, return an error message.

**get\_bpbynumber** (*arg*)

Return a breakpoint specified by the given number. If *arg* is a string, it will be converted to a number. If *arg* is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

在 3.2 版被加入。

**get\_break** (*filename*, *lineno*)

Return `True` if there is a breakpoint for *lineno* in *filename*.

**get\_breaks** (*filename*, *lineno*)

Return all breakpoints for *lineno* in *filename*, or an empty list if none are set.

**get\_file\_breaks** (*filename*)

Return all breakpoints in *filename*, or an empty list if none are set.

**get\_all\_breaks** ()

Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

**get\_stack** (*f*, *t*)

Return a list of (frame, lineno) tuples in a stack trace, and a size.

The most recently called frame is last in the list. The size is the number of frames below the frame where the debugger was invoked.

**format\_stack\_entry** (*frame\_lineno*, *lprefix*=':')

Return a string with information about a stack entry, which is a (frame, lineno) tuple. The return string contains:

- The canonical filename which contains the frame.
- 函式名稱或 "<lambda>"。
- 輸入引數。
- 回傳值。
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a *statement*, given as a string.

**run** (*cmd*, *globals*=None, *locals*=None)

Debug a statement executed via the `exec()` function. *globals* defaults to `__main__.__dict__`, *locals* defaults to *globals*.

**runeval** (*expr*, *globals*=None, *locals*=None)

Debug an expression executed via the `eval()` function. *globals* and *locals* have the same meaning as in `run()`.

**runctx** (*cmd*, *globals*, *locals*)

For backwards compatibility. Calls the `run()` method.

`runcall(func, /, *args, **kwargs)`

Debug a single function call, and return its result.

Finally, the module defines the following functions:

`bdb.checkfuncname(b, frame)`

Return `True` if we should break here, depending on the way the *Breakpoint* `b` was set.

If it was set via line number, it checks if `b.line` is the same as the one in `frame`. If the breakpoint was set via *function name*, we have to check we are in the right *frame* (the right function) and if we are on its first executable line.

`bdb.effective(file, line, frame)`

Return (active breakpoint, delete temporary flag) or `(None, None)` as the breakpoint to act upon.

The *active breakpoint* is the first entry in `bplist` for the `(file, line)` (which must exist) that is *enabled*, for which `checkfuncname()` is true, and that has neither a false *condition* nor positive *ignore* count. The *flag*, meaning that a temporary breakpoint should be deleted, is `False` only when the *cond* cannot be evaluated (in which case, *ignore* count is ignored).

If no such entry exists, then `(None, None)` is returned.

`bdb.set_trace()`

Start debugging with a *Bdb* instance from caller's frame.

## 28.3 faulthandler --- 傾印 Python 回溯

在 3.3 版被加入。

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the `SIGSEGV`, `SIGFPE`, `SIGABRT`, `SIGBUS`, and `SIGILL` signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.

By default, the Python traceback is written to `sys.stderr`. To see tracebacks, applications must be run in the terminal. A log file can alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a crash or when Python is deadlocked.

The *Python Development Mode* calls `faulthandler.enable()` at Python startup.

 也參考

**pdb 模組**

Interactive source code debugger for Python programs.

**traceback 模組**

Standard interface to extract, format and print stack traces of Python programs.

### 28.3.1 Dumping the traceback

`faulthandler.dump_traceback` (*file=sys.stderr, all\_threads=True*)

Dump the tracebacks of all threads into *file*. If *all\_threads* is `False`, dump only the current thread.

**也參考**

`traceback.print_tb()`, which can be used to print a traceback object.

在 3.5 版的變更: Added support for passing file descriptor to this function.

### 28.3.2 Fault handler state

`faulthandler.enable` (*file=sys.stderr, all\_threads=True*)

Enable the fault handler: install handlers for the `SIGSEGV`, `SIGFPE`, `SIGABRT`, `SIGBUS` and `SIGILL` signals to dump the Python traceback. If *all\_threads* is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The *file* must be kept open until the fault handler is disabled: see *issue with file descriptors*.

在 3.5 版的變更: Added support for passing file descriptor to this function.

在 3.6 版的變更: On Windows, a handler for Windows exception is also installed.

在 3.10 版的變更: The dump now mentions if a garbage collector collection is running if *all\_threads* is `true`.

`faulthandler.disable` ()

Disable the fault handler: uninstall the signal handlers installed by `enable` ().

`faulthandler.is_enabled` ()

Check if the fault handler is enabled.

### 28.3.3 Dumping the tracebacks after a timeout

`faulthandler.dump_traceback_later` (*timeout, repeat=False, file=sys.stderr, exit=False*)

Dump the tracebacks of all threads, after a timeout of *timeout* seconds, or every *timeout* seconds if *repeat* is `True`. If *exit* is `True`, call `_exit()` with `status=1` after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The *file* must be kept open until the traceback is dumped or `cancel_dump_traceback_later()` is called: see *issue with file descriptors*.

This function is implemented using a watchdog thread.

在 3.5 版的變更: Added support for passing file descriptor to this function.

在 3.7 版的變更: This function is now always available.

`faulthandler.cancel_dump_traceback_later` ()

Cancel the last call to `dump_traceback_later()`.

### 28.3.4 Dumping the traceback on a user signal

`faulthandler.register()` (*signum*, *file=sys.stderr*, *all\_threads=True*, *chain=False*)

Register a user signal: install a handler for the *signum* signal to dump the traceback of all threads, or of the current thread if *all\_threads* is `False`, into *file*. Call the previous handler if *chain* is `True`.

The *file* must be kept open until the signal is unregistered by `unregister()`: see *issue with file descriptors*.

Not available on Windows.

在 3.5 版的變更: Added support for passing file descriptor to this function.

`faulthandler.unregister()` (*signum*)

Unregister a user signal: uninstall the handler of the *signum* signal installed by `register()`. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.

### 28.3.5 Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their *file* argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.

### 28.3.6 范例

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault

Current thread 0x00007fb899f39700 (most recent call first):
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 486 in string_at
  File "<stdin>", line 1 in <module>
Segmentation fault
```

## 28.4 pdb --- Python 偵錯器

原始碼: `Lib/pdb.py`

`pdb` 模組定義了一個 Python 程式的互動式原始碼偵錯器。它支援在原始碼列層級 (source line level) 設定 (條件式的) 斷點 (breakpoint) 和單步執行、檢視 stack frame (堆棧框)、列出原始碼、以及在任何 stack frame 情境 (context) 中任意 Python 程式碼求值 (evaluation)。它還支援事後偵錯 (post-mortem debugging), 可以在程式控制下呼叫。

偵錯器是可擴充的——偵錯器實際被定義 `Pdb` 類。該類目前有文件, 但可以很容易地透過讀原始碼來理解它。擴充套件介面使用了 `bdb` 和 `cmd` 模組。

#### 也參考

##### `faulthandler` 模組

用於在出現故障時、超時 (timeout) 後或於接收到使用者訊號時, 顯式地轉儲 (dump) Python 回溯 (traceback)。

**traceback** 模組

用於提取、格式化和印出 Python 程式 stack trace (堆追) 的標準介面。

自一個執行中程式切入偵錯器的典型用法插入：

```
import pdb; pdb.set_trace()
```

或：

```
breakpoint()
```

到你想切入偵錯器的位置，然後執行程式，就可以單步執行上述陳述式之後的程式碼，`continue` 命令來離開偵錯器、繼續執行。

在 3.7 版的變更：當使用預設值呼叫時，可以使用`breakpoint()` 來取代 `import pdb; pdb.set_trace()`。

```
def double(x):
    breakpoint()
    return x * 2
val = 3
print(f"{val} * 2 is {double(val)}")
```

偵錯器的提示字元是 `(Pdb)`，這表示你處於偵錯模式：

```
> ... (2) double()
-> breakpoint()
(Pdb) p x
3
(Pdb) continue
3 * 2 is 6
```

在 3.3 版的變更：透過 `readline` 模組達成的 `tab` 補全可用於補全本模組的命令和命令的引數，例如會提供當前的全域和區域名稱以作 `p` 命令的引數。

你還可以從命令列調用 `pdb` 來偵錯其他`Python`。例如：

```
python -m pdb myscript.py
```

當作`Python`模組調用時，如果被偵錯的程序不正常地退出，`pdb` 將自動進入事後偵錯。事後偵錯後（或程式正常退出後），`pdb` 將重新`Python`動程式。自動重新`Python`動會保留 `pdb` 的狀態（例如斷點），且在大多數情況下比在程式退出時退出偵錯器更有用。

在 3.2 版的變更：新增了 `-c` 選項來執行命令，就像能在 `.pdbrc` 檔案中給定的那樣；請參`Python`偵錯器命令。

在 3.7 版的變更：新增了 `-m` 選項以類似於 `python -m` 的方式來執行模組。與`Python`本一樣，偵錯器將在模組的第一列之前暫停執行。

在偵錯器控制下執行陳述式的典型用法是：

```
>>> import pdb
>>> def f(x):
...     print(1 / x)
>>> pdb.run("f(2)")
> <string>(1) <module>()
(Pdb) continue
0.5
>>>
```

檢查一個損壞程式的典型用法：

```

>>> import pdb
>>> def f(x):
...     print(1 / x)
...
>>> f(0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in f
ZeroDivisionError: division by zero
>>> pdb.pm()
> <stdin>(2)f()
(Pdb) p x
0
(Pdb)

```

在 3.13 版的變更: [PEP 667](#) 的實作意味著透過 `pdb` 進行的名稱賦予 (name assignments) 會立即影響有效作用域，即使在最佳化作用域運作也是如此。

本模組定義了下列函式，每個函式進入偵錯器的方式略有不同：

`pdb.run(statement, globals=None, locals=None)`

在偵錯器控制下執行 *statement*（以字串或程式碼物件形式給定）。偵錯提示字元會在執行任何程式碼前出現；你可以設定斷點輸入 `continue`，或也可以使用 `step` 或 `next` 逐步執行陳述式（這些命令在下面都有說明）。可選引數 `globals` 和 `locals` 指定程式碼執行的環境；預設使用 `__main__` 模組的字典。（請參閱 `exec()` 或 `eval()` 的說明。）

`pdb.runeval(expression, globals=None, locals=None)`

在偵錯器控制下對 *expression* 求值（以字串或程式碼物件形式給定）。當 `runeval()` 回傳時，它回傳 *expression* 的值。除此之外，該函式與 `run()` 類似。

`pdb.runcall(function, *args, **kwargs)`

使用給定的引數呼叫 *function*（只可以是函式或方法物件，不能是字串）。`runcall()` 回傳的是所呼叫函式的回傳值。偵錯器提示字元將在進入函式後立即出現。

`pdb.set_trace(*, header=None)`

在呼叫此函式的 stack frame 進入偵錯器。用於在程式中給定之處寫死 (hard-code) 一個斷點，即便該程式碼不在偵錯狀態（如斷言失敗時）。如有給定 *header*，它將在偵錯正要開始前被印出到控制台。

在 3.7 版的變更: 僅限關鍵字引數 *header*。

在 3.13 版的變更: `set_trace()` 將立即進入偵錯器，而不是在下一列要執行的程式碼中。

`pdb.post_mortem(t=None)`

進入所給定例外或回溯物件的事後偵錯。如果 *t* 有給定，預設使用當前正在處理的例外，或如果 *t* 有例外則會引發 `ValueError`。

在 3.13 版的變更: 新增對例外物件的支援。

`pdb.pm()`

進入在 `sys.last_exc` 中發現的例外的事後偵錯。

`run*` 函式和 `set_trace()` 都是 `Pdb` 類名，用於實例化 (instantiate) `Pdb` 類並呼叫同名方法。如果要使用更多功能，則必須自己執行以下操作：

`class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False, readrc=True)`

`Pdb` 是偵錯器類。

`completekey`、`stdin` 與 `stdout` 引數會被傳到底層的 `cmd.Cmd` 類；請於該文件閱讀相關描述。

如果給定 `skip` 引數，則它必須是一個給出 `glob` 樣式之模組名稱的代器。如果遇到匹配這些樣式的模組，偵錯器將不會進入來自該模組的 frame。<sup>1</sup>

<sup>1</sup> 一個 frame 是否會被認源自特定模組是由該 frame 全域性變數中的 `__name__` 來定義的。

預設情況下，當你發出 `continue` 命令時，Pdb 會 SIGINT 訊號（即使用者在控制台上按下 `Ctrl-C` 時會發送的訊號）設定一個處理程式 (handler)，這允許你透過按下 `Ctrl-C` 再次切入偵錯器。如果你希望 Pdb 不影響到 SIGINT 處理程式，請將 `nosigint` 設定 `true`。

`readrc` 引數預設 `true`，它控制 Pdb 是否從檔案系統載入 `.pdbrc` 檔案。

用 `trace` (tracing) 且帶有 `skip` 引數的呼叫示範：

```
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

不帶引數地引發一個稽核事件 (auditing event) `pdb.Pdb`。

在 3.1 版的變更：新增了 `skip` 參數。

在 3.2 版的變更：新增了 `nosigint` 參數。以前 SIGINT 處理程式從未被 Pdb 設定過。

在 3.6 版的變更：`readrc` 引數。

`run (statement, globals=None, locals=None)`

`runeval (expression, globals=None, locals=None)`

`runcall (function, *args, **kwargs)`

`set_trace ()`

請見上面關於這些函式的文件說明。

## 28.4.1 偵錯器命令

下方列出的是偵錯器能認得的命令。如下所示，大多數命令可以縮寫一個或兩個字母。如 `h(elp)` 表示可以輸入 `h` 或 `help` 來輸入幫助命令（但不能輸入 `he` 或 `hel`，也不能是 `H` 或 `Help` 或 `HELP`）。命令的引數必須用空格（空格符 (spaces)）或 `tab` 符 (tabs) 分隔。在命令語法中，可選引數被括在方括號 (`[]`) 中；使用時請勿輸入方括號。命令語法中的選擇項由 `[]` (`()`) 分隔。

輸入一個空白列 (blank line) 將重上次輸入的命令。例外：如果上一個命令是 `list` 命令，則會列出接下來的 11 列。

偵錯器無法識的命令將被認是 Python 陳述式，以正在偵錯的程式之情境來執行。Python 陳述式也可以用驚嘆號 (!) 作前綴，這是檢視正在偵錯之程式的大方法，甚至可以修改變數或呼叫函式。當此類陳述式發生例外，將印出例外名稱，但偵錯器的狀態不會改變。

在 3.13 版的變更：現在可以正確辨識執行前綴 `pdb` 命令的運算式/陳述式。

偵錯器有支援設定 `名`。名可以有參數，使得偵錯器對被檢查的情境有一定程度的適應性。

在一列中可以輸入多個以 `;;` 分隔的命令。（不能使用單個 `;`，因它用於分隔傳遞給 Python 剖析器一列中的多個命令。）切分命令運用什高深的方式；輸入總是在第一處 `;;` 被切分開，即使它位於引號的字串之中。對於具有雙分號字串的一個變通解法，是使用隱式字串連接 `';;'` 或 `";;"`。

要設定臨時全域變數，請使用便利變數 (convenience variable)。便利變數是名稱以 `$` 開頭的變數。例如 `$foo = 1` 會設定一個全域變數 `$foo`，你可以在偵錯器會話 (debugger session) 中使用它。當程式恢復執行時，便利變數將被清除，因此與使用 `foo = 1` 等普通變數相比，它不太會去干擾你的程式。

共有三個預先設定的便利變數：

- `$_frame`：當前正在偵錯的 frame
- `$_retval`：frame 回傳時的回傳值
- `$_exception`：frame 引發例外時的例外

在 3.12 版被加入：新增了便利變數功能。

如果 `.pdbrc` 檔案存在於使用者的家目或當前目中，則會使用 `'utf-8'` 編碼讀取執行該檔案，就像在偵錯器提示字元下鍵入該檔案一樣，除了空列和以 `#` 開頭的列會被忽略之外。這對於名設定特別有用。如果兩個檔案都存在，則先讀取家目中的檔案，且定義於其中的名可以被本地檔案覆蓋。

在 3.2 版的變更：`.pdbrc` 現在可以包含繼續偵錯的命令，如 `continue` 或 `next`。以前檔案中的這些命令是無效的。

在 3.11 版的變更：`.pdbrc` 現在使用 `'utf-8'` 編碼讀取。以前它是使用系統區域設定編碼讀取的。

**h(elp)** [command]

如不帶引數，印出可用的命令列表。引數 `command` 時，印出有關該命令的幫助訊息，`help pdb` 會顯示完整文件（即 `pdb` 模組的 `__doc__` 明字串 (docstring)）。由於 `command` 引數必須是一個識字 (identifier)，若要獲取！命令的幫助訊息則必須輸入 `help exec`。

**w(here)**

印出 `stack trace`，最新的 `frame` 會位於底部。箭頭 (`>`) 表示當前的 `frame`，它也固定了大多數命令的情境。

**d(own)** [count]

在 `stack trace` 中，將當前 `frame` 向下移動 `count` 級（預設 1 級，移往較新的 `frame`）。

**u(p)** [count]

在 `stack trace` 中，將當前 `frame` 向上移動 `count` 級（預設 1 級，移向較舊的 `frame`）。

**b(break)** [(filename:lineno | function) [, condition]]

如帶有 `lineno` 引數，則在目前檔案中的 `lineno` 列處設定中斷。列號可以以 `filename` 和冒號前綴，以指定另一個檔案（可能是尚未載入的檔案）中的斷點。該檔案會在 `sys.path` 上搜尋。可接受的 `filename` 形式 `/abspath/to/file.py`、`relpath/file.py`、`module` 和 `package.module`。

如帶有 `function` 引數，在該函式的第一個可執行陳述式處設定中斷。`function` 可以是任何其求值結果目前命名空間中函式的運算式。

如果第二個引數存在，它是一個運算式，在斷點生效前其必須求值 `true`

如果不帶引數執行會列出所有斷點資訊，包括每個斷點、命中該斷點的次數、當前的忽略次數以及關聯的條件（如存在）。

每個斷點都有賦予一個編號，所有其他斷點命令都參照該編號。

**tbreak** [(filename:lineno | function) [, condition]]

臨時斷點，在第一次遇見時會自動被刪除。它的引數與 `break` 相同。

**cl(ear)** [filename:lineno | bnumber ...]

如帶有 `filename:lineno` 引數，則清除此列上的所有斷點。如果引數是空格分隔的斷點編號列表，則清除這些斷點。如果不帶引數則清除所有斷點（但會先提示確認）。

**disable** bnumber [bnumber ...]

停用斷點，斷點以空格分隔的斷點編號列表來給定。停用斷點表示它不會導致程式停止執行，但是與清除斷點不同，停用的斷點將保留在斷點列表中且可以（重新）啟用。

**enable** bnumber [bnumber ...]

啟用指定的斷點。

**ignore** bnumber [count]

給定的斷點編號設定忽略計數。如果省略 `count` 則忽略計數設定 0。當忽略計數 0 時，斷點將變有效狀態。當非 0 時，每次到達斷點，且斷點有被禁用，且任何關聯的條件被求值 `true`，則 `count` 就會遞。

**condition** bnumber [condition]

斷點設定一個新 `condition`，一個運算式，且其求值結果 `true` 時斷點才會起作用。如果有給定 `condition`，則除任何現有條件，也就是不斷點設定條件。

**commands** [bnumber]

編號是 `bnumber` 的斷點指定一系列命令。命令內容出現在後續的幾列中。輸入僅包含 `end` 的一列來結束命令列表。例如：

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

要刪除斷點上的所有命令，請輸入 `commands` 立即以 `end` 結尾，也就是不指定任何命令。

不帶有 `bnumber` 引數則 `commands` 會關聯到上一個設定的斷點。

可以使用斷點命令來重新啟動程式，只需使用 `continue` 或 `step` 命令，或其他可以繼續執行程式的命令。

如果指定了某個繼續執行程式的命令（目前包括 `continue`、`step`、`next`、`return`、`jump`、`quit` 及它們的縮寫）將終止命令列表（就像該命令後馬上跟著 `end`）。因在任何時候繼續執行下去（即使是簡單的 `next` 或 `step`），都可能會遇到另一個斷點，該斷點可能具有自己的命令列表，這會導致無法確定要執行哪個列表。

如果你在命令列表中使用 `silent` 命令，則平常會有的那些關於停止於斷點處的訊息就不會印出。對於要印出特定訊息再繼續的斷點來，這可能會是需要的功能。如果其他命令都有印出任何內容，那你就看不到已到達斷點的圖象。

#### **s (step)**

執行當前列，在第一個可以停止的位置（在被呼叫的函式部或在當前函式的下一列）停止。

#### **n (ext)**

繼續執行，直至執行到當前函式的下一列或者當前函式回傳止。（`next` 和 `step` 之間的區別在於 `step` 會在被呼叫函式的部停止、而 `next`（幾乎）全速執行被呼叫的函式，僅在當前函式的下一列停止。）

#### **unt (il) [lineno]**

如果不帶引數則繼續執行，直到列號比當前的列大時停止。

如帶有 `lineno` 則繼續執行，直到到達列號大於或等於 `lineno` 的那一列。在這兩種情況下，當前 frame 回傳時也會停止。

在 3.2 版的變更：允許明確給定一個列號。

#### **r (eturn)**

繼續執行，直到目前的函式回傳。

#### **c (ont (inue))**

繼續執行，除非遇到斷點才停下來。

#### **j (ump) lineno**

設定即將執行的下一列，僅可用於堆中最底部的 frame。這讓你可以跳回去再次執行程式碼，或者往前跳以跳過不想執行的程式碼。

需要注意的是，不是所有的跳轉都是被允許的 -- 例如不能跳轉到 `for` 圈的中間或跳出 `finally` 子句。

#### **l (ist) [first[, last]]**

列出當前檔案的原始碼。如果不帶引數，則列出當前列周圍的 11 列，或繼續先前的列表操作。如果用 `.` 作引數，則列出當前列周圍的 11 列。如果帶有一個引數，則列出那一列周圍的 11 列。如果帶有兩個引數，則列出給定範圍中的程式碼；如果第二個引數小於第一個引數，則將其直譯要列出的列數。

當前 frame 中的當前列會用 `->` 標記出來。如果正在偵錯一個例外，且引發或傳遞該例外的那一列不是當前列，則會用 `>>` 來標記該列。

在 3.2 版的變更：新增了 `>>` 標記。

#### **ll | longlist**

列出當前函式或 frame 的所有原始碼。相關列的標記方式與 `list` 相同。

在 3.2 版被加入。

#### **a (rgs)**

印出當前函式的引數及它們當前的值。

**p** expression在當前情境中 `expression` 求值印出其值。**備**也可以使用 `print()`，但它不是一個偵錯器命令 --- 它會執行 Python `print()` 函式。**pp** expression與 `p` 命令類似，除了 `expression` 的值是使用 `pprint` 模組美化後印出來的。**whatis** expression印出 `expression` 的型。**source** expression嘗試獲取 `expression` 的原始碼顯示它。

在 3.2 版被加入。

**display** [expression]每次在當前 frame 中停止執行時，顯示 `expression` 的值（如果有變更）。如果不帶有 `expression`，則列出當前 frame 的所有運算式。**備**`display` 會對 `expression` 求值將結果與之前 `expression` 的求值結果進行比較，因此當結果可變時，`display` 可能無法獲取其變更。

範例如下：

```
lst = []
breakpoint()
pass
lst.append(1)
print(lst)
```

`display` 不會意識到 `lst` 已更改，因其求值結果在比較之前已被 `lst.append(1)` 原地 (in place) 修改：

```
> example.py(3)<module>()
-> pass
(Pdb) display lst
display lst: []
(Pdb) n
> example.py(4)<module>()
-> lst.append(1)
(Pdb) n
> example.py(5)<module>()
-> print(lst)
(Pdb)
```

你可以運用 `display` 機制的一些技巧來使其能運作：

```
> example.py(3)<module>()
-> pass
(Pdb) display lst[:]
display lst[:]: []
(Pdb) n
> example.py(4)<module>()
```

(繼續下一頁)

(繼續上一頁)

```
-> lst.append(1)
(Pdb) n
> example.py(5)<module>()
-> print(lst)
display lst[:]: [1] [old: []]
(Pdb)
```

在 3.2 版被加入。

**undisplay** [expression]

不再顯示當前 frame 中的 *expression*。如果不帶有 *expression*，則清除當前 frame 的所有顯示運算式。

在 3.2 版被加入。

**interact**

在從目前作用域的區域和全域命名空間初始化的新全域命名空間中啟動互動式直譯器（使用 *code* 模組）。可使用 `exit()` 或 `quit()` 退出直譯器回到偵錯器。

### 備

由於 `interact` 程式碼執行建立了一個新的專用命名空間，因此變數的賦值不會影響原始命名空間，但是對任何被參照的可變物件的修改將像往常一樣反映在原始命名空間中。

在 3.2 版被加入。

在 3.13 版的變更：`exit()` 和 `quit()` 可用來退出 `interact` 命令。

在 3.13 版的變更：`interact` 將其輸出導向到偵錯器的輸出通道 (output channel)，而不是 `sys.stderr`。

**alias** [name [command]]

建立一個名 *name* 的 `alias`，用於執行 *command*。*command* 不得用引號包起來。可被替換的參數要用 `%1`、`%2`、... 和 `%9` 標示，而 `%*` 則被所有參數替換。如果省略 *command*，則顯示 *name* 的目前 `alias`。如果未給定引數，則列出所有 `alias`。

巢狀 `alias` 是允許的，且可包含能在 `pdb` 提示字元下合法輸入的任何內容。請注意，局部 `alias` 命令可以被 `alias` 名所覆蓋。這樣的命令在 `alias` 名被移除前都將被隱藏。`alias` 名會遞進地應用到命令列的第一個單詞；該列的其他單詞則不會受影響。

作範例，這列出了兩個有用的 `alias`（特別是放在 `.pdbrc` 檔案中時）：

```
# 印出實例變數（用法如 "pi classInst"）
alias pi for k in %1.__dict__.keys(): print(f"%1.{k} = {%1.__dict__[k]}")
# 印出 self 中的實例變數
alias ps pi self
```

**unalias** name

刪除指定的 `alias` 名 *name*。

**!** statement

在當前 stack frame 的情境中執行（單列）*statement*。除非陳述式的第一個單詞類似於偵錯器命令，否則可以省略驚嘆號，例如：

```
(Pdb) ! n=42
(Pdb)
```

要設定全域變數，你可以在同一列的賦值命令前面加上 `global` 陳述式，例如：

```
(Pdb) global list_options; list_options = ['-l']
(Pdb)
```

**run** [args ...]

**restart** [args ...]

重新啟動已偵錯完畢的 Python 程式。如果提供了 *args*，它將以 *shlex* 分割，將結果用作新的 *sys.argv*。歷史記錄、斷點、操作和偵錯器選項均會被保留。*restart* 是 *run* 的別名。

**q(uit)**

離開偵錯器，執行中的程式會被中止。

**debug** code

進入一個遞進偵錯器，逐步執行 *code*（這是要在當前環境中執行的任意運算式或陳述式）。

**retval**

印出當前函式最後一次回傳的回傳值。

**exceptions** [excnnumber]

列出鏈接例外 (chained exceptions)，或在其間跳轉。

當使用 `pdb.pm()` 或 `Pdb.post_mortem(...)` 於鏈接例外而不是回溯時，它允許使用者在鏈接例外之間移動，使用 `exceptions` 命令以列出例外，使用 `exception <number>` 切到該例外。

範例如下：

```
def out():
    try:
        middle()
    except Exception as e:
        raise ValueError("reraise middle() error") from e

def middle():
    try:
        return inner(0)
    except Exception as e:
        raise ValueError("Middle fail")

def inner(x):
    1 / x

out()
```

呼叫 `pdb.pm()` 將允許在例外之間移動：

```
> example.py(5)out()
-> raise ValueError("reraise middle() error") from e

(Pdb) exceptions
 0 ZeroDivisionError('division by zero')
 1 ValueError('Middle fail')
> 2 ValueError('reraise middle() error')

(Pdb) exceptions 0
> example.py(16)inner()
-> 1 / x

(Pdb) up
> example.py(10)middle()
-> return inner(0)
```

在 3.13 版被加入。

## 28.5 Python 的分析器

原始碼: Lib/profile.py 與 Lib/pstats.py

### 28.5.1 Introduction to the profilers

`cProfile` and `profile` provide *deterministic profiling* of Python programs. A *profile* is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the `pstats` module.

The Python standard library provides two different implementations of the same profiling interface:

1. `cProfile` is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on `lsprof`, contributed by Brett Rosen and Ted Czotter.
2. `profile`, a pure Python module whose interface is imitated by `cProfile`, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

#### 備 F

The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is `timeit` for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.

### 28.5.2 Instant User's Manual

This section is provided for users that "don't want to read the manual." It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
214 function calls (207 primitive calls) in 0.002 seconds

Ordered by: cumulative time

ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
   1    0.000    0.000    0.002    0.002  {built-in method builtins.exec}
   1    0.000    0.000    0.001    0.001  <string>:1(<module>)
   1    0.000    0.000    0.001    0.001  __init__.py:250(compile)
   1    0.000    0.000    0.001    0.001  __init__.py:289(_compile)
   1    0.000    0.000    0.000    0.000  _compiler.py:759(compile)
   1    0.000    0.000    0.000    0.000  _parser.py:937(parse)
   1    0.000    0.000    0.000    0.000  _compiler.py:598(_code)
   1    0.000    0.000    0.000    0.000  _parser.py:435(_parse_sub)
```

The first line indicates that 214 calls were monitored. Of those calls, 207 were *primitive*, meaning that the call was not induced via recursion. The next line: `Ordered by: cumulative time` indicates the output is sorted by the `cumtime` values. The column headings include:

**ncalls**

for the number of calls.

**tottime**

for the total time spent in the given function (and excluding time made in calls to sub-functions)

**percall**

is the quotient of `tottime` divided by `ncalls`

**cumtime**

is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate *even* for recursive functions.

**percall**

is the quotient of `cumtime` divided by primitive calls

**filename:lineno(function)**

provides the respective data of each function

When there are two numbers in the first column (for example `3/1`), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the `run()` function:

```
import cProfile
import re
cProfile.run('re.compile("foo|bar")', 'restats')
```

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The files `cProfile` and `profile` can also be invoked as a script to profile another script. For example:

```
python -m cProfile [-o output_file] [-s sort_order] (-m module | myscript.py)
```

**-o** <output\_file>

Writes the profile results to a file instead of to stdout.

**-s** <sort\_order>

Specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

**-m** <module>

Specifies that a module is being profiled instead of a script.

在 3.7 版被加入: 新增 `-m` 選項到 `cProfile`。

在 3.8 版被加入: 新增 `-m` 選項到 `profile`。

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```
import pstats
from pstats import SortKey
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```
p.sort_stats(SortKey.NAME)
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```
p.sort_stats(SortKey.CUMULATIVE).print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```
p.sort_stats(SortKey.TIME).print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```
p.sort_stats(SortKey.FILENAME).print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```
p.sort_stats(SortKey.TIME, SortKey.CUMULATIVE).print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: `.5`) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.

### 28.5.3 profile and cProfile Module Reference

Both the `profile` and `cProfile` modules provide the following functions:

`profile.run (command, filename=None, sort=-1)`

This function takes a single argument that can be passed to the `exec()` function, and an optional file name. In all cases this routine executes:

```
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a `Stats` instance and prints a simple profiling report. If the sort value is specified, it is passed to this `Stats` instance to control how the results are sorted.

`profile.runcx (command, globals, locals, filename=None, sort=-1)`

This function is similar to `run()`, with added arguments to supply the globals and locals mappings for the `command` string. This routine executes:

```
exec(command, globals, locals)
```

and gathers profiling statistics as in the `run()` function above.

**class** `profile.Profile` (*timer=None, timeunit=0.0, subcalls=True, builtins=True*)

This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the *timer* argument. This must be a function that returns a single number representing the current time. If the number is an integer, the *timeunit* specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```
import cProfile, pstats, io
from pstats import SortKey
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = SortKey.CUMULATIVE
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

The `Profile` class can also be used as a context manager (supported only in `cProfile` module. see 情境管理器型 F):

```
import cProfile

with cProfile.Profile() as pr:
    # ... do something ...

pr.print_stats()
```

在 3.8 版的變更: 新增情境管理器的支援。

**enable()**

Start collecting profiling data. Only in `cProfile`.

**disable()**

Stop collecting profiling data. Only in `cProfile`.

**create\_stats()**

Stop collecting profiling data and record the results internally as the current profile.

**print\_stats** (*sort=-1*)

Create a `Stats` object based on the current profile and print the results to stdout.

The *sort* parameter specifies the sorting order of the displayed statistics. It accepts a single key or a tuple of keys to enable multi-level sorting, as in `Stats.sort_stats`.

在 3.13 版被加入: `print_stats()` now accepts a tuple of keys.

**dump\_stats** (*filename*)

Write the results of the current profile to *filename*.

**run** (*cmd*)

Profile the *cmd* via `exec()`.

**runctx** (*cmd, globals, locals*)

Profile the *cmd* via `exec()` with the specified global and local environment.

**runcall** (*func, /, \*args, \*\*kwargs*)

Profile `func(*args, **kwargs)`

Note that profiling will only work if the called command/function actually returns. If the interpreter is terminated (e.g. via a `sys.exit()` call during the called command/function execution) no profiling results will be printed.

## 28.5.4 The `Stats` Class

Analysis of the profiler data is done using the `Stats` class.

```
class pstats.Stats (*filenames or profile, stream=sys.stdout)
```

This class constructor creates an instance of a "statistics object" from a *filename* (or list of filenames) or from a `Profile` instance. Output will be printed to the stream specified by *stream*.

The file selected by the above constructor must have been created by the corresponding version of `profile` or `cProfile`. To be specific, there is *no* file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers, or the same profiler run on a different operating system. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing `Stats` object, the `add()` method can be used.

Instead of reading the profile data from a file, a `cProfile.Profile` or `profile.Profile` object can be used as the profile data source.

`Stats` objects have the following methods:

```
strip_dirs ()
```

This method for the `Stats` class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its entries in a "random" order, as it was just after object initialization and loading. If `strip_dirs()` causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

```
add (*filenames)
```

This method of the `Stats` class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of `profile.run()` or `cProfile.run()`. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

```
dump_stats (filename)
```

Save the data loaded into the `Stats` object to a file named *filename*. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the `profile.Profile` and `cProfile.Profile` classes.

```
sort_stats (*keys)
```

This method modifies the `Stats` object by sorting it according to the supplied criteria. The argument can be either a string or a `SortKey` enum identifying the basis of a sort (example: 'time', 'name', `SortKey.TIME` or `SortKey.NAME`). The `SortKey` enums argument have advantage over the string argument in that it is more robust and less error prone.

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, `sort_stats(SortKey.NAME, SortKey.FILE)` will sort all the entries according to their function name, and resolve all ties (identical function names) by sorting by file name.

For the string argument, abbreviations can be used for any key names, as long as the abbreviation is unambiguous.

The following are the valid string and `SortKey`:

Valid String Arg	Valid enum Arg	含義
'calls'	SortKey.CALLS	call count
'cumulative'	SortKey.CUMULATIVE	cumulative time
'cumtime'	N/A	cumulative time
'file'	N/A	file name (檔案名稱)
'filename'	SortKey.FILENAME	file name (檔案名稱)
'module'	N/A	file name (檔案名稱)
'ncalls'	N/A	call count
'pcalls'	SortKey.PCALLS	primitive call count
'line'	SortKey.LINE	列號
'name'	SortKey.NAME	function name
'nfl'	SortKey.NFL	name/file/line
'stdname'	SortKey.STDNAME	standard name
'time'	SortKey.TIME	internal time
'tottime'	N/A	internal time

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between `SortKey.NFL` and `SortKey.STDNAME` is that the standard name is a sort of the name as printed, which means that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, `SortKey.NFL` does a numeric compare of the line numbers. In fact, `sort_stats(SortKey.NFL)` is the same as `sort_stats(SortKey.NAME, SortKey.FILENAME, SortKey.LINE)`.

For backward-compatibility reasons, the numeric arguments `-1`, `0`, `1`, and `2` are permitted. They are interpreted as `'stdname'`, `'calls'`, `'time'`, and `'cumulative'` respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

在 3.7 版被加入: Added the `SortKey` enum.

#### `reverse_order()`

This method for the `Stats` class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

#### `print_stats(*restrictions)`

This method for the `Stats` class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename `.*foo:.`. In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names `.*foo:.`, and then proceed to only print the first 10% of them.

#### `print_callers(*restrictions)`

This method for the `Stats` class prints a list of all functions that called each function in the profiled

database. The ordering is identical to that provided by `print_stats()`, and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With `profile`, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With `cProfile`, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current function while it was invoked by this specific caller.

`print_callees` (\*restrictions)

This method for the `Stats` class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the `print_callers()` method.

`get_stats_profile` ()

This method returns an instance of `StatsProfile`, which contains a mapping of function names to instances of `FunctionProfile`. Each `FunctionProfile` instance holds information related to the function's profile such as how long the function took to run, how many times it was called, etc...

在 3.9 版被加入: Added the following dataclasses: `StatsProfile`, `FunctionProfile`. Added the following function: `get_stats_profile`.

## 28.5.5 What Is Deterministic Profiling?

*Deterministic profiling* is meant to reflect the fact that all *function call*, *function return*, and *exception* events are monitored, and precise timings are made for the intervals between these events (during which time the user's code is executing). In contrast, *statistical profiling* (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required in order to do deterministic profiling. Python automatically provides a *hook* (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify "hot loops" that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.

## 28.5.6 限制

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying "clock" is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the "error" will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it "takes a while" from when an event is dispatched until the profiler's call to get the time actually *gets* the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock's value was obtained (and then squirreled away), until the user's code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it *can* accumulate and become very significant.

The problem is more important with `profile` than with the lower-overhead `cProfile`. For this reason, `profile` provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average)

removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do *not* be alarmed by negative numbers in the profile. They should *only* appear if you have calibrated your profiler, and the results are actually better than without calibration.

### 28.5.7 校正

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see 限制).

```
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running macOS, and using Python's `time.process_time()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is *very* fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```
import profile

# 1. Apply computed bias to all Profile instances created hereafter.
profile.Profile.bias = your_computed_bias

# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)
```

If you have a choice, you are better off choosing a smaller constant, and then your results will "less often" show up as negative in profile statistics.

### 28.5.8 Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the `Profile` class constructor:

```
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`'s return value will be interpreted differently:

#### `profile.Profile`

`your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see 校正). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is *pretty* bad, as it returns a tuple of floating-point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

**cProfile.Profile**

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```
pr = cProfile.Profile(your_integer_time_func, 0.001)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.

## 28.6 timeit --- 測量小量程式片段的執行時間

原始碼: `Lib/timeit.py`

該模組提供了一種對少量 Python 程式碼進行計時的簡單方法。它有一個命令列介面和一個可呼叫介面，它避免了許多測量執行時間的常見陷阱。另請參閱由 O'Reilly 出版的 *Python 錦囊妙計 (Python Cookbook)* 第二版中 Tim Peters 所寫的「演算法」章節的介紹。

### 28.6.1 基礎范例

以下範例展示了如何使用命令列介面來比較三個不同的運算式：

```
$ python -m timeit "'-'.join(str(n) for n in range(100))"
10000 loops, best of 5: 30.2 usec per loop
$ python -m timeit "'-'.join([str(n) for n in range(100)])"
10000 loops, best of 5: 27.5 usec per loop
$ python -m timeit "'-'.join(map(str, range(100)))"
10000 loops, best of 5: 23.2 usec per loop
```

這可以透過 `Python` 介面來實現：

```
>>> import timeit
>>> timeit.timeit("'-'.join(str(n) for n in range(100))', number=10000)
0.3018611848820001
>>> timeit.timeit("'-'.join([str(n) for n in range(100)])', number=10000)
0.2727368790656328
>>> timeit.timeit("'-'.join(map(str, range(100)))', number=10000)
0.23702679807320237
```

也可以在 `Python` 介面傳遞可呼叫物件：

```
>>> timeit.timeit(lambda: "'-'.join(map(str, range(100))), number=10000)
0.19665591977536678
```

但請注意，僅當使用命令列介面時 `timeit()` 才會自動確定重覆次數。在範例章節中有更進階的範例。

### 28.6.2 Python 介面

該模組定義了三個便利函式和一個公開類別：

```
timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000, globals=None)
```

使用給定的陳述式、`setup` 程式碼和 `timer` 函式建立一個 `Timer` 實例，執行其 `timeit()` 方法 `number` 次。可選的 `globals` 引數指定會在其中執行程式碼的命名空間。

在 3.5 版的變更：新增 `globals` 選用參數。

`timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=5, number=1000000, globals=None)`

使用給定的陳述式、`setup` 程式碼和 `timer` 函式建立一個 `Timer` 實例，使用給定的 `repeat` 計數和 `number` 來運行其 `repeat()` 方法。可選的 `globals` 引數指定會在其中執行程式碼的命名空間。

在 3.5 版的變更: 新增 `globals` 選用參數。

在 3.7 版的變更: `repeat` 的預設值從 3 更改 5。

`timeit.default_timer()`

預設計時器始終 `time.perf_counter()`，會回傳浮點秒數。另一種方法是 `time.perf_counter_ns`，會回傳整數奈秒。

在 3.3 版的變更: `time.perf_counter()` 現在是預設計時器。

**class** `timeit.Timer(stmt='pass', setup='pass', timer=<timer function>, globals=None)`

用於計時小程式碼片段執行速度的類。

建構函式接受一個要計時的陳述式、一個用於設定的附加陳述式和一個計時器函式。兩個陳述式都預設 `'pass'`；計時器函式會與平台相依（請參閱模組文件字串 (doc string)）。`stmt` 和 `setup` 還可以包含由 `;` 或 `\n` 行符號分隔的多個陳述式，只要它們不包含多行字串文字即可。預設情況下，該陳述式將在 `timeit` 的命名空間執行；可以透過將命名空間傳遞給 `globals` 來控制此行。

要測量第一個陳述式的執行時間，請使用 `timeit()` 方法。`repeat()` 和 `autorange()` 方法是多次呼叫 `timeit()` 的便捷方法。

`setup` 的執行時間不包含在總體運行計時中。

`stmt` 和 `setup` 參數還可以接受無需引數即可呼叫的物件。這會把對它們的呼叫嵌入到計時器函式中，然後由 `timeit()` 去執行。請注意，在這種情況下，因有額外的函式呼叫，時間開銷 (timing overhead) 會稍大一些。

在 3.5 版的變更: 新增 `globals` 選用參數。

`timeit(number=1000000)`

主陳述式執行 `number` 次的時間。這將執行一次設定陳述式，然後回傳多次執行主陳述式所需的時間。預設計時器以浮點形式回傳秒數，引數是重覆的次數，預設一百萬次。要使用的主陳述式、設定陳述式和計時器函式會被傳遞給建構函式。

#### 備註

預設情況下 `timeit()` 在計時期間會暫時關閉垃圾回收。這種方法的優點是它使獨立時序更具可比較性，缺點是 GC 可能是被測函式性能的重要組成部分。如果是這樣，可以將 GC 作 `setup` 字串中的第一個陳述式以重新啟用。例如：

```
timeit.Timer('for i in range(10): oct(i)', 'gc.enable()').timeit()
```

**autorange** (`callback=None`)

自動重覆呼叫 `timeit()` 次數。

這是一個便捷函式，它重覆呼叫 `timeit()` 以使得總時間  $\geq 0.2$  秒，再回傳最終結果（重覆數、該重覆數所花費的時間）。它以 1、2、5、10、20、50... 的順序遞增數字來呼叫 `timeit()` 直到所用時間至少 0.2 秒。

如果有給定 `callback` 且不是 `None`，則每次試驗後都會使用兩個引數來呼叫它：`callback(number, time_taken)`。

在 3.6 版被加入。

**repeat** (`repeat=5, number=1000000`)

呼叫 `timeit()` 數次。

這是一個方便的函式，它會重覆呼叫 `timeit()` 回傳結果列表。第一個引數指定呼叫 `timeit()` 的次數，第二個引數指定 `timeit()` 的 `number` 引數。

**i** 備

人們很容易根據結果向量來計算出平均值和標準差，將其作依歸，然而這不是很有用。在典型情況下，最低值給出了機器運行給定程式碼片段的速度的下限；結果向量中較高的值通常不是由 Python 速度的變化所引起，而是由干擾計時精度的其他行程造成的。因此，結果中的 `min()` 可能是你應該感興趣的唯一數字。在解讀該數據後，你應該查看整個向量以常識判讀而非單純仰賴統計資訊。

在 3.7 版的變更: `repeat` 的預設值從 3 更改 5。

`print_exc (file=None)`

從計時程式碼印出回溯 (traceback) 的輔助函式。

典型用法:

```
t = Timer(...)           # outside the try/except
try:
    t.timeit(...)       # or t.repeat(...)
except Exception:
    t.print_exc()
```

相對於標準回溯的優點是，已編譯模板中的原始程式碼會被顯示出來。可選的 `file` 引數指定回溯的發送位置；它預設 `sys.stderr`。

### 28.6.3 命令列介面

當從命令列作程式呼叫時，請使用以下形式：

```
python -m timeit [-n N] [-r N] [-u U] [-s S] [-p] [-v] [-h] [statement ...]
```

其中之以下選項：

**-n N, --number=N**

執行 'statement' 多少次

**-r N, --repeat=N**

計時器重執行多少次 (預設 5)

**-s S, --setup=S**

會在一開始執行一次的陳述式 (預設 `pass`)

**-p, --process**

若要測量行程時間 (process time) 而非鐘時間 (wallclock time)，請使用 `time.process_time()` 而不是預設的 `time.perf_counter()`

在 3.3 版被加入。

**-u, --unit=U**

指定定時器輸出的時間單位；可以選擇 `nsec`、`usec`、`msec` 或 `sec`

在 3.5 版被加入。

**-v, --verbose**

印出原始計時結果；重執行以獲得更高的數字精度

**-h, --help**

印出一條簡短的使用訊息退出

可以透過將每一列陳述式指定單獨引數來給定多列陳述式；可透過將引數括在引號中使用前導空格以實現縮進列 (indented lines)。多個 `-s` 選項的作用類似。

如果 `-n` 有給定，則透過嘗試從序列 1, 2, 5, 10, 20, 50, ... 中增加數字來計算合適的圈次數，直到總時間至少 0.2 秒。

`default_timer()` 測量可能會受到同一台機器上運行的其他程式的影響，因此，當需要精確計時時，最好的做法是重計時幾次使用最佳時間。`-r` 選項對此很有用；在大多數情況下，預設的重計時 5 次可能就足夠了。你可以使用 `time.process_time()` 來測量 CPU 時間。

### 備

執行 `pass` 陳述式會生一定的基本開銷。這的程式碼不試圖隱藏它，但你應該意識到它的存在。可以透過不帶引數呼叫程式來測量這個基本開銷，且不同 Python 版本之間的基本開銷可能有所不同。

## 28.6.4 范例

可以提供一個僅會在開始時執行一次的設定陳述式：

```
$ python -m timeit -s "text = 'sample string'; char = 'g'" "char in text"
5000000 loops, best of 5: 0.0877 usec per loop
$ python -m timeit -s "text = 'sample string'; char = 'g'" "text.find(char)"
1000000 loops, best of 5: 0.342 usec per loop
```

輸出中包含三個欄位。圈計數，它告訴你每次計時圈重運行陳述式主體的次數。重計數（「最好的 5 次」）告訴你計時圈重了多少次。以及最後陳述式主體在計時圈的最佳的幾次重執行平均花費的時間。也就是，最快的幾次重執行所花費的總時間除以圈計數。

```
>>> import timeit
>>> timeit.timeit('char in text', setup='text = "sample string"; char = "g"')
0.41440500499993504
>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char = "g"')
1.7246671520006203
```

同樣可以使用 `Timer` 類及其方法來完成：

```
>>> import timeit
>>> t = timeit.Timer('char in text', setup='text = "sample string"; char = "g"')
>>> t.timeit()
0.3955516149999312
>>> t.repeat()
[0.40183617287970225, 0.37027556854118704, 0.38344867356679524, 0.3712595970846668, 0.
↪37866875250654886]
```

以下範例展示如何對包含多行的運算式進行計時。這我們使用 `hasattr()` 與 `try/except` 來測試缺失和存在之物件屬性比較其花費 (cost)：

```
$ python -m timeit "try: " str.__bool__ "except AttributeError: " pass"
20000 loops, best of 5: 15.7 usec per loop
$ python -m timeit "if hasattr(str, '__bool__'): pass"
50000 loops, best of 5: 4.26 usec per loop

$ python -m timeit "try: " int.__bool__ "except AttributeError: " pass"
200000 loops, best of 5: 1.43 usec per loop
$ python -m timeit "if hasattr(int, '__bool__'): pass"
100000 loops, best of 5: 2.23 usec per loop
```

```
>>> import timeit
>>> # attribute is missing
>>> s = ""
... try:
...     str.__bool__
... except AttributeError:
...     pass
... ""
```

(繼續下一頁)

(繼續上一頁)

```

>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>>
>>> # attribute is present
>>> s = """\
... try:
...     int.__bool__
... except AttributeError:
...     pass
... """
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603

```

要讓 `timeit` 模組存取你定義的函式，你可以傳遞一個包含 `import` 陳述式的 `setup` 參數：

```

def test():
    """Stupid test function"""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))

```

另一種選擇是將 `globals()` 傳遞給 `globals` 參數，這將導致程式碼在當前的全域命名空間中執行，這比單獨指定 `import` 更方便：

```

def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]', globals=globals()))

```

## 28.7 trace --- 追 F 或追查 Python 陳述式執行

原始碼：Lib/trace.py

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

### 也參考

#### Coverage.py

A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.

## 28.7.1 Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

### **--help**

Display usage and exit.

### **--version**

Display the version of the module and exit.

在 3.8 版被加入: Added `--module` option that allows to run an executable module.

## Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

### **-c, --count**

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

### **-t, --trace**

Display lines as they are executed.

### **-l, --listfuncs**

Display the functions executed by running the program.

### **-r, --report**

Produce an annotated list from an earlier program run that used the `--count` and `--file` option. This does not execute any code.

### **-T, --trackcalls**

Display the calling relationships exposed by running the program.

## Modifiers

### **-f, --file=<file>**

Name of a file to accumulate counts over several tracing runs. Should be used with the `--count` option.

### **-C, --coverdir=<dir>**

Directory where the report files go. The coverage report for `package.module` is written to file `dir/package/module.cover`.

### **-m, --missing**

When generating annotated listings, mark lines which were not executed with `>>>>>>`.

### **-s, --summary**

When using `--count` or `--report`, write a brief summary to stdout for each file processed.

### **-R, --no-report**

Do not generate annotated listings. This is useful if you intend to make several runs with `--count`, and then produce a single set of annotated listings at the end.

### **-g, --timing**

Prefix each line with the time since the program started. Only used while tracing.

## Filters

These options may be repeated multiple times.

**--ignore-module**=<mod>

Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

**--ignore-dir**=<dir>

Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by `os.pathsep`.

## 28.7.2 Programmatic Interface

```
class trace.Trace (count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(), infile=None,
                   outfile=None, timing=False)
```

Create an object to trace execution of a single statement or expression. All parameters are optional. `count` enables counting of line numbers. `trace` enables line execution tracing. `countfuncs` enables listing of the functions called during the run. `countcallers` enables call relationship tracking. `ignoremods` is a list of modules or packages to ignore. `ignoredirs` is a list of directories whose modules or packages should be ignored. `infile` is the name of the file from which to read stored count information. `outfile` is the name of the file in which to write updated count information. `timing` enables a timestamp relative to when tracing was started to be displayed.

**run** (*cmd*)

Execute the command and gather statistics from the execution with the current tracing parameters. *cmd* must be a string or code object, suitable for passing into `exec()`.

**runtcx** (*cmd*, *globals*=None, *locals*=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, *globals* and *locals* default to empty dictionaries.

**runfunc** (*func*, *l*, \**args*, \*\**kwds*)

Call *func* with the given arguments under control of the `Trace` object with the current tracing parameters.

**results** ()

Return a `CoverageResults` object that contains the cumulative results of all previous calls to `run`, `runtcx` and `runfunc` for the given `Trace` instance. Does not reset the accumulated trace results.

```
class trace.CoverageResults
```

A container for coverage results, created by `Trace.results()`. Should not be created directly by the user.

**update** (*other*)

Merge in data from another `CoverageResults` object.

**write\_results** (*show\_missing*=True, *summary*=False, *coverdir*=None, \*, *ignore\_missing\_files*=False)

Write coverage results. Set *show\_missing* to show lines that had no hits. Set *summary* to include in the output the coverage summary per module. *coverdir* specifies the directory into which the coverage result files will be output. If `None`, the results for each source file are placed in its directory.

If *ignore\_missing\_files* is `True`, coverage counts for files that no longer exist are silently ignored. Otherwise, a missing file will raise a `FileNotFoundError`.

在 3.13 版的變更: Added *ignore\_missing\_files* parameter.

A simple example demonstrating the use of the programmatic interface:

```
import sys
import trace

# create a Trace object, telling it what to ignore, and whether to
# do tracing or line-counting or both.
tracer = trace.Trace(
```

(繼續下一頁)

(繼續上一頁)

```

ignoredirs=[sys.prefix, sys.exec_prefix],
trace=0,
count=1)

# run the new command using the given tracer
tracer.run('main()')

# make a report, placing output in the current directory
r = tracer.results()
r.write_results(show_missing=True, coverdir=".")

```

## 28.8 tracemalloc --- 追 F 記憶體配置

在 3.4 版被加入。

原始碼: `Lib/tracemalloc.py`

The `tracemalloc` module is a debug tool to trace memory blocks allocated by Python. It provides the following information:

- Traceback where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

To trace most memory blocks allocated by Python, the module should be started as early as possible by setting the `PYTHONTRACEMALLOC` environment variable to 1, or by using `-X tracemalloc` command line option. The `tracemalloc.start()` function can be called at runtime to start tracing Python memory allocations.

By default, a trace of an allocated memory block only stores the most recent frame (1 frame). To store 25 frames at startup: set the `PYTHONTRACEMALLOC` environment variable to 25, or use the `-X tracemalloc=25` command line option.

### 28.8.1 范例

#### Display the top 10

Display the 10 files allocating the most memory:

```

import tracemalloc

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('lineno')

print("[ Top 10 ]")
for stat in top_stats[:10]:
    print(stat)

```

Example of output of the Python test suite:

```

[ Top 10 ]
<frozen importlib._bootstrap>:716: size=4855 KiB, count=39328, average=126 B
<frozen importlib._bootstrap>:284: size=521 KiB, count=3199, average=167 B

```

(繼續下一頁)

(繼續上一頁)

```

/usr/lib/python3.4/collections/__init__.py:368: size=244 KiB, count=2315, average=108 B
/usr/lib/python3.4/unittest/case.py:381: size=185 KiB, count=779, average=243 B
/usr/lib/python3.4/unittest/case.py:402: size=154 KiB, count=378, average=416 B
/usr/lib/python3.4/abc.py:133: size=88.7 KiB, count=347, average=262 B
<frozen importlib._bootstrap>:1446: size=70.4 KiB, count=911, average=79 B
<frozen importlib._bootstrap>:1454: size=52.0 KiB, count=25, average=2131 B
<string>:5: size=49.7 KiB, count=148, average=344 B
/usr/lib/python3.4/sysconfig.py:411: size=48.0 KiB, count=1, average=48.0 KiB

```

We can see that Python loaded 4855 KiB data (bytecode and constants) from modules and that the `collections` module allocated 244 KiB to build `namedtuple` types.

更多選項請見 `Snapshot.statistics()`。

## Compute differences

Take two snapshots and display the differences:

```

import tracemalloc
tracemalloc.start()
# ... start your application ...

snapshot1 = tracemalloc.take_snapshot()
# ... call the function leaking memory ...
snapshot2 = tracemalloc.take_snapshot()

top_stats = snapshot2.compare_to(snapshot1, 'lineno')

print("[ Top 10 differences ]")
for stat in top_stats[:10]:
    print(stat)

```

Example of output before/after running some tests of the Python test suite:

```

[ Top 10 differences ]
<frozen importlib._bootstrap>:716: size=8173 KiB (+4428 KiB), count=71332 (+39369), ↵
↵average=117 B
/usr/lib/python3.4/linecache.py:127: size=940 KiB (+940 KiB), count=8106 (+8106), ↵
↵average=119 B
/usr/lib/python3.4/unittest/case.py:571: size=298 KiB (+298 KiB), count=589 (+589), ↵
↵average=519 B
<frozen importlib._bootstrap>:284: size=1005 KiB (+166 KiB), count=7423 (+1526), average=139 ↵
↵B
/usr/lib/python3.4/mimetypes.py:217: size=112 KiB (+112 KiB), count=1334 (+1334), average=86 ↵
↵B
/usr/lib/python3.4/http/server.py:848: size=96.0 KiB (+96.0 KiB), count=1 (+1), average=96.0 ↵
↵KiB
/usr/lib/python3.4/inspect.py:1465: size=83.5 KiB (+83.5 KiB), count=109 (+109), average=784 ↵
↵B
/usr/lib/python3.4/unittest/mock.py:491: size=77.7 KiB (+77.7 KiB), count=143 (+143), ↵
↵average=557 B
/usr/lib/python3.4/urllib/parse.py:476: size=71.8 KiB (+71.8 KiB), count=969 (+969), ↵
↵average=76 B
/usr/lib/python3.4/contextlib.py:38: size=67.2 KiB (+67.2 KiB), count=126 (+126), ↵
↵average=546 B

```

We can see that Python has loaded 8173 KiB of module data (bytecode and constants), and that this is 4428 KiB more than had been loaded before the tests, when the previous snapshot was taken. Similarly, the `linecache` module has cached 940 KiB of Python source code to format tracebacks, all of it since the previous snapshot.

If the system has little free memory, snapshots can be written on disk using the `Snapshot.dump()` method to analyze the snapshot offline. Then use the `Snapshot.load()` method reload the snapshot.

## Get the traceback of a memory block

Code to display the traceback of the biggest memory block:

```
import tracemalloc

# Store 25 frames
tracemalloc.start(25)

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
top_stats = snapshot.statistics('traceback')

# pick the biggest memory block
stat = top_stats[0]
print("%s memory blocks: %.1f KiB" % (stat.count, stat.size / 1024))
for line in stat.traceback.format():
    print(line)
```

Example of output of the Python test suite (traceback limited to 25 frames):

```
903 memory blocks: 870.1 KiB
File "<frozen importlib._bootstrap>", line 716
File "<frozen importlib._bootstrap>", line 1036
File "<frozen importlib._bootstrap>", line 934
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/doctest.py", line 101
import pdb
File "<frozen importlib._bootstrap>", line 284
File "<frozen importlib._bootstrap>", line 938
File "<frozen importlib._bootstrap>", line 1068
File "<frozen importlib._bootstrap>", line 619
File "<frozen importlib._bootstrap>", line 1581
File "<frozen importlib._bootstrap>", line 1614
File "/usr/lib/python3.4/test/support/__init__.py", line 1728
import doctest
File "/usr/lib/python3.4/test/test_pickletools.py", line 21
    support.run_doctest(pickletools)
File "/usr/lib/python3.4/test/regrtest.py", line 1276
    test_runner()
File "/usr/lib/python3.4/test/regrtest.py", line 976
    display_failure=not verbose)
File "/usr/lib/python3.4/test/regrtest.py", line 761
    match_tests=ns.match_tests)
File "/usr/lib/python3.4/test/regrtest.py", line 1563
    main()
File "/usr/lib/python3.4/test/__main__.py", line 3
    regrtest.main_in_temp_cwd()
File "/usr/lib/python3.4/runpy.py", line 73
    exec(code, run_globals)
File "/usr/lib/python3.4/runpy.py", line 160
    "__main__", fname, loader, pkg_name)
```

We can see that the most memory was allocated in the `importlib` module to load data (bytecode and constants) from modules: 870.1 KiB. The traceback is where the `importlib` loaded data most recently: on the `import pdb` line of the `doctest` module. The traceback may change if a new module is loaded.

## Pretty top

Code to display the 10 lines allocating the most memory with a pretty output, ignoring `<frozen importlib._bootstrap>` and `<unknown>` files:

```
import linecache
import os
import tracemalloc

def display_top(snapshot, key_type='lineno', limit=10):
    snapshot = snapshot.filter_traces((
        tracemalloc.Filter(False, "<frozen importlib._bootstrap>"),
        tracemalloc.Filter(False, "<unknown>"),
    ))
    top_stats = snapshot.statistics(key_type)

    print("Top %s lines" % limit)
    for index, stat in enumerate(top_stats[:limit], 1):
        frame = stat.traceback[0]
        print("#%s: %s:%s: %.1f KiB"
              % (index, frame.filename, frame.lineno, stat.size / 1024))
        line = linecache.getline(frame.filename, frame.lineno).strip()
        if line:
            print('    %s' % line)

    other = top_stats[limit:]
    if other:
        size = sum(stat.size for stat in other)
        print("%s other: %.1f KiB" % (len(other), size / 1024))
    total = sum(stat.size for stat in top_stats)
    print("Total allocated size: %.1f KiB" % (total / 1024))

tracemalloc.start()

# ... run your application ...

snapshot = tracemalloc.take_snapshot()
display_top(snapshot)
```

Example of output of the Python test suite:

```
Top 10 lines
#1: Lib/base64.py:414: 419.8 KiB
   _b85chars2 = [(a + b) for a in _b85chars for b in _b85chars]
#2: Lib/base64.py:306: 419.8 KiB
   _a85chars2 = [(a + b) for a in _a85chars for b in _a85chars]
#3: collections/_init_.py:368: 293.6 KiB
   exec(class_definition, namespace)
#4: Lib/abc.py:133: 115.2 KiB
   cls = super().__new__(mcls, name, bases, namespace)

   for a in _hexdig for b in _hexdig}
#8: <string>:5: 62.0 KiB
#9: Lib/_weakrefset.py:37: 60.0 KiB
   self.data = set()
#10: Lib/base64.py:142: 59.8 KiB
   _b32tab2 = [a + b for a in _b32tab for b in _b32tab]
6220 other: 3602.8 KiB
Total allocated size: 5303.1 KiB
```

更多選項請見 `Snapshot.statistics()`。

### Record the current and peak size of all traced memory blocks

The following code computes two sums like  $0 + 1 + 2 + \dots$  inefficiently, by creating a list of those numbers. This list consumes a lot of memory temporarily. We can use `get_traced_memory()` and `reset_peak()` to observe the small memory usage after the sum is computed as well as the peak memory usage during the computations:

```
import tracemalloc

tracemalloc.start()

# Example code: compute a sum with a large temporary list
large_sum = sum(list(range(100000)))

first_size, first_peak = tracemalloc.get_traced_memory()

tracemalloc.reset_peak()

# Example code: compute a sum with a small temporary list
small_sum = sum(list(range(1000)))

second_size, second_peak = tracemalloc.get_traced_memory()

print(f"first_size={}, first_peak={}")
print(f"second_size={}, second_peak={}")
```

輸出：

```
first_size=664, first_peak=3592984
second_size=804, second_peak=29704
```

Using `reset_peak()` ensured we could accurately record the peak during the computation of `small_sum`, even though it is much smaller than the overall peak size of memory blocks since the `start()` call. Without the call to `reset_peak()`, `second_peak` would still be the peak from the computation `large_sum` (that is, equal to `first_peak`). In this case, both peaks are much higher than the final memory usage, and which suggests we could optimise (by removing the unnecessary call to `list`, and writing `sum(range(...))`).

## 28.8.2 API

### 函式

`tracemalloc.clear_traces()`

Clear traces of memory blocks allocated by Python.

另請參閱 `stop()`。

`tracemalloc.get_object_traceback(obj)`

Get the traceback where the Python object `obj` was allocated. Return a `Traceback` instance, or `None` if the `tracemalloc` module is not tracing memory allocations or did not trace the allocation of the object.

另請參閱 `gc.get_referrers()` 與 `sys.getsizeof()` 函式。

`tracemalloc.get_traceback_limit()`

Get the maximum number of frames stored in the traceback of a trace.

The `tracemalloc` module must be tracing memory allocations to get the limit, otherwise an exception is raised.

The limit is set by the `start()` function.

`tracemalloc.get_traced_memory()`

Get the current size and peak size of memory blocks traced by the `tracemalloc` module as a tuple: (current: int, peak: int).

`tracemalloc.reset_peak()`

Set the peak size of memory blocks traced by the `tracemalloc` module to the current size.

Do nothing if the `tracemalloc` module is not tracing memory allocations.

This function only modifies the recorded peak size, and does not modify or clear any traces, unlike `clear_traces()`. Snapshots taken with `take_snapshot()` before a call to `reset_peak()` can be meaningfully compared to snapshots taken after the call.

另請參閱 `get_traced_memory()`。

在 3.9 版被加入。

`tracemalloc.get_tracemalloc_memory()`

Get the memory usage in bytes of the `tracemalloc` module used to store traces of memory blocks. Return an `int`.

`tracemalloc.is_tracing()`

True if the `tracemalloc` module is tracing Python memory allocations, False otherwise.

另請參閱 `start()` 與 `stop()` 函式。

`tracemalloc.start(nframe: int = 1)`

Start tracing Python memory allocations: install hooks on Python memory allocators. Collected tracebacks of traces will be limited to `nframe` frames. By default, a trace of a memory block only stores the most recent frame: the limit is 1. `nframe` must be greater or equal to 1.

You can still read the original number of total frames that composed the traceback by looking at the `Traceback.total_nframe` attribute.

Storing more than 1 frame is only useful to compute statistics grouped by 'traceback' or to compute cumulative statistics: see the `Snapshot.compare_to()` and `Snapshot.statistics()` methods.

Storing more frames increases the memory and CPU overhead of the `tracemalloc` module. Use the `get_tracemalloc_memory()` function to measure how much memory is used by the `tracemalloc` module.

The `PYTHONTRACEMALLOC` environment variable (`PYTHONTRACEMALLOC=NFRAME`) and the `-X tracemalloc=NFRAME` command line option can be used to start tracing at startup.

See also `stop()`, `is_tracing()` and `get_traceback_limit()` functions.

`tracemalloc.stop()`

Stop tracing Python memory allocations: uninstall hooks on Python memory allocators. Also clears all previously collected traces of memory blocks allocated by Python.

Call `take_snapshot()` function to take a snapshot of traces before clearing them.

See also `start()`, `is_tracing()` and `clear_traces()` functions.

`tracemalloc.take_snapshot()`

Take a snapshot of traces of memory blocks allocated by Python. Return a new `Snapshot` instance.

The snapshot does not include memory blocks allocated before the `tracemalloc` module started to trace memory allocations.

Tracebacks of traces are limited to `get_traceback_limit()` frames. Use the `nframe` parameter of the `start()` function to store more frames.

The `tracemalloc` module must be tracing memory allocations to take a snapshot, see the `start()` function.

另請參閱 `get_object_traceback()` 函式。

## DomainFilter

**class** tracemalloc.**DomainFilter** (*inclusive*: bool, *domain*: int)

Filter traces of memory blocks by their address space (domain).

在 3.6 版被加入。

### **inclusive**

If *inclusive* is True (include), match memory blocks allocated in the address space *domain*.

If *inclusive* is False (exclude), match memory blocks not allocated in the address space *domain*.

### **domain**

Address space of a memory block (int). Read-only property.

## Filter

**class** tracemalloc.**Filter** (*inclusive*: bool, *filename\_pattern*: str, *lineno*: int = None, *all\_frames*: bool = False, *domain*: int = None)

Filter on traces of memory blocks.

See the `fnmatch.fnmatch()` function for the syntax of *filename\_pattern*. The '.pyc' file extension is replaced with '.py'.

範例：

- `Filter(True, subprocess.__file__)` only includes traces of the `subprocess` module
- `Filter(False, tracemalloc.__file__)` excludes traces of the `tracemalloc` module
- `Filter(False, "<unknown>")` excludes empty tracebacks

在 3.5 版的變更: The '.pyo' file extension is no longer replaced with '.py'.

在 3.6 版的變更: 新增 *domain* 屬性。

### **domain**

Address space of a memory block (int or None).

tracemalloc uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

### **inclusive**

If *inclusive* is True (include), only match memory blocks allocated in a file with a name matching *filename\_pattern* at line number *lineno*.

If *inclusive* is False (exclude), ignore memory blocks allocated in a file with a name matching *filename\_pattern* at line number *lineno*.

### **lineno**

Line number (int) of the filter. If *lineno* is None, the filter matches any line number.

### **filename\_pattern**

Filename pattern of the filter (str). Read-only property.

### **all\_frames**

If *all\_frames* is True, all frames of the traceback are checked. If *all\_frames* is False, only the most recent frame is checked.

This attribute has no effect if the traceback limit is 1. See the `get_traceback_limit()` function and `Snapshot.traceback_limit` attribute.

## Frame

**class** `tracemalloc.Frame`

Frame of a traceback.

The `Traceback` class is a sequence of `Frame` instances.

**filename**

Filename (str).

**lineno**

Line number (int).

## Snapshot

**class** `tracemalloc.Snapshot`

Snapshot of traces of memory blocks allocated by Python.

The `take_snapshot()` function creates a snapshot instance.

**compare\_to** (*old\_snapshot: Snapshot, key\_type: str, cumulative: bool = False*)

Compute the differences with an old snapshot. Get statistics as a sorted list of `StatisticDiff` instances grouped by `key_type`.

See the `Snapshot.statistics()` method for `key_type` and `cumulative` parameters.

The result is sorted from the biggest to the smallest by: absolute value of `StatisticDiff.size_diff`, `StatisticDiff.size`, absolute value of `StatisticDiff.count_diff`, `Statistic.count` and then by `StatisticDiff.traceback`.

**dump** (*filename*)

Write the snapshot into a file.

Use `load()` to reload the snapshot.

**filter\_traces** (*filters*)

Create a new `Snapshot` instance with a filtered `traces` sequence, `filters` is a list of `DomainFilter` and `Filter` instances. If `filters` is an empty list, return a new `Snapshot` instance with a copy of the traces.

All inclusive filters are applied at once, a trace is ignored if no inclusive filters match it. A trace is ignored if at least one exclusive filter matches it.

在 3.6 版的變更: `DomainFilter` instances are now also accepted in `filters`.

**classmethod** `load` (*filename*)

Load a snapshot from a file.

另請參 `dump()`。

**statistics** (*key\_type: str, cumulative: bool = False*)

Get statistics as a sorted list of `Statistic` instances grouped by `key_type`:

key_type	描述
'filename'	filename
'lineno'	filename and line number
'traceback'	traceback

If `cumulative` is `True`, cumulate size and count of memory blocks of all frames of the traceback of a trace, not only the most recent frame. The cumulative mode can only be used with `key_type` equals to 'filename' and 'lineno'.

The result is sorted from the biggest to the smallest by: `Statistic.size`, `Statistic.count` and then by `Statistic.traceback`.

**traceback\_limit**

Maximum number of frames stored in the traceback of *traces*: result of the *get\_traceback\_limit()* when the snapshot was taken.

**traces**

Traces of all memory blocks allocated by Python: sequence of *Trace* instances.

The sequence has an undefined order. Use the *Snapshot.statistics()* method to get a sorted list of statistics.

**Statistic****class** tracemalloc.**Statistic**

Statistic on memory allocations.

*Snapshot.statistics()* returns a list of *Statistic* instances.

See also the *StatisticDiff* class.

**count**

Number of memory blocks (*int*).

**size**

Total size of memory blocks in bytes (*int*).

**traceback**

Traceback where the memory block was allocated, *Traceback* instance.

**StatisticDiff****class** tracemalloc.**StatisticDiff**

Statistic difference on memory allocations between an old and a new *Snapshot* instance.

*Snapshot.compare\_to()* returns a list of *StatisticDiff* instances. See also the *Statistic* class.

**count**

Number of memory blocks in the new snapshot (*int*): 0 if the memory blocks have been released in the new snapshot.

**count\_diff**

Difference of number of memory blocks between the old and the new snapshots (*int*): 0 if the memory blocks have been allocated in the new snapshot.

**size**

Total size of memory blocks in bytes in the new snapshot (*int*): 0 if the memory blocks have been released in the new snapshot.

**size\_diff**

Difference of total size of memory blocks in bytes between the old and the new snapshots (*int*): 0 if the memory blocks have been allocated in the new snapshot.

**traceback**

Traceback where the memory blocks were allocated, *Traceback* instance.

**Trace****class** tracemalloc.**Trace**

Trace of a memory block.

The *Snapshot.traces* attribute is a sequence of *Trace* instances.

在 3.6 版的變更: 新增 *domain* 屬性。

**domain**

Address space of a memory block (`int`). Read-only property.

`tracemalloc` uses the domain 0 to trace memory allocations made by Python. C extensions can use other domains to trace other resources.

**size**

Size of the memory block in bytes (`int`).

**traceback**

Traceback where the memory block was allocated, `Traceback` instance.

**Traceback****class** `tracemalloc.Traceback`

Sequence of `Frame` instances sorted from the oldest frame to the most recent frame.

A traceback contains at least 1 frame. If the `tracemalloc` module failed to get a frame, the filename "`<unknown>`" at line number 0 is used.

When a snapshot is taken, tracebacks of traces are limited to `get_traceback_limit()` frames. See the `take_snapshot()` function. The original number of frames of the traceback is stored in the `Traceback.total_nframe` attribute. That allows to know if a traceback has been truncated by the traceback limit.

The `Trace.traceback` attribute is an instance of `Traceback` instance.

在 3.7 版的變更: Frames are now sorted from the oldest to the most recent, instead of most recent to oldest.

**total\_nframe**

Total number of frames that composed the traceback before truncation. This attribute can be set to `None` if the information is not available.

在 3.9 版的變更: The `Traceback.total_nframe` attribute was added.

**format** (`limit=None, most_recent_first=False`)

Format the traceback as a list of lines. Use the `linecache` module to retrieve lines from the source code. If `limit` is set, format the `limit` most recent frames if `limit` is positive. Otherwise, format the `abs(limit)` oldest frames. If `most_recent_first` is `True`, the order of the formatted frames is reversed, returning the most recent frame first instead of last.

Similar to the `traceback.format_tb()` function, except that `format()` does not include newlines.

範例:

```
print("Traceback (most recent call first):")
for line in traceback:
    print(line)
```

輸出:

```
Traceback (most recent call first):
  File "test.py", line 9
    obj = Object()
  File "test.py", line 12
    tb = tracemalloc.get_object_traceback(f())
```

這些函式庫可以幫助你發布和安裝 Python 軟體。雖然這些模組設計是為與 Python 套件索引 (Python Package Index) 結合使用，但它們也可以搭配本地索引伺服器，甚至可以在沒有任何索引伺服器的情況下使用。

## 29.1 ensurepip --- pip 安裝器的初始建置 (bootstrapping)

在 3.4 版被加入。

原始碼：[Lib/ensurepip](#)

`ensurepip` 套件 (package) 為既有的 Python 安裝或虛擬環境提供 `pip` 安裝器初始建置 (bootstrapping) 的支援。這個初始建置的方式應證了事實——`pip` 是有其獨立發布週期的專案，且其最新可用穩定的版本，會與 CPython 直譯器 (interpreter) 之維護和功能發布綁定。

大多數情況下，Python 的終端使用者不需要直接調用此模組（因為 `pip` 預設應為初始建置），但若安裝 Python 時 `pip` 被省略（或建立一虛擬環境時），又或是 `pip` 被明確解除安裝時，則此模組的初始建置仍有可能用上。

### 備註

此模組不會通過網路存取。所有需要用來初始建置 `pip` 的元件都已包含在套件之內。

### 也參考

#### **installing-index**

對於終端使用者安裝 Python 套件的指引

#### **PEP 453: 在 Python 安裝中的 pip 明確初始建置**

此模組的最初設計理念與規範。

適用：not Android, not iOS, not WASI.

此模組在行動平台或 *WebAssembly* 平台上不支援。

### 29.1.1 命令列介面

使用直譯器 (interpreter) 的 `-m` 來調用命令列介面

最簡單可行的調用：

```
python -m ensurepip
```

若 `pip` 未安裝，此調用會將其安裝；否則甚也不做。可透過傳入 `--upgrade` 參數來確保 `pip` 的安裝版本至少與當前 `ensurepip` 中最新可用的版本：

```
python -m ensurepip --upgrade
```

預設上，`pip` 會被安裝至當前虛擬環境（若已啟動虛擬環境）或系統端的套件（若沒有啟動的虛擬環境）。安裝位置可透過兩個額外的命令列選項來控制：

**--root <dir>**

Installs `pip` relative to the given root directory rather than the root of the currently active virtual environment (if any) or the default root for the current Python installation.

**--user**

Installs `pip` into the user site packages directory rather than globally for the current Python installation (this option is not permitted inside an active virtual environment).

預設會安裝 `pipX` 和 `pipX.Y` 版本（`X.Y` 代表用來調用 `ensurepip` 的 Python 之版本）。安裝的版本可透過兩個額外的命令列選項來控制：

**--altinstall**

If an alternate installation is requested, the `pipX` script will *not* be installed.

**--default-pip**

If a "default pip" installation is requested, the `pip` script will be installed in addition to the two regular scripts.

提供兩種指令選項將會導致例外 (exception)。

### 29.1.2 模組 API

`ensurepip` 開放了兩個用於編寫程式的函式：

`ensurepip.version()`

回傳一個字串，用以標明初始建置時，安裝的 `pip` 的可行版本號。

`ensurepip.bootstrap(root=None, upgrade=False, user=False, altinstall=False, default_pip=False, verbosity=0)`

在當前或指定的環境之中建立 `pip`。

`root` 指定一個替代的根目錄，作安裝的相對路徑。若 `root` 為 `None`，則安裝使用當前環境的預設安裝位置。

`upgrade` 指出是否要將一個既有的較早版本的 `pip` 升級至可用的新版。

`user` 指出是否要使用使用者的安裝方案而不是全域安裝。

預設會安裝 `pipX` 和 `pipX.Y` 版本（`X.Y` 代表 Python 的當前版本）。

如果用了 `altinstall`，則不會安裝 `pipX`。

如果用了 `default_pip`，則會安裝 `pip`，以及 2 個常規版本。

同時用 `altinstall` 跟 `default_pip`，將會觸發 `ValueError`。

`verbosity` 用來控制初始建置操作，對於 `sys.stdout` 的輸出等級。

引發一個附帶引數 `root` 的稽核事件 `ensurepip.bootstrap`。

**備**

初始建置的過程對於 `sys.path` 及 `os.environ` 均有副作用。改在一子行程 (subprocess) 調用命令列介面可避免這些副作用。

**備**

初始建置的過程也許會安裝 `pip` 所需要的額外的模組，但其他軟體不應該假設這些相依 (dependency) 總是預設存在 (因這些相依很可能會在未來版本的 `pip` 中被移除)。

## 29.2 venv --- 建立擬環境

在 3.3 版被加入。

原始碼: [Lib/venv/](#)

The `venv` module supports creating lightweight “virtual environments”, each with their own independent set of Python packages installed in their *site* directories. A virtual environment is created on top of an existing Python installation, known as the virtual environment’s “base” Python, and may optionally be isolated from the packages in the base environment, so only those explicitly installed in the virtual environment are available.

When used from within a virtual environment, common installation tools such as `pip` will install Python packages into a virtual environment without needing to be told to do so explicitly.

A virtual environment is (amongst other things):

- Used to contain a specific Python interpreter and software libraries and binaries which are needed to support a project (library or application). These are by default isolated from software in other virtual environments and Python interpreters and libraries installed in the operating system.
- Contained in a directory, conventionally named `.venv` or `venv` in the project directory, or under a container directory for lots of virtual environments, such as `~/.virtualenvs`.
- Not checked into source control systems such as Git.
- Considered as disposable -- it should be simple to delete and recreate it from scratch. You don’t place any project code in the environment.
- Not considered as movable or copyable -- you just recreate the same environment in the target location.

更多關於 Python 擬環境的背景資訊請見 [PEP 405](#)。

**也參考**

[Python Packaging User Guide: Creating and using virtual environments](#)

適用: not Android, not iOS, not WASI.

此模組在行動平台或 *WebAssembly* 平台上不支援。

### 29.2.1 建立擬環境

擬環境是透過執行 `venv` 模組來建立:

```
python -m venv /path/to/new/virtual/environment
```

執行此命令會建立目標目錄（同時也會建立任何還不存在的父目錄）並在目標目錄中放置一個名為 `pyvenv.cfg` 的檔案，其中包含一個指向執行該命令的 Python 安裝路徑的 `home` 鍵。它同時會建立一個 `bin`（在 Windows 上為 `Scripts`）子目錄，其中包含一個 Python 二進位檔案的副本/符號連結（根據建立環境時使用的平台或引數而定）。此外，它還會建立一個 `lib/pythonX.Y/site-packages` 子目錄（在 Windows 上為 `Libsite-packages`）。如果指定的目錄已存在，則將重新使用該目錄。

在 3.5 版的變更：目前建議使用 `venv` 來建立虛擬環境。

Deprecated since version 3.6, removed in version 3.8: `pyvenv` 是在 Python 3.3 和 3.4 中建立虛擬環境的推薦工具，但在 Python 3.5 中已被直接執行 `venv` 所取代。

在 Windows 上，執行以下命令以使用 `venv`：

```
PS> python -m venv C:\path\to\new\virtual\environment
```

如果使用 `-h` 選項執行該命令，將會顯示可用的選項：

```
usage: venv [-h] [--system-site-packages] [--symlinks | --copies] [--clear]
           [--upgrade] [--without-pip] [--prompt PROMPT] [--upgrade-deps]
           [--without-scm-ignore-files]
           ENV_DIR [ENV_DIR ...]

Creates virtual Python environments in one or more target directories.

positional arguments:
  ENV_DIR                A directory to create the environment in.

options:
  -h, --help            show this help message and exit
  --system-site-packages
                        Give the virtual environment access to the system
                        site-packages dir.
  --symlinks            Try to use symlinks rather than copies, when
                        symlinks are not the default for the platform.
  --copies              Try to use copies rather than symlinks, even when
                        symlinks are the default for the platform.
  --clear              Delete the contents of the environment directory
                        if it already exists, before environment creation.
  --upgrade            Upgrade the environment directory to use this
                        version of Python, assuming Python has been
                        upgraded in-place.
  --without-pip        Skips installing or upgrading pip in the virtual
                        environment (pip is bootstrapped by default)
  --prompt PROMPT     Provides an alternative prompt prefix for this
                        environment.
  --upgrade-deps      Upgrade core dependencies (pip) to the latest
                        version in PyPI
  --without-scm-ignore-files
                        Skips adding SCM ignore files to the environment
                        directory (Git is supported by default).

Once an environment has been created, you may wish to activate it, e.g. by
sourcing an activate script in its bin directory.
```

在 3.4 版的變更：預設會安裝 `pip`，新增了 `--without-pip` 和 `--copies` 選項

在 3.4 版的變更：在較早的版本中，如果目標目錄已存在，除非提供了 `--clear` 或 `--upgrade` 選項，否則會引發錯誤。

在 3.9 版的變更：新增 `--upgrade-deps` 選項以將 `pip` 和 `setuptools` 升級至 PyPI 上的最新版本

在 3.12 版的變更：`setuptools` is no longer a core `venv` dependency.

在 3.13 版的變更：新增 `--without-scm-ignore-files` 選項

在 3.13 版的變更：`venv` now creates a `.gitignore` file for Git by default.

**i** 備

雖然在 Windows 上支援符號連結，但不建議使用。特需要注意的是，在檔案總管中按兩下 `python.exe` 會急切地解析符號連結而忽略擬環境。

**i** 備

在 Microsoft Windows 上，可能需要通過設置使用者的執行策略來用 `Activate.ps1` 本。你可以發出以下 PowerShell 命令來執行此操作：

```
PS C:\> Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
```

有關更多資訊，請參關於執行策略。

被建立的 `pyvenv.cfg` 檔案還包括了 `include-system-site-packages` 的鍵，如果使用 `venv` 執行時帶有 `--system-site-packages` 選項，則設置 `true`，否則設置 `false`。

除非 `--without-pip` 選項被提供，否則將調用 `ensurepip` 來動 `pip` 到擬環境中。

可以向 `venv` 提供多個路徑，這樣每個提供的路徑都將根據給定的選項建立一個相同的擬環境。

## 29.2.2 擬環境如何運作

當 Python 直譯器跑在擬環境時，`sys.prefix` 和 `sys.exec_prefix` 會指向擬環境的目錄，而 `sys.base_prefix` 和 `sys.base_exec_prefix` 會指向建立擬環境的基礎 Python 的目錄。檢查 `sys.prefix != sys.base_prefix` 就可以確定目前的直譯器是否跑在擬環境中。

擬環境可以透過位於二進位檔案目錄中的本「用」（在 POSIX 上 `bin`；在 Windows 上 `Scripts`）這會將該目錄加入到你的 `PATH`，當你運行 `python` 時就會調用該環境的直譯器且執行已安裝的本，而不需要使用完整的路徑。動本的方式因平台而（`<venv>` 需要替成包含擬環境的目錄路徑）

平台	Shell	動擬環境的指令
POSIX	<code>bash/zsh</code>	<code>\$ source &lt;venv&gt;/bin/activate</code>
	<code>fish</code>	<code>\$ source &lt;venv&gt;/bin/activate.fish</code>
	<code>csh/tcsh</code>	<code>\$ source &lt;venv&gt;/bin/activate.csh</code>
	<code>pwsh</code>	<code>\$ &lt;venv&gt;/bin/Activate.ps1</code>
Windows	<code>cmd.exe</code>	<code>C:\&gt; &lt;venv&gt;\Scripts\activate.bat</code>
	<code>PowerShell</code>	<code>PS C:\&gt; &lt;venv&gt;\Scripts\Activate.ps1</code>

在 3.4 版被加入：`fish` 和 `csh` 動本。

在 3.8 版被加入：PowerShell 的動本安裝在 POSIX 上支援 PowerShell Core。

你不用開擬環境，你可以在調用 Python 時指定該環境下 Python 直譯器的完整路徑。此外，所有安裝在環境的本都應該都可以在未用擬環境的情況下運行。

了實現這一點，安裝在擬環境中的本會有一個“shebang”列，此列指向該環境的 Python 直譯器 `#!/<path-to-venv>/bin/python`。這代表無論 `PATH` 的值何，該本都會在直譯器上運行。在 Windows 上，如果你安裝了 `launcher`，則支援“shebang”列處理。因此，在 Windows 檔案總管（Windows Explorer）中雙擊已安裝的本，應該可以在有環境或將其加入 `PATH` 的情況下正確地運行。

當擬環境被用時，`VIRTUAL_ENV` 環境變數會被設置該環境的路徑。由於不需要明確用擬環境才能使用它。因此，無法依賴 `VIRTUAL_ENV` 來判斷是否正在使用擬環境。

**警告**

因安裝在環境中的本不應該預期該環境已經被動，所以它們的 shebang 列會包含環境直譯器的對路徑。因此，在一般情況下，環境本質上是不可帶的。你應該使用一個簡單的方法來重新建立一個環境（例如：如果你有一個名 requirements.txt 的需求檔案，你可以使用環境的 pip install -r requirements.txt 來安裝環境所需的所有套件）。如果出於某種原因，你需要將環境移至新位置，你應該在所需位置重新建立它，除舊位置的環境。如果你移動環境是因移動了其父目，你應該在新位置重新建立環境。否則，安裝在該環境中的軟體可能無法正常運作。

你可以在 shell 輸入 deactivate 來關閉擬環境。具體的使用方式因平台而，是部實作的細節（通常會使用本或是 shell 函式）

### 29.2.3 API

上述提到的高階 method（方法）透過簡單的 API 使用，第三方擬環境建立者提供可以依據他們需求來建立環境的客化機制：EnvBuilder class。

```
class venv.EnvBuilder(system_site_packages=False, clear=False, symlinks=False, upgrade=False,
                    with_pip=False, prompt=None, upgrade_deps=False, *, scm_ignore_files=frozenset())
```

進行實例化時，class EnvBuilder 接受下列的關鍵字引數：

- `system_site_packages` -- 一個 boolean（布林值），表明系統的 Python site-packages 是否可以在環境中可用（預設 False）。
- `clear` -- 一個 boolean，如果 true，則在建立環境之前，除目標目所有存在的容。
- `symlinks` -- 一個 boolean，表明是否嘗試與 Python 二進位檔案建立符號連結而不是該檔案。
- `upgrade` -- 一個 boolean，若 true，則會在執行 Python 時現有的環境進行升級。目的是讓 Python 可以升級到位（預設 False）。
- `with_pip` -- 一個 boolean，若 true，則確保 pip 有安裝至擬環境之中。當有 `--default-pip` 的選項時，會使用 `ensurepip`。
- `prompt` -- 一個 String（字串），該字串會在擬環境動時被使用。（預設 None，代表該環境的目名稱會被使用）倘若出現特殊字串 "."，則當前目的 basename 會做提示路徑使用。
- `upgrade_deps` -- 更新基礎 venv 模組至 PyPI 的最新版本
- `scm_ignore_files` -- Create ignore files based for the specified source control managers (SCM) in the iterable. Support is defined by having a method named `create_{scm}_ignore_file`. The only value supported by default is "git" via `create_git_ignore_file()`.

在 3.4 版的變更：新增 `with_pip` 參數

在 3.6 版的變更：新增 `prompt` 參數

在 3.9 版的變更：新增 `upgrade_deps` 參數

在 3.13 版的變更：新增 `scm_ignore_files` 參數

EnvBuilder 可以被用作基底類。

**create** (env\_dir)

透過指定將會容納擬環境的目標目來建立一個擬環境（對路徑或相對路徑到該目），也就是在該目中容納擬環境。create method 將會在指定的目下建立環境，或是觸發適當的例外。

EnvBuilder class 的 create method 會闡述可用的 Hooks 以客化 subclass（子類）：

```
def create(self, env_dir):
    """
    Create a virtualized Python environment in a directory.
    env_dir is the target directory to create an environment in.
```

(繼續下一頁)

(繼續上一頁)

```

"""
env_dir = os.path.abspath(env_dir)
context = self.ensure_directories(env_dir)
self.create_configuration(context)
self.setup_python(context)
self.setup_scripts(context)
self.post_setup(context)

```

每個 methods `ensure_directories()`、`create_configuration()`、`setup_python()`、`setup_scripts()` 及 `post_setup()` 都可以被覆寫。

#### **ensure\_directories** (*env\_dir*)

建立還不存在的環境目錄及必要的子目錄，回傳一個情境物件 (context object)。這個情境物件只是一個屬性 (例如：路徑) 的所有者，可被其他 method 使用。如果 `EnvBuilder` 已被建立且帶有 `clear=True` 的引數，該環境目錄下的內容將被清空，以及所有必要的子目錄將被重新建立。

回傳的情境物件 (context object) 其型會是 `types.SimpleNamespace`，包含以下屬性：

- `env_dir` - The location of the virtual environment. Used for `__VENV_DIR__` in activation scripts (see `install_scripts()`).
- `env_name` - The name of the virtual environment. Used for `__VENV_NAME__` in activation scripts (see `install_scripts()`).
- `prompt` - The prompt to be used by the activation scripts. Used for `__VENV_PROMPT__` in activation scripts (see `install_scripts()`).
- `executable` - The underlying Python executable used by the virtual environment. This takes into account the case where a virtual environment is created from another virtual environment.
- `inc_path` - The include path for the virtual environment.
- `lib_path` - The purelib path for the virtual environment.
- `bin_path` - 擬環境的本地路徑。
- `bin_name` - The name of the script path relative to the virtual environment location. Used for `__VENV_BIN_NAME__` in activation scripts (see `install_scripts()`).
- `env_exe` - The name of the Python interpreter in the virtual environment. Used for `__VENV_PYTHON__` in activation scripts (see `install_scripts()`).
- `env_exec_cmd` - The name of the Python interpreter, taking into account filesystem redirections. This can be used to run Python in the virtual environment.

在 3.11 版的變更: The `venv sysconfig installation scheme` is used to construct the paths of the created directories.

在 3.12 版的變更: The attribute `lib_path` was added to the context, and the context object was documented.

#### **create\_configuration** (*context*)

在環境中建立 `pyvenv.cfg` 設定檔。

#### **setup\_python** (*context*)

Creates a copy or symlink to the Python executable in the environment. On POSIX systems, if a specific executable `python3.x` was used, symlinks to `python` and `python3` will be created pointing to that executable, unless files with those names already exist.

#### **setup\_scripts** (*context*)

Installs activation scripts appropriate to the platform into the virtual environment.

**upgrade\_dependencies** (*context*)

Upgrades the core venv dependency packages (currently `pip`) in the environment. This is done by shelling out to the `pip` executable in the environment.

在 3.9 版被加入。

在 3.12 版的變更: `setuptools` 不再是核心 `venv` 的依賴。

**post\_setup** (*context*)

A placeholder method which can be overridden in third party implementations to pre-install packages in the virtual environment or perform other post-creation steps.

**install\_scripts** (*context, path*)

This method can be called from `setup_scripts()` or `post_setup()` in subclasses to assist in installing custom scripts into the virtual environment.

*path* is the path to a directory that should contain subdirectories `common`, `posix`, `nt`; each containing scripts destined for the `bin` directory in the environment. The contents of `common` and the directory corresponding to `os.name` are copied after some text replacement of placeholders:

- `__VENV_DIR__` is replaced with the absolute path of the environment directory.
- `__VENV_NAME__` is replaced with the environment name (final path segment of environment directory).
- `__VENV_PROMPT__` is replaced with the prompt (the environment name surrounded by parentheses and with a following space)
- `__VENV_BIN_NAME__` is replaced with the name of the bin directory (either `bin` or `Scripts`).
- `__VENV_PYTHON__` is replaced with the absolute path of the environment's executable.

The directories are allowed to exist (for when an existing environment is being upgraded).

**create\_git\_ignore\_file** (*context*)

Creates a `.gitignore` file within the virtual environment that causes the entire directory to be ignored by the Git source control manager.

在 3.13 版被加入。

在 3.7.2 版的變更: Windows now uses redirector scripts for `python[w].exe` instead of copying the actual binaries. In 3.7.2 only `setup_python()` does nothing unless running from a build in the source tree.

在 3.7.3 版的變更: Windows copies the redirector scripts as part of `setup_python()` instead of `setup_scripts()`. This was not the case in 3.7.2. When using symlinks, the original executables will be linked.

There is also a module-level convenience function:

```
venv.create(env_dir, system_site_packages=False, clear=False, symlinks=False, with_pip=False, prompt=None,
            upgrade_deps=False, *, scm_ignore_files=frozenset())
```

Create an `EnvBuilder` with the given keyword arguments, and call its `create()` method with the `env_dir` argument.

在 3.3 版被加入。

在 3.4 版的變更: 新增 `with_pip` 參數

在 3.6 版的變更: 新增 `prompt` 參數

在 3.9 版的變更: 新增 `upgrade_deps` 參數

在 3.13 版的變更: 新增 `scm_ignore_files` 參數

## 29.2.4 一個擴展 `EnvBuilder` 的范例

The following script shows how to extend `EnvBuilder` by implementing a subclass which installs `setuptools` and `pip` into a created virtual environment:

```
import os
import os.path
from subprocess import Popen, PIPE
import sys
from threading import Thread
from urllib.parse import urlparse
from urllib.request import urlretrieve
import venv

class ExtendedEnvBuilder(venv.EnvBuilder):
    """
    This builder installs setuptools and pip so that you can pip or
    easy_install other packages into the created virtual environment.

    :param nodist: If true, setuptools and pip are not installed into the
        created virtual environment.
    :param nopip: If true, pip is not installed into the created
        virtual environment.
    :param progress: If setuptools or pip are installed, the progress of the
        installation can be monitored by passing a progress
        callable. If specified, it is called with two
        arguments: a string indicating some progress, and a
        context indicating where the string is coming from.
        The context argument can have one of three values:
        'main', indicating that it is called from virtualize()
        itself, and 'stdout' and 'stderr', which are obtained
        by reading lines from the output streams of a subprocess
        which is used to install the app.

        If a callable is not specified, default progress
        information is output to sys.stderr.
    """

    def __init__(self, *args, **kwargs):
        self.nodist = kwargs.pop('nodist', False)
        self.nopip = kwargs.pop('nopip', False)
        self.progress = kwargs.pop('progress', None)
        self.verbose = kwargs.pop('verbose', False)
        super().__init__(*args, **kwargs)

    def post_setup(self, context):
        """
        Set up any packages which need to be pre-installed into the
        virtual environment being created.

        :param context: The information for the virtual environment
            creation request being processed.
        """
        os.environ['VIRTUAL_ENV'] = context.env_dir
        if not self.nodist:
            self.install_setuptools(context)
        # Can't install pip without setuptools
        if not self.nopip and not self.nodist:
            self.install_pip(context)

    def reader(self, stream, context):
        """
        Read lines from a subprocess' output stream and either pass to a progress
        """
```

(繼續下一頁)

```

callable (if specified) or write progress information to sys.stderr.
"""

```

This script is also available for download [online](#).

## 29.3 zipapp --- 管理可執行的 Python zip 封存檔案

在 3.5 版被加入。

原始碼: [Lib/zipapp.py](#)

This module provides tools to manage the creation of zip files containing Python code, which can be executed directly by the Python interpreter. The module provides both a [命令執行列介面](#) and a *Python API*.

### 29.3.1 基本范例

The following example shows how the [命令執行列介面](#) can be used to create an executable archive from a directory containing Python code. When run, the archive will execute the `main` function from the module `myapp` in the archive.

```

$ python -m zipapp myapp -m "myapp:main"
$ python myapp.pyz
<output from myapp>

```

### 29.3.2 命令執行列介面

When called as a program from the command line, the following form is used:

```

$ python -m zipapp source [options]

```

If `source` is a directory, this will create an archive from the contents of `source`. If `source` is a file, it should be an archive, and it will be copied to the target archive (or the contents of its shebang line will be displayed if the `--info` option is specified).

The following options are understood:

**-o** <output>, **--output**=<output>

Write the output to a file named *output*. If this option is not specified, the output filename will be the same as the input *source*, with the extension `.pyz` added. If an explicit filename is given, it is used as is (so a `.pyz` extension should be included if required).

An output filename must be specified if the *source* is an archive (and in that case, *output* must not be the same as *source*).

**-p** <interpreter>, **--python**=<interpreter>

Add a `#!` line to the archive specifying *interpreter* as the command to run. Also, on POSIX, make the archive executable. The default is to write no `#!` line, and not make the file executable.

**-m** <mainfn>, **--main**=<mainfn>

Write a `__main__.py` file to the archive that executes *mainfn*. The *mainfn* argument should have the form `"pkg.mod:fn"`, where `"pkg.mod"` is a package/module in the archive, and `"fn"` is a callable in the given module. The `__main__.py` file will execute that callable.

`--main` cannot be specified when copying an archive.

**-c**, **--compress**

Compress files with the deflate method, reducing the size of the output file. By default, files are stored uncompressed in the archive.

`--compress` has no effect when copying an archive.

在 3.7 版被加入。

**--info**

Display the interpreter embedded in the archive, for diagnostic purposes. In this case, any other options are ignored and `SOURCE` must be an archive, not a directory.

**-h**, **--help**

Print a short usage message and exit.

### 29.3.3 Python API

The module defines two convenience functions:

`zipapp.create_archive(source, target=None, interpreter=None, main=None, filter=None, compressed=False)`

Create an application archive from *source*. The source can be any of the following:

- The name of a directory, or a *path-like object* referring to a directory, in which case a new application archive will be created from the content of that directory.
- The name of an existing application archive file, or a *path-like object* referring to such a file, in which case the file is copied to the target (modifying it to reflect the value given for the *interpreter* argument). The file name should include the `.pyz` extension, if required.
- A file object open for reading in bytes mode. The content of the file should be an application archive, and the file object is assumed to be positioned at the start of the archive.

The *target* argument determines where the resulting archive will be written:

- If it is the name of a file, or a *path-like object*, the archive will be written to that file.
- If it is an open file object, the archive will be written to that file object, which must be open for writing in bytes mode.
- If the target is omitted (or `None`), the source must be a directory and the target will be a file with the same name as the source, with a `.pyz` extension added.

The *interpreter* argument specifies the name of the Python interpreter with which the archive will be executed. It is written as a "shebang" line at the start of the archive. On POSIX, this will be interpreted by the OS, and on Windows it will be handled by the Python launcher. Omitting the *interpreter* results in no shebang line being written. If an interpreter is specified, and the target is a filename, the executable bit of the target file will be set.

The *main* argument specifies the name of a callable which will be used as the main program for the archive. It can only be specified if the source is a directory, and the source does not already contain a `__main__.py` file. The *main* argument should take the form `"pkg.module:callable"` and the archive will be run by importing `"pkg.module"` and executing the given callable with no arguments. It is an error to omit *main* if the source is a directory and does not contain a `__main__.py` file, as otherwise the resulting archive would not be executable.

The optional *filter* argument specifies a callback function that is passed a `Path` object representing the path to the file being added (relative to the source directory). It should return `True` if the file is to be added.

The optional *compressed* argument determines whether files are compressed. If set to `True`, files in the archive are compressed with the deflate method; otherwise, files are stored uncompressed. This argument has no effect when copying an existing archive.

If a file object is specified for *source* or *target*, it is the caller's responsibility to close it after calling `create_archive`.

When copying an existing archive, file objects supplied only need `read` and `readline`, or `write` methods. When creating an archive from a directory, if the target is a file object it will be passed to the `zipfile.ZipFile` class, and must supply the methods needed by that class.

在 3.7 版的變更: 新增 *filter* 與 *compressed* 參數。

`zipapp.get_interpreter (archive)`

Return the interpreter specified in the `#!` line at the start of the archive. If there is no `#!` line, return `None`. The *archive* argument can be a filename or a file-like object open for reading in bytes mode. It is assumed to be at the start of the archive.

### 29.3.4 范例

Pack up a directory into an archive, and run it.

```
$ python -m zipapp myapp
$ python myapp.pyz
<output from myapp>
```

The same can be done using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('myapp', 'myapp.pyz')
```

To make the application directly executable on POSIX, specify an interpreter to use.

```
$ python -m zipapp myapp -p "/usr/bin/env python"
$ ./myapp.pyz
<output from myapp>
```

To replace the shebang line on an existing archive, create a modified archive using the `create_archive()` function:

```
>>> import zipapp
>>> zipapp.create_archive('old_archive.pyz', 'new_archive.pyz', '/usr/bin/python3')
```

To update the file in place, do the replacement in memory using a `BytesIO` object, and then overwrite the source afterwards. Note that there is a risk when overwriting a file in place that an error will result in the loss of the original file. This code does not protect against such errors, but production code should do so. Also, this method will only work if the archive fits in memory:

```
>>> import zipapp
>>> import io
>>> temp = io.BytesIO()
>>> zipapp.create_archive('myapp.pyz', temp, '/usr/bin/python2')
>>> with open('myapp.pyz', 'wb') as f:
>>>     f.write(temp.getvalue())
```

### 29.3.5 Specifying the Interpreter

Note that if you specify an interpreter and then distribute your application archive, you need to ensure that the interpreter used is portable. The Python launcher for Windows supports most common forms of POSIX `#!` line, but there are other issues to consider:

- If you use `"/usr/bin/env python"` (or other forms of the `"python"` command, such as `"/usr/bin/python"`), you need to consider that your users may have either Python 2 or Python 3 as their default, and write your code to work under both versions.
- If you use an explicit version, for example `"/usr/bin/env python3"` your application will not work for users who do not have that version. (This may be what you want if you have not made your code Python 2 compatible).
- There is no way to say `"python X.Y or later"`, so be careful of using an exact version like `"/usr/bin/env python3.4"` as you will need to change your shebang line for users of Python 3.5, for example.

Typically, you should use an `"/usr/bin/env python2"` or `"/usr/bin/env python3"`, depending on whether your code is written for Python 2 or 3.

### 29.3.6 Creating Standalone Applications with zipapp

Using the `zipapp` module, it is possible to create self-contained Python programs, which can be distributed to end users who only need to have a suitable version of Python installed on their system. The key to doing this is to bundle all of the application's dependencies into the archive, along with the application code.

The steps to create a standalone archive are as follows:

1. Create your application in a directory as normal, so you have a `myapp` directory containing a `__main__.py` file, and any supporting application code.
2. Install all of your application's dependencies into the `myapp` directory, using `pip`:

```
$ python -m pip install -r requirements.txt --target myapp
```

(this assumes you have your project requirements in a `requirements.txt` file - if not, you can just list the dependencies manually on the `pip` command line).

3. Package the application using:

```
$ python -m zipapp -p "interpreter" myapp
```

This will produce a standalone executable, which can be run on any machine with the appropriate interpreter available. See *Specifying the Interpreter* for details. It can be shipped to users as a single file.

On Unix, the `myapp.pyz` file is executable as it stands. You can rename the file to remove the `.pyz` extension if you prefer a "plain" command name. On Windows, the `myapp.pyz[w]` file is executable by virtue of the fact that the Python interpreter registers the `.pyz` and `.pyzw` file extensions when installed.

#### Caveats

If your application depends on a package that includes a C extension, that package cannot be run from a zip file (this is an OS limitation, as executable code must be present in the filesystem for the OS loader to load it). In this case, you can exclude that dependency from the zipfile, and either require your users to have it installed, or ship it alongside your zipfile and add code to your `__main__.py` to include the directory containing the unzipped module in `sys.path`. In this case, you will need to make sure to ship appropriate binaries for your target architecture(s) (and potentially pick the correct version to add to `sys.path` at runtime, based on the user's machine).

### 29.3.7 The Python Zip Application Archive Format

Python has been able to execute zip files which contain a `__main__.py` file since version 2.6. In order to be executed by Python, an application archive simply has to be a standard zip file containing a `__main__.py` file which will be run as the entry point for the application. As usual for any Python script, the parent of the script (in this case the zip file) will be placed on `sys.path` and thus further modules can be imported from the zip file.

The zip file format allows arbitrary data to be prepended to a zip file. The zip application format uses this ability to prepend a standard POSIX "shebang" line to the file (`#!/path/to/interpreter`).

Formally, the Python zip application format is therefore:

1. An optional shebang line, containing the characters `b'#!'` followed by an interpreter name, and then a newline (`b'\n'`) character. The interpreter name can be anything acceptable to the OS "shebang" processing, or the Python launcher on Windows. The interpreter should be encoded in UTF-8 on Windows, and in `sys.getfilesystemencoding()` on POSIX.
2. Standard zipfile data, as generated by the `zipfile` module. The zipfile content *must* include a file called `__main__.py` (which must be in the "root" of the zipfile - i.e., it cannot be in a subdirectory). The zipfile data can be compressed or uncompressed.

If an application archive has a shebang line, it may have the executable bit set on POSIX systems, to allow it to be executed directly.

There is no requirement that the tools in this module are used to create application archives - the module is a convenience, but archives in the above format created by any means are acceptable to Python.

The modules described in this chapter provide a wide range of services related to the Python interpreter and its interaction with its environment. Here's an overview:

## 30.1 `sys` --- 系統特定的參數與函式

This module provides access to some variables used or maintained by the interpreter and to functions that interact strongly with the interpreter. It is always available. Unless explicitly noted otherwise, all variables are read-only.

### `sys.abiflags`

On POSIX systems where Python was built with the standard `configure` script, this contains the ABI flags as specified by [PEP 3149](#).

在 3.2 版被加入。

在 3.8 版的變更: Default flags became an empty string (m flag for pymalloc has been removed).

適用: Unix.

### `sys.addaudithook(hook)`

Append the callable *hook* to the list of active auditing hooks for the current (sub)interpreter.

When an auditing event is raised through the `sys.audit()` function, each hook will be called in the order it was added with the event name and the tuple of arguments. Native hooks added by `PySys_AddAuditHook()` are called first, followed by hooks added in the current (sub)interpreter. Hooks can then log the event, raise an exception to abort the operation, or terminate the process entirely.

Note that audit hooks are primarily for collecting information about internal or otherwise unobservable actions, whether by Python or libraries written in Python. They are not suitable for implementing a "sandbox". In particular, malicious code can trivially disable or bypass hooks added using this function. At a minimum, any security-sensitive hooks must be added using the C API `PySys_AddAuditHook()` before initialising the runtime, and any modules allowing arbitrary memory modification (such as `ctypes`) should be completely removed or closely monitored.

呼叫 `sys.addaudithook()` 本身會引發一個不帶任何引數、名 `sys.addaudithook` 的稽核事件。如果任何現有的 `hook` 引發從 `RuntimeError` 衍生的例外，則不會添加新的 `hook` 以抑制異常。因此，除非呼叫者控制所有已存在的 `hook`，他們不能假設他們的 `hook` 已被添加。

所有會被 CPython 所引發的事件請參考稽核事件總表、設計相關討論請見 [PEP 578](#)。

在 3.8 版被加入。

在 3.8.1 版的變更: Exceptions derived from *Exception* but not *RuntimeError* are no longer suppressed.

**CPython 實作細節:** When tracing is enabled (see *settrace()*), Python hooks are only traced if the callable has a `__cantrace__` member that is set to a true value. Otherwise, trace functions will skip the hook.

#### `sys.argv`

The list of command line arguments passed to a Python script. `argv[0]` is the script name (it is operating system dependent whether this is a full pathname or not). If the command was executed using the `-c` command line option to the interpreter, `argv[0]` is set to the string `'-c'`. If no script name was passed to the Python interpreter, `argv[0]` is the empty string.

To loop over the standard input, or the list of files given on the command line, see the *fileinput* module.

另請參 `sys.orig_argv`。

#### 備

On Unix, command line arguments are passed by bytes from OS. Python decodes them with filesystem encoding and "surrogateescape" error handler. When you need original bytes, you can get it by `[os.fsencode(arg) for arg in sys.argv]`.

#### `sys.audit(event, *args)`

Raise an auditing event and trigger any active auditing hooks. *event* is a string identifying the event, and *args* may contain optional arguments with more information about the event. The number and types of arguments for a given event are considered a public and stable API and should not be modified between releases.

舉例來，一個名 `os.chdir` 的稽核事件擁有一個引數 *path*，其容所要求的新工作目。

`sys.audit()` will call the existing auditing hooks, passing the event name and arguments, and will re-raise the first exception from any hook. In general, if an exception is raised, it should not be handled and the process should be terminated as quickly as possible. This allows hook implementations to decide how to respond to particular events: they can merely log the event or abort the operation by raising an exception.

Hooks are added using the `sys.addaudithook()` or `PySys_AddAuditHook()` functions.

The native equivalent of this function is `PySys_Audit()`. Using the native function is preferred when possible.

所有會被 CPython 所引發的事件請參考稽核事件總表。

在 3.8 版被加入。

#### `sys.base_exec_prefix`

Set during Python startup, before `site.py` is run, to the same value as *exec\_prefix*. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of *prefix* and *exec\_prefix* will be changed to point to the virtual environment, whereas *base\_prefix* and *base\_exec\_prefix* will remain pointing to the base Python installation (the one which the virtual environment was created from).

在 3.3 版被加入。

#### `sys.base_prefix`

Set during Python startup, before `site.py` is run, to the same value as *prefix*. If not running in a *virtual environment*, the values will stay the same; if `site.py` finds that a virtual environment is in use, the values of *prefix* and *exec\_prefix* will be changed to point to the virtual environment, whereas *base\_prefix* and *base\_exec\_prefix* will remain pointing to the base Python installation (the one which the virtual environment was created from).

在 3.3 版被加入。

#### `sys.byteorder`

An indicator of the native byte order. This will have the value `'big'` on big-endian (most-significant byte first) platforms, and `'little'` on little-endian (least-significant byte first) platforms.

**sys.builtin\_module\_names**

A tuple of strings containing the names of all modules that are compiled into this Python interpreter. (This information is not available in any other way --- `modules.keys()` only lists the imported modules.)

另請參閱 `sys.stdlib_module_names` 清單。

**sys.call\_tracing(func, args)**

Call `func(*args)`, while tracing is enabled. The tracing state is saved, and restored afterwards. This is intended to be called from a debugger from a checkpoint, to recursively debug or profile some other code.

Tracing is suspended while calling a tracing function set by `settrace()` or `setprofile()` to avoid infinite recursion. `call_tracing()` enables explicit recursion of the tracing function.

**sys.copyright**

A string containing the copyright pertaining to the Python interpreter.

**sys.\_clear\_type\_cache()**

Clear the internal type cache. The type cache is used to speed up attribute and method lookups. Use the function *only* to drop unnecessary references during reference leak debugging.

This function should be used for internal and specialized purposes only.

在 3.13 版之後被禁用: Use the more general `_clear_internal_caches()` function instead.

**sys.\_clear\_internal\_caches()**

Clear all internal performance-related caches. Use this function *only* to release unnecessary references and memory blocks when hunting for leaks.

在 3.13 版被加入。

**sys.\_current\_frames()**

Return a dictionary mapping each thread's identifier to the topmost stack frame currently active in that thread at the time the function is called. Note that functions in the `traceback` module can build the call stack given such a frame.

This is most useful for debugging deadlock: this function does not require the deadlocked threads' cooperation, and such threads' call stacks are frozen for as long as they remain deadlocked. The frame returned for a non-deadlocked thread may bear no relationship to that thread's current activity by the time calling code examines the frame.

This function should be used for internal and specialized purposes only.

引發一個不附帶引數的稽核事件 `sys._current_frames`。

**sys.\_current\_exceptions()**

Return a dictionary mapping each thread's identifier to the topmost exception currently active in that thread at the time the function is called. If a thread is not currently handling an exception, it is not included in the result dictionary.

This is most useful for statistical profiling.

This function should be used for internal and specialized purposes only.

引發一個不附帶引數的稽核事件 `sys._current_exceptions`。

在 3.12 版的變更: Each value in the dictionary is now a single exception instance, rather than a 3-tuple as returned from `sys.exc_info()`.

**sys.breakpointhook()**

This hook function is called by built-in `breakpoint()`. By default, it drops you into the `pdb` debugger, but it can be set to any other function so that you can choose which debugger gets used.

The signature of this function is dependent on what it calls. For example, the default binding (e.g. `pdb.set_trace()`) expects no arguments, but you might bind it to a function that expects additional arguments (positional and/or keyword). The built-in `breakpoint()` function passes its `*args` and `**kws` straight through. Whatever `breakpointhooks()` returns is returned from `breakpoint()`.

The default implementation first consults the environment variable `PYTHONBREAKPOINT`. If that is set to `"0"` then this function returns immediately; i.e. it is a no-op. If the environment variable is not set, or is set to the empty string, `pdb.set_trace()` is called. Otherwise this variable should name a function to run, using Python's dotted-import nomenclature, e.g. `package.subpackage.module.function`. In this case, `package.subpackage.module` would be imported and the resulting module must have a callable named `function()`. This is run, passing in `*args` and `**kws`, and whatever `function()` returns, `sys.breakpointhook()` returns to the built-in `breakpoint()` function.

Note that if anything goes wrong while importing the callable named by `PYTHONBREAKPOINT`, a `RuntimeWarning` is reported and the breakpoint is ignored.

Also note that if `sys.breakpointhook()` is overridden programmatically, `PYTHONBREAKPOINT` is *not* consulted.

在 3.7 版被加入。

`sys._debugmallocstats()`

Print low-level information to `stderr` about the state of CPython's memory allocator.

If Python is built in debug mode (configure `--with-pydebug` option), it also performs some expensive internal consistency checks.

在 3.3 版被加入。

**CPython 實作細節：** This function is specific to CPython. The exact output format is not defined here, and may change.

`sys.dllhandle`

Integer specifying the handle of the Python DLL.

適用: Windows.

`sys.displayhook(value)`

If `value` is not `None`, this function prints `repr(value)` to `sys.stdout`, and saves `value` in `builtins._`. If `repr(value)` is not encodable to `sys.stdout.encoding` with `sys.stdout.errors` error handler (which is probably `'strict'`), encode it to `sys.stdout.encoding` with `'backslashreplace'` error handler.

`sys.displayhook` is called on the result of evaluating an *expression* entered in an interactive Python session. The display of these values can be customized by assigning another one-argument function to `sys.displayhook`.

Pseudo-code:

```
def displayhook(value):
    if value is None:
        return
    # Set '_' to None to avoid recursion
    builtins._ = None
    text = repr(value)
    try:
        sys.stdout.write(text)
    except UnicodeEncodeError:
        bytes = text.encode(sys.stdout.encoding, 'backslashreplace')
        if hasattr(sys.stdout, 'buffer'):
            sys.stdout.buffer.write(bytes)
        else:
            text = bytes.decode(sys.stdout.encoding, 'strict')
            sys.stdout.write(text)
    sys.stdout.write("\n")
    builtins._ = value
```

在 3.2 版的變更: Use `'backslashreplace'` error handler on `UnicodeEncodeError`.

**sys.dont\_write\_bytecode**

If this is true, Python won't try to write `.pyc` files on the import of source modules. This value is initially set to `True` or `False` depending on the `-B` command line option and the `PYTHONDONTWRITEBYTECODE` environment variable, but you can set it yourself to control bytecode file generation.

**sys.\_emscripten\_info**

A *named tuple* holding information about the environment on the *wasm32-emscripten* platform. The named tuple is provisional and may change in the future.

**\_emscripten\_info.emscripten\_version**

Emscripten version as tuple of ints (major, minor, micro), e.g. (3, 1, 8).

**\_emscripten\_info.runtime**

運行環境字串，例如 瀏覽器使用者代理 (browser user agent) `'Node.js v14.18.2'` 或 `'UNKNOWN'`。

**\_emscripten\_info.pthreads**

True if Python is compiled with Emscripten pthreads support.

**\_emscripten\_info.shared\_memory**

True if Python is compiled with shared memory support.

適用: Emscripten.

在 3.11 版被加入。

**sys.pycache\_prefix**

If this is set (not `None`), Python will write bytecode-cache `.pyc` files to (and read them from) a parallel directory tree rooted at this directory, rather than from `__pycache__` directories in the source code tree. Any `__pycache__` directories in the source code tree will be ignored and new `.pyc` files written within the pycache prefix. Thus if you use `compileall` as a pre-build step, you must ensure you run it with the same pycache prefix (if any) that you will use at runtime.

A relative path is interpreted relative to the current working directory.

This value is initially set based on the value of the `-X pycache_prefix=PATH` command-line option or the `PYTHONPYCACHEPREFIX` environment variable (command-line takes precedence). If neither are set, it is `None`.

在 3.8 版被加入。

**sys.excepthook** (*type, value, traceback*)

This function prints out a given traceback and exception to `sys.stderr`.

When an exception other than `SystemExit` is raised and uncaught, the interpreter calls `sys.excepthook` with three arguments, the exception class, exception instance, and a traceback object. In an interactive session this happens just before control is returned to the prompt; in a Python program this happens just before the program exits. The handling of such top-level exceptions can be customized by assigning another three-argument function to `sys.excepthook`.

Raise an auditing event `sys.excepthook` with arguments `hook, type, value, traceback` when an uncaught exception occurs. If no hook has been set, `hook` may be `None`. If any hook raises an exception derived from `RuntimeError` the call to the hook will be suppressed. Otherwise, the audit hook exception will be reported as unraisable and `sys.excepthook` will be called.

**也參考**

The `sys.unraisablehook()` function handles unraisable exceptions and the `threading.excepthook()` function handles exception raised by `threading.Thread.run()`.

**sys.\_\_breakpointhook\_\_**

`sys.__displayhook__`

`sys.__excepthook__`

`sys.__unraisablehook__`

These objects contain the original values of `breakpointhook`, `displayhook`, `excepthook`, and `unraisablehook` at the start of the program. They are saved so that `breakpointhook`, `displayhook` and `excepthook`, `unraisablehook` can be restored in case they happen to get replaced with broken or alternative objects.

在 3.7 版被加入: `__breakpointhook__`

在 3.8 版被加入: `__unraisablehook__`

`sys.exception()`

This function, when called while an exception handler is executing (such as an `except` or `except*` clause), returns the exception instance that was caught by this handler. When exception handlers are nested within one another, only the exception handled by the innermost handler is accessible.

If no exception handler is executing, this function returns `None`.

在 3.11 版被加入.

`sys.exc_info()`

This function returns the old-style representation of the handled exception. If an exception `e` is currently handled (so `exception()` would return `e`), `exc_info()` returns the tuple `(type(e), e, e.__traceback__)`. That is, a tuple containing the type of the exception (a subclass of `BaseException`), the exception itself, and a traceback object which typically encapsulates the call stack at the point where the exception last occurred.

If no exception is being handled anywhere on the stack, this function return a tuple containing three `None` values.

在 3.11 版的變更: The `type` and `traceback` fields are now derived from the `value` (the exception instance), so when an exception is modified while it is being handled, the changes are reflected in the results of subsequent calls to `exc_info()`.

`sys.exec_prefix`

A string giving the site-specific directory prefix where the platform-dependent Python files are installed; by default, this is also `'/usr/local'`. This can be set at build time with the `--exec-prefix` argument to the `configure` script. Specifically, all configuration files (e.g. the `pyconfig.h` header file) are installed in the directory `exec_prefix/lib/pythonX.Y/config`, and shared library modules are installed in `exec_prefix/lib/pythonX.Y/lib-dynload`, where `X.Y` is the version number of Python, for example 3.2.

 備 備

If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_exec_prefix`.

`sys.executable`

A string giving the absolute path of the executable binary for the Python interpreter, on systems where this makes sense. If Python is unable to retrieve the real path to its executable, `sys.executable` will be an empty string or `None`.

`sys.exit([arg])`

Raise a `SystemExit` exception, signaling an intention to exit the interpreter.

The optional argument `arg` can be an integer giving the exit status (defaulting to zero), or another type of object. If it is an integer, zero is considered "successful termination" and any nonzero value is considered "abnormal termination" by shells and the like. Most systems require it to be in the range 0--127, and produce undefined results otherwise. Some systems have a convention for assigning specific meanings to specific exit codes, but these are generally underdeveloped; Unix programs generally use 2 for command line syntax errors and 1 for all

other kind of errors. If another type of object is passed, `None` is equivalent to passing zero, and any other object is printed to `stderr` and results in an exit code of 1. In particular, `sys.exit("some error message")` is a quick way to exit a program when an error occurs.

Since `exit()` ultimately "only" raises an exception, it will only exit the process when called from the main thread, and the exception is not intercepted. Cleanup actions specified by finally clauses of `try` statements are honored, and it is possible to intercept the exit attempt at an outer level.

在 3.6 版的變更: If an error occurs in the cleanup after the Python interpreter has caught `SystemExit` (such as an error flushing buffered data in the standard streams), the exit status is changed to 120.

#### `sys.flags`

The *named tuple flags* exposes the status of command line flags. The attributes are read only.

<code>flags.debug</code>	<code>-d</code>
<code>flags.inspect</code>	<code>-i</code>
<code>flags.interactive</code>	<code>-i</code>
<code>flags.isolated</code>	<code>-I</code>
<code>flags.optimize</code>	<code>-O</code> 或 <code>-OO</code>
<code>flags.dont_write_bytecode</code>	<code>-B</code>
<code>flags.no_user_site</code>	<code>-s</code>
<code>flags.no_site</code>	<code>-S</code>
<code>flags.ignore_environment</code>	<code>-E</code>
<code>flags.verbose</code>	<code>-v</code>
<code>flags.bytes_warning</code>	<code>-b</code>
<code>flags.quiet</code>	<code>-q</code>
<code>flags.hash_randomization</code>	<code>-R</code>
<code>flags.dev_mode</code>	<code>-X dev</code> ( <i>Python 開發模式</i> )
<code>flags.utf8_mode</code>	<code>-X utf8</code>
<code>flags.safe_path</code>	<code>-P</code>
<code>flags.int_max_str_digits</code>	<code>-X int_max_str_digits</code> ( <i>integer string conversion length limitation</i> )
<code>flags.warn_default_encoding</code>	<code>-X warn_default_encoding</code>

在 3.2 版的變更: 新增 `quiet` 屬性, 用於新的 `-q` 旗標。

在 3.2.3 版被加入: `hash_randomization` 屬性。

在 3.3 版的變更: 移除過時的 `division_warning` 屬性。

在 3.4 版的變更: 新增 `isolated` 屬性, 用於 `-I isolated` 旗標。

在 3.7 版的變更: Added the `dev_mode` attribute for the new *Python Development Mode* and the `utf8_mode` attribute for the new `-X utf8` flag.

在 3.10 版的變更: 新增 `warn_default_encoding` 屬性, 用於 `-X warn_default_encoding` 旗標。

在 3.11 版的變更: 新增 `safe_path` 屬性, 用於 `-P` 選項。

在 3.11 版的變更: 新增 `int_max_str_digits` 屬性。

#### `sys.float_info`

A *named tuple* holding information about the float type. It contains low level information about the precision and internal representation. The values correspond to the various floating-point constants defined in the standard header file `float.h` for the 'C' programming language; see section 5.2.4.2.2 of the 1999 ISO/IEC C standard [C99], 'Characteristics of floating types', for details.

表格 1: Attributes of the `float_info` named tuple

屬性	float.h macro	解釋
<code>float_info.epsilon</code>	DBL_EPSILON	difference between 1.0 and the least value greater than 1.0 that is representable as a float. 另請參 F <code>math.ulp()</code> 。
<code>float_info.dig</code>	DBL_DIG	The maximum number of decimal digits that can be faithfully represented in a float; see below.
<code>float_info.mant_dig</code>	DBL_MANT_DIG	Float precision: the number of base-radix digits in the significand of a float.
<code>float_info.max</code>	DBL_MAX	The maximum representable positive finite float.
<code>float_info.max_exp</code>	DBL_MAX_EXP	The maximum integer $e$ such that $\text{radix}^{e-1}$ is a representable finite float.
<code>float_info.max_10_exp</code>	DBL_MAX_10_EXP	The maximum integer $e$ such that $10^{*e}$ is in the range of representable finite floats.
<code>float_info.min</code>	DBL_MIN	The minimum representable positive <i>normalized</i> float. Use <code>math.ulp(0.0)</code> to get the smallest positive <i>denormalized</i> representable float.
<code>float_info.min_exp</code>	DBL_MIN_EXP	The minimum integer $e$ such that $\text{radix}^{e-1}$ is a normalized float.
<code>float_info.min_10_exp</code>	DBL_MIN_10_EXP	The minimum integer $e$ such that $10^{*e}$ is a normalized float.
<code>float_info.radix</code>	FLT_RADIX	The radix of exponent representation.
<code>float_info.rounds</code>	FLT_ROUNDS	An integer representing the rounding mode for floating-point arithmetic. This reflects the value of the system <code>FLT_ROUNDS</code> macro at interpreter startup time: <ul style="list-style-type: none"> <li>• -1: indeterminate</li> <li>• 0: toward zero</li> <li>• 1: to nearest</li> <li>• 2: toward positive infinity</li> <li>• 3: toward negative infinity</li> </ul> All other values for <code>FLT_ROUNDS</code> characterize implementation-defined rounding behavior.

The attribute `sys.float_info.dig` needs further explanation. If  $s$  is any string representing a decimal number with at most `sys.float_info.dig` significant digits, then converting  $s$  to a float and back again will recover a string representing the same decimal value:

```
>>> import sys
>>> sys.float_info.dig
15
```

(繼續下一頁)

(繼續上一頁)

```
>>> s = '3.14159265358979'      # decimal string with 15 significant digits
>>> format(float(s), '.15g')  # convert to float and back -> same value
'3.14159265358979'
```

But for strings with more than `sys.float_info.dig` significant digits, this isn't always true:

```
>>> s = '9876543211234567'    # 16 significant digits is too many!
>>> format(float(s), '.16g')  # conversion changes value
'9876543211234568'
```

### `sys.float_repr_style`

A string indicating how the `repr()` function behaves for floats. If the string has value `'short'` then for a finite float `x`, `repr(x)` aims to produce a short string with the property that `float(repr(x)) == x`. This is the usual behaviour in Python 3.1 and later. Otherwise, `float_repr_style` has value `'legacy'` and `repr(x)` behaves in the same way as it did in versions of Python prior to 3.1.

在 3.1 版被加入。

### `sys.getallocatedblocks()`

Return the number of memory blocks currently allocated by the interpreter, regardless of their size. This function is mainly useful for tracking and debugging memory leaks. Because of the interpreter's internal caches, the result can vary from call to call; you may have to call `_clear_internal_caches()` and `gc.collect()` to get more predictable results.

If a Python build or implementation cannot reasonably compute this information, `getallocatedblocks()` is allowed to return 0 instead.

在 3.4 版被加入。

### `sys.getunicodeinternedsize()`

Return the number of unicode objects that have been interned.

在 3.12 版被加入。

### `sys.getandroidapilevel()`

Return the build-time API level of Android as an integer. This represents the minimum version of Android this build of Python can run on. For runtime version information, see `platform.android_ver()`.

適用: Android.

在 3.7 版被加入。

### `sys.getdefaultencoding()`

Return `'utf-8'`. This is the name of the default string encoding, used in methods like `str.encode()`.

### `sys.getdlopenflags()`

Return the current value of the flags that are used for `dlopen()` calls. Symbolic names for the flag values can be found in the `os` module (RTLD\_XXX constants, e.g. `os.RTLD_LAZY`).

適用: Unix.

### `sys.getfilesystemencoding()`

Get the *filesystem encoding*: the encoding used with the *filesystem error handler* to convert between Unicode filenames and bytes filenames. The filesystem error handler is returned from `getfilesystemencodeerrors()`.

For best compatibility, `str` should be used for filenames in all cases, although representing filenames as bytes is also supported. Functions accepting or returning filenames should support either `str` or bytes and internally convert to the system's preferred representation.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.2 版的變更: `getfilesystemencoding()` 的結果不再 `None`。

在 3.6 版的變更: Windows is no longer guaranteed to return `'mbcs'`. See [PEP 529](#) and `_enablelegacywindowsfsencoding()` for more information.

在 3.7 版的變更: Return `'utf-8'` if the *Python UTF-8 Mode* is enabled.

`sys.getfilesystemencodeerrors()`

Get the *filesystem error handler*: the error handler used with the *filesystem encoding* to convert between Unicode filenames and bytes filenames. The filesystem encoding is returned from `getfilesystemencoding()`.

`os.fsencode()` and `os.fsdecode()` should be used to ensure that the correct encoding and errors mode are used.

The *filesystem encoding and error handler* are configured at Python startup by the `PyConfig_Read()` function: see `filesystem_encoding` and `filesystem_errors` members of `PyConfig`.

在 3.6 版被加入。

`sys.get_int_max_str_digits()`

Returns the current value for the *integer string conversion length limitation*. See also `set_int_max_str_digits()`.

在 3.11 版被加入。

`sys.getrefcount(object)`

Return the reference count of the *object*. The count returned is generally one higher than you might expect, because it includes the (temporary) reference as an argument to `getrefcount()`.

Note that the returned value may not actually reflect how many references to the object are actually held. For example, some objects are *immortal* and have a very high refcount that does not reflect the actual number of references. Consequently, do not rely on the returned value to be accurate, other than a value of 0 or 1.

在 3.12 版的變更: Immortal objects have very large refcounts that do not match the actual number of references to the object.

`sys.getrecursionlimit()`

Return the current value of the recursion limit, the maximum depth of the Python interpreter stack. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python. It can be set by `setrecursionlimit()`.

`sys.getsizeof(object[, default])`

Return the size of an object in bytes. The object can be any type of object. All built-in objects will return correct results, but this does not have to hold true for third-party extensions as it is implementation specific.

Only the memory consumption directly attributed to the object is accounted for, not the memory consumption of objects it refers to.

If given, *default* will be returned if the object does not provide means to retrieve the size. Otherwise a `TypeError` will be raised.

`getsizeof()` calls the object's `__sizeof__` method and adds an additional garbage collector overhead if the object is managed by the garbage collector.

See [recursive sizeof recipe](#) for an example of using `getsizeof()` recursively to find the size of containers and all their contents.

`sys.getswitchinterval()`

Return the interpreter's "thread switch interval" in seconds; see `setswitchinterval()`.

在 3.2 版被加入。

`sys._getframe([depth])`

Return a frame object from the call stack. If optional integer *depth* is given, return the frame object that many calls below the top of the stack. If that is deeper than the call stack, `ValueError` is raised. The default for *depth* is zero, returning the frame at the top of the call stack.

引發一個附帶引數 *frame* 的稽核事件 `sys._getframe`。

**CPython 實作細節：** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys._getframemodulename([depth])`

Return the name of a module from the call stack. If optional integer *depth* is given, return the module that many calls below the top of the stack. If that is deeper than the call stack, or if the module is unidentifiable, `None` is returned. The default for *depth* is zero, returning the module at the top of the call stack.

引發一個附帶引數 *depth* 的稽核事件 `sys._getframemodulename`。

**CPython 實作細節：** This function should be used for internal and specialized purposes only. It is not guaranteed to exist in all implementations of Python.

`sys.getobjects(limit[, type])`

This function only exists if CPython was built using the specialized configure option `--with-trace-refs`. It is intended only for debugging garbage-collection issues.

Return a list of up to *limit* dynamically allocated Python objects. If *type* is given, only objects of that exact type (not subtypes) are included.

Objects from the list are not safe to use. Specifically, the result will include objects from all interpreters that share their object allocator state (that is, ones created with `PyInterpreterConfig.use_main_obmalloc` set to 1 or using `Py_NewInterpreter()`, and the main interpreter). Mixing objects from different interpreters may lead to crashes or other unexpected behavior.

**CPython 實作細節：** This function should be used for specialized purposes only. It is not guaranteed to exist in all implementations of Python.

在 3.13.1 版的變更: The result may include objects from other interpreters.

`sys.getprofile()`

Get the profiler function as set by `setprofile()`.

`sys.gettrace()`

Get the trace function as set by `settrace()`.

**CPython 實作細節：** The `gettrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

`sys.getwindowsversion()`

Return a named tuple describing the Windows version currently running. The named elements are *major*, *minor*, *build*, *platform*, *service\_pack*, *service\_pack\_minor*, *service\_pack\_major*, *suite\_mask*, *product\_type* and *platform\_version*. *service\_pack* contains a string, *platform\_version* a 3-tuple and all other values are integers. The components can also be accessed by name, so `sys.getwindowsversion()[0]` is equivalent to `sys.getwindowsversion().major`. For compatibility with prior versions, only the first 5 elements are retrievable by indexing.

*platform* will be 2 (`VER_PLATFORM_WIN32_NT`).

*product\_type* may be one of the following values:

Constant	含義
1 ( <code>VER_NT_WORKSTATION</code> )	The system is a workstation.
2 ( <code>VER_NT_DOMAIN_CONTROLLER</code> )	The system is a domain controller.
3 ( <code>VER_NT_SERVER</code> )	The system is a server, but not a domain controller.

This function wraps the Win32 `GetVersionEx()` function; see the Microsoft documentation on `OSVERSIONINFOEX()` for more information about these fields.

`platform_version` returns the major version, minor version and build number of the current operating system, rather than the version that is being emulated for the process. It is intended for use in logging rather than for feature detection.

**備 F**

`platform_version` derives the version from `kernel32.dll` which can be of a different version than the OS version. Please use `platform` module for achieving accurate OS version.

適用: Windows.

在 3.2 版的變更: Changed to a named tuple and added `service_pack_minor`, `service_pack_major`, `suite_mask`, and `product_type`.

在 3.6 版的變更: 新增 `platform_version`

`sys.get_asyncgen_hooks()`

Returns an `asyncgen_hooks` object, which is similar to a `namedtuple` of the form `(firstiter, finalizer)`, where `firstiter` and `finalizer` are expected to be either `None` or functions which take an *asynchronous generator iterator* as an argument, and are used to schedule finalization of an asynchronous generator by an event loop.

在 3.6 版被加入: 更多細節請見 [PEP 525](#)。

**備 F**

This function has been added on a provisional basis (see [PEP 411](#) for details.)

`sys.get_coroutine_origin_tracking_depth()`

Get the current coroutine origin tracking depth, as set by `set_coroutine_origin_tracking_depth()`.

在 3.7 版被加入。

**備 F**

This function has been added on a provisional basis (see [PEP 411](#) for details.) Use it only for debugging purposes.

`sys.hash_info`

A *named tuple* giving parameters of the numeric hash implementation. For more details about hashing of numeric types, see [數值型 F 的雜 F](#).

`hash_info.width`

The width in bits used for hash values

`hash_info.modulus`

The prime modulus P used for numeric hash scheme

`hash_info.inf`

The hash value returned for a positive infinity

`hash_info.nan`

(This attribute is no longer used)

`hash_info.imag`

The multiplier used for the imaginary part of a complex number

`hash_info.algorithm`

The name of the algorithm for hashing of str, bytes, and memoryview

`hash_info.hash_bits`

The internal output size of the hash algorithm

`hash_info.seed_bits`

The size of the seed key of the hash algorithm

在 3.2 版被加入。

在 3.4 版的變更: 新增 `algorithm`、`hash_bits` 與 `seed_bits`

`sys.hexversion`

The version number encoded as a single integer. This is guaranteed to increase with each version, including proper support for non-production releases. For example, to test that the Python interpreter is at least version 1.5.2, use:

```

if sys.hexversion >= 0x010502F0:
    # use some advanced feature
    ...
else:
    # use an alternative implementation or warn the user
    ...

```

This is called `hexversion` since it only really looks meaningful when viewed as the result of passing it to the built-in `hex()` function. The *named tuple* `sys.version_info` may be used for a more human-friendly encoding of the same information.

More details of `hexversion` can be found at [apiabiversion](#).

`sys.implementation`

An object containing information about the implementation of the currently running Python interpreter. The following attributes are required to exist in all Python implementations.

`name` is the implementation's identifier, e.g. 'cpython'. The actual string is defined by the Python implementation, but it is guaranteed to be lower case.

`version` is a named tuple, in the same format as `sys.version_info`. It represents the version of the Python *implementation*. This has a distinct meaning from the specific version of the Python *language* to which the currently running interpreter conforms, which `sys.version_info` represents. For example, for PyPy 1.8 `sys.implementation.version` might be `sys.version_info(1, 8, 0, 'final', 0)`, whereas `sys.version_info` would be `sys.version_info(2, 7, 2, 'final', 0)`. For CPython they are the same value, since it is the reference implementation.

`hexversion` is the implementation version in hexadecimal format, like `sys.hexversion`.

`cache_tag` is the tag used by the import machinery in the filenames of cached modules. By convention, it would be a composite of the implementation's name and version, like 'cpython-33'. However, a Python implementation may use some other value if appropriate. If `cache_tag` is set to `None`, it indicates that module caching should be disabled.

`sys.implementation` may contain additional attributes specific to the Python implementation. These non-standard attributes must start with an underscore, and are not described here. Regardless of its contents, `sys.implementation` will not change during a run of the interpreter, nor between implementation versions. (It may change between Python language versions, however.) See [PEP 421](#) for more information.

在 3.3 版被加入。

## 備 F

The addition of new required attributes must go through the normal PEP process. See [PEP 421](#) for more information.

`sys.int_info`

A *named tuple* that holds information about Python's internal representation of integers. The attributes are read only.

`int_info.bits_per_digit`

The number of bits held in each digit. Python integers are stored internally in base  $2^{**int\_info.bits\_per\_digit}$ .

`int_info.sizeof_digit`

The size in bytes of the C type used to represent a digit.

`int_info.default_max_str_digits`

The default value for `sys.get_int_max_str_digits()` when it is not otherwise explicitly configured.

`int_info.str_digits_check_threshold`

The minimum non-zero value for `sys.set_int_max_str_digits()`, `PYTHONINTMAXSTRDIGITS`, or `-X int_max_str_digits`.

在 3.1 版被加入。

在 3.11 版的變更: 新增 `default_max_str_digits` 和 `str_digits_check_threshold`。

`sys.__interactivehook__`

When this attribute exists, its value is automatically called (with no arguments) when the interpreter is launched in interactive mode. This is done after the `PYTHONSTARTUP` file is read, so that you can set this hook there. The `site` module *sets this*.

Raises an *auditing event* `cpython.run_interactivehook` with the hook object as the argument when the hook is called on startup.

在 3.4 版被加入。

`sys.intern(string)`

Enter *string* in the table of "interned" strings and return the interned string -- which is *string* itself or a copy. Interning strings is useful to gain a little performance on dictionary lookup -- if the keys in a dictionary are interned, and the lookup key is interned, the key comparisons (after hashing) can be done by a pointer compare instead of a string compare. Normally, the names used in Python programs are automatically interned, and the dictionaries used to hold module, class or instance attributes have interned keys.

Interned strings are not *immortal*; you must keep a reference to the return value of `intern()` around to benefit from it.

`sys._is_gil_enabled()`

Return *True* if the *GIL* is enabled and *False* if it is disabled.

在 3.13 版被加入。

`sys.is_finalizing()`

Return *True* if the main Python interpreter is *shutting down*. Return *False* otherwise.

See also the `PythonFinalizationError` exception.

在 3.5 版被加入。

`sys.last_exc`

This variable is not always defined; it is set to the exception instance when an exception is not handled and the interpreter prints an error message and a stack traceback. Its intended use is to allow an interactive user to import a debugger module and engage in post-mortem debugging without having to re-execute the command that caused the error. (Typical use is `import pdb; pdb.pm()` to enter the post-mortem debugger; see *pdb* module for more information.)

在 3.12 版被加入。

`sys._is_interned(string)`

Return *True* if the given string is "interned", *False* otherwise.

在 3.13 版被加入。

**CPython 實作細節：** It is not guaranteed to exist in all implementations of Python.

`sys.last_type``sys.last_value``sys.last_traceback`

These three variables are deprecated; use *sys.last\_exc* instead. They hold the legacy representation of *sys.last\_exc*, as returned from *exc\_info()* above.

`sys.maxsize`

An integer giving the maximum value a variable of type `Py_ssize_t` can take. It's usually  $2^{31} - 1$  on a 32-bit platform and  $2^{63} - 1$  on a 64-bit platform.

`sys.maxunicode`

An integer giving the value of the largest Unicode code point, i.e. 1114111 (0x10FFFF in hexadecimal).

在 3.3 版的變更: Before **PEP 393**, `sys.maxunicode` used to be either 0xFFFF or 0x10FFFF, depending on the configuration option that specified whether Unicode characters were stored as UCS-2 or UCS-4.

`sys.meta_path`

A list of *meta path finder* objects that have their *find\_spec()* methods called to see if one of the objects can find the module to be imported. By default, it holds entries that implement Python's default import semantics. The *find\_spec()* method is called with at least the absolute name of the module being imported. If the module to be imported is contained in a package, then the parent package's `__path__` attribute is passed in as a second argument. The method returns a *module spec*, or *None* if the module cannot be found.

 也參考
`importlib.abc.MetaPathFinder`

The abstract base class defining the interface of finder objects on *meta\_path*.

`importlib.machinery.ModuleSpec`

The concrete class which *find\_spec()* should return instances of.

在 3.4 版的變更: *Module specs* were introduced in Python 3.4, by **PEP 451**.

在 3.12 版的變更: Removed the fallback that looked for a *find\_module()* method if a *meta\_path* entry didn't have a *find\_spec()* method.

`sys.modules`

This is a dictionary that maps module names to modules which have already been loaded. This can be manipulated to force reloading of modules and other tricks. However, replacing the dictionary will not necessarily work as expected and deleting essential items from the dictionary may cause Python to fail. If you want to iterate over this global dictionary always use `sys.modules.copy()` or `tuple(sys.modules)` to avoid exceptions as its size may change during iteration as a side effect of code or activity in other threads.

**sys.orig\_argv**

The list of the original command line arguments passed to the Python executable.

The elements of `sys.orig_argv` are the arguments to the Python interpreter, while the elements of `sys.argv` are the arguments to the user's program. Arguments consumed by the interpreter itself will be present in `sys.orig_argv` and missing from `sys.argv`.

在 3.10 版被加入。

**sys.path**

A list of strings that specifies the search path for modules. Initialized from the environment variable `PYTHONPATH`, plus an installation-dependent default.

By default, as initialized upon program startup, a potentially unsafe path is prepended to `sys.path` (before the entries inserted as a result of `PYTHONPATH`):

- `python -m module` command line: prepend the current working directory.
- `python script.py` command line: prepend the script's directory. If it's a symbolic link, resolve symbolic links.
- `python -c code` and `python (REPL)` command lines: prepend an empty string, which means the current working directory.

To not prepend this potentially unsafe path, use the `-P` command line option or the `PYTHONSAFEPATH` environment variable.

A program is free to modify this list for its own purposes. Only strings should be added to `sys.path`; all other data types are ignored during import.

 **也參考**

- Module `site` This describes how to use `.pth` files to extend `sys.path`.

**sys.path\_hooks**

A list of callables that take a path argument to try to create a *finder* for the path. If a finder can be created, it is to be returned by the callable, else raise `ImportError`.

Originally specified in **PEP 302**.

**sys.path\_importer\_cache**

A dictionary acting as a cache for *finder* objects. The keys are paths that have been passed to `sys.path_hooks` and the values are the finders that are found. If a path is a valid file system path but no finder is found on `sys.path_hooks` then `None` is stored.

Originally specified in **PEP 302**.

**sys.platform**

A string containing a platform identifier. Known values are:

System	platform value
AIX	'aix'
Android	'android'
Emscripten	'emscripten'
iOS	'ios'
Linux	'linux'
macOS	'darwin'
Windows	'win32'
Windows/Cygwin	'cygwin'
WASI	'wasi'

On Unix systems not listed in the table, the value is the lowercased OS name as returned by `uname -s`, with the first part of the version as returned by `uname -r` appended, e.g. 'sunos5' or 'freebsd8', *at the time when Python was built*. Unless you want to test for a specific system version, it is therefore recommended to use the following idiom:

```
if sys.platform.startswith('freebsd'):
    # FreeBSD-specific code here...
```

在 3.3 版的變更: On Linux, `sys.platform` doesn't contain the major version anymore. It is always 'linux', instead of 'linux2' or 'linux3'.

在 3.8 版的變更: On AIX, `sys.platform` doesn't contain the major version anymore. It is always 'aix', instead of 'aix5' or 'aix7'.

在 3.13 版的變更: On Android, `sys.platform` now returns 'android' rather than 'linux'.

### 也參考

`os.name` has a coarser granularity. `os.uname()` gives system-dependent version information.

The `platform` module provides detailed checks for the system's identity.

### `sys.platlibdir`

Name of the platform-specific library directory. It is used to build the path of standard library and the paths of installed extension modules.

It is equal to "lib" on most platforms. On Fedora and SuSE, it is equal to "lib64" on 64-bit platforms which gives the following `sys.path` paths (where X.Y is the Python major.minor version):

- `/usr/lib64/pythonX.Y/`: Standard library (like `os.py` of the `os` module)
- `/usr/lib64/pythonX.Y/lib-dynload/`: C extension modules of the standard library (like the `errno` module, the exact filename is platform specific)
- `/usr/lib/pythonX.Y/site-packages/` (always use `lib`, not `sys.platlibdir`): Third-party modules
- `/usr/lib64/pythonX.Y/site-packages/`: C extension modules of third-party packages

在 3.9 版被加入。

### `sys.prefix`

A string giving the site-specific directory prefix where the platform independent Python files are installed; on Unix, the default is `/usr/local`. This can be set at build time with the `--prefix` argument to the `configure` script. See *Installation paths* for derived paths.

### 備 F

If a *virtual environment* is in effect, this value will be changed in `site.py` to point to the virtual environment. The value for the Python installation will still be available, via `base_prefix`.

### `sys.ps1`

### `sys.ps2`

Strings specifying the primary and secondary prompt of the interpreter. These are only defined if the interpreter is in interactive mode. Their initial values in this case are '`>>>`' and '`...`'. If a non-string object is assigned to either variable, its `str()` is re-evaluated each time the interpreter prepares to read a new interactive command; this can be used to implement a dynamic prompt.

### `sys.setdlopenflags(n)`

Set the flags used by the interpreter for `dlopen()` calls, such as when the interpreter loads extension modules.

Among other things, this will enable a lazy resolving of symbols when importing a module, if called as `sys.setdlopenflags(0)`. To share symbols across extension modules, call as `sys.setdlopenflags(os.RTLD_GLOBAL)`. Symbolic names for the flag values can be found in the `os` module (`RTLD_XXX` constants, e.g. `os.RTLD_LAZY`).

適用: Unix.

`sys.set_int_max_str_digits(maxdigits)`

Set the *integer string conversion length limitation* used by this interpreter. See also `get_int_max_str_digits()`.

在 3.11 版被加入。

`sys.setprofile(profilefunc)`

Set the system's profile function, which allows you to implement a Python source code profiler in Python. See chapter *Python 的分析器* for more information on the Python profiler. The system's profile function is called similarly to the system's trace function (see `settrace()`), but it is called with different events, for example it isn't called for each executed line of code (only on call and return, but the return event is reported even when an exception has been set). The function is thread-specific, but there is no way for the profiler to know about context switches between threads, so it does not make sense to use this in the presence of multiple threads. Also, its return value is not used, so it can simply return `None`. Error in the profile function will cause itself unset.

#### 備F

The same tracing mechanism is used for `setprofile()` as `settrace()`. To trace calls with `setprofile()` inside a tracing function (e.g. in a debugger breakpoint), see `call_tracing()`.

Profile functions should have three arguments: *frame*, *event*, and *arg*. *frame* is the current stack frame. *event* is a string: 'call', 'return', 'c\_call', 'c\_return', or 'c\_exception'. *arg* depends on the event type.

The events have the following meaning:

'call'

A function is called (or some other code block entered). The profile function is called; *arg* is `None`.

'return'

A function (or other code block) is about to return. The profile function is called; *arg* is the value that will be returned, or `None` if the event is caused by an exception being raised.

'c\_call'

A C function is about to be called. This may be an extension function or a built-in. *arg* is the C function object.

'c\_return'

A C function has returned. *arg* is the C function object.

'c\_exception'

A C function has raised an exception. *arg* is the C function object.

引發一個不附帶引數的稽核事件 `sys.setprofile`。

`sys.setrecursionlimit(limit)`

Set the maximum depth of the Python interpreter stack to *limit*. This limit prevents infinite recursion from causing an overflow of the C stack and crashing Python.

The highest possible limit is platform-dependent. A user may need to set the limit higher when they have a program that requires deep recursion and a platform that supports a higher limit. This should be done with care, because a too-high limit can lead to a crash.

If the new limit is too low at the current recursion depth, a `RecursionError` exception is raised.

在 3.5.1 版的變更: A `RecursionError` exception is now raised if the new limit is too low at the current recursion depth.

`sys.setswitchinterval(interval)`

Set the interpreter's thread switch interval (in seconds). This floating-point value determines the ideal duration of the "timeslices" allocated to concurrently running Python threads. Please note that the actual value can be higher, especially if long-running internal functions or methods are used. Also, which thread becomes scheduled at the end of the interval is the operating system's decision. The interpreter doesn't have its own scheduler.

在 3.2 版被加入。

`sys.settrace(tracefunc)`

Set the system's trace function, which allows you to implement a Python source code debugger in Python. The function is thread-specific; for a debugger to support multiple threads, it must register a trace function using `settrace()` for each thread being debugged or use `threading.settrace()`.

Trace functions should have three arguments: `frame`, `event`, and `arg`. `frame` is the current stack frame. `event` is a string: 'call', 'line', 'return', 'exception' or 'opcode'. `arg` depends on the event type.

The trace function is invoked (with `event` set to 'call') whenever a new local scope is entered; it should return a reference to a local trace function to be used for the new scope, or `None` if the scope shouldn't be traced.

The local trace function should return a reference to itself, or to another function which would then be used as the local trace function for the scope.

If there is any error occurred in the trace function, it will be unset, just like `settrace(None)` is called.

#### 備 F

Tracing is disabled while calling the trace function (e.g. a function set by `settrace()`). For recursive tracing see `call_tracing()`.

The events have the following meaning:

#### 'call'

A function is called (or some other code block entered). The global trace function is called; `arg` is `None`; the return value specifies the local trace function.

#### 'line'

The interpreter is about to execute a new line of code or re-execute the condition of a loop. The local trace function is called; `arg` is `None`; the return value specifies the new local trace function. See `Objects/lnotab_notes.txt` for a detailed explanation of how this works. Per-line events may be disabled for a frame by setting `f_trace_lines` to `False` on that frame.

#### 'return'

A function (or other code block) is about to return. The local trace function is called; `arg` is the value that will be returned, or `None` if the event is caused by an exception being raised. The trace function's return value is ignored.

#### 'exception'

An exception has occurred. The local trace function is called; `arg` is a tuple (`exception`, `value`, `traceback`); the return value specifies the new local trace function.

#### 'opcode'

The interpreter is about to execute a new opcode (see `dis` for opcode details). The local trace function is called; `arg` is `None`; the return value specifies the new local trace function. Per-opcode events are not emitted by default: they must be explicitly requested by setting `f_trace_opcodes` to `True` on the frame.

Note that as an exception is propagated down the chain of callers, an 'exception' event is generated at each level.

For more fine-grained usage, it's possible to set a trace function by assigning `frame.f_trace = tracefunc` explicitly, rather than relying on it being set indirectly via the return value from an already installed trace function. This is also required for activating the trace function on the current frame, which `settrace()` doesn't do. Note that in order for this to work, a global tracing function must have been installed with `settrace()` in order to enable the runtime tracing machinery, but it doesn't need to be the same tracing function (e.g. it could be a low overhead tracing function that simply returns `None` to disable itself immediately on each frame).

For more information on code and frame objects, refer to types.

引發一個不附帶引數的稽核事件 `sys.settrace`。

**CPython 實作細節：** The `settrace()` function is intended only for implementing debuggers, profilers, coverage tools and the like. Its behavior is part of the implementation platform, rather than part of the language definition, and thus may not be available in all Python implementations.

在 3.7 版的變更: 'opcode' event type added; `f_trace_lines` and `f_trace_opcodes` attributes added to frames

`sys.set_asyncgen_hooks` (*[firstiter]* [, *finalizer*])

Accepts two optional keyword arguments which are callables that accept an *asynchronous generator iterator* as an argument. The *firstiter* callable will be called when an asynchronous generator is iterated for the first time. The *finalizer* will be called when an asynchronous generator is about to be garbage collected.

引發一個不附帶引數的稽核事件 `sys.set_asyncgen_hooks_firstiter`。

引發一個不附帶引數的稽核事件 `sys.set_asyncgen_hooks_finalizer`。

Two auditing events are raised because the underlying API consists of two calls, each of which must raise its own event.

在 3.6 版被加入: See [PEP 525](#) for more details, and for a reference example of a *finalizer* method see the implementation of `asyncio.Loop.shutdown_asyncgens` in [Lib/asyncio/base\\_events.py](#)

**備 F**

This function has been added on a provisional basis (see [PEP 411](#) for details.)

`sys.set_coroutine_origin_tracking_depth` (*depth*)

Allows enabling or disabling coroutine origin tracking. When enabled, the `cr_origin` attribute on coroutine objects will contain a tuple of (filename, line number, function name) tuples describing the traceback where the coroutine object was created, with the most recent call first. When disabled, `cr_origin` will be `None`.

To enable, pass a *depth* value greater than zero; this sets the number of frames whose information will be captured. To disable, pass set *depth* to zero.

This setting is thread-specific.

在 3.7 版被加入。

**備 F**

This function has been added on a provisional basis (see [PEP 411](#) for details.) Use it only for debugging purposes.

`sys.activate_stack_trampoline` (*backend*, *l*)

Activate the stack profiler trampoline *backend*. The only supported backend is "perf".

適用: Linux.

在 3.12 版被加入。

### 也參考

- `perf_profiling`
- <https://perf.wiki.kernel.org>

`sys.deactivate_stack_trampoline()`

Deactivate the current stack profiler trampoline backend.

If no stack profiler is activated, this function has no effect.

適用: Linux.

在 3.12 版被加入。

`sys.is_stack_trampoline_active()`

Return `True` if a stack profiler trampoline is active.

適用: Linux.

在 3.12 版被加入。

`sys._enablelegacywindowsfsencoding()`

Changes the *filesystem encoding and error handler* to 'mbcs' and 'replace' respectively, for consistency with versions of Python prior to 3.6.

This is equivalent to defining the `PYTHONLEGACYWINDOWSFSENCODING` environment variable before launching Python.

See also `sys.getfilesystemencoding()` and `sys.getfilesystemencodeerrors()`.

適用: Windows.

### 備 F

Changing the filesystem encoding after Python startup is risky because the old fsencoding or paths encoded by the old fsencoding may be cached somewhere. Use `PYTHONLEGACYWINDOWSFSENCODING` instead.

在 3.6 版被加入: 更多細節請見 [PEP 529](#)。

Deprecated since version 3.13, will be removed in version 3.16: Use `PYTHONLEGACYWINDOWSFSENCODING` instead.

`sys.stdin`

`sys.stdout`

`sys.stderr`

*File objects* used by the interpreter for standard input, output and errors:

- `stdin` is used for all interactive input (including calls to `input()`);
- `stdout` is used for the output of `print()` and *expression* statements and for the prompts of `input()`;
- The interpreter's own prompts and its error messages go to `stderr`.

These streams are regular *text files* like those returned by the `open()` function. Their parameters are chosen as follows:

- The encoding and error handling are initialized from `PyConfig.stdio_encoding` and `PyConfig.stdio_errors`.

On Windows, UTF-8 is used for the console device. Non-character devices such as disk files and pipes use the system locale encoding (i.e. the ANSI codepage). Non-console character devices such as NUL (i.e. where `isatty()` returns `True`) use the value of the console input and output codepages at startup,

respectively for `stdin` and `stdout/stderr`. This defaults to the system *locale encoding* if the process is not initially attached to a console.

The special behaviour of the console can be overridden by setting the environment variable `PYTHONLEGACYWINDOWSSTDIO` before starting Python. In that case, the console codepages are used as for any other character device.

Under all platforms, you can override the character encoding by setting the `PYTHONIOENCODING` environment variable before starting Python or by using the new `-X utf8` command line option and `PYTHONUTF8` environment variable. However, for the Windows console, this only applies when `PYTHONLEGACYWINDOWSSTDIO` is also set.

- When interactive, the `stdout` stream is line-buffered. Otherwise, it is block-buffered like regular text files. The `stderr` stream is line-buffered in both cases. You can make both streams unbuffered by passing the `-u` command-line option or setting the `PYTHONUNBUFFERED` environment variable.

在 3.9 版的變更: Non-interactive `stderr` is now line-buffered instead of fully buffered.

#### 備 F

To write or read binary data from/to the standard streams, use the underlying binary *buffer* object. For example, to write bytes to `stdout`, use `sys.stdout.buffer.write(b'abc')`.

However, if you are writing a library (and do not control in which context its code will be executed), be aware that the standard streams may be replaced with file-like objects like `io.StringIO` which do not support the `buffer` attribute.

`sys.__stdin__`

`sys.__stdout__`

`sys.__stderr__`

These objects contain the original values of `stdin`, `stderr` and `stdout` at the start of the program. They are used during finalization, and could be useful to print to the actual standard stream no matter if the `sys.std*` object has been redirected.

It can also be used to restore the actual files to known working file objects in case they have been overwritten with a broken object. However, the preferred way to do this is to explicitly save the previous stream before replacing it, and restore the saved object.

#### 備 F

Under some conditions `stdin`, `stdout` and `stderr` as well as the original values `__stdin__`, `__stdout__` and `__stderr__` can be `None`. It is usually the case for Windows GUI apps that aren't connected to a console and Python apps started with `pythonw`.

`sys.stdlib_module_names`

A frozenset of strings containing the names of standard library modules.

It is the same on all platforms. Modules which are not available on some platforms and modules disabled at Python build are also listed. All module kinds are listed: pure Python, built-in, frozen and extension modules. Test modules are excluded.

For packages, only the main package is listed: sub-packages and sub-modules are not listed. For example, the `email` package is listed, but the `email.mime` sub-package and the `email.message` sub-module are not listed.

另請參閱 `sys.builtin_module_names` 清單。

在 3.10 版被加入。

`sys.thread_info`

A *named tuple* holding information about the thread implementation.

`thread_info.name`

The name of the thread implementation:

- "nt": Windows 執行緒
- "pthread": POSIX 執行緒
- "pthread-stubs": stub POSIX threads (on WebAssembly platforms without threading support)
- "solaris": Solaris threads

`thread_info.lock`

The name of the lock implementation:

- "semaphore": a lock uses a semaphore
- "mutex+cond": a lock uses a mutex and a condition variable
-  None 表示此資訊未知

`thread_info.version`

The name and version of the thread library. It is a string, or `None` if this information is unknown.

在 3.3 版被加入。

`sys.tracebacklimit`

When this variable is set to an integer value, it determines the maximum number of levels of traceback information printed when an unhandled exception occurs. The default is 1000. When set to 0 or less, all traceback information is suppressed and only the exception type and value are printed.

`sys.unraisablehook (unraisable, /)`

處理一個不可被引發的例外。

Called when an exception has occurred but there is no way for Python to handle it. For example, when a destructor raises an exception or during garbage collection (`gc.collect()`).

The *unraisable* argument has the following attributes:

- `exc_type`: 例外型 。
- `exc_value`: 例外值，可以  `None`。
- `exc_traceback`: 例外追 ，可以  `None`。
- `err_msg`: 錯誤訊息，可以  `None`。
- `object`: 導致例外的物件，可以  `None`。

The default hook formats `err_msg` and `object` as: `f'{err_msg}: {object!r}'`; use "Exception ignored in" error message if `err_msg` is `None`.

`sys.unraisablehook()` can be overridden to control how unraisable exceptions are handled.

 也參考

處理未被捕捉到例外的 `excepthook()`。

 警告

Storing `exc_value` using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing `object` using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing `object` after the custom hook completes to avoid resurrecting objects.

Raise an auditing event `sys.unraisablehook` with arguments `hook`, `unraisable` when an exception that cannot be handled occurs. The `unraisable` object is the same as what will be passed to the hook. If no hook has been set, `hook` may be `None`.

在 3.8 版被加入。

#### `sys.version`

A string containing the version number of the Python interpreter plus additional information on the build number and compiler used. This string is displayed when the interactive interpreter is started. Do not extract version information out of it, rather, use `version_info` and the functions provided by the `platform` module.

#### `sys.api_version`

The C API version for this interpreter. Programmers may find this useful when debugging version conflicts between Python and extension modules.

#### `sys.version_info`

A tuple containing the five components of the version number: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. The `version_info` value corresponding to the Python version 2.0 is (2, 0, 0, 'final', 0). The components can also be accessed by name, so `sys.version_info[0]` is equivalent to `sys.version_info.major` and so on.

在 3.1 版的變更: 新增了附名的元件屬性。

#### `sys.warnoptions`

This is an implementation detail of the warnings framework; do not modify this value. Refer to the `warnings` module for more information on the warnings framework.

#### `sys.winver`

The version number used to form registry keys on Windows platforms. This is stored as string resource 1000 in the Python DLL. The value is normally the major and minor versions of the running Python interpreter. It is provided in the `sys` module for informational purposes; modifying this value has no effect on the registry keys used by Python.

適用: Windows.

#### `sys.monitoring`

Namespace containing functions and constants for register callbacks and controlling monitoring events. See `sys.monitoring` for details.

#### `sys._xoptions`

A dictionary of the various implementation-specific flags passed through the `-X` command-line option. Option names are either mapped to their values, if given explicitly, or to `True`. Example:

```
$ ./python -Xa=b -Xc
Python 3.2a3+ (py3k, Oct 16 2010, 20:14:50)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> import sys
>>> sys._xoptions
{'a': 'b', 'c': True}
```

**CPython 實作細節:** This is a CPython-specific way of accessing options passed through `-X`. Other implementations may export them through other means, or not at all.

在 3.2 版被加入。

## 引用

## 30.2 sys.monitoring --- 執行事件監控

在 3.12 版被加入。

**備**

`sys.monitoring` 是 `sys` 模組的一個命名空間，不是一個獨立的模組，所以不需要 `import sys.monitoring`，只需 `import sys` 然後使用 `sys.monitoring`。

此命名空間提供對自動和控制事件監控所需的函式和常數的存取。

當程式執行時，會發生一些能被監控工具關注的事件。`sys.monitoring` 命名空間提供了在發生欲關注事件時接收回呼的方法。

監控 API 由三個元件組成：

- 工具識器
- 事件
- 回呼 (*callbacks*)

### 30.2.1 工具識器

工具識器是一個整數和關聯的名稱。工具識器用於防止工具相互干擾允許多個工具同時運作。目前工具是完全獨立的，不能用來互相監控。將來此限制可能會取消。

在啟動或自動事件之前，工具應選擇一個識器。識器是 0 到 5（含）範圍的整數。

#### 和工具

`sys.monitoring.use_tool_id(tool_id: int, name: str, /) → None`

必須在使用 `tool_id` 之前呼叫。`tool_id` 必須在 0 到 5（含）範圍。如果 `tool_id` 正在使用，則引發 `ValueError`。

`sys.monitoring.free_tool_id(tool_id: int, /) → None`

一旦工具不再需要 `tool_id` 就應該被呼叫。

**備**

`free_tool_id()` 不會停用與 `tool_id` 相關的全域或區域事件，也不會取消任何回呼函式。這個函式只是用來通知擬機器 (VM) 不再使用特定的 `tool_id`。

`sys.monitoring.get_tool(tool_id: int, /) → str | None`

如果 `tool_id` 正在使用，則回傳該工具的名稱，否則回傳 `None`。`tool_id` 必須在 0 到 5（含）範圍。

對於事件，擬機器對所有 ID 的處理都是相同的，但預先定義了以下 ID，以使工具間的協作更容易：

```
sys.monitoring.DEBUGGER_ID = 0
sys.monitoring.COVERAGE_ID = 1
sys.monitoring.PROFILER_ID = 2
sys.monitoring.OPTIMIZER_ID = 5
```

### 30.2.2 事件

支援以下事件：

`sys.monitoring.events.BRANCH`

取 (或不取) 一個條件分支。

`sys.monitoring.events.CALL`

Python 程式碼中的呼叫 (事件發生在呼叫之前)。

`sys.monitoring.events.C_RAISE`

從任何可呼叫物件引發的例外，除 Python 函式外 (事件發生在退出之後)。

`sys.monitoring.events.C_RETURN`

從任何可呼叫函式回傳，除 Python 函式外 (事件發生在回傳之後)。

`sys.monitoring.events.EXCEPTION_HANDLED`

一個例外被處理。

`sys.monitoring.events.INSTRUCTION`

擬機器指令即將被執行。

`sys.monitoring.events.JUMP`

在控制流程圖中進行無條件跳轉。

`sys.monitoring.events.LINE`

即將執行的指令與前一條指令的列號不同。

`sys.monitoring.events.PY_RESUME`

Python 函式的繼續執行 (對於生成器和協程函式)，除了 `throw()` 呼叫。

`sys.monitoring.events.PY_RETURN`

從 Python 函式回傳 (發生在即將回傳之前，被呼叫者的 frame 將位於堆上)。

`sys.monitoring.events.PY_START`

Python 函式的開始 (在呼叫後立即發生，被呼叫者的 frame 將位於堆上)。

`sys.monitoring.events.PY_THROW`

Python 函式透過 `throw()` 呼叫來繼續。

`sys.monitoring.events.PY_UNWIND`

在例外展開 (unwind) 期間從 Python 函式退出。

`sys.monitoring.events.PY_YIELD`

來自 Python 函式的 `yield` (在即將 `yield` 之前發生，被呼叫者的 frame 將位於堆上)。

`sys.monitoring.events.RAISE`

例外被引發，除了那些會導致 `STOP_ITERATION` 的事件外。

`sys.monitoring.events.RERAISE`

例外被重新引發 (re-raise)，例如在 `finally` 區塊的最後。

`sys.monitoring.events.STOP_ITERATION`

一個人工的 `StopIteration` 被引發；請參 `STOP_ITERATION` 事件。

將來可能會新增更多事件。

這些事件是 `sys.monitoring.events` 命名空間的屬性。每個事件以 2 次方的整數常數表示。要定義一組事件，只要將個事件以 bitwise or 相接即可。例如，若要指定 `PY_RETURN` 和 `PY_START` 兩個事件，請使用運算式 `PY_RETURN | PY_START`。

`sys.monitoring.events.NO_EVENTS`

0 的代名，以便使用者可以進行明確比較，例如：

```
if get_events(DEBUGGER_ID) == NO_EVENTS:
    ...
```

事件被分三組：

### 區域事件

區域事件與程式的正常執行相關，發生在明確定義的位置。所有區域事件都可以被停用。區域事件有：

- *PY\_START*
- *PY\_RESUME*
- *PY\_RETURN*
- *PY\_YIELD*
- *CALL*
- *LINE*
- *INSTRUCTION*
- *JUMP*
- *BRANCH*
- *STOP\_ITERATION*

### 附屬事件 (ancillary events)

附屬事件可以像其他事件一樣被監控，但由另一個事件所控制：

- *C\_RAISE*
- *C\_RETURN*

*C\_RETURN* 和 *C\_RAISE* 事件由 *CALL* 事件控制。只有當對應的 *CALL* 事件受到監控時，才會看到 *C\_RETURN* 和 *C\_RAISE* 事件。

### 其他事件

其他事件不一定與程式中的特定位置相關聯，也不能單獨停用。

其他可以監控的事件有：

- *PY\_THROW*
- *PY\_UNWIND*
- *RAISE*
- *EXCEPTION\_HANDLED*

### STOP\_ITERATION 事件

**PEP 380** 指出從生成器或協程回傳值時要引發 *StopIteration* 例外。然而，這是一種非常低效的回傳值方式，因此有一些 Python 實作（特別是 CPython 3.12+）不會引發例外，除非它對其他程式碼是可見的。

為了允許工具去監控真正的例外而不慢生成器和協程的速度，提供了 *STOP\_ITERATION* 事件。與 *RAISE* 不同，*STOP\_ITERATION* 可以區域停用。

### 30.2.3 開和關閉事件

為了監控一個事件，必須打開它相應的回呼。可以透過將事件設定全域或只特定程式碼物件來開或關閉事件。

## 全域設定事件

可以透過修改正在監控的事件集合來全域地控制事件。

```
sys.monitoring.get_events(tool_id: int, /) → int
```

回傳代表所有有效事件的 `int`。

```
sys.monitoring.set_events(tool_id: int, event_set: int, /) → None
```

啟動 `event_set` 中設定的所有事件。如果 `tool_id` 未正在被使用，則引發 `ValueError`。

預設有有效事件。

## 各程式碼物件事件

事件還可以基於各程式碼物件進行控制。下面定義的、接受 `types.CodeType` 的函式應該準備好接受來自 Python 中未定義函式的類似物件（請參 `c-api-monitoring`）。

```
sys.monitoring.get_local_events(tool_id: int, code: CodeType, /) → int
```

回傳 `code` 的所有區域事件

```
sys.monitoring.set_local_events(tool_id: int, code: CodeType, event_set: int, /) → None
```

啟動 `event_set` 中針對 `code` 設定的所有區域事件。如果 `tool_id` 未正在被使用，則引發 `ValueError`。

區域事件會加入到全域事件中，但不會掩蓋它們。句話，無論區域事件如何，所有全域事件都將程式碼物件觸發。

## 停用事件

```
sys.monitoring.DISABLE
```

可以從回呼函式回傳的特殊值，以停用當前程式碼位置的事件。

可透過回呼函式回傳 `sys.monitoring.DISABLE` 來停用特定程式碼位置的區域事件。這不會改變被設定的事件，或相同事件的任何其他程式碼位置。

停用特定位置的事件對於高效能監控非常重要。舉例來，如果除少數斷點外，偵錯器可以停用所有監控，那在偵錯器下執行程式就不會有任何開銷 (overhead)。

```
sys.monitoring.restart_events() → None
```

所有工具用由 `sys.monitoring.DISABLE` 停用的所有事件。

## 30.2.4 回呼函式

用來對事件呼叫的可呼叫物件

```
sys.monitoring.register_callback(tool_id: int, event: int, func: Callable | None, /) → Callable | None
```

使用給定的 `tool_id` 來對 `event` 的可呼叫物件 `func`

如果給定的 `tool_id` 和 `event` 已經了另一個回呼，則會取消回傳。否則 `register_callback()` 會回傳 `None`。

可以透過呼叫 `sys.monitoring.register_callback(tool_id, event, None)` 來取消回呼函式。

回呼函式可以隨時被和取消。

或取消回呼函式將生 `sys.audit()` 事件。

## 回呼函式引數

```
sys.monitoring.MISSING
```

傳遞給回呼函式的特殊值，表示該呼叫有引數。

當有效事件發生時，已的回呼函式會被呼叫。不同的事件會回呼函式提供不同的引數，如下所示：

- `PY_START` 和 `PY_RESUME`：

```
func(code: CodeType, instruction_offset: int) -> DISABLE | Any
```

- `PY_RETURN` 和 `PY_YIELD`:

```
func(code: CodeType, instruction_offset: int, retval: object) -> DISABLE | Any
```

- `CALL`、`C_RAISE` 和 `C_RETURN`:

```
func(code: CodeType, instruction_offset: int, callable: object, arg0: object | MISSING) -> DISABLE | Any
```

如果 有引數，`arg0` 將被設定 `sys.monitoring.MISSING`。

- `RAISE`、`RERAISE`、`EXCEPTION_HANDLED`、`PY_UNWIND`、`PY_THROW` 和 `STOP_ITERATION`:

```
func(code: CodeType, instruction_offset: int, exception: BaseException) -> DISABLE | Any
```

- `LINE`:

```
func(code: CodeType, line_number: int) -> DISABLE | Any
```

- `BRANCH` 和 `JUMP`:

```
func(code: CodeType, instruction_offset: int, destination_offset: int) -> DISABLE | Any
```

請注意，`destination_offset` 是程式碼接下來要執行的地方。對於未用的分支，這將是該分支之後的指令的偏移量。

- `INSTRUCTION`:

```
func(code: CodeType, instruction_offset: int) -> DISABLE | Any
```

## 30.3 sysconfig --- 提供 Python 設定資訊的存取

在 3.2 版被加入。

原始碼: [Lib/sysconfig](#)

The `sysconfig` module provides access to Python's configuration information like the list of installation paths and the configuration variables relevant for the current platform.

### 30.3.1 Configuration variables

A Python distribution contains a `Makefile` and a `pyconfig.h` header file that are necessary to build both the Python binary itself and third-party C extensions compiled using `setuptools`.

`sysconfig` puts all variables found in these files in a dictionary that can be accessed using `get_config_vars()` or `get_config_var()`.

Notice that on Windows, it's a much smaller set.

```
sysconfig.get_config_vars(*args)
```

With no arguments, return a dictionary of all configuration variables relevant for the current platform.

With arguments, return a list of values that result from looking up each argument in the configuration variable dictionary.

For each argument, if the value is not found, return `None`.

`sysconfig.get_config_var(name)`

Return the value of a single variable *name*. Equivalent to `get_config_vars().get(name)`.

If *name* is not found, return `None`.

用法範例:

```
>>> import sysconfig
>>> sysconfig.get_config_var('Py_ENABLE_SHARED')
0
>>> sysconfig.get_config_var('LIBDIR')
'/usr/local/lib'
>>> sysconfig.get_config_vars('AR', 'CXX')
['ar', 'g++']
```

### 30.3.2 Installation paths

Python uses an installation scheme that differs depending on the platform and on the installation options. These schemes are stored in `sysconfig` under unique identifiers based on the value returned by `os.name`. The schemes are used by package installers to determine where to copy files to.

Python currently supports nine schemes:

- *posix\_prefix*: scheme for POSIX platforms like Linux or macOS. This is the default scheme used when Python or a component is installed.
- *posix\_home*: scheme for POSIX platforms, when the *home* option is used. This scheme defines paths located under a specific home prefix.
- *posix\_user*: scheme for POSIX platforms, when the *user* option is used. This scheme defines paths located under the user's home directory (`site.USER_BASE`).
- *posix\_venv*: scheme for *Python virtual environments* on POSIX platforms; by default it is the same as *posix\_prefix*.
- *nt*: scheme for Windows. This is the default scheme used when Python or a component is installed.
- *nt\_user*: scheme for Windows, when the *user* option is used.
- *nt\_venv*: scheme for *Python virtual environments* on Windows; by default it is the same as *nt*.
- *venv*: a scheme with values from either *posix\_venv* or *nt\_venv* depending on the platform Python runs on.
- *osx\_framework\_user*: scheme for macOS, when the *user* option is used.

Each scheme is itself composed of a series of paths and each path has a unique identifier. Python currently uses eight paths:

- *stdlib*: directory containing the standard Python library files that are not platform-specific.
- *platstdlib*: directory containing the standard Python library files that are platform-specific.
- *platlib*: directory for site-specific, platform-specific files.
- *purelib*: directory for site-specific, non-platform-specific files ('pure' Python).
- *include*: directory for non-platform-specific header files for the Python C-API.
- *platinclude*: directory for platform-specific header files for the Python C-API.
- *scripts*: directory for script files.
- *data*: directory for data files.

### 30.3.3 User scheme

This scheme is designed to be the most convenient solution for users that don't have write permission to the global `site-packages` directory or don't want to install into it.

Files will be installed into subdirectories of `site.USER_BASE` (written as `userbase` hereafter). This scheme installs pure Python modules and extension modules in the same location (also known as `site.USER_SITE`).

#### `posix_user`

Path	Installation directory
<i>stdlib</i>	<code>userbase/lib/pythonX.Y</code>
<i>platstdlib</i>	<code>userbase/lib/pythonX.Y</code>
<i>platlib</i>	<code>userbase/lib/pythonX.Y/site-packages</code>
<i>purelib</i>	<code>userbase/lib/pythonX.Y/site-packages</code>
<i>include</i>	<code>userbase/include/pythonX.Y</code>
<i>scripts</i>	<code>userbase/bin</code>
<i>data</i>	<code>userbase</code>

#### `nt_user`

Path	Installation directory
<i>stdlib</i>	<code>userbase\PythonXY</code>
<i>platstdlib</i>	<code>userbase\PythonXY</code>
<i>platlib</i>	<code>userbase\PythonXY\site-packages</code>
<i>purelib</i>	<code>userbase\PythonXY\site-packages</code>
<i>include</i>	<code>userbase\PythonXY\Include</code>
<i>scripts</i>	<code>userbase\PythonXY\Scripts</code>
<i>data</i>	<code>userbase</code>

#### `osx_framework_user`

Path	Installation directory
<i>stdlib</i>	<code>userbase/lib/python</code>
<i>platstdlib</i>	<code>userbase/lib/python</code>
<i>platlib</i>	<code>userbase/lib/python/site-packages</code>
<i>purelib</i>	<code>userbase/lib/python/site-packages</code>
<i>include</i>	<code>userbase/include/pythonX.Y</code>
<i>scripts</i>	<code>userbase/bin</code>
<i>data</i>	<code>userbase</code>

### 30.3.4 Home scheme

The idea behind the "home scheme" is that you build and maintain a personal stash of Python modules. This scheme's name is derived from the idea of a "home" directory on Unix, since it's not unusual for a Unix user to make their home directory have a layout similar to `/usr/` or `/usr/local/`. This scheme can be used by anyone, regardless of the operating system they are installing for.

`posix_home`

Path	Installation directory
<i>stdlib</i>	<i>home/lib/python</i>
<i>platstdlib</i>	<i>home/lib/python</i>
<i>platlib</i>	<i>home/lib/python</i>
<i>purelib</i>	<i>home/lib/python</i>
<i>include</i>	<i>home/include/python</i>
<i>platinclude</i>	<i>home/include/python</i>
<i>scripts</i>	<i>home/bin</i>
<i>data</i>	<i>home</i>

### 30.3.5 Prefix scheme

The "prefix scheme" is useful when you wish to use one Python installation to perform the build/install (i.e., to run the setup script), but install modules into the third-party module directory of a different Python installation (or something that looks like a different Python installation). If this sounds a trifle unusual, it is---that's why the user and home schemes come before. However, there are at least two known cases where the prefix scheme will be useful.

First, consider that many Linux distributions put Python in `/usr`, rather than the more traditional `/usr/local`. This is entirely appropriate, since in those cases Python is part of "the system" rather than a local add-on. However, if you are installing Python modules from source, you probably want them to go in `/usr/local/lib/python2.X` rather than `/usr/lib/python2.X`.

Another possibility is a network filesystem where the name used to write to a remote directory is different from the name used to read it: for example, the Python interpreter accessed as `/usr/local/bin/python` might search for modules in `/usr/local/lib/python2.X`, but those modules would have to be installed to, say, `/mnt/@server/export/lib/python2.X`.

`posix_prefix`

Path	Installation directory
<i>stdlib</i>	<i>prefix/lib/pythonX.Y</i>
<i>platstdlib</i>	<i>prefix/lib/pythonX.Y</i>
<i>platlib</i>	<i>prefix/lib/pythonX.Y/site-packages</i>
<i>purelib</i>	<i>prefix/lib/pythonX.Y/site-packages</i>
<i>include</i>	<i>prefix/include/pythonX.Y</i>
<i>platinclude</i>	<i>prefix/include/pythonX.Y</i>

### 30.3.6 安裝路徑函式

`sysconfig` provides some functions to determine these installation paths.

`sysconfig.get_scheme_names()`

Return a tuple containing all schemes currently supported in `sysconfig`.

`sysconfig.get_default_scheme()`

Return the default scheme name for the current platform.

在 3.10 版被加入: This function was previously named `_get_default_scheme()` and considered an implementation detail.

在 3.11 版的變更: When Python runs from a virtual environment, the `venv` scheme is returned.

`sysconfig.get_preferred_scheme(key)`

Return a preferred scheme name for an installation layout specified by `key`.

`key` must be either "prefix", "home", or "user".

The return value is a scheme name listed in `get_scheme_names()`. It can be passed to `sysconfig` functions that take a `scheme` argument, such as `get_paths()`.

在 3.10 版被加入.

在 3.11 版的變更: When Python runs from a virtual environment and `key="prefix"`, the `venv` scheme is returned.

`sysconfig._get_preferred_schemes()`

Return a dict containing preferred scheme names on the current platform. Python implementers and redistributors may add their preferred schemes to the `_INSTALL_SCHEMES` module-level global value, and modify this function to return those scheme names, to e.g. provide different schemes for system and language package managers to use, so packages installed by either do not mix with those by the other.

End users should not use this function, but `get_default_scheme()` and `get_preferred_scheme()` instead.

在 3.10 版被加入.

`sysconfig.get_path_names()`

Return a tuple containing all path names currently supported in `sysconfig`.

`sysconfig.get_path(name[, scheme[, vars[, expand]]])`

Return an installation path corresponding to the path `name`, from the install scheme named `scheme`.

`name` has to be a value from the list returned by `get_path_names()`.

`sysconfig` stores installation paths corresponding to each path name, for each platform, with variables to be expanded. For instance the `stdlib` path for the `nt` scheme is: `{base}/Lib`.

`get_path()` will use the variables returned by `get_config_vars()` to expand the path. All variables have default values for each platform so one may call this function and get the default value.

If `scheme` is provided, it must be a value from the list returned by `get_scheme_names()`. Otherwise, the default scheme for the current platform is used.

If `vars` is provided, it must be a dictionary of variables that will update the dictionary returned by `get_config_vars()`.

If `expand` is set to `False`, the path will not be expanded using the variables.

如果找不到 `name`, 則引發 `KeyError`。

`sysconfig.get_paths([scheme[, vars[, expand]]])`

Return a dictionary containing all installation paths corresponding to an installation scheme. See `get_path()` for more information.

If `scheme` is not provided, will use the default scheme for the current platform.

If *vars* is provided, it must be a dictionary of variables that will update the dictionary used to expand the paths.

If *expand* is set to false, the paths will not be expanded.

If *scheme* is not an existing scheme, `get_paths()` will raise a `KeyError`.

### 30.3.7 其他函式

`sysconfig.get_python_version()`

回傳 MAJOR.MINOR Python 版本號碼字串。類似於 '%d.%d' % sys.version\_info[:2]。

`sysconfig.get_platform()`

Return a string that identifies the current platform.

This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by `os.uname()`), although the exact information included depends on the OS; e.g., on Linux, the kernel version isn't particularly important.

Examples of returned values:

- linux-i586
- linux-alpha (?)
- solaris-2.6-sun4u

Windows will return one of:

- win-amd64 (64-bit Windows on AMD64, aka x86\_64, Intel64, and EM64T)
- win-arm64 (64-bit Windows on ARM64, aka AArch64)
- win32 (all others - specifically, `sys.platform` is returned)

macOS can return:

- macosx-10.6-ppc
- macosx-10.4-ppc64
- macosx-10.3-i386
- macosx-10.4-fat

For other non-POSIX platforms, currently just returns `sys.platform`.

`sysconfig.is_python_build()`

Return `True` if the running Python interpreter was built from source and is being run from its built location, and not from a location resulting from e.g. running `make install` or installing via a binary installer.

`sysconfig.parse_config_h(fp[, vars])`

Parse a `config.h`-style file.

*fp* is a file-like object pointing to the `config.h`-like file.

A dictionary containing name/value pairs is returned. If an optional dictionary is passed in as the second argument, it is used instead of a new dictionary, and updated with the values read in the file.

`sysconfig.get_config_h_filename()`

回傳 `pyconfig.h` 的路徑。

`sysconfig.get_makefile_filename()`

回傳 `Makefile` 的路徑。

### 30.3.8 將 `sysconfig` 作本使用

You can use `sysconfig` as a script with Python's `-m` option:

```
$ python -m sysconfig
Platform: "macosx-10.4-i386"
Python version: "3.2"
Current installation scheme: "posix_prefix"

Paths:
    data = "/usr/local"
    include = "/Users/tarek/Dev/svn.python.org/py3k/Include"
    platinclude = "."
    platlib = "/usr/local/lib/python3.2/site-packages"
    platstdlib = "/usr/local/lib/python3.2"
    purelib = "/usr/local/lib/python3.2/site-packages"
    scripts = "/usr/local/bin"
    stdlib = "/usr/local/lib/python3.2"

Variables:
    AC_APPLE_UNIVERSAL_BUILD = "0"
    AIX_GENUINE_CPLUSPLUS = "0"
    AR = "ar"
    ARFLAGS = "rc"
    ...
```

This call will print in the standard output the information returned by `get_platform()`, `get_python_version()`, `get_path()` and `get_config_vars()`.

## 30.4 `builtins` --- 物件

該模組提供對 Python 所有' 識符號的直接存取；例如 `builtins.open` 是函式 `open()` 的全名。大多數應用程式通常不會顯式地存取此模組，但在提供與 建值同名之物件的模組中可能很有用，不過其中還會需要 建該名稱。例如，在一個將 建 `open()` 包裝起來以實現另一版本 `open()` 函式的模組中，這個模組可以直接被使用：

```
import builtins

def open(path):
    f = builtins.open(path, 'r')
    return UpperCaser(f)

class UpperCaser:
    '''將輸出轉成大寫的檔案包裝器'''

    def __init__(self, f):
        self._f = f

    def read(self, count=-1):
        return self._f.read(count).upper()

# ...
```

有個實作細節是，大多數模組都將名稱 `__builtins__` 作其全域性變數的一部分以提使用。`__builtins__` 的值通常是這個模組或者這個模組的 `__dict__` 屬性值。由於這是一個實作細節，因此 Python 的其他實作可能不會使用它。

## 30.5 `__main__` --- 頂層程式碼環境

在 Python 中，特殊名稱 `__main__` 用於兩個重要的建構：

1. 程式頂層環境的名稱，可以使用 `__name__ == '__main__'` 運算式進行檢查；和
2. 在 Python 套件中的 `__main__.py` 檔案。

這兩種機制都與 Python 模組有關；使用者如何與它們互動以及它們如何彼此互動。下面會詳細解釋它們。如果你不熟悉 Python 模組，請參教學章節 `tut-modules` 的介紹。

### 30.5.1 `__name__ == '__main__'`

當引入 Python 模組或套件時，`__name__` 設定模組的名稱。通常來，這是 Python 檔案本身的名稱，且不含 `.py` 副檔名：

```
>>> import configparser
>>> configparser.__name__
'configparser'
```

如果檔案是套件的一部分，則 `__name__` 也會包含父套件 (parent package) 的路徑：

```
>>> from concurrent.futures import process
>>> process.__name__
'concurrent.futures.process'
```

但是，如果模組在頂層程式碼環境中執行，則其 `__name__` 將被設定字串 `'__main__'`。

#### 什麼是「頂層程式碼環境」？

`__main__` 是執行頂層程式碼的環境名稱。「頂層程式碼」是使用者指定且第一個開始運作的 Python 模組。它是「頂層」的原因是因它引入程式所需的所有其他模組。有時「頂層程式碼」被稱應用程式的入口點。

頂層程式碼環境可以是：

- 互動式提示字元的作用域：

```
>>> __name__
'__main__'
```

- 將 Python 模組作檔案引數傳遞給 Python 直譯器：

```
$ python helloworld.py
Hello, world!
```

- 使用 `-m` 引數傳遞給 Python 直譯器的 Python 模組或套件：

```
$ python -m tarfile
usage: tarfile.py [-h] [-v] (...)
```

- Python 直譯器從標準輸入讀取 Python 程式碼：

```
$ echo "import this" | python
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

- 使用 `-c` 引數傳遞給 Python 直譯器的 Python 程式碼：

```
$ python -c "import this"
The Zen of Python, by Tim Peters

Beautiful is better than ugly.
Explicit is better than implicit.
...
```

在這些情況下，頂層模組的 `__name__` 都會設定為 `'__main__'`。

因此，模組可以透過檢查自己的 `__name__` 來發現它是否在頂層環境中執行，這允許當模組未從 `import` 陳述式初始化時，使用常見的慣用語法 (idiom) 來有條件地執程式碼：

```
if __name__ == '__main__':
    # Execute when the module is not initialized from an import statement.
    ...
```

### 也參考

若要更詳細地了解如何在所有情況下設定 `__name__`，請參閱教學章節 `tut-modules`。

### 慣用 (Idiomatic) 用法

某些模組包含僅供本使用的程式碼，例如剖析命令列引數或從標準輸入取得資料。如果從不同的模組匯入這樣的模組（例如對其進行單元測試 (unit test)），則本程式碼也會無意間執行。

這就是使用 `if __name__ == '__main__'` 程式碼區塊派上用場的地方。除非該模組在頂層環境中執行，否則此區塊中的程式碼不會執行。

在 `if __name__ == '__main__'` 下面的區塊中放置盡可能少的陳述式可以提高程式碼的清晰度和正確性。大多數情況下，名 `main` 的函式封裝 (encapsulate) 了程式的主要行：

```
# echo.py

import shlex
import sys

def echo(phrase: str) -> None:
    """A dummy wrapper around print."""
    # for demonstration purposes, you can imagine that there is some
    # valuable and reusable logic inside this function
    print(phrase)

def main() -> int:
    """Echo the input arguments to standard output"""
    phrase = shlex.join(sys.argv)
    echo(phrase)
    return 0

if __name__ == '__main__':
    sys.exit(main()) # next section explains the use of sys.exit
```

請注意，如果模組有將程式碼封裝在 `main` 函式中，而是直接將其放在 `if __name__ == '__main__':` 區塊中，則 `phrase` 變數對於整個模組來將是全域的。這很容易出錯，因模組中的其他函式可能會無意中使用此全域變數而不是區域變數。`main` 函式解了這個問題。

使用 `main` 函式還有一個額外的好處，`echo` 函式本身是隔離的 (isolated) 且可以在其他地方引入。當引入 `echo.py` 時，`echo` 和 `main` 函式將被定義，但它們都不會被呼叫，因 `__name__ != '__main__'`。

### 打包時須考慮的事情

`main` 函式通常用於透過將它們指定控制台本的人口點來建立命令列工具。完成後，`pip` 將函式呼叫插入到模板本中，其中 `main` 的回傳值被傳遞到 `sys.exit()` 中。例如：

```
sys.exit(main())
```

由於對 `main` 的呼叫包含在 `sys.exit()` 中，因此期望你的函式將傳回一些可接受作 `sys.exit()` 輸入的值；通常來，會是一個整數或 `None`（如果你的函式有 `return` 陳述式，則相當於回傳此值）。

透過我們自己主動遵循這個慣例，我們的模組在直接執行時（即 `python echo.py`）的行，將和我們稍後將其打包 `pip` 可安裝套件中的控制台本入口點相同。

特別是，要謹慎處理從 `main` 函式回傳字串。`sys.exit()` 會將字串引數直譯失敗訊息，因此你的程式將有一個表示失敗的結束代碼 1，且該字串將被寫入 `sys.stderr`。前面的 `echo.py` 範例使用慣例的 `sys.exit(main())` 進行示範。

### 也參考

Python 打包使用者指南包含一系列如何使用現代工具發行和安裝 Python 套件的教學和參考資料。

## 30.5.2 Python 套件中的 `__main__.py`

如果你不熟悉 Python 套件，請參 `tut-packages` 的教學章節。最常見的是，`__main__.py` 檔案用於提供命令列介面。假設下面有構的套件“bandclass”：

```
bandclass
├── __init__.py
├── __main__.py
└── student.py
```

當使用 `-m` 旗標 (flag) 直接從命令列呼叫套件本身時，將執行 `__main__.py`。例如：

```
$ python -m bandclass
```

該命令將導致 `__main__.py` 執行。如何利用此機制將取於你正在編寫的套件的性質，但在這種構的情況下，允許教師搜尋學生可能是有意義的：

```
# bandclass/__main__.py

import sys
from .student import search_students

student_name = sys.argv[1] if len(sys.argv) >= 2 else ''
print(f'Found student: {search_students(student_name)}')
```

請注意，`from .student import search_students` 是相對引入的範例。在引用套件的模組時，可以使用此引入樣式。有關更多詳細資訊，請參 `tut-modules` 教學章節中的 `intra-package-references`。

## 慣用 (Idiomatic) 用法

`__main__.py` 的內容通常不會被 `if __name__ == '__main__':` 區塊包圍。相反的，這些檔案保持簡短引入其他模組的函式來執行。那些其他模組就可以輕鬆地進行單元測試且可以正確地重用。

如果在套件內部的 `__main__.py` 檔案使用 `if __name__ == '__main__':` 區塊，它依然會如預期般地運作。因當引入套件，其 `__name__` 屬性將會包含套件的路徑：

```
>>> import asyncio.__main__
>>> asyncio.__main__.__name__
'asyncio.__main__'
```

但這對於 `.zip` 檔案根目錄中的 `__main__.py` 檔案不起作用。因此，為了保持一致性，最小的、有 `__name__` 檢查的 `__main__.py` 會是首選。

### 也參考

請參 `venv` 作標準函式庫中具有最小 `__main__.py` 的套件範例。它不包含 `if __name__ == '__main__':` 區塊。你可以使用 `python -m venv [directory]` 來呼叫它。

請參 `runpy` 取得有關直譯器可執行檔的 `-m` 旗標的更多詳細資訊。

請參 `zipapp` 了解如何執行打包成 `.zip` 檔案的應用程式。在這種情況下，Python 會在封存檔案的根目錄中尋找 `__main__.py` 檔案。

## 30.5.3 import \_\_main\_\_

無論 Python 程式是從哪個模組啟動的，在同一程式中執行的其他模組都可以透過匯入 `__main__` 模組來引入頂層環境的作用域 (*namespace*)。這不會引入 `__main__.py` 檔案，而是引入接收特殊名稱 `'__main__'` 的模組。

這是一個使用 `__main__` 命名空間的範例模組：

```
# namely.py

import __main__

def did_user_define_their_name():
    return 'my_name' in dir(__main__)

def print_user_name():
    if not did_user_define_their_name():
        raise ValueError('Define the variable `my_name`!')

    if '__file__' in dir(__main__):
        print(__main__.my_name, "found in file", __main__.__file__)
    else:
        print(__main__.my_name)
```

該模組的範例用法如下：

```
# start.py

import sys

from namely import print_user_name

# my_name = "Dinsdale"

def main():
    try:
        print_user_name()
```

(繼續下一頁)

(繼續上一頁)

```

except ValueError as ve:
    return str(ve)

if __name__ == "__main__":
    sys.exit(main())

```

現在，如果我們執行程式，結果將如下所示：

```

$ python start.py
Define the variable `my_name`!

```

程式的結束代碼將 1，表示出現錯誤。取消解 my\_name = "Dinsdale" 而修復程式後，現在它以狀態碼 0 結束，表示成功：

```

$ python start.py
Dinsdale found in file /path/to/start.py

```

請注意，引入 `__main__` 不會因不經意地執行放在 `start` 模組中 `if __name__ == "__main__"` 區塊的頂層程式碼（本來是給本使用的）而造成任何問題。什麼這樣做會如預期運作？

當 Python 直譯器執行時，會在 `sys.modules` 中插入一個空的 `__main__` 模組，透過執行頂層程式碼來填充它。在我們的範例中，這是 `start` 模組，它將逐行執行引入 `namely`。接著，`namely` 引入 `__main__`（其實是 `start`）。這就是一個引入循環！幸運的是，由於部分填充的 `__main__` 模組存在於 `sys.modules` 中，Python 將其傳遞給 `namely`。請參閱引入系統參考文件中的關於 `__main__` 的特考了解其工作原理的詳細資訊。

Python REPL 是「頂層環境」的另一個範例，因此 REPL 中定義的任何內容都成作用域的一部分：

```

>>> import namely
>>> namely.did_user_define_their_name()
False
>>> namely.print_user_name()
Traceback (most recent call last):
...
ValueError: Define the variable `my_name`!
>>> my_name = 'Jabberwocky'
>>> namely.did_user_define_their_name()
True
>>> namely.print_user_name()
Jabberwocky

```

請注意，在這種情況下，`__main__` 作用域不包含 `__file__` 屬性，因為它是互動式的。

`__main__` 作用域用於 `pdb` 和 `rlcompleter` 的實作。

## 30.6 warnings --- 警告控制

原始碼：[Lib/warnings.py](#)

Warning messages are typically issued in situations where it is useful to alert the user of some condition in a program, where that condition (normally) doesn't warrant raising an exception and terminating the program. For example, one might want to issue a warning when a program uses an obsolete module.

Python programmers issue warnings by calling the `warn()` function defined in this module. (C programmers use `PyErr_WarnEx()`; see [exceptionhandling](#) for details).

Warning messages are normally written to `sys.stderr`, but their disposition can be changed flexibly, from ignoring all warnings to turning them into exceptions. The disposition of warnings can vary based on the *warning category*, the text of the warning message, and the source location where it is issued. Repetitions of a particular warning for the same source location are typically suppressed.

There are two stages in warning control: first, each time a warning is issued, a determination is made whether a message should be issued or not; next, if a message is to be issued, it is formatted and printed using a user-settable hook.

The determination whether to issue a warning message is controlled by the *warning filter*, which is a sequence of matching rules and actions. Rules can be added to the filter by calling `filterwarnings()` and reset to its default state by calling `resetwarnings()`.

The printing of warning messages is done by calling `showwarning()`, which may be overridden; the default implementation of this function formats the message by calling `formatwarning()`, which is also available for use by custom implementations.

### 也參考

`logging.captureWarnings()` allows you to handle all warnings with the standard logging infrastructure.

## 30.6.1 Warning Categories

There are a number of built-in exceptions that represent warning categories. This categorization is useful to be able to filter out groups of warnings.

While these are technically *built-in exceptions*, they are documented here, because conceptually they belong to the warnings mechanism.

User code can define additional warning categories by subclassing one of the standard warning categories. A warning category must always be a subclass of the *Warning* class.

The following warnings category classes are currently defined:

Class	描述
<code>Warning</code>	This is the base class of all warning category classes. It is a subclass of <i>Exception</i> .
<code>UserWarning</code>	The default category for <code>warn()</code> .
<code>DeprecationWarning</code>	Base category for warnings about deprecated features when those warnings are intended for other Python developers (ignored by default, unless triggered by code in <code>__main__</code> ).
<code>SyntaxWarning</code>	Base category for warnings about dubious syntactic features.
<code>RuntimeWarning</code>	Base category for warnings about dubious runtime features.
<code>FutureWarning</code>	Base category for warnings about deprecated features when those warnings are intended for end users of applications that are written in Python.
<code>PendingDeprecationWarning</code>	Base category for warnings about features that will be deprecated in the future (ignored by default).
<code>ImportWarning</code>	Base category for warnings triggered during the process of importing a module (ignored by default).
<code>UnicodeWarning</code>	Base category for warnings related to Unicode.
<code>BytesWarning</code>	Base category for warnings related to <i>bytes</i> and <i>bytearray</i> .
<code>ResourceWarning</code>	Base category for warnings related to resource usage (ignored by default).

在 3.7 版的變更: Previously `DeprecationWarning` and `FutureWarning` were distinguished based on whether a feature was being removed entirely or changing its behaviour. They are now distinguished based on their intended audience and the way they're handled by the default warnings filters.

## 30.6.2 The Warnings Filter

The warnings filter controls whether warnings are ignored, displayed, or turned into errors (raising an exception).

Conceptually, the warnings filter maintains an ordered list of filter specifications; any specific warning is matched against each filter specification in the list in turn until a match is found; the filter determines the disposition of the match. Each entry is a tuple of the form (*action*, *message*, *category*, *module*, *lineno*), where:

- *action* is one of the following strings:

Value	Disposition
"default"	print the first occurrence of matching warnings for each location (module + line number) where the warning is issued
"error"	turn matching warnings into exceptions
"ignore"	never print matching warnings
"always"	always print matching warnings
"module"	print the first occurrence of matching warnings for each module where the warning is issued (regardless of line number)
"once"	print only the first occurrence of matching warnings, regardless of location

- *message* is a string containing a regular expression that the start of the warning message must match, case-insensitively. In `-W` and `PYTHONWARNINGS`, *message* is a literal string that the start of the warning message must contain (case-insensitively), ignoring any whitespace at the start or end of *message*.
- *category* is a class (a subclass of `Warning`) of which the warning category must be a subclass in order to match.
- *module* is a string containing a regular expression that the start of the fully qualified module name must match, case-sensitively. In `-W` and `PYTHONWARNINGS`, *module* is a literal string that the fully qualified module name must be equal to (case-sensitively), ignoring any whitespace at the start or end of *module*.
- *lineno* is an integer that the line number where the warning occurred must match, or 0 to match all line numbers.

Since the `Warning` class is derived from the built-in `Exception` class, to turn a warning into an error we simply raise `category(message)`.

If a warning is reported and doesn't match any registered filter then the "default" action is applied (hence its name).

### Repeated Warning Suppression Criteria

The filters that suppress repeated warnings apply the following criteria to determine if a warning is considered a repeat:

- "default": A warning is considered a repeat only if the (*message*, *category*, *module*, *lineno*) are all the same.
- "module": A warning is considered a repeat if the (*message*, *category*, *module*) are the same, ignoring the line number.
- "once": A warning is considered a repeat if the (*message*, *category*) are the same, ignoring the module and line number.

### Describing Warning Filters

The warnings filter is initialized by `-W` options passed to the Python interpreter command line and the `PYTHONWARNINGS` environment variable. The interpreter saves the arguments for all supplied entries without interpretation in `sys.warnoptions`; the `warnings` module parses these when it is first imported (invalid options are ignored, after printing a message to `sys.stderr`).

Individual warnings filters are specified as a sequence of fields separated by colons:

```
action:message:category:module:line
```

The meaning of each of these fields is as described in *The Warnings Filter*. When listing multiple filters on a single line (as for `PYTHONWARNINGS`), the individual filters are separated by commas and the filters listed later take precedence

over those listed before them (as they're applied left-to-right, and the most recently applied filters take precedence over earlier ones).

Commonly used warning filters apply to either all warnings, warnings in a particular category, or warnings raised by particular modules or packages. Some examples:

```
default           # Show all warnings (even those ignored by default)
ignore           # Ignore all warnings
error            # Convert all warnings to errors
error::ResourceWarning # Treat ResourceWarning messages as errors
default::DeprecationWarning # Show DeprecationWarning messages
ignore,default:::mymodule # Only report warnings triggered by "mymodule"
error:::mymodule   # Convert warnings to errors in "mymodule"
```

## Default Warning Filter

By default, Python installs several warning filters, which can be overridden by the `-w` command-line option, the `PYTHONWARNINGS` environment variable and calls to `filterwarnings()`.

In regular release builds, the default warning filter has the following entries (in order of precedence):

```
default::DeprecationWarning:__main__
ignore::DeprecationWarning
ignore::PendingDeprecationWarning
ignore::ImportWarning
ignore::ResourceWarning
```

In a debug build, the list of default warning filters is empty.

在 3.2 版的變更: `DeprecationWarning` is now ignored by default in addition to `PendingDeprecationWarning`.

在 3.7 版的變更: `DeprecationWarning` is once again shown by default when triggered directly by code in `__main__`.

在 3.7 版的變更: `BytesWarning` no longer appears in the default filter list and is instead configured via `sys.warnoptions` when `-b` is specified twice.

## Overriding the default filter

Developers of applications written in Python may wish to hide *all* Python level warnings from their users by default, and only display them when running tests or otherwise working on the application. The `sys.warnoptions` attribute used to pass filter configurations to the interpreter can be used as a marker to indicate whether or not warnings should be disabled:

```
import sys

if not sys.warnoptions:
    import warnings
    warnings.simplefilter("ignore")
```

Developers of test runners for Python code are advised to instead ensure that *all* warnings are displayed by default for the code under test, using code like:

```
import sys

if not sys.warnoptions:
    import os, warnings
    warnings.simplefilter("default") # Change the filter in this process
    os.environ["PYTHONWARNINGS"] = "default" # Also affect subprocesses
```

Finally, developers of interactive shells that run user code in a namespace other than `__main__` are advised to ensure that `DeprecationWarning` messages are made visible by default, using code like the following (where `user_ns` is the module used to execute code entered interactively):

```
import warnings
warnings.filterwarnings("default", category=DeprecationWarning,
                       module=user_ns.get("__name__"))
```

### 30.6.3 Temporarily Suppressing Warnings

If you are using code that you know will raise a warning, such as a deprecated function, but do not want to see the warning (even when warnings have been explicitly configured via the command line), then it is possible to suppress the warning using the `catch_warnings` context manager:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings():
    warnings.simplefilter("ignore")
    fxn()
```

While within the context manager all warnings will simply be ignored. This allows you to use known-deprecated code without having to see the warning while not suppressing the warning for other code that might not be aware of its use of deprecated code. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

### 30.6.4 Testing Warnings

To test warnings raised by code, use the `catch_warnings` context manager. With it you can temporarily mutate the warnings filter to facilitate your testing. For instance, do the following to capture all raised warnings to check:

```
import warnings

def fxn():
    warnings.warn("deprecated", DeprecationWarning)

with warnings.catch_warnings(record=True) as w:
    # Cause all warnings to always be triggered.
    warnings.simplefilter("always")
    # Trigger a warning.
    fxn()
    # Verify some things
    assert len(w) == 1
    assert isinstance(w[-1].category, DeprecationWarning)
    assert "deprecated" in str(w[-1].message)
```

One can also cause all warnings to be exceptions by using `error` instead of `always`. One thing to be aware of is that if a warning has already been raised because of a `once/default` rule, then no matter what filters are set the warning will not be seen again unless the warnings registry related to the warning has been cleared.

Once the context manager exits, the warnings filter is restored to its state when the context was entered. This prevents tests from changing the warnings filter in unexpected ways between tests and leading to indeterminate test results. The `showwarning()` function in the module is also restored to its original value. Note: this can only be guaranteed in a single-threaded application. If two or more threads use the `catch_warnings` context manager at the same time, the behavior is undefined.

When testing multiple operations that raise the same kind of warning, it is important to test them in a manner that confirms each operation is raising a new warning (e.g. set warnings to be raised as exceptions and check the operations raise exceptions, check that the length of the warning list continues to increase after each operation, or else delete the previous entries from the warnings list before each new operation).

### 30.6.5 Updating Code For New Versions of Dependencies

Warning categories that are primarily of interest to Python developers (rather than end users of applications written in Python) are ignored by default.

Notably, this “ignored by default” list includes `DeprecationWarning` (for every module except `__main__`), which means developers should make sure to test their code with typically ignored warnings made visible in order to receive timely notifications of future breaking API changes (whether in the standard library or third party packages).

In the ideal case, the code will have a suitable test suite, and the test runner will take care of implicitly enabling all warnings when running tests (the test runner provided by the `unittest` module does this).

In less ideal cases, applications can be checked for use of deprecated interfaces by passing `-Wd` to the Python interpreter (this is shorthand for `-W default`) or setting `PYTHONWARNINGS=default` in the environment. This enables default handling for all warnings, including those that are ignored by default. To change what action is taken for encountered warnings you can change what argument is passed to `-W` (e.g. `-W error`). See the `-W` flag for more details on what is possible.

### 30.6.6 Available Functions

`warnings.warn(message, category=None, stacklevel=1, source=None, *, skip_file_prefixes=())`

Issue a warning, or maybe ignore it or raise an exception. The `category` argument, if given, must be a *warning category class*; it defaults to `UserWarning`. Alternatively, `message` can be a `Warning` instance, in which case `category` will be ignored and `message.__class__` will be used. In this case, the message text will be `str(message)`. This function raises an exception if the particular warning issued is changed into an error by the *warnings filter*. The `stacklevel` argument can be used by wrapper functions written in Python, like this:

```
def deprecated_api(message):
    warnings.warn(message, DeprecationWarning, stacklevel=2)
```

This makes the warning refer to `deprecated_api`’s caller, rather than to the source of `deprecated_api` itself (since the latter would defeat the purpose of the warning message).

The `skip_file_prefixes` keyword argument can be used to indicate which stack frames are ignored when counting stack levels. This can be useful when you want the warning to always appear at call sites outside of a package when a constant `stacklevel` does not fit all call paths or is otherwise challenging to maintain. If supplied, it must be a tuple of strings. When prefixes are supplied, `stacklevel` is implicitly overridden to be `max(2, stacklevel)`. To cause a warning to be attributed to the caller from outside of the current package you might write:

```
# example/lower.py
_warn_skips = (os.path.dirname(__file__),)

def one_way(r_luxury_yacht=None, t_wobbler_mangrove=None):
    if r_luxury_yacht:
        warnings.warn("Please migrate to t_wobbler_mangrove=",
                      skip_file_prefixes=_warn_skips)

# example/higher.py
from . import lower

def another_way(**kw):
    lower.one_way(**kw)
```

This makes the warning refer to both the `example.lower.one_way()` and `package.higher.another_way()` call sites only from calling code living outside of `example` package.

`source`, if supplied, is the destroyed object which emitted a `ResourceWarning`.

在 3.6 版的變更: 新增 `source` 參數。

在 3.12 版的變更: 新增 `skip_file_prefixes`。

`warnings.warn_explicit` (*message, category, filename, lineno, module=None, registry=None, module\_globals=None, source=None*)

This is a low-level interface to the functionality of `warn()`, passing in explicitly the message, category, filename and line number, and optionally the module name and the registry (which should be the `__warningregistry__` dictionary of the module). The module name defaults to the filename with `.py` stripped; if no registry is passed, the warning is never suppressed. *message* must be a string and *category* a subclass of `Warning` or *message* may be a `Warning` instance, in which case *category* will be ignored.

*module\_globals*, if supplied, should be the global namespace in use by the code for which the warning is issued. (This argument is used to support displaying source for modules found in zipfiles or other non-filesystem import sources).

*source*, if supplied, is the destroyed object which emitted a `ResourceWarning`.

在 3.6 版的變更: Add the *source* parameter.

`warnings.showwarning` (*message, category, filename, lineno, file=None, line=None*)

Write a warning to a file. The default implementation calls `formatwarning(message, category, filename, lineno, line)` and writes the resulting string to *file*, which defaults to `sys.stderr`. You may replace this function with any callable by assigning to `warnings.showwarning`. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `showwarning()` will try to read the line specified by *filename* and *lineno*.

`warnings.formatwarning` (*message, category, filename, lineno, line=None*)

Format a warning the standard way. This returns a string which may contain embedded newlines and ends in a newline. *line* is a line of source code to be included in the warning message; if *line* is not supplied, `formatwarning()` will try to read the line specified by *filename* and *lineno*.

`warnings.filterwarnings` (*action, message="", category=Warning, module="", lineno=0, append=False*)

Insert an entry into the list of `warnings filter specifications`. The entry is inserted at the front by default; if *append* is true, it is inserted at the end. This checks the types of the arguments, compiles the *message* and *module* regular expressions, and inserts them as a tuple in the list of warnings filters. Entries closer to the front of the list override entries later in the list, if both match a particular warning. Omitted arguments default to a value that matches everything.

`warnings.simplefilter` (*action, category=Warning, lineno=0, append=False*)

Insert a simple entry into the list of `warnings filter specifications`. The meaning of the function parameters is as for `filterwarnings()`, but regular expressions are not needed as the filter inserted always matches any message in any module as long as the category and line number match.

`warnings.resetwarnings` ()

Reset the warnings filter. This discards the effect of all previous calls to `filterwarnings()`, including that of the `-W` command line options and calls to `simplefilter()`.

`@warnings.deprecated` (*msg, \*, category=DeprecationWarning, stacklevel=1*)

Decorator to indicate that a class, function or overload is deprecated.

When this decorator is applied to an object, deprecation warnings may be emitted at runtime when the object is used. `static type checkers` will also generate a diagnostic on usage of the deprecated object.

Usage:

```
from warnings import deprecated
from typing import overload

@deprecated("Use B instead")
class A:
    pass

@deprecated("Use g instead")
def f():
    pass
```

(繼續下一頁)

(繼續上一頁)

```

@overload
@deprecated("int support is deprecated")
def g(x: int) -> int: ...
@overload
def g(x: str) -> int: ...

```

The warning specified by *category* will be emitted at runtime on use of deprecated objects. For functions, that happens on calls; for classes, on instantiation and on creation of subclasses. If the *category* is *None*, no warning is emitted at runtime. The *stacklevel* determines where the warning is emitted. If it is 1 (the default), the warning is emitted at the direct caller of the deprecated object; if it is higher, it is emitted further up the stack. Static type checker behavior is not affected by the *category* and *stacklevel* arguments.

The deprecation message passed to the decorator is saved in the `__deprecated__` attribute on the decorated object. If applied to an overload, the decorator must be after the `@overload` decorator for the attribute to exist on the overload as returned by `typing.get_overloads()`.

在 3.13 版被加入: See [PEP 702](#).

### 30.6.7 Available Context Managers

```
class warnings.catch_warnings(*, record=False, module=None, action=None, category=Warning,
                               lineno=0, append=False)
```

A context manager that copies and, upon exit, restores the warnings filter and the `showwarning()` function. If the *record* argument is *False* (the default) the context manager returns *None* on entry. If *record* is *True*, a list is returned that is progressively populated with objects as seen by a custom `showwarning()` function (which also suppresses output to `sys.stdout`). Each object in the list has attributes with the same names as the arguments to `showwarning()`.

The *module* argument takes a module that will be used instead of the module returned when you import `warnings` whose filter will be protected. This argument exists primarily for testing the `warnings` module itself.

If the *action* argument is not *None*, the remaining arguments are passed to `simplefilter()` as if it were called immediately on entering the context.

See [The Warnings Filter](#) for the meaning of the *category* and *lineno* parameters.

#### 備 F

The `catch_warnings` manager works by replacing and then later restoring the module's `showwarning()` function and internal list of filter specifications. This means the context manager is modifying global state and therefore is not thread-safe.

在 3.11 版的變更: 新增 *action*、*category*、*lineno* 和 *append* 參數。

## 30.7 dataclasses --- Data Classes

原始碼: [Lib/dataclasses.py](#)

This module provides a decorator and functions for automatically adding generated *special methods* such as `__init__()` and `__repr__()` to user-defined classes. It was originally described in [PEP 557](#).

The member variables to use in these generated methods are defined using [PEP 526](#) type annotations. For example, this code:

```

from dataclasses import dataclass

@dataclass
class InventoryItem:
    """Class for keeping track of an item in inventory."""
    name: str
    unit_price: float
    quantity_on_hand: int = 0

    def total_cost(self) -> float:
        return self.unit_price * self.quantity_on_hand

```

will add, among other things, a `__init__()` that looks like:

```

def __init__(self, name: str, unit_price: float, quantity_on_hand: int = 0):
    self.name = name
    self.unit_price = unit_price
    self.quantity_on_hand = quantity_on_hand

```

Note that this method is automatically added to the class: it is not directly specified in the `InventoryItem` definition shown above.

在 3.7 版被加入。

### 30.7.1 模組內容

```

@dataclasses.dataclass(*, init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False,
                       match_args=True, kw_only=False, slots=False, weakref_slot=False)

```

This function is a *decorator* that is used to add generated *special methods* to classes, as described below.

The `@dataclass` decorator examines the class to find *fields*. A *field* is defined as a class variable that has a *type annotation*. With two exceptions described below, nothing in `@dataclass` examines the type specified in the variable annotation.

The order of the fields in all of the generated methods is the order in which they appear in the class definition.

The `@dataclass` decorator will add various "dunder" methods to the class, described below. If any of the added methods already exist in the class, the behavior depends on the parameter, as documented below. The decorator returns the same class that it is called on; no new class is created.

If `@dataclass` is used just as a simple decorator with no parameters, it acts as if it has the default values documented in this signature. That is, these three uses of `@dataclass` are equivalent:

```

@dataclass
class C:
    ...

@dataclass()
class C:
    ...

@dataclass(init=True, repr=True, eq=True, order=False, unsafe_hash=False, frozen=False,
           match_args=True, kw_only=False, slots=False, weakref_slot=False)
class C:
    ...

```

`@dataclass` 的參數是：

- *init*: If true (the default), a `__init__()` method will be generated. If the class already defines `__init__()`, this parameter is ignored.
- *repr*: If true (the default), a `__repr__()` method will be generated. The generated repr string will have the class name and the name and repr of each field, in the order they are defined in the

class. Fields that are marked as being excluded from the repr are not included. For example: `InventoryItem(name='widget', unit_price=3.0, quantity_on_hand=10)`.

If the class already defines `__repr__()`, this parameter is ignored.

- *eq*: If true (the default), an `__eq__()` method will be generated. This method compares the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type.

If the class already defines `__eq__()`, this parameter is ignored.

- *order*: If true (the default is `False`), `__lt__()`, `__le__()`, `__gt__()`, and `__ge__()` methods will be generated. These compare the class as if it were a tuple of its fields, in order. Both instances in the comparison must be of the identical type. If *order* is true and *eq* is false, a `ValueError` is raised.

If the class already defines any of `__lt__()`, `__le__()`, `__gt__()`, or `__ge__()`, then `TypeError` is raised.

- *unsafe\_hash*: If `False` (the default), a `__hash__()` method is generated according to how *eq* and *frozen* are set.

`__hash__()` is used by built-in `hash()`, and when objects are added to hashed collections such as dictionaries and sets. Having a `__hash__()` implies that instances of the class are immutable. Mutability is a complicated property that depends on the programmer's intent, the existence and behavior of `__eq__()`, and the values of the *eq* and *frozen* flags in the `@dataclass` decorator.

By default, `@dataclass` will not implicitly add a `__hash__()` method unless it is safe to do so. Neither will it add or change an existing explicitly defined `__hash__()` method. Setting the class attribute `__hash__ = None` has a specific meaning to Python, as described in the `__hash__()` documentation.

If `__hash__()` is not explicitly defined, or if it is set to `None`, then `@dataclass` may add an implicit `__hash__()` method. Although not recommended, you can force `@dataclass` to create a `__hash__()` method with `unsafe_hash=True`. This might be the case if your class is logically immutable but can still be mutated. This is a specialized use case and should be considered carefully.

Here are the rules governing implicit creation of a `__hash__()` method. Note that you cannot both have an explicit `__hash__()` method in your dataclass and set `unsafe_hash=True`; this will result in a `TypeError`.

If *eq* and *frozen* are both true, by default `@dataclass` will generate a `__hash__()` method for you. If *eq* is true and *frozen* is false, `__hash__()` will be set to `None`, marking it unhashable (which it is, since it is mutable). If *eq* is false, `__hash__()` will be left untouched meaning the `__hash__()` method of the superclass will be used (if the superclass is *object*, this means it will fall back to id-based hashing).

- *frozen*: If true (the default is `False`), assigning to fields will generate an exception. This emulates read-only frozen instances. If `__setattr__()` or `__delattr__()` is defined in the class, then `TypeError` is raised. See the discussion below.
- *match\_args*: If true (the default is `True`), the `__match_args__` tuple will be created from the list of parameters to the generated `__init__()` method (even if `__init__()` is not generated, see above). If false, or if `__match_args__` is already defined in the class, then `__match_args__` will not be generated.

在 3.10 版被加入。

- *kw\_only*: If true (the default value is `False`), then all fields will be marked as keyword-only. If a field is marked as keyword-only, then the only effect is that the `__init__()` parameter generated from a keyword-only field must be specified with a keyword when `__init__()` is called. There is no effect on any other aspect of dataclasses. See the *parameter* glossary entry for details. Also see the `KW_ONLY` section.

在 3.10 版被加入。

- *slots*: If true (the default is `False`), `__slots__` attribute will be generated and new class will be returned instead of the original one. If `__slots__` is already defined in the class, then `TypeError` is raised.

**警告**

Calling no-arg `super()` in dataclasses using `slots=True` will result in the following exception being raised: `TypeError: super(type, obj): obj must be an instance or subtype of type`. The two-arg `super()` is a valid workaround. See [gh-90562](#) for full details.

**警告**

Passing parameters to a base class `__init_subclass__()` when using `slots=True` will result in a `TypeError`. Either use `__init_subclass__` with no parameters or use default values as a workaround. See [gh-91126](#) for full details.

在 3.10 版被加入。

在 3.11 版的變更: If a field name is already included in the `__slots__` of a base class, it will not be included in the generated `__slots__` to prevent overriding them. Therefore, do not use `__slots__` to retrieve the field names of a dataclass. Use `fields()` instead. To be able to determine inherited slots, base class `__slots__` may be any iterable, but *not* an iterator.

- `weakref_slot`: If true (the default is `False`), add a slot named `"__weakref__"`, which is required to make an instance *weakref-able*. It is an error to specify `weakref_slot=True` without also specifying `slots=True`.

在 3.11 版被加入。

`fields` may optionally specify a default value, using normal Python syntax:

```
@dataclass
class C:
    a: int          # 'a' has no default value
    b: int = 0      # assign a default value for 'b'
```

In this example, both `a` and `b` will be included in the added `__init__()` method, which will be defined as:

```
def __init__(self, a: int, b: int = 0):
```

`TypeError` will be raised if a field without a default value follows a field with a default value. This is true whether this occurs in a single class, or as a result of class inheritance.

`dataclasses.field(*, default=MISSING, default_factory=MISSING, init=True, repr=True, hash=None, compare=True, metadata=None, kw_only=MISSING)`

For common and simple use cases, no other functionality is required. There are, however, some dataclass features that require additional per-field information. To satisfy this need for additional information, you can replace the default field value with a call to the provided `field()` function. For example:

```
@dataclass
class C:
    mylist: list[int] = field(default_factory=list)

c = C()
c.mylist += [1, 2, 3]
```

As shown above, the `MISSING` value is a sentinel object used to detect if some parameters are provided by the user. This sentinel is used because `None` is a valid value for some parameters with a distinct meaning. No code should directly use the `MISSING` value.

`field()` 的參數是:

- *default*: If provided, this will be the default value for this field. This is needed because the `field()` call itself replaces the normal position of the default value.
- *default\_factory*: If provided, it must be a zero-argument callable that will be called when a default value is needed for this field. Among other purposes, this can be used to specify fields with mutable default values, as discussed below. It is an error to specify both *default* and *default\_factory*.
- *init*: If true (the default), this field is included as a parameter to the generated `__init__()` method.
- *repr*: If true (the default), this field is included in the string returned by the generated `__repr__()` method.
- *hash*: This can be a bool or `None`. If true, this field is included in the generated `__hash__()` method. If false, this field is excluded from the generated `__hash__()`. If `None` (the default), use the value of *compare*: this would normally be the expected behavior, since a field should be included in the hash if it's used for comparisons. Setting this value to anything other than `None` is discouraged.

One possible reason to set `hash=False` but `compare=True` would be if a field is expensive to compute a hash value for, that field is needed for equality testing, and there are other fields that contribute to the type's hash value. Even if a field is excluded from the hash, it will still be used for comparisons.

- *compare*: If true (the default), this field is included in the generated equality and comparison methods (`__eq__()`, `__gt__()`, et al.).
- *metadata*: This can be a mapping or `None`. `None` is treated as an empty dict. This value is wrapped in `MappingProxyType()` to make it read-only, and exposed on the `Field` object. It is not used at all by Data Classes, and is provided as a third-party extension mechanism. Multiple third-parties can each have their own key, to use as a namespace in the metadata.
- *kw\_only*: If true, this field will be marked as keyword-only. This is used when the generated `__init__()` method's parameters are computed.

在 3.10 版被加入。

If the default value of a field is specified by a call to `field()`, then the class attribute for this field will be replaced by the specified *default* value. If *default* is not provided, then the class attribute will be deleted. The intent is that after the `@dataclass` decorator runs, the class attributes will all contain the default values for the fields, just as if the default value itself were specified. For example, after:

```
@dataclass
class C:
    x: int
    y: int = field(repr=False)
    z: int = field(repr=False, default=10)
    t: int = 20
```

The class attribute `C.z` will be 10, the class attribute `C.t` will be 20, and the class attributes `C.x` and `C.y` will not be set.

**class** `dataclasses.Field`

`Field` objects describe each defined field. These objects are created internally, and are returned by the `fields()` module-level method (see below). Users should never instantiate a `Field` object directly. Its documented attributes are:

- `name`: 欄位的名稱。
- `type`: 欄位的型 F。
- `default`, `default_factory`, `init`, `repr`, `hash`, `compare`, `metadata`, and `kw_only` have the identical meaning and values as they do in the `field()` function.

Other attributes may exist, but they are private and must not be inspected or relied on.

`dataclasses.fields` (*class\_or\_instance*)

Returns a tuple of *Field* objects that define the fields for this dataclass. Accepts either a dataclass, or an instance of a dataclass. Raises *TypeError* if not passed a dataclass or instance of one. Does not return pseudo-fields which are *ClassVar* or *InitVar*.

`dataclasses.asdict` (*obj*, \*, *dict\_factory=dict*)

Converts the dataclass *obj* to a dict (by using the factory function *dict\_factory*). Each dataclass is converted to a dict of its fields, as `name: value` pairs. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with `copy.deepcopy()`.

Example of using `asdict()` on nested dataclasses:

```
@dataclass
class Point:
    x: int
    y: int

@dataclass
class C:
    mylist: list[Point]

p = Point(10, 20)
assert asdict(p) == {'x': 10, 'y': 20}

c = C([Point(0, 0), Point(10, 4)])
assert asdict(c) == {'mylist': [{'x': 0, 'y': 0}, {'x': 10, 'y': 4}]}
```

To create a shallow copy, the following workaround may be used:

```
{field.name: getattr(obj, field.name) for field in fields(obj)}
```

`asdict()` raises *TypeError* if *obj* is not a dataclass instance.

`dataclasses.astuple` (*obj*, \*, *tuple\_factory=tuple*)

Converts the dataclass *obj* to a tuple (by using the factory function *tuple\_factory*). Each dataclass is converted to a tuple of its field values. dataclasses, dicts, lists, and tuples are recursed into. Other objects are copied with `copy.deepcopy()`.

從前面的例子繼續:

```
assert astuple(p) == (10, 20)
assert astuple(c) == ((0, 0), (10, 4),)
```

To create a shallow copy, the following workaround may be used:

```
tuple(getattr(obj, field.name) for field in dataclasses.fields(obj))
```

`astuple()` raises *TypeError* if *obj* is not a dataclass instance.

`dataclasses.make_dataclass` (*cls\_name*, *fields*, \*, *bases=()*, *namespace=None*, *init=True*, *repr=True*, *eq=True*, *order=False*, *unsafe\_hash=False*, *frozen=False*, *match\_args=True*, *kw\_only=False*, *slots=False*, *weakref\_slot=False*, *module=None*)

Creates a new dataclass with name *cls\_name*, fields as defined in *fields*, base classes as given in *bases*, and initialized with a namespace as given in *namespace*. *fields* is an iterable whose elements are each either *name*, (*name*, *type*), or (*name*, *type*, *Field*). If just *name* is supplied, *typing.Any* is used for *type*. The values of *init*, *repr*, *eq*, *order*, *unsafe\_hash*, *frozen*, *match\_args*, *kw\_only*, *slots*, and *weakref\_slot* have the same meaning as they do in `@dataclass`.

If *module* is defined, the `__module__` attribute of the dataclass is set to that value. By default, it is set to the module name of the caller.

This function is not strictly required, because any Python mechanism for creating a new class with `__annotations__` can then apply the `@dataclass` function to convert that class to a dataclass. This function is provided as a convenience. For example:

```
C = make_dataclass('C',
                  [ ('x', int),
                    'y',
                    ('z', int, field(default=5)) ],
                  namespace={'add_one': lambda self: self.x + 1})
```

相當於：

```
@dataclass
class C:
    x: int
    y: 'typing.Any'
    z: int = 5

    def add_one(self):
        return self.x + 1
```

`dataclasses.replace(obj, /, **changes)`

Creates a new object of the same type as `obj`, replacing fields with values from `changes`. If `obj` is not a Data Class, raises `TypeError`. If keys in `changes` are not field names of the given dataclass, raises `TypeError`.

The newly returned object is created by calling the `__init__()` method of the dataclass. This ensures that `__post_init__()`, if present, is also called.

Init-only variables without default values, if any exist, must be specified on the call to `replace()` so that they can be passed to `__init__()` and `__post_init__()`.

It is an error for `changes` to contain any fields that are defined as having `init=False`. A `ValueError` will be raised in this case.

Be forewarned about how `init=False` fields work during a call to `replace()`. They are not copied from the source object, but rather are initialized in `__post_init__()`, if they're initialized at all. It is expected that `init=False` fields will be rarely and judiciously used. If they are used, it might be wise to have alternate class constructors, or perhaps a custom `replace()` (or similarly named) method which handles instance copying.

Dataclass instances are also supported by generic function `copy.replace()`.

`dataclasses.is_dataclass(obj)`

Return `True` if its parameter is a dataclass (including subclasses of a dataclass) or an instance of one, otherwise return `False`.

If you need to know if a class is an instance of a dataclass (and not a dataclass itself), then add a further check for `not isinstance(obj, type)`:

```
def is_dataclass_instance(obj):
    return is_dataclass(obj) and not isinstance(obj, type)
```

`dataclasses.MISSING`

A sentinel value signifying a missing default or `default_factory`.

`dataclasses.KW_ONLY`

A sentinel value used as a type annotation. Any fields after a pseudo-field with the type of `KW_ONLY` are marked as keyword-only fields. Note that a pseudo-field of type `KW_ONLY` is otherwise completely ignored. This includes the name of such a field. By convention, a name of `_` is used for a `KW_ONLY` field. Keyword-only fields signify `__init__()` parameters that must be specified as keywords when the class is instantiated.

In this example, the fields `y` and `z` will be marked as keyword-only fields:

```
@dataclass
class Point:
    x: float
    _: KW_ONLY
    y: float
    z: float

p = Point(0, y=1.5, z=2.0)
```

In a single dataclass, it is an error to specify more than one field whose type is `KW_ONLY`.

在 3.10 版被加入。

#### exception `dataclasses.FrozenInstanceError`

Raised when an implicitly defined `__setattr__()` or `__delattr__()` is called on a dataclass which was defined with `frozen=True`. It is a subclass of `AttributeError`.

### 30.7.2 Post-init processing

#### `dataclasses.__post_init__()`

When defined on the class, it will be called by the generated `__init__()`, normally as `self.__post_init__()`. However, if any `InitVar` fields are defined, they will also be passed to `__post_init__()` in the order they were defined in the class. If no `__init__()` method is generated, then `__post_init__()` will not automatically be called.

Among other uses, this allows for initializing field values that depend on one or more other fields. For example:

```
@dataclass
class C:
    a: float
    b: float
    c: float = field(init=False)

    def __post_init__(self):
        self.c = self.a + self.b
```

The `__init__()` method generated by `@dataclass` does not call base class `__init__()` methods. If the base class has an `__init__()` method that has to be called, it is common to call this method in a `__post_init__()` method:

```
class Rectangle:
    def __init__(self, height, width):
        self.height = height
        self.width = width

@dataclass
class Square(Rectangle):
    side: float

    def __post_init__(self):
        super().__init__(self.side, self.side)
```

Note, however, that in general the dataclass-generated `__init__()` methods don't need to be called, since the derived dataclass will take care of initializing all fields of any base class that is a dataclass itself.

See the section below on `init-only` variables for ways to pass parameters to `__post_init__()`. Also see the warning about how `replace()` handles `init=False` fields.

### 30.7.3 類變數

One of the few places where `@dataclass` actually inspects the type of a field is to determine if a field is a class variable as defined in [PEP 526](#). It does this by checking if the type of the field is `typing.ClassVar`. If a field is a `ClassVar`, it is excluded from consideration as a field and is ignored by the dataclass mechanisms. Such `ClassVar` pseudo-fields are not returned by the module-level `fields()` function.

### 30.7.4 Init-only variables

Another place where `@dataclass` inspects a type annotation is to determine if a field is an init-only variable. It does this by seeing if the type of a field is of type `dataclasses.InitVar`. If a field is an `InitVar`, it is considered a pseudo-field called an init-only field. As it is not a true field, it is not returned by the module-level `fields()` function. Init-only fields are added as parameters to the generated `__init__()` method, and are passed to the optional `__post_init__()` method. They are not otherwise used by dataclasses.

For example, suppose a field will be initialized from a database, if a value is not provided when creating the class:

```
@dataclass
class C:
    i: int
    j: int | None = None
    database: InitVar[DatabaseType | None] = None

    def __post_init__(self, database):
        if self.j is None and database is not None:
            self.j = database.lookup('j')

c = C(10, database=my_database)
```

In this case, `fields()` will return `Field` objects for `i` and `j`, but not for `database`.

### 30.7.5 凍結實例

It is not possible to create truly immutable Python objects. However, by passing `frozen=True` to the `@dataclass` decorator you can emulate immutability. In that case, dataclasses will add `__setattr__()` and `__delattr__()` methods to the class. These methods will raise a `FrozenInstanceError` when invoked.

There is a tiny performance penalty when using `frozen=True`: `__init__()` cannot use simple assignment to initialize fields, and must use `object.__setattr__()`.

### 30.7.6 繼承

When the dataclass is being created by the `@dataclass` decorator, it looks through all of the class's base classes in reverse MRO (that is, starting at `object`) and, for each dataclass that it finds, adds the fields from that base class to an ordered mapping of fields. After all of the base class fields are added, it adds its own fields to the ordered mapping. All of the generated methods will use this combined, calculated ordered mapping of fields. Because the fields are in insertion order, derived classes override base classes. An example:

```
@dataclass
class Base:
    x: Any = 15.0
    y: int = 0

@dataclass
class C(Base):
    z: int = 10
    x: int = 15
```

The final list of fields is, in order, `x`, `y`, `z`. The final type of `x` is `int`, as specified in class `C`.

The generated `__init__()` method for `C` will look like:

```
def __init__(self, x: int = 15, y: int = 0, z: int = 10):
```

### 30.7.7 Re-ordering of keyword-only parameters in `__init__()`

After the parameters needed for `__init__()` are computed, any keyword-only parameters are moved to come after all regular (non-keyword-only) parameters. This is a requirement of how keyword-only parameters are implemented in Python: they must come after non-keyword-only parameters.

In this example, `Base.y`, `Base.w`, and `D.t` are keyword-only fields, and `Base.x` and `D.z` are regular fields:

```
@dataclass
class Base:
    x: Any = 15.0
    _: KW_ONLY
    y: int = 0
    w: int = 1

@dataclass
class D(Base):
    z: int = 10
    t: int = field(kw_only=True, default=0)
```

The generated `__init__()` method for `D` will look like:

```
def __init__(self, x: Any = 15.0, z: int = 10, *, y: int = 0, w: int = 1, t: int = 0):
```

Note that the parameters have been re-ordered from how they appear in the list of fields: parameters derived from regular fields are followed by parameters derived from keyword-only fields.

The relative ordering of keyword-only parameters is maintained in the re-ordered `__init__()` parameter list.

### 30.7.8 預設工廠函式

If a `field()` specifies a `default_factory`, it is called with zero arguments when a default value for the field is needed. For example, to create a new instance of a list, use:

```
mylist: list = field(default_factory=list)
```

If a field is excluded from `__init__()` (using `init=False`) and the field also specifies `default_factory`, then the default factory function will always be called from the generated `__init__()` function. This happens because there is no other way to give the field an initial value.

### 30.7.9 可變預設值

Python stores default member variable values in class attributes. Consider this example, not using dataclasses:

```
class C:
    x = []
    def add(self, element):
        self.x.append(element)

o1 = C()
o2 = C()
o1.add(1)
o2.add(2)
assert o1.x == [1, 2]
assert o1.x is o2.x
```

Note that the two instances of class `C` share the same class variable `x`, as expected.

Using dataclasses, *if* this code was valid:

```
@dataclass
class D:
    x: list = [] # This code raises ValueError
    def add(self, element):
        self.x.append(element)
```

它會生成類似的程式碼：

```
class D:
    x = []
    def __init__(self, x=x):
        self.x = x
    def add(self, element):
        self.x.append(element)

assert D().x is D().x
```

This has the same issue as the original example using class C. That is, two instances of class D that do not specify a value for x when creating a class instance will share the same copy of x. Because dataclasses just use normal Python class creation they also share this behavior. There is no general way for Data Classes to detect this condition. Instead, the `@dataclass` decorator will raise a `ValueError` if it detects an unhashable default parameter. The assumption is that if a value is unhashable, it is mutable. This is a partial solution, but it does protect against many common errors.

Using default factory functions is a way to create new instances of mutable types as default values for fields:

```
@dataclass
class D:
    x: list = field(default_factory=list)

assert D().x is not D().x
```

在 3.11 版的變更: Instead of looking for and disallowing objects of type `list`, `dict`, or `set`, unhashable objects are now not allowed as default values. Unhashability is used to approximate mutability.

### 30.7.10 Descriptor-typed fields

Fields that are assigned descriptor objects as their default value have the following special behaviors:

- The value for the field passed to the dataclass's `__init__()` method is passed to the descriptor's `__set__()` method rather than overwriting the descriptor object.
- Similarly, when getting or setting the field, the descriptor's `__get__()` or `__set__()` method is called rather than returning or overwriting the descriptor object.
- To determine whether a field contains a default value, `@dataclass` will call the descriptor's `__get__()` method using its class access form: `descriptor.__get__(obj=None, type=cls)`. If the descriptor returns a value in this case, it will be used as the field's default. On the other hand, if the descriptor raises `AttributeError` in this situation, no default value will be provided for the field.

```
class IntConversionDescriptor:
    def __init__(self, *, default):
        self._default = default

    def __set_name__(self, owner, name):
        self._name = "_" + name

    def __get__(self, obj, type):
        if obj is None:
            return self._default

        return getattr(obj, self._name, self._default)
```

(繼續下一頁)

(繼續上一頁)

```

def __set__(self, obj, value):
    setattr(obj, self._name, int(value))

@dataclass
class InventoryItem:
    quantity_on_hand: IntConversionDescriptor = IntConversionDescriptor(default=100)

i = InventoryItem()
print(i.quantity_on_hand) # 100
i.quantity_on_hand = 2.5 # calls __set__ with 2.5
print(i.quantity_on_hand) # 2

```

Note that if a field is annotated with a descriptor type, but is not assigned a descriptor object as its default value, the field will act like a normal field.

## 30.8 contextlib --- Utilities for with-statement contexts

原始碼: `Lib/contextlib.py`

This module provides utilities for common tasks involving the `with` statement. For more information see also [情境管理器型 F](#) and `context-managers`.

### 30.8.1 Utilities

Functions and classes provided:

**class** `contextlib.AbstractContextManager`

An *abstract base class* for classes that implement `object.__enter__()` and `object.__exit__()`. A default implementation for `object.__enter__()` is provided which returns `self` while `object.__exit__()` is an abstract method which by default returns `None`. See also the definition of [情境管理器型 F](#).

在 3.6 版被加入.

**class** `contextlib.AbstractAsyncContextManager`

An *abstract base class* for classes that implement `object.__aenter__()` and `object.__aexit__()`. A default implementation for `object.__aenter__()` is provided which returns `self` while `object.__aexit__()` is an abstract method which by default returns `None`. See also the definition of `async-context-managers`.

在 3.7 版被加入.

**@contextlib.contextmanager**

This function is a *decorator* that can be used to define a factory function for `with` statement context managers, without needing to create a class or separate `__enter__()` and `__exit__()` methods.

While many objects natively support use in `with` statements, sometimes a resource needs to be managed that isn't a context manager in its own right, and doesn't implement a `close()` method for use with `contextlib.closing`

An abstract example would be the following to ensure correct resource management:

```

from contextlib import contextmanager

@contextmanager
def managed_resource(*args, **kwds):
    # Code to acquire resource, e.g.:

```

(繼續下一頁)

(繼續上一頁)

```

resource = acquire_resource(*args, **kwargs)
try:
    yield resource
finally:
    # Code to release resource, e.g.:
    release_resource(resource)

```

The function can then be used like this:

```

>>> with managed_resource(timeout=3600) as resource:
...     # Resource is released at the end of this block,
...     # even if code in the block raises an exception

```

The function being decorated must return a *generator*-iterator when called. This iterator must yield exactly one value, which will be bound to the targets in the `with` statement's `as` clause, if any.

At the point where the generator yields, the block nested in the `with` statement is executed. The generator is then resumed after the block is exited. If an unhandled exception occurs in the block, it is reraised inside the generator at the point where the `yield` occurred. Thus, you can use a `try...except...finally` statement to trap the error (if any), or ensure that some cleanup takes place. If an exception is trapped merely in order to log it or to perform some action (rather than to suppress it entirely), the generator must reraise that exception. Otherwise the generator context manager will indicate to the `with` statement that the exception has been handled, and execution will resume with the statement immediately following the `with` statement.

`contextmanager()` uses `ContextDecorator` so the context managers it creates can be used as decorators as well as in `with` statements. When used as a decorator, a new generator instance is implicitly created on each function call (this allows the otherwise "one-shot" context managers created by `contextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators).

在 3.2 版的變更: Use of `ContextDecorator`.

#### @contextlib.asynccontextmanager

Similar to `contextmanager()`, but creates an asynchronous context manager.

This function is a *decorator* that can be used to define a factory function for `async with` statement asynchronous context managers, without needing to create a class or separate `__aenter__()` and `__aexit__()` methods. It must be applied to an *asynchronous generator* function.

一個簡單範例:

```

from contextlib import asynccontextmanager

@asynccontextmanager
async def get_connection():
    conn = await acquire_db_connection()
    try:
        yield conn
    finally:
        await release_db_connection(conn)

async def get_all_users():
    async with get_connection() as conn:
        return conn.query('SELECT ...')

```

在 3.7 版被加入.

Context managers defined with `asynccontextmanager()` can be used either as decorators or with `async with` statements:

```

import time
from contextlib import asynccontextmanager

```

(繼續下一頁)

(繼續上一頁)

```

@asynccontextmanager
async def timeit():
    now = time.monotonic()
    try:
        yield
    finally:
        print(f'it took {time.monotonic() - now}s to run')

@timeit()
async def main():
    # ... async code ...

```

When used as a decorator, a new generator instance is implicitly created on each function call. This allows the otherwise "one-shot" context managers created by `asynccontextmanager()` to meet the requirement that context managers support multiple invocations in order to be used as decorators.

在 3.10 版的變更: Async context managers created with `asynccontextmanager()` can be used as decorators.

`contextlib.closing(thing)`

Return a context manager that closes *thing* upon completion of the block. This is basically equivalent to:

```

from contextlib import contextmanager

@contextmanager
def closing(thing):
    try:
        yield thing
    finally:
        thing.close()

```

And lets you write code like this:

```

from contextlib import closing
from urllib.request import urlopen

with closing(urlopen('https://www.python.org')) as page:
    for line in page:
        print(line)

```

without needing to explicitly close `page`. Even if an error occurs, `page.close()` will be called when the `with` block is exited.

### 備 F

Most types managing resources support the *context manager* protocol, which closes *thing* on leaving the `with` statement. As such, `closing()` is most useful for third party types that don't support context managers. This example is purely for illustration purposes, as `urlopen()` would normally be used in a context manager.

`contextlib.aclosing(thing)`

Return an async context manager that calls the `aclose()` method of *thing* upon completion of the block. This is basically equivalent to:

```

from contextlib import asynccontextmanager

@asynccontextmanager
async def aclosing(thing):
    try:

```

(繼續下一頁)

(繼續上一頁)

```

    yield thing
finally:
    await thing.aclose()

```

Significantly, `aclosing()` supports deterministic cleanup of async generators when they happen to exit early by `break` or an exception. For example:

```

from contextlib import aclosing

async with aclosing(my_generator()) as values:
    async for value in values:
        if value == 42:
            break

```

This pattern ensures that the generator's async exit code is executed in the same context as its iterations (so that exceptions and context variables work as expected, and the exit code isn't run after the lifetime of some task it depends on).

在 3.10 版被加入。

`contextlib.nullcontext` (*enter\_result=None*)

Return a context manager that returns *enter\_result* from `__enter__`, but otherwise does nothing. It is intended to be used as a stand-in for an optional context manager, for example:

```

def myfunction(arg, ignore_exceptions=False):
    if ignore_exceptions:
        # Use suppress to ignore all exceptions.
        cm = contextlib.suppress(Exception)
    else:
        # Do not ignore any exceptions, cm has no effect.
        cm = contextlib.nullcontext()
    with cm:
        # Do something

```

一個使用 *enter\_result* 的範例：

```

def process_file(file_or_path):
    if isinstance(file_or_path, str):
        # If string, open file
        cm = open(file_or_path)
    else:
        # Caller is responsible for closing file
        cm = nullcontext(file_or_path)

    with cm as file:
        # Perform processing on the file

```

It can also be used as a stand-in for asynchronous context managers:

```

async def send_http(session=None):
    if not session:
        # If no http session, create it with aiohttp
        cm = aiohttp.ClientSession()
    else:
        # Caller is responsible for closing the session
        cm = nullcontext(session)

    async with cm as session:
        # Send http requests with session

```

在 3.7 版被加入。

在 3.10 版的變更: *asynchronous context manager* support was added.

`contextlib.suppress(*exceptions)`

Return a context manager that suppresses any of the specified exceptions if they occur in the body of a `with` statement and then resumes execution with the first statement following the end of the `with` statement.

As with any other mechanism that completely suppresses exceptions, this context manager should be used only to cover very specific errors where silently continuing with program execution is known to be the right thing to do.

舉例來:

```
from contextlib import suppress

with suppress(FileNotFoundError):
    os.remove('somefile.tmp')

with suppress(FileNotFoundError):
    os.remove('someotherfile.tmp')
```

This code is equivalent to:

```
try:
    os.remove('somefile.tmp')
except FileNotFoundError:
    pass

try:
    os.remove('someotherfile.tmp')
except FileNotFoundError:
    pass
```

This context manager is *reentrant*.

If the code within the `with` block raises a *BaseExceptionGroup*, suppressed exceptions are removed from the group. Any exceptions of the group which are not suppressed are re-raised in a new group which is created using the original group's *derive()* method.

在 3.4 版被加入.

在 3.12 版的變更: `suppress` now supports suppressing exceptions raised as part of a *BaseExceptionGroup*.

`contextlib.redirect_stdout(new_target)`

Context manager for temporarily redirecting `sys.stdout` to another file or file-like object.

This tool adds flexibility to existing functions or classes whose output is hardwired to `stdout`.

For example, the output of `help()` normally is sent to `sys.stdout`. You can capture that output in a string by redirecting the output to an *io.StringIO* object. The replacement stream is returned from the `__enter__` method and so is available as the target of the `with` statement:

```
with redirect_stdout(io.StringIO()) as f:
    help(pow)
s = f.getvalue()
```

To send the output of `help()` to a file on disk, redirect the output to a regular file:

```
with open('help.txt', 'w') as f:
    with redirect_stdout(f):
        help(pow)
```

To send the output of `help()` to `sys.stderr`:

```
with redirect_stdout(sys.stderr):
    help(pow)
```

Note that the global side effect on `sys.stdout` means that this context manager is not suitable for use in library code and most threaded applications. It also has no effect on the output of subprocesses. However, it is still a useful approach for many utility scripts.

This context manager is *reentrant*.

在 3.4 版被加入。

`contextlib.redirect_stderr(new_target)`

Similar to `redirect_stdout()` but redirecting `sys.stderr` to another file or file-like object.

This context manager is *reentrant*.

在 3.5 版被加入。

`contextlib.chdir(path)`

Non parallel-safe context manager to change the current working directory. As this changes a global state, the working directory, it is not suitable for use in most threaded or async contexts. It is also not suitable for most non-linear code execution, like generators, where the program execution is temporarily relinquished -- unless explicitly desired, you should not yield when this context manager is active.

This is a simple wrapper around `chdir()`, it changes the current working directory upon entering and restores the old one on exit.

This context manager is *reentrant*.

在 3.11 版被加入。

**class** `contextlib.ContextDecorator`

A base class that enables a context manager to also be used as a decorator.

Context managers inheriting from `ContextDecorator` have to implement `__enter__` and `__exit__` as normal. `__exit__` retains its optional exception handling even when used as a decorator.

`ContextDecorator` is used by `contextmanager()`, so you get this functionality automatically.

`ContextDecorator` 範例：

```
from contextlib import ContextDecorator

class mycontext(ContextDecorator):
    def __enter__(self):
        print('Starting')
        return self

    def __exit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```
>>> @mycontext()
... def function():
...     print('The bit in the middle')
...
>>> function()
Starting
The bit in the middle
Finishing

>>> with mycontext():
...     print('The bit in the middle')
```

(繼續下一頁)

(繼續上一頁)

```
...
Starting
The bit in the middle
Finishing
```

This change is just syntactic sugar for any construct of the following form:

```
def f():
    with cm():
        # Do stuff
```

`ContextDecorator` lets you instead write:

```
@cm()
def f():
    # Do stuff
```

It makes it clear that the `cm` applies to the whole function, rather than just a piece of it (and saving an indentation level is nice, too).

Existing context managers that already have a base class can be extended by using `ContextDecorator` as a mixin class:

```
from contextlib import ContextDecorator

class mycontext(ContextBaseClass, ContextDecorator):
    def __enter__(self):
        return self

    def __exit__(self, *exc):
        return False
```

### 備 F

As the decorated function must be able to be called multiple times, the underlying context manager must support use in multiple `with` statements. If this is not the case, then the original construct with the explicit `with` statement inside the function should be used.

在 3.2 版被加入。

**class** `contextlib.AsyncContextDecorator`

Similar to `ContextDecorator` but only for asynchronous functions.

`AsyncContextDecorator` 範例:

```
from asyncio import run
from contextlib import AsyncContextDecorator

class mycontext(AsyncContextDecorator):
    async def __aenter__(self):
        print('Starting')
        return self

    async def __aexit__(self, *exc):
        print('Finishing')
        return False
```

The class can then be used like this:

```

>>> @mycontext ()
... async def function():
...     print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing

>>> async def function():
...     async with mycontext():
...         print('The bit in the middle')
...
>>> run(function())
Starting
The bit in the middle
Finishing

```

在 3.10 版被加入。

**class** contextlib.**ExitStack**

A context manager that is designed to make it easy to programmatically combine other context managers and cleanup functions, especially those that are optional or otherwise driven by input data.

For example, a set of files may easily be handled in a single with statement as follows:

```

with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # All opened files will automatically be closed at the end of
    # the with statement, even if attempts to open files later
    # in the list raise an exception

```

The `__enter__()` method returns the *ExitStack* instance, and performs no additional operations.

Each instance maintains a stack of registered callbacks that are called in reverse order when the instance is closed (either explicitly or implicitly at the end of a `with` statement). Note that callbacks are *not* invoked implicitly when the context stack instance is garbage collected.

This stack model is used so that context managers that acquire their resources in their `__init__` method (such as file objects) can be handled correctly.

Since registered callbacks are invoked in the reverse order of registration, this ends up behaving as if multiple nested `with` statements had been used with the registered set of callbacks. This even extends to exception handling - if an inner callback suppresses or replaces an exception, then outer callbacks will be passed arguments based on that updated state.

This is a relatively low level API that takes care of the details of correctly unwinding the stack of exit callbacks. It provides a suitable foundation for higher level context managers that manipulate the exit stack in application specific ways.

在 3.3 版被加入。

**enter\_context** (*cm*)

Enters a new context manager and adds its `__exit__()` method to the callback stack. The return value is the result of the context manager's own `__enter__()` method.

These context managers may suppress exceptions just as they normally would if used directly as part of a `with` statement.

在 3.11 版的變更: Raises *TypeError* instead of *AttributeError* if *cm* is not a context manager.

**push** (*exit*)

Adds a context manager's `__exit__()` method to the callback stack.

As `__enter__` is *not* invoked, this method can be used to cover part of an `__enter__()` implementation with a context manager's own `__exit__()` method.

If passed an object that is not a context manager, this method assumes it is a callback with the same signature as a context manager's `__exit__()` method and adds it directly to the callback stack.

By returning true values, these callbacks can suppress exceptions the same way context manager `__exit__()` methods can.

The passed in object is returned from the function, allowing this method to be used as a function decorator.

**callback** (*callback*, /, \*args, \*\*kwargs)

Accepts an arbitrary callback function and arguments and adds it to the callback stack.

Unlike the other methods, callbacks added this way cannot suppress exceptions (as they are never passed the exception details).

The passed in callback is returned from the function, allowing this method to be used as a function decorator.

**pop\_all** ()

Transfers the callback stack to a fresh `ExitStack` instance and returns it. No callbacks are invoked by this operation - instead, they will now be invoked when the new stack is closed (either explicitly or implicitly at the end of a `with` statement).

For example, a group of files can be opened as an "all or nothing" operation as follows:

```
with ExitStack() as stack:
    files = [stack.enter_context(open(fname)) for fname in filenames]
    # Hold onto the close method, but don't call it yet.
    close_files = stack.pop_all().close
    # If opening any file fails, all previously opened files will be
    # closed automatically. If all files are opened successfully,
    # they will remain open even after the with statement ends.
    # close_files() can then be invoked explicitly to close them all.
```

**close** ()

Immediately unwinds the callback stack, invoking callbacks in the reverse order of registration. For any context managers and exit callbacks registered, the arguments passed in will indicate that no exception occurred.

**class** `contextlib.AsyncExitStack`

An asynchronous context manager, similar to `ExitStack`, that supports combining both synchronous and asynchronous context managers, as well as having coroutines for cleanup logic.

The `close()` method is not implemented; `aclose()` must be used instead.

**async enter\_async\_context** (*cm*)

Similar to `ExitStack.enter_context()` but expects an asynchronous context manager.

在 3.11 版的變更: Raises `TypeError` instead of `AttributeError` if *cm* is not an asynchronous context manager.

**push\_async\_exit** (*exit*)

Similar to `ExitStack.push()` but expects either an asynchronous context manager or a coroutine function.

**push\_async\_callback** (*callback*, /, \*args, \*\*kwargs)

Similar to `ExitStack.callback()` but expects a coroutine function.

**async aclose** ()

Similar to `ExitStack.close()` but properly handles awaitables.

Continuing the example for `asynccontextmanager`:

```

async with AsyncExitStack() as stack:
    connections = [await stack.enter_async_context(get_connection())
                   for i in range(5)]
    # All opened connections will automatically be released at the end of
    # the async with statement, even if attempts to open a connection
    # later in the list raise an exception.

```

在 3.7 版被加入。

## 30.8.2 Examples and Recipes

This section describes some examples and recipes for making effective use of the tools provided by `contextlib`.

### Supporting a variable number of context managers

The primary use case for `ExitStack` is the one given in the class documentation: supporting a variable number of context managers and other cleanup operations in a single `with` statement. The variability may come from the number of context managers needed being driven by user input (such as opening a user specified collection of files), or from some of the context managers being optional:

```

with ExitStack() as stack:
    for resource in resources:
        stack.enter_context(resource)
    if need_special_resource():
        special = acquire_special_resource()
        stack.callback(release_special_resource, special)
    # Perform operations that use the acquired resources

```

As shown, `ExitStack` also makes it quite easy to use `with` statements to manage arbitrary resources that don't natively support the context management protocol.

### Catching exceptions from `__enter__` methods

It is occasionally desirable to catch exceptions from an `__enter__` method implementation, *without* inadvertently catching exceptions from the `with` statement body or the context manager's `__exit__` method. By using `ExitStack` the steps in the context management protocol can be separated slightly in order to allow this:

```

stack = ExitStack()
try:
    x = stack.enter_context(cm)
except Exception:
    # handle __enter__ exception
else:
    with stack:
        # Handle normal case

```

Actually needing to do this is likely to indicate that the underlying API should be providing a direct resource management interface for use with `try/except/finally` statements, but not all APIs are well designed in that regard. When a context manager is the only resource management API provided, then `ExitStack` can make it easier to handle various situations that can't be handled directly in a `with` statement.

### Cleaning up in an `__enter__` implementation

As noted in the documentation of `ExitStack.push()`, this method can be useful in cleaning up an already allocated resource if later steps in the `__enter__()` implementation fail.

Here's an example of doing this for a context manager that accepts resource acquisition and release functions, along with an optional validation function, and maps them to the context management protocol:

```

from contextlib import contextmanager, AbstractContextManager, ExitStack

class ResourceManager(AbstractContextManager):

    def __init__(self, acquire_resource, release_resource, check_resource_ok=None):
        self.acquire_resource = acquire_resource
        self.release_resource = release_resource
        if check_resource_ok is None:
            def check_resource_ok(resource):
                return True
        self.check_resource_ok = check_resource_ok

    @contextmanager
    def _cleanup_on_error(self):
        with ExitStack() as stack:
            stack.push(self)
            yield
            # The validation check passed and didn't raise an exception
            # Accordingly, we want to keep the resource, and pass it
            # back to our caller
            stack.pop_all()

    def __enter__(self):
        resource = self.acquire_resource()
        with self._cleanup_on_error():
            if not self.check_resource_ok(resource):
                msg = "Failed validation for {!r}"
                raise RuntimeError(msg.format(resource))
        return resource

    def __exit__(self, *exc_details):
        # We don't need to duplicate any of our resource release logic
        self.release_resource()

```

### Replacing any use of try-finally and flag variables

A pattern you will sometimes see is a try-finally statement with a flag variable to indicate whether or not the body of the finally clause should be executed. In its simplest form (that can't already be handled just by using an except clause instead), it looks something like this:

```

cleanup_needed = True
try:
    result = perform_operation()
    if result:
        cleanup_needed = False
finally:
    if cleanup_needed:
        cleanup_resources()

```

As with any try statement based code, this can cause problems for development and review, because the setup code and the cleanup code can end up being separated by arbitrarily long sections of code.

`ExitStack` makes it possible to instead register a callback for execution at the end of a with statement, and then later decide to skip executing that callback:

```

from contextlib import ExitStack

with ExitStack() as stack:
    stack.callback(cleanup_resources)
    result = perform_operation()
    if result:
        stack.pop_all()

```

This allows the intended cleanup behaviour to be made explicit up front, rather than requiring a separate flag variable.

If a particular application uses this pattern a lot, it can be simplified even further by means of a small helper class:

```
from contextlib import ExitStack

class Callback(ExitStack):
    def __init__(self, callback, /, *args, **kwargs):
        super().__init__()
        self.callback(callback, *args, **kwargs)

    def cancel(self):
        self.pop_all()

with Callback(cleanup_resources) as cb:
    result = perform_operation()
    if result:
        cb.cancel()
```

If the resource cleanup isn't already neatly bundled into a standalone function, then it is still possible to use the decorator form of `ExitStack.callback()` to declare the resource cleanup in advance:

```
from contextlib import ExitStack

with ExitStack() as stack:
    @stack.callback
    def cleanup_resources():
        ...
    result = perform_operation()
    if result:
        stack.pop_all()
```

Due to the way the decorator protocol works, a callback function declared this way cannot take any parameters. Instead, any resources to be released must be accessed as closure variables.

### Using a context manager as a function decorator

`ContextDecorator` makes it possible to use a context manager in both an ordinary `with` statement and also as a function decorator.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, inheriting from `ContextDecorator` provides both capabilities in a single definition:

```
from contextlib import ContextDecorator
import logging

logging.basicConfig(level=logging.INFO)

class track_entry_and_exit(ContextDecorator):
    def __init__(self, name):
        self.name = name

    def __enter__(self):
        logging.info('Entering: %s', self.name)

    def __exit__(self, exc_type, exc, exc_tb):
        logging.info('Exiting: %s', self.name)
```

Instances of this class can be used as both a context manager:

```
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

And also as a function decorator:

```
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Note that there is one additional limitation when using context managers as function decorators: there's no way to access the return value of `__enter__()`. If that value is needed, then it is still necessary to use an explicit `with` statement.

### 也參考

#### PEP 343 - "with" 陳述式

The specification, background, and examples for the Python `with` statement.

## 30.8.3 Single use, reusable and reentrant context managers

Most context managers are written in a way that means they can only be used effectively in a `with` statement once. These single use context managers must be created afresh each time they're used - attempting to use them a second time will trigger an exception or otherwise not work correctly.

This common limitation means that it is generally advisable to create context managers directly in the header of the `with` statement where they are used (as shown in all of the usage examples above).

Files are an example of effectively single use context managers, since the first `with` statement will close the file, preventing any further IO operations using that file object.

Context managers created using `contextmanager()` are also single use context managers, and will complain about the underlying generator failing to yield if an attempt is made to use them a second time:

```
>>> from contextlib import contextmanager
>>> @contextmanager
... def singleuse():
...     print("Before")
...     yield
...     print("After")
...
>>> cm = singleuse()
>>> with cm:
...     pass
...
Before
After
>>> with cm:
...     pass
...
Traceback (most recent call last):
...
RuntimeError: generator didn't yield
```

## Reentrant context managers

More sophisticated context managers may be "reentrant". These context managers can not only be used in multiple `with` statements, but may also be used *inside* a `with` statement that is already using the same context manager.

`threading.RLock` is an example of a reentrant context manager, as are `suppress()`, `redirect_stdout()`, and `chdir()`. Here's a very simple example of reentrant use:

```
>>> from contextlib import redirect_stdout
>>> from io import StringIO
>>> stream = StringIO()
>>> write_to_stream = redirect_stdout(stream)
>>> with write_to_stream:
...     print("This is written to the stream rather than stdout")
...     with write_to_stream:
...         print("This is also written to the stream")
...
>>> print("This is written directly to stdout")
This is written directly to stdout
>>> print(stream.getvalue())
This is written to the stream rather than stdout
This is also written to the stream
```

Real world examples of reentrancy are more likely to involve multiple functions calling each other and hence be far more complicated than this example.

Note also that being reentrant is *not* the same thing as being thread safe. `redirect_stdout()`, for example, is definitely not thread safe, as it makes a global modification to the system state by binding `sys.stdout` to a different stream.

## Reusable context managers

Distinct from both single use and reentrant context managers are "reusable" context managers (or, to be completely explicit, "reusable, but not reentrant" context managers, since reentrant context managers are also reusable). These context managers support being used multiple times, but will fail (or otherwise not work correctly) if the specific context manager instance has already been used in a containing `with` statement.

`threading.Lock` is an example of a reusable, but not reentrant, context manager (for a reentrant lock, it is necessary to use `threading.RLock` instead).

Another example of a reusable, but not reentrant, context manager is `ExitStack`, as it invokes *all* currently registered callbacks when leaving any `with` statement, regardless of where those callbacks were added:

```
>>> from contextlib import ExitStack
>>> stack = ExitStack()
>>> with stack:
...     stack.callback(print, "Callback: from first context")
...     print("Leaving first context")
...
Leaving first context
Callback: from first context
>>> with stack:
...     stack.callback(print, "Callback: from second context")
...     print("Leaving second context")
...
Leaving second context
Callback: from second context
>>> with stack:
...     stack.callback(print, "Callback: from outer context")
...     with stack:
...         stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
```

(繼續下一頁)

(繼續上一頁)

```
...
Leaving inner context
Callback: from inner context
Callback: from outer context
Leaving outer context
```

As the output from the example shows, reusing a single stack object across multiple with statements works correctly, but attempting to nest them will cause the stack to be cleared at the end of the innermost with statement, which is unlikely to be desirable behaviour.

Using separate `ExitStack` instances instead of reusing a single instance avoids that problem:

```
>>> from contextlib import ExitStack
>>> with ExitStack() as outer_stack:
...     outer_stack.callback(print, "Callback: from outer context")
...     with ExitStack() as inner_stack:
...         inner_stack.callback(print, "Callback: from inner context")
...         print("Leaving inner context")
...     print("Leaving outer context")
...
Leaving inner context
Callback: from inner context
Leaving outer context
Callback: from outer context
```

## 30.9 abc --- 抽象基底類

原始碼: Lib/abc.py

如同在 [PEP 3119](#) 中所述，該模組提供了在 Python 中定義抽象基底類 (ABC) 的基礎元件；若想解開什需要在 Python 中增加這個模組，請見 PEP 文件。（也請見 [PEP 3141](#) 以及 `numbers` 模組以解基於 ABC 的數字型階層關）

`collections` 模組中有一些衍生自 ABC 的具體類；當然這些類還可以進一步衍生出其他類。此外，`collections.abc` 子模組中有一些 ABC 可被用於測試一個類或實例是否提供特定介面，例如它是否可雜 (`hashable`) 或它是否對映。

該模組提供了一個用來定義 ABC 的元類 (`metaclass`) `ABCMeta` 和另一個以繼承的方式定義 ABC 的工具類 `ABC`：

```
class abc.ABC
```

一個使用 `ABCMeta` 作元類的工具類。抽象基底類可以透過自 `ABC` 衍生而建立，這就避免了在某些情況下會令人混淆的元類用法，用法如下範例：

```
from abc import ABC

class MyABC(ABC):
    pass
```

注意 `ABC` 的型仍然是 `ABCMeta`，因此繼承 `ABC` 仍然需要關注使用元類的注意事項，如多重繼承可能會導致元類衝突。當然你也可以傳入元類關鍵字直接使用 `ABCMeta` 來定義一個抽象基底類，例如：

```
from abc import ABCMeta

class MyABC(metaclass=ABCMeta):
    pass
```

在 3.4 版被加入。

`class abc.ABCMeta`

用於定義抽象基底類 (ABC) 的元類。

使用該元類以建立一個 ABC。一個 ABC 可以像 mix-in 類一樣直接被子類繼承。你也可以將不相關的具體類 (甚至是建類) 和 ABC 擬子類 (virtual subclass) —— 這些類以及它們的子類會被建函式 `issubclass()` 識已 ABC 的子類, 但是該 ABC 不會出現在其 MRO (Method Resolution Order, 方法解析順序) 中, 由該 ABC 所定義的方法實作也不可呼叫 (即使透過 `super()` 呼叫也不行)。<sup>1</sup>

使用 `ABCMeta` 作元類建立的類含有以下的方法:

`register(subclass)`

將子類該 ABC 的「抽象子類」, 例如:

```
from abc import ABC

class MyABC(ABC):
    pass

MyABC.register(tuple)

assert issubclass(tuple, MyABC)
assert isinstance(), MyABC)
```

在 3.3 版的變更: 回傳已的子類, 使其能作類裝飾器。

在 3.4 版的變更: 你可以使用 `get_cache_token()` 函式來檢測對 `register()` 的呼叫。

你也可以覆寫 (override) 擬基底類中的這個方法:

`__subclasshook__(subclass)`

(必須定義類方法。)

檢查 `subclass` 是否該被認是該 ABC 的子類, 也就是你可以直接自訂 `issubclass()` 的行, 而不用對於那些你希望定義該 ABC 的子類的類都個呼叫 `register()` 方法。(這個類方法是在 ABC 的 `__subclasscheck__()` 方法中呼叫。)

此方法必須回傳 `True`、`False` 或是 `NotImplemented`。如果回傳 `True`, `subclass` 就會被認是這個 ABC 的子類。如果回傳 `False`, `subclass` 就會被判定非該 ABC 的子類, 即便正常情應如此。如果回傳 `NotImplemented`, 子類檢查會按照正常機制繼續執行。

了對這些概念做一演示, 請見以下定義 ABC 的範例:

```
class Foo:
    def __getitem__(self, index):
        ...
    def __len__(self):
        ...
    def get_iterator(self):
        return iter(self)

class MyIterable(ABC):

    @abstractmethod
    def __iter__(self):
        while False:
            yield None

    def get_iterator(self):
        return self.__iter__()

    @classmethod
```

(繼續下一頁)

<sup>1</sup> C++ 程式設計師需要注意到 Python 中擬基底類的概念和 C++ 中的不相同。

(繼續上一頁)

```

def __subclasshook__(cls, C):
    if cls is MyIterable:
        if any("__iter__" in B.__dict__ for B in C.__mro__):
            return True
        return NotImplemented

MyIterable.register(Foo)

```

The ABC `MyIterable` defines the standard iterable method, `__iter__()`, as an abstract method. The implementation given here can still be called from subclasses. The `get_iterator()` method is also part of the `MyIterable` abstract base class, but it does not have to be overridden in non-abstract derived classes.

The `__subclasshook__()` class method defined here says that any class that has an `__iter__()` method in its `__dict__` (or in that of one of its base classes, accessed via the `__mro__` list) is considered a `MyIterable` too.

Finally, the last line makes `Foo` a virtual subclass of `MyIterable`, even though it does not define an `__iter__()` method (it uses the old-style iterable protocol, defined in terms of `__len__()` and `__getitem__()`). Note that this will not make `get_iterator` available as a method of `Foo`, so it is provided separately.

`abc` 模組也提供了這些裝飾器：

`@abc.abstractmethod`

用於表示抽象方法的裝飾器。

類 `C` 的元類 `Metaclass` 是 `ABCMeta` 或是從該類 `Metaclass` 衍生才能使用此裝飾器。一個具有衍生自 `ABCMeta` 之元類 `Metaclass` 的類 `C` 不可以被實例化，除非它全部的抽象方法和特性均已被覆寫。抽象方法可透過任何一般的 `super` 呼叫機制來呼叫。`abstractmethod()` 可被用於 `C` 特性和描述器宣告的抽象方法。

僅在使用 `update_abstractmethods()` 函式時，才能 `C` 動態地 `C` 一個類 `C` 新增抽象方法，或者嘗試在方法或類 `C` 被建立後修改其抽象狀態。`abstractmethod()` 只會影響使用常規繼承所衍生出的子類 `C`；透過 `ABC` 的 `register()` 方法 `C` 的「`C` 擬子類 `C`」不會受到影響。

當 `abstractmethod()` 與其他方法描述器 (method descriptor) 配合應用時，它應被當最 `C` 層的裝飾器，如以下用法範例所示：

```

class C(ABC):
    @abstractmethod
    def my_abstract_method(self, arg1):
        ...

    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg2):
        ...

    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg3):
        ...

    @property
    @abstractmethod
    def my_abstract_property(self):
        ...

    @my_abstract_property.setter
    @abstractmethod
    def my_abstract_property(self, val):
        ...

    @abstractmethod
    def _get_x(self):
        ...

```

(繼續下一頁)

(繼續上一頁)

```
@abstractmethod
def _set_x(self, val):
    ...
x = property(_get_x, _set_x)
```

為了能正確地與 ABC 機制實作相互操作，描述器必須使用 `__isabstractmethod__` 將自身標識抽象的。一般來講，如果被用於組成描述器的任一方法是抽象的，則此屬性應當為 `True`。例如，Python 的 `property` 所做的就等價於：

```
class Descriptor:
    ...
    @property
    def __isabstractmethod__(self):
        return any(getattr(f, '__isabstractmethod__', False) for
                   f in (self._fget, self._fset, self._fdel))
```

### 備註

不同於 Java 抽象方法，這些抽象方法可能具有一個實作。這個實作可在覆寫它的類上透過 `super()` 機制來呼叫。這在使用協作多重繼承 (cooperative multiple-inheritance) 的框架中，可以被用作 `super` 呼叫的一個端點 (end-point)。

abc 模組還支援下列舊式裝飾器：

#### @abc.abstractmethod

在 3.2 版被加入。

在 3.3 版之後被採用：現在可以讓 `classmethod` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建立 `classmethod()` 的子類，表示一個抽象類方法。在其他方面它都類似於 `abstractmethod()`。

這個特例已被採用，因為現在當 `classmethod()` 裝飾器應用於抽象方法時已會被正確地標識是抽象的：

```
class C(ABC):
    @classmethod
    @abstractmethod
    def my_abstract_classmethod(cls, arg):
        ...
```

#### @abc.abstractstaticmethod

在 3.2 版被加入。

在 3.3 版之後被採用：現在可以讓 `staticmethod` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建立 `staticmethod()` 的子類，表示一個抽象靜態方法。在其他方面它都類似於 `abstractmethod()`。

這個特例已被採用，因為現在當 `staticmethod()` 裝飾器應用於抽象方法時已會被正確地標識是抽象的：

```
class C(ABC):
    @staticmethod
    @abstractmethod
    def my_abstract_staticmethod(arg):
        ...
```

`@abc.abstractproperty`

在 3.3 版之後被 用：現在可以讓 `property`、`property.getter()`、`property.setter()` 和 `property.deleter()` 配合 `abstractmethod()` 使用，使得此裝飾器變得冗余。

建 `property()` 的子類，表示一個抽象特性。

這個特例已被 用，因 現在當 `property()` 裝飾器應用於抽象方法時已被正確地標識 是抽象的：

```
class C(ABC):
    @property
    @abstractmethod
    def my_abstract_property(self):
        ...
```

上面的例子定義了一個唯讀特性；你也可以透過適當地將一個或多個底層方法標記 抽象的來定義可讀寫的抽象特性：

```
class C(ABC):
    @property
    def x(self):
        ...

    @x.setter
    @abstractmethod
    def x(self, val):
        ...
```

如果只有某些元件是抽象的，則只需更新那些元件即可在子類 中建立具體的特性：

```
class D(C):
    @C.x.setter
    def x(self, val):
        ...
```

`abc` 模組也提供了這些函式：

`abc.get_cache_token()`

回傳當前 ABC 快取令牌 (cache token)。

此令牌是一個（支援相等性測試的）不透明物件 (opaque object)，用於 擬子類 標識抽象基底類 快取的當前版本。此令牌會在任何 ABC 上每次呼叫 `ABCMeta.register()` 時發生更改。

在 3.4 版被加入。

`abc.update_abstractmethods(cls)`

重新計算一個抽象類 之抽象狀態的函式。如果一個類 的抽象方法在建立後被實作或被修改，則應當呼叫此函式。通常此函式應在一個類 裝飾器 部被呼叫。

回傳 `cls`，使其能 用作 類 的裝飾器。

如果 `cls` 不是 `ABCMeta` 的實例則不做任何操作。

 備

此函式會假定 `cls` 的超類 (superclass) 已經被更新。它不會更新任何子類。

在 3.10 版被加入。

解

## 30.10 atexit --- 退出處理函式

`atexit` 模組定義了 `atexit` 和 `atexit` 銷清理函式 (cleanup function) 的函式，這樣的 `atexit` 函式會在直譯器正常終止時自動執行。`atexit` 按照這些函式 `atexit` 之反序來運行這些函式；如果你有 `atexit` A、B 和 C，則在直譯器終止時它們將按 C、B、A 的順序運行。

**注意：**當程式被一個不是來自 Python 的訊號終止、偵測到有 Python 嚴重 `atexit` 部錯誤時或者 `os._exit()` 被呼叫時，透過此模組 `atexit` 的函式就不會被呼叫。

**注意：**在清理函式中 `atexit` 或 `atexit` 銷函式的作用 `atexit` 未定義。

在 3.7 版的變更：當與 C-API 子直譯器 (subinterpreter) 一起使用時，已 `atexit` 函式對於它們所 `atexit` 的直譯器來 `atexit` 是區域的 (local)。

`atexit.register(func, *args, **kwargs)`

將 `func` `atexit` 要在終止時執行的函式。任何要傳遞給 `func` 的可選引數都必須作 `atexit` 引數傳遞給 `register()`。可以多次 `atexit` 相同的函式和引數。

在程式正常終止時 (例如呼叫 `sys.exit()` 或主要模組執行完成)，所有已 `atexit` 函式都會依照後進先出的順序呼叫。這邊做的假設是較低階的模組通常會在較高階模組之前被引入，因此較低階模組必須在比較後面才被清理。

如果在執行退出處理函式期間引發例外，則會列印回溯 (traceback) (除非引發 `SystemExit`) `atexit` 儲存例外資訊。在所有退出處理函式都有嘗試運作過後，將重新引發最後一個引發的例外。

該函式回傳 `func`，這使得可以將其作 `atexit` 裝飾器使用。

### 警告

`atexit` 動新執行緒或從已 `atexit` 函式呼叫 `os.fork()` 可能會導致 Python 主要 runtime 執行緒釋放執行緒狀態，而 `atexit` `threading` 例程或新行程嘗試使用該狀態所形成的競態條件 (race condition)。這可能會導致崩潰 (crash) 而不是完整關閉中止。

在 3.12 版的變更：嘗試在已 `atexit` 函式中 `atexit` 動新執行緒或 `os.fork()` 新行程現在會導致 `RuntimeError`。

`atexit.unregister(func)`

從在直譯器中止時會執行之函式串列中 `atexit` 除 `func`。如果 `func` 先前未被 `atexit`，則 `unregister()` 不會執行任何操作。如果 `func` 已被 `atexit` 多次，則該函式在 `atexit` 呼叫堆 `atexit` (call stack) 中的所有存在都會被 `atexit` 除。會在 `atexit` 銷期間於 `atexit` 部使用相等性比較 (==)，因此函式參照不需要具有匹配的 `atexit` 性。

### 也參考

#### `readline` 模組

`atexit` 用於讀取和寫入 `readline` 歷史檔案的一個不錯的範例。

### 30.10.1 atexit 范例

以下的簡單範例示範了模組如何在被引入時以檔案來初始化計數器，`atexit` 在程式終止時自動儲存計數器的更新值，而不需要仰賴應用程式在終止時明確呼叫該模組。

```
try:
    with open('counterfile') as infile:
        _count = int(infile.read())
except FileNotFoundError:
```

(繼續下一頁)

(繼續上一頁)

```

_count = 0

def incrcounter(n):
    global _count
    _count = _count + n

def savecounter():
    with open('counterfile', 'w') as outfile:
        outfile.write('%d' % _count)

import atexit

atexit.register(savecounter)

```

位置引數和關鍵字引數也可以被傳遞給 `register()`，以便在呼叫時也傳遞給已 `FF` 函式：

```

def goodbye(name, adjective):
    print('Goodbye %s, it was %s to meet you.' % (name, adjective))

import atexit

atexit.register(goodbye, 'Donny', 'nice')
# or:
atexit.register(goodbye, adjective='nice', name='Donny')

```

作 `FF` 裝飾器使用：

```

import atexit

@atexit.register
def goodbye():
    print('You are now leaving the Python sector.')

```

這只適用於可以不帶引數呼叫的函式。

## 30.11 `traceback` --- 列印或取得堆 `FF` 回溯 (stack traceback)

原始碼：[Lib/traceback.py](#)

This module provides a standard interface to extract, format and print stack traces of Python programs. It is more flexible than the interpreter's default traceback display, and therefore makes it possible to configure certain aspects of the output. Finally, it contains a utility for capturing enough information about an exception to print it later, without the need to save a reference to the actual exception. Since exceptions can be the roots of large objects graph, this utility can significantly improve memory management.

The module uses traceback objects --- these are objects of type `types.TracebackType`, which are assigned to the `__traceback__` field of `BaseException` instances.

### 也參考

#### `faulthandler` 模組

Used to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal.

#### `pdb` 模組

Interactive source code debugger for Python programs.

The module's API can be divided into two parts:

- Module-level functions offering basic functionality, which are useful for interactive inspection of exceptions and tracebacks.
- `TracebackException` class and its helper classes `StackSummary` and `FrameSummary`. These offer both more flexibility in the output generated and the ability to store the information necessary for later formatting without holding references to actual exception and traceback objects.

### 30.11.1 Module-Level Functions

`traceback.print_tb` (*tb*, *limit=None*, *file=None*)

Print up to *limit* stack trace entries from traceback object *tb* (starting from the caller's frame) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. If *file* is omitted or `None`, the output goes to `sys.stderr`; otherwise it should be an open *file* or *file-like object* to receive the output.

 備 F

The meaning of the *limit* parameter is different than the meaning of `sys.tracebacklimit`. A negative *limit* value corresponds to a positive value of `sys.tracebacklimit`, whereas the behaviour of a positive *limit* value cannot be achieved with `sys.tracebacklimit`.

在 3.5 版的變更: 新增負數 *limit* 的支援。

`traceback.print_exception` (*exc*, /, [*value*, *tb*, ] *limit=None*, *file=None*, *chain=True*)

Print exception information and stack trace entries from traceback object *tb* to *file*. This differs from `print_tb()` in the following ways:

- if *tb* is not `None`, it prints a header `Traceback (most recent call last):`
- it prints the exception type and *value* after the stack trace
- if `type(value)` is `SyntaxError` and *value* has the appropriate format, it prints the line where the syntax error occurred with a caret indicating the approximate position of the error.

Since Python 3.10, instead of passing *value* and *tb*, an exception object can be passed as the first argument. If *value* and *tb* are provided, the first argument is ignored in order to provide backwards compatibility.

The optional *limit* argument has the same meaning as for `print_tb()`. If *chain* is true (the default), then chained exceptions (the `__cause__` or `__context__` attributes of the exception) will be printed as well, like the interpreter itself does when printing an unhandled exception.

在 3.5 版的變更: The *etype* argument is ignored and inferred from the type of *value*.

在 3.10 版的變更: The *etype* parameter has been renamed to *exc* and is now positional-only.

`traceback.print_exc` (*limit=None*, *file=None*, *chain=True*)

This is a shorthand for `print_exception(sys.exception(), limit=limit, file=file, chain=chain)`.

`traceback.print_last` (*limit=None*, *file=None*, *chain=True*)

This is a shorthand for `print_exception(sys.last_exc, limit=limit, file=file, chain=chain)`. In general it will work only after an exception has reached an interactive prompt (see `sys.last_exc`).

`traceback.print_stack` (*f=None*, *limit=None*, *file=None*)

Print up to *limit* stack trace entries (starting from the invocation point) if *limit* is positive. Otherwise, print the last `abs(limit)` entries. If *limit* is omitted or `None`, all entries are printed. The optional *f* argument can be used to specify an alternate stack frame to start. The optional *file* argument has the same meaning as for `print_tb()`.

在 3.5 版的變更: 新增負數 *limit* 的支援。

`traceback.extract_tb(tb, limit=None)`

Return a *StackSummary* object representing a list of "pre-processed" stack trace entries extracted from the traceback object *tb*. It is useful for alternate formatting of stack traces. The optional *limit* argument has the same meaning as for *print\_tb()*. A "pre-processed" stack trace entry is a *FrameSummary* object containing attributes *filename*, *lineno*, *name*, and *line* representing the information that is usually printed for a stack trace.

`traceback.extract_stack(f=None, limit=None)`

Extract the raw traceback from the current stack frame. The return value has the same format as for *extract\_tb()*. The optional *f* and *limit* arguments have the same meaning as for *print\_stack()*.

`traceback.print_list(extracted_list, file=None)`

Print the list of tuples as returned by *extract\_tb()* or *extract\_stack()* as a formatted stack trace to the given file. If *file* is *None*, the output is written to *sys.stderr*.

`traceback.format_list(extracted_list)`

Given a list of tuples or *FrameSummary* objects as returned by *extract\_tb()* or *extract\_stack()*, return a list of strings ready for printing. Each string in the resulting list corresponds to the item with the same index in the argument list. Each string ends in a newline; the strings may contain internal newlines as well, for those items whose source text line is not *None*.

`traceback.format_exception_only(exc, /, [value, ]*, show_group=False)`

Format the exception part of a traceback using an exception value such as given by *sys.last\_value*. The return value is a list of strings, each ending in a newline. The list contains the exception's message, which is normally a single string; however, for *SyntaxError* exceptions, it contains several lines that (when printed) display detailed information about where the syntax error occurred. Following the message, the list contains the exception's *notes*.

Since Python 3.10, instead of passing *value*, an exception object can be passed as the first argument. If *value* is provided, the first argument is ignored in order to provide backwards compatibility.

When *show\_group* is *True*, and the exception is an instance of *BaseExceptionGroup*, the nested exceptions are included as well, recursively, with indentation relative to their nesting depth.

在 3.10 版的變更: The *etype* parameter has been renamed to *exc* and is now positional-only.

在 3.11 版的變更: The returned list now includes any *notes* attached to the exception.

在 3.13 版的變更: *show\_group* parameter was added.

`traceback.format_exception(exc, /, [value, tb, ]limit=None, chain=True)`

Format a stack trace and the exception information. The arguments have the same meaning as the corresponding arguments to *print\_exception()*. The return value is a list of strings, each ending in a newline and some containing internal newlines. When these lines are concatenated and printed, exactly the same text is printed as does *print\_exception()*.

在 3.5 版的變更: The *etype* argument is ignored and inferred from the type of *value*.

在 3.10 版的變更: This function's behavior and signature were modified to match *print\_exception()*.

`traceback.format_exc(limit=None, chain=True)`

This is like *print\_exc(limit)* but returns a string instead of printing to a file.

`traceback.format_tb(tb, limit=None)`

*format\_list(extract\_tb(tb, limit))* 的簡寫。

`traceback.format_stack(f=None, limit=None)`

*format\_list(extract\_stack(f, limit))* 的簡寫。

`traceback.clear_frames(tb)`

Clears the local variables of all the stack frames in a traceback *tb* by calling the *clear()* method of each frame object.

在 3.4 版被加入。

`traceback.walk_stack(f)`

Walk a stack following `f.f_back` from the given frame, yielding the frame and line number for each frame. If `f` is `None`, the current stack is used. This helper is used with `StackSummary.extract()`.

在 3.5 版被加入。

`traceback.walk_tb(tb)`

Walk a traceback following `tb_next` yielding the frame and line number for each frame. This helper is used with `StackSummary.extract()`.

在 3.5 版被加入。

### 30.11.2 TracebackException 物件

在 3.5 版被加入。

`TracebackException` objects are created from actual exceptions to capture data for later printing. They offer a more lightweight method of storing this information by avoiding holding references to traceback and frame objects. In addition, they expose more options to configure the output compared to the module-level functions described above.

```
class traceback.TracebackException(exc_type, exc_value, exc_traceback, *, limit=None,
                                   lookup_lines=True, capture_locals=False, compact=False,
                                   max_group_width=15, max_group_depth=10)
```

Capture an exception for later rendering. The meaning of `limit`, `lookup_lines` and `capture_locals` are as for the `StackSummary` class.

If `compact` is true, only data that is required by `TracebackException`'s `format()` method is saved in the class attributes. In particular, the `__context__` field is calculated only if `__cause__` is `None` and `__suppress_context__` is false.

Note that when locals are captured, they are also shown in the traceback.

`max_group_width` and `max_group_depth` control the formatting of exception groups (see `BaseExceptionGroup`). The depth refers to the nesting level of the group, and the width refers to the size of a single exception group's exceptions array. The formatted output is truncated when either limit is exceeded.

在 3.10 版的變更: 新增 `compact` 參數。

在 3.11 版的變更: 新增 `max_group_width` 和 `max_group_depth` 參數。

`__cause__`

A `TracebackException` of the original `__cause__`.

`__context__`

A `TracebackException` of the original `__context__`.

`exceptions`

If `self` represents an `ExceptionGroup`, this field holds a list of `TracebackException` instances representing the nested exceptions. Otherwise it is `None`.

在 3.11 版被加入。

`__suppress_context__`

The `__suppress_context__` value from the original exception.

`__notes__`

The `__notes__` value from the original exception, or `None` if the exception does not have any notes. If it is not `None` is it formatted in the traceback after the exception string.

在 3.11 版被加入。

`stack`

A `StackSummary` representing the traceback.

**exc\_type**

The class of the original traceback.

在 3.13 版之後被用。

**exc\_type\_str**

String display of the class of the original exception.

在 3.13 版被加入。

**filename**

For syntax errors - the file name where the error occurred.

**lineno**

For syntax errors - the line number where the error occurred.

**end\_lineno**

For syntax errors - the end line number where the error occurred. Can be `None` if not present.

在 3.10 版被加入。

**text**

For syntax errors - the text where the error occurred.

**offset**

For syntax errors - the offset into the text where the error occurred.

**end\_offset**

For syntax errors - the end offset into the text where the error occurred. Can be `None` if not present.

在 3.10 版被加入。

**msg**

For syntax errors - the compiler error message.

**classmethod from\_exception** (*exc*, \*, *limit=None*, *lookup\_lines=True*, *capture\_locals=False*)

Capture an exception for later rendering. *limit*, *lookup\_lines* and *capture\_locals* are as for the `StackSummary` class.

Note that when locals are captured, they are also shown in the traceback.

**print** (\*, *file=None*, *chain=True*)

Print to *file* (default `sys.stderr`) the exception information returned by `format()`.

在 3.11 版被加入。

**format** (\*, *chain=True*)

Format the exception.

If *chain* is not `True`, `__cause__` and `__context__` will not be formatted.

The return value is a generator of strings, each ending in a newline and some containing internal newlines. `print_exception()` is a wrapper around this method which just prints the lines to a file.

**format\_exception\_only** (\*, *show\_group=False*)

Format the exception part of the traceback.

The return value is a generator of strings, each ending in a newline.

When *show\_group* is `False`, the generator emits the exception's message followed by its notes (if it has any). The exception message is normally a single string; however, for `SyntaxError` exceptions, it consists of several lines that (when printed) display detailed information about where the syntax error occurred.

When *show\_group* is `True`, and the exception is an instance of `BaseExceptionGroup`, the nested exceptions are included as well, recursively, with indentation relative to their nesting depth.

在 3.11 版的變更: The exception's *notes* are now included in the output.

在 3.13 版的變更: 新增 *show\_group* 參數。

### 30.11.3 StackSummary 物件

在 3.5 版被加入。

StackSummary objects represent a call stack ready for formatting.

**class** traceback.StackSummary

**classmethod** extract (*frame\_gen*, \*, *limit=None*, *lookup\_lines=True*, *capture\_locals=False*)

Construct a StackSummary object from a frame generator (such as is returned by *walk\_stack()* or *walk\_tb()*).

If *limit* is supplied, only this many frames are taken from *frame\_gen*. If *lookup\_lines* is `False`, the returned *FrameSummary* objects will not have read their lines in yet, making the cost of creating the StackSummary cheaper (which may be valuable if it may not actually get formatted). If *capture\_locals* is `True` the local variables in each *FrameSummary* are captured as object representations.

在 3.12 版的變更: Exceptions raised from *repr()* on a local variable (when *capture\_locals* is `True`) are no longer propagated to the caller.

**classmethod** from\_list (*a\_list*)

Construct a StackSummary object from a supplied list of *FrameSummary* objects or old-style list of tuples. Each tuple should be a 4-tuple with *filename*, *lineno*, *name*, *line* as the elements.

**format** ()

Returns a list of strings ready for printing. Each string in the resulting list corresponds to a single frame from the stack. Each string ends in a newline; the strings may contain internal newlines as well, for those items with source text lines.

For long sequences of the same frame and line, the first few repetitions are shown, followed by a summary line stating the exact number of further repetitions.

在 3.6 版的變更: Long sequences of repeated frames are now abbreviated.

**format\_frame\_summary** (*frame\_summary*)

Returns a string for printing one of the frames involved in the stack. This method is called for each *FrameSummary* object to be printed by *StackSummary.format()*. If it returns `None`, the frame is omitted from the output.

在 3.11 版被加入。

### 30.11.4 FrameSummary 物件

在 3.5 版被加入。

A FrameSummary object represents a single frame in a traceback.

**class** traceback.FrameSummary (*filename*, *lineno*, *name*, \*, *lookup\_line=True*, *locals=None*, *line=None*, *end\_lineno=None*, *colno=None*, *end\_colno=None*)

Represents a single frame in the traceback or stack that is being formatted or printed. It may optionally have a stringified version of the frame's locals included in it. If *lookup\_line* is `False`, the source code is not looked up until the *FrameSummary* has the *line* attribute accessed (which also happens when casting it to a *tuple*). *line* may be directly provided, and will prevent line lookups happening at all. *locals* is an optional local variable mapping, and if supplied the variable representations are stored in the summary for later display.

FrameSummary instances have the following attributes:

**filename**

The filename of the source code for this frame. Equivalent to accessing *f.f\_code.co\_filename* on a frame object *f*.

**lineno**

The line number of the source code for this frame.

**name**

Equivalent to accessing `f.f_code.co_name` on a frame object `f`.

**line**

A string representing the source code for this frame, with leading and trailing whitespace stripped. If the source is not available, it is `None`.

**end\_lineno**

The last line number of the source code for this frame. By default, it is set to `lineno` and indexation starts from 1.

在 3.13 版的變更: The default value changed from `None` to `lineno`.

**colno**

The column number of the source code for this frame. By default, it is `None` and indexation starts from 0.

**end\_colno**

The last column number of the source code for this frame. By default, it is `None` and indexation starts from 0.

### 30.11.5 Examples of Using the Module-Level Functions

This simple example implements a basic read-eval-print loop, similar to (but less useful than) the standard Python interactive interpreter loop. For a more complete implementation of the interpreter loop, refer to the `code` module.

```
import sys, traceback

def run_user_code(envdir):
    source = input(">>> ")
    try:
        exec(source, envdir)
    except Exception:
        print("Exception in user code:")
        print("-"*60)
        traceback.print_exc(file=sys.stdout)
        print("-"*60)

envdir = {}
while True:
    run_user_code(envdir)
```

The following example demonstrates the different ways to print and format the exception and traceback:

```
import sys, traceback

def lumberjack():
    bright_side_of_life()

def bright_side_of_life():
    return tuple()[0]

try:
    lumberjack()
except IndexError as exc:
    print("*** print_tb:")
    traceback.print_tb(exc.__traceback__, limit=1, file=sys.stdout)
    print("*** print_exception:")
    traceback.print_exception(exc, limit=2, file=sys.stdout)
```

(繼續下一頁)

(繼續上一頁)

```

print("*** print_exc:")
traceback.print_exc(limit=2, file=sys.stdout)
print("*** format_exc, first and last line:")
formatted_lines = traceback.format_exc().splitlines()
print(formatted_lines[0])
print(formatted_lines[-1])
print("*** format_exception:")
print(repr(traceback.format_exception(exc)))
print("*** extract_tb:")
print(repr(traceback.extract_tb(exc.__traceback__)))
print("*** format_tb:")
print(repr(traceback.format_tb(exc.__traceback__)))
print("*** tb_lineno:", exc.__traceback__.tb_lineno)

```

The output for the example would look similar to this:

```

*** print_tb:
  File "<doctest...>", line 10, in <module>
    lumberjack()
    ~~~~~^
*** print_exception:
Traceback (most recent call last):
  File "<doctest...>", line 10, in <module>
    lumberjack()
    ~~~~~^
  File "<doctest...>", line 4, in lumberjack
    bright_side_of_life()
    ~~~~~^
IndexError: tuple index out of range
*** print_exc:
Traceback (most recent call last):

 '  File "<doctest default[0]>", line 4, in lumberjack\n    bright_side_of_life()\n    ~~~~~\n',
 ↪ ~~~~~^\\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n    return tuple()[0]\n    ↪\n',
 ↪ ~~~~~^\\n',
 'IndexError: tuple index out of range\\n']
*** extract_tb:
[<FrameSummary file <doctest...>, line 10 in <module>>,
 <FrameSummary file <doctest...>, line 4 in lumberjack>,
 <FrameSummary file <doctest...>, line 7 in bright_side_of_life>]
*** format_tb:
['  File "<doctest default[0]>", line 10, in <module>\n    lumberjack()\n    ~~~~~^\\n',
 '  File "<doctest default[0]>", line 4, in lumberjack\n    bright_side_of_life()\n    ~~~~~\n',
 ↪ ~~~~~^\\n',
 '  File "<doctest default[0]>", line 7, in bright_side_of_life\n    return tuple()[0]\n    ↪\n',
 ↪ ~~~~~^\\n']
*** tb_lineno: 10

```

The following example shows the different ways to print and format the stack:

```

>>> import traceback
>>> def another_function():
...     lumberstack()
...
>>> def lumberstack():
...     traceback.print_stack()
...     print(repr(traceback.extract_stack()))
...     print(repr(traceback.format_stack()))
...
>>> another_function()
File "<doctest>", line 10, in <module>
    another_function()
File "<doctest>", line 3, in another_function
    lumberstack()
File "<doctest>", line 6, in lumberstack
    traceback.print_stack()
[('<doctest>', 10, '<module>', 'another_function()'),
 ('<doctest>', 3, 'another_function', 'lumberstack()'),
 ('<doctest>', 7, 'lumberstack', 'print(repr(traceback.extract_stack()))')]
[' File "<doctest>", line 10, in <module>\n    another_function()\n',
 ' File "<doctest>", line 3, in another_function\n    lumberstack()\n',
 ' File "<doctest>", line 8, in lumberstack\n    print(repr(traceback.format_stack()))\n']

```

This last example demonstrates the final few formatting functions:

```

>>> import traceback
>>> traceback.format_list([('spam.py', 3, '<module>', 'spam.eggs()'),
...                       ('eggs.py', 42, 'eggs', 'return "bacon"')])
[' File "spam.py", line 3, in <module>\n    spam.eggs()\n',
 ' File "eggs.py", line 42, in eggs\n    return "bacon"\n']
>>> an_error = IndexError('tuple index out of range')
>>> traceback.format_exception_only(an_error)
['IndexError: tuple index out of range\n']

```

### 30.11.6 TracebackException 的使用范例

With the helper class, we have more options:

```

>>> import sys
>>> from traceback import TracebackException
>>>
>>> def lumberjack():
...     bright_side_of_life()
...
>>> def bright_side_of_life():
...     t = "bright", "side", "of", "life"
...     return t[5]
...
>>> try:
...     lumberjack()
... except IndexError as e:
...     exc = e
...
>>> try:
...     try:
...         lumberjack()
...     except:
...         1/0
... except Exception as e:
...     chained_exc = e
...

```

(繼續下一頁)

(繼續上一頁)

```

>>> # limit works as with the module-level functions
>>> TracebackException.from_exception(exc, limit=-2).print()
Traceback (most recent call last):
  File "<python-input-1>", line 6, in lumberjack
    bright_side_of_life()
    ~~~~~^
  File "<python-input-1>", line 10, in bright_side_of_life
    return t[5]
    ~^^^
IndexError: tuple index out of range

>>> # capture_locals adds local variables in frames
>>> TracebackException.from_exception(exc, limit=-2, capture_locals=True).print()
Traceback (most recent call last):
  File "<python-input-1>", line 6, in lumberjack
    bright_side_of_life()
    ~~~~~^
  File "<python-input-1>", line 10, in bright_side_of_life
    return t[5]
    ~^^^
    t = ("bright", "side", "of", "life")
IndexError: tuple index out of range

>>> # The *chain* kwarg to print() controls whether chained
>>> # exceptions are displayed
>>> TracebackException.from_exception(chained_exc).print()
Traceback (most recent call last):
  File "<python-input-19>", line 4, in <module>
    lumberjack()
    ~~~~~^
  File "<python-input-8>", line 7, in lumberjack
    bright_side_of_life()
    ~~~~~^
  File "<python-input-8>", line 11, in bright_side_of_life
    return t[5]
    ~^^^
IndexError: tuple index out of range

During handling of the above exception, another exception occurred:

Traceback (most recent call last):

    ^^
ZeroDivisionError: division by zero

```

## 30.12 `__future__` --- Future 陳述式定義

原始碼: `Lib/__future__.py`

from `__future__` import feature 形式的引入被稱 `future` 陳述式。這些是 Python 編譯器的特殊情 `FE`，允許在該功能成 `FE` 標準版本之前在包含 `future` 陳述式的模組中使用新的 Python 功能。

雖然這些 `future` 陳述式被 Python 編譯器賦予了額外的特殊意義，但它們仍然像任何其他 `import` 陳述式一樣執行，且 `__future__` 由引入系統以和任何其他 Python 模組相同的方式處理。這個設計有三個目的：

- 為了避免混淆分析引入陳述式預期要找到它們正在引入之模組的現有工具。
- 記何時出現不相容的變更，以及何時開始制執行這些變更。這是一種可執行文件的形式，可以透過引入 `__future__` 檢查其內容以程式化的方式進行檢查。
- 確保 `future` 陳述式在 Python 2.1 之前的版本中運行至少會產生 `runtime` 例外（`__future__` 的引入將會失敗，因 2.1 之前有該名稱的模組）。

### 30.12.1 模組內容

不會從 `__future__` 中除任何功能描述。自從在 Python 2.1 中引入以來，以下功能已透過這種機制引入到該語言中：

功能	可選的版本	制性的版本	影響
<code>nested_scopes</code>	2.1.0b1	2.2	<a href="#">PEP 227</a> : 態巢狀作用域 ( <i>Statically Nested Scopes</i> )
<code>generators</code>	2.2.0a1	2.3	<a href="#">PEP 255</a> : 簡單生成器 ( <i>Simple Generators</i> )
<code>division</code>	2.2.0a2	3.0	<a href="#">PEP 238</a> : 更改除法運算子 ( <i>Changing the Division Operator</i> )
<code>absolute_import</code>	2.5.0a1	3.0	<a href="#">PEP 328</a> : 引入: 多列與對/相對 ( <i>Imports: Multi-Line and Absolute/Relative</i> )
<code>with_statement</code>	2.5.0a1	2.6	<a href="#">PEP 343</a> : "with" 陳述式 ( <i>The "with" Statement</i> )
<code>print_function</code>	2.6.0a2	3.0	<a href="#">PEP 3105</a> : 使 <code>print</code> 成一個函式 ( <i>Make print a function</i> )
<code>unicode_literals</code>	2.6.0a2	3.0	<a href="#">PEP 3112</a> : Python 3000 中的位元組字面值 ( <i>Bytes literals in Python 3000</i> )
<code>generator_stop</code>	3.5.0b1	3.7	<a href="#">PEP 479</a> : 生成器內的 <code>StopIteration</code> 處理 ( <i>StopIteration handling inside generators</i> )
<code>annotations</code>	3.7.0b1	TBD <sup>1</sup>	<a href="#">PEP 563</a> : 推遲對釋的求值 ( <i>Postponed evaluation of annotations</i> )

`class __future__.Feature`

`__future__.py` 中的每個陳述式的形式如下：

```
FeatureName = _Feature(OptionalRelease, MandatoryRelease,
                        CompilerFlag)
```

通常，`OptionalRelease` 會小於 `MandatoryRelease`，且兩者都是與 `sys.version_info` 形式相同的 5 元組 (5-tuple)：

```
(PY_MAJOR_VERSION, # the 2 in 2.1.0a3; an int
PY_MINOR_VERSION, # the 1; an int
PY_MICRO_VERSION, # the 0; an int
PY_RELEASE_LEVEL, # "alpha", "beta", "candidate" or "final"; string
PY_RELEASE_SERIAL # the 3; an int
)
```

`_Feature.getOptionalRelease()`

`OptionalRelease` 記該功能首次發布時的 Python 版本。

`_Feature.getMandatoryRelease()`

如果 `MandatoryRelease` 尚未發布，`MandatoryRelease` 會預測該功能將成該語言一部分的版本。

否則 `MandatoryRelease` 會記該功能是何時成該語言的一部分；在該版本或之後的版本中，模組不再需要 `future` 聲明來使用相關功能，但可以繼續使用此種引入方式。

`MandatoryRelease` 也可能是 `None`，這意味著計劃中的功能被或尚未。

<sup>1</sup> 之前原本計劃在 Python 3.10 中制使用 `from __future__ import annotations`，但 Python 指導委員會 (Python Steering Council) 兩次推遲這一變動 (Python 3.10 的公告; Python 3.11 的公告)。目前還尚未做出。另請參 [PEP 563](#) 和 [PEP 649](#)。

`_Feature.compiler_flag`

`CompilerFlag` 是 (位元欄位 (bitfield)) 旗標, 應在第四個引數中傳遞給 `compile()` 以在動態編譯的程式碼中用該功能。此旗標存儲在 `_Feature` 實例上的 `_Feature.compiler_flag` 屬性中。

 也參考
**future**

編譯器如何處理 future 引入。

**PEP 236 - 回到 `__future__`**

`__future__` 機制的原始提案。

## 30.13 gc --- 垃圾回收器介面 (Garbage Collector interface)

此 module (模組) 提供可選的垃圾回收器介面, 提供的功能包括: 關閉回收器、調整回收頻率、設定除錯選項。它同時提供對回收器有找到但是無法釋放的不可達物件 (unreachable object) 的存取。由於 Python 使用了帶有參照計數的回收器, 如果你確定你的程式不會 `in` 參照 `in` 圈 (reference cycle), 你可以關閉回收器。可以透過呼叫 `gc.disable()` 關閉自動垃圾回收。若要 `in` 一個存在記憶體流失的程式 (leaking program) 除錯, 請呼叫 `gc.set_debug(gc.DEBUG_LEAK)`; 需要注意的是, 它包含 `gc.DEBUG_SAVEALL`, 使得被回收的物件會被存放在 `gc.garbage` 中以待檢查。

`gc` module 提供下列函式:

`gc.enable()`

`in` 用自動垃圾回收。

`gc.disable()`

停用自動垃圾回收。

`gc.isenabled()`

如果 `in` 用了自動回收則回傳 `True`。

`gc.collect (generation=2)`

若被呼叫時 `in` 有引數, 則 `in` 動完整垃圾回收。可選的引數 `generation` 可以是一個指明需要回收哪一代垃圾的整數 (從 0 到 2)。當引數 `generation` 無效時, 會引發 `ValueError` 例外。發現的不可達物件數目會被回傳。

每當執行完整回收或最高代 (2) 回收時, `in` 多個 `in` 建型 `in` 所維護的空 `in` 列表會被清空。`in` 了特定型 `in` 的實現, 特別是 `float`, 在某些空 `in` 列表中 `in` 非所有項目都會被釋放。

當直譯器已經執行收集時呼叫 `gc.collect()` 的效果是未定義的。

`gc.set_debug (flags)`

設定垃圾回收器的除錯旗標。除錯資訊會被寫入 `sys.stderr`。請見下方的除錯旗標列表, 可以使用位元操作 (bit operation) 進行設定以控制除錯程式。

`gc.get_debug ()`

回傳當前設置的除錯旗標。

`gc.get_objects (generation=None)`

回傳一個包含回收器正在追 `in` 的所有物件的 list, 除去所回傳的 list。如果 `generation` 不 `in` `None`, 只回傳回收器正在追 `in` 且屬於該代的物件。

在 3.8 版的變更: 新增 `generation` 參數。

引發一個附帶引數 `generation` 的稽核事件 (auditing event) `gc.get_objects`。

`gc.get_stats()`

回傳一個包含三個字典物件的 `list`，每個字典分包含對應代中自從直譯器開始執行後的垃圾回收統計資料。字典的鍵的數目在將來可能會改變，但目前每個字典包含以下項目：

- `collections` 是該代被回收的次數；
- `collected` 是該代中被回收的物件總數；
- `uncollectable` 是在這一代中被發現無法回收的物件總數（因此被移到 `garbage list` 中）。

在 3.4 版被加入。

`gc.set_threshold(threshold0[, threshold1[, threshold2]])`

設定垃圾回收值（回收頻率）。將 `threshold0` 設零會停止回收。

垃圾回收器會根據物件在多少次垃圾回收後仍存來把所有物件分類三代。新建物件會被放在最年輕代（第 0 代）。如果一個物件在一次垃圾回收後存，它會被移入下一個較老代。由於第 2 代是最老代，這一代的物件在一次垃圾回收後仍會保留原樣。為了確定何時要執行，垃圾回收器會追自上一次回收後物件分配和釋放的數量。當分配數量去釋放數量的結果大於 `threshold0` 時，垃圾回收就會開始。初始時只有第 0 代會被檢查。如果自第 1 代被檢查後第 0 代已被檢查超過 `threshold1` 次，則第 1 代也會被檢查。對於第三代來，情況還會更複雜一些，請參 `Collecting the oldest generation` 來了解詳情。

`gc.get_count()`

將當前回收計數以 `(count0, count1, count2)` 形式的 `tuple` 回傳。

`gc.get_threshold()`

將當前回收值以 `(threshold0, threshold1, threshold2)` 形式的 `tuple` 回傳。

`gc.get_referrers(*objs)`

回傳包含直接參照 `objs` 中任一個物件的物件 `list`。這個函式只定位支援垃圾回收的容器；參照了其它物件但不支援垃圾回收的擴充套件型無法被找到。

需要注意的是，已經解除參照的物件，但仍存在於參照圈中未被回收時，該物件仍然會被作參照者出現在回傳的 `list` 中。若只要獲取當前正在參照的物件，需要在呼叫 `get_referrers()` 之前呼叫 `collect()`。

### 警告

在使用 `get_referrers()` 回傳的物件時必須要小心，因其中的一些物件可能仍在建構中而處於暫時無效的狀態。不要把 `get_referrers()` 用於除錯以外的其它目的。

引發一個附帶引數 `objs` 的稽核事件 `gc.get_referrers`。

`gc.get_referents(*objs)`

回傳包含被任意一個引數直接參照之物件的 `list`。回傳的被參照物件是有被引數的 C 語言級 `tp_traverse` 方法（若存在）訪問到的物件，可能不是所有的實際直接可達物件。只有支援垃圾回收的物件支援 `tp_traverse` 方法，且此方法只會訪問涉及參照圈的物件。因此，可以有以下例子：一個整數對於一個引數是直接可達的，這個整數物件有可能出現或不出現在結果的 `list` 當中。

引發一個附帶引數 `objs` 的稽核事件 `gc.get_referents`。

`gc.is_tracked(obj)`

當物件正在被垃圾回收器追時回傳 `True`，否則回傳 `False`。一般來，原子型（`atomic type`）的實例不會被追，而非原子型（如容器、使用者自己定義的物件）會被追。然而，有一些特定型最佳化會被用來少垃圾回收器在簡單實例（如只含有原子性的鍵和值的字典）上的足：

```
>>> gc.is_tracked(0)
False
>>> gc.is_tracked("a")
False
>>> gc.is_tracked([])
```

(繼續下一頁)

(繼續上一頁)

```
True
>>> gc.is_tracked({})
False
>>> gc.is_tracked({"a": 1})
False
>>> gc.is_tracked({"a": []})
True
```

在 3.1 版被加入。

`gc.is_finalized(obj)`

如果給定物件已被垃圾回收器終結則回傳 True，否則回傳 False。:

```
>>> x = None
>>> class Lazarus:
...     def __del__(self):
...         global x
...         x = self
...
>>> lazarus = Lazarus()
>>> gc.is_finalized(lazarus)
False
>>> del lazarus
>>> gc.is_finalized(x)
True
```

在 3.9 版被加入。

`gc.freeze()`

凍結 (freeze) 垃圾回收器所追隨的所有物件；將它們移至永久代以忽略所有未來的收集動作。

如果一個行程將在有 `exec()` 的情況下進行 `fork()`，避免子行程中不必要的寫入時應將最大化記憶體共享減少整體記憶體使用。這需要避免在父行程的記憶體頁面中建立已釋放的「漏洞」，確保子行程中的 GC 收集不會觸及源自父行程的長壽命物件的 `gc_refs` 計數器。要實現這兩個目標，請在父行程的早期呼叫 `gc.disable()`，在 `fork()` 之前呼叫 `gc.freeze()`，在子行程中呼叫 `gc.enable()`。

在 3.7 版被加入。

`gc.unfreeze()`

解凍 (unfreeze) 永久代中的物件，將它們放回到最年老代中。

在 3.7 版被加入。

`gc.get_freeze_count()`

回傳永久代中的物件數量。

在 3.7 版被加入。

以下變數僅供唯讀存取（你可以修改其值但不應該重新綁結 (rebind) 它們）:

`gc.garbage`

一個回收器發現不可達而又無法被釋放的物件（不可回收物件）list。從 Python 3.4 開始，該 list 在大多數時候都應該是空的，除非使用了有非 NULL `tp_del` 槽位的 C 擴充套件型的實例。

如果設定了 `DEBUG_SAVEALL`，則所有不可達物件將被加進該 list 而不會被釋放。

在 3.2 版的變更: 當 *interpreter shutdown* 即直譯器關閉時，若此 list 非空，會產生 `ResourceWarning`，在預設情況下此警告不會被提醒。如果設定了 `DEBUG_UNCOLLECTABLE`，所有無法被回收的物件會被印出。

在 3.4 版的變更: 根據 [PEP 442](#)，帶有 `__del__()` method 的物件最終不會在 `gc.garbage` 中。

**gc.callbacks**

會被垃圾回收器在回收開始前和完成後呼叫的一系列回呼函式 (callback)。這些回呼函式在被呼叫時附帶兩個引數：*phase* 和 *info*。

*phase* 可以下兩者之一：

”start”：垃圾回收即將開始。

”stop”：垃圾回收已結束。

*info* 是一個字典，提供回呼函式更多資訊。已有定義的鍵有：

”generation” (代)：正在被回收的最年老的一代。

”collected” (已回收的)：當 *phase* 為 ”stop” 時，被成功回收的物件的數目。

”uncollectable” (不可回收的)：當 *phase* 為 ”stop” 時，不能被回收被放入 *garbage* 的物件的數目。

應用程式可以把他們自己的回呼函式加入此 list。主要的使用場景有：

收集垃圾回收的統計資料，如：不同代的回收頻率、回收任務所花費的時間。

讓應用程式可以識別和清理他們自己在 *garbage* 中的不可回收型物件。

在 3.3 版被加入。

以下常數是和 `set_debug()` 一起使用所提供：

**gc.DEBUG\_STATS**

在回收完成後印出統計資訊。當調校回收頻率設定時，這些資訊會很有用。

**gc.DEBUG\_COLLECTABLE**

當發現可回收物件時印出資訊。

**gc.DEBUG\_UNCOLLECTABLE**

印出找到的不可回收物件的資訊 (指不能被回收器回收的不可達物件)。這些物件會被新增到 *garbage list* 中。

在 3.2 版的變更：當 *interpreter shutdown* (直譯器關閉) 時，若 *garbage list* 不是空的，那這些內容也會被印出。

**gc.DEBUG\_SAVEALL**

設定後，所有回收器找到的不可達物件會被加進 *garbage* 而不是直接被釋放。這在一個記憶體流失的程式除錯時會很有用。

**gc.DEBUG\_LEAK**

要印出記憶體流失程式之相關資訊時，回收器所需的除錯旗標。(等同於 `DEBUG_COLLECTABLE | DEBUG_UNCOLLECTABLE | DEBUG_SAVEALL`)。

## 30.14 inspect --- 檢視活動物件

原始碼：[Lib/inspect.py](#)

The *inspect* module provides several useful functions to help get information about live objects such as modules, classes, methods, functions, tracebacks, frame objects, and code objects. For example, it can help you examine the contents of a class, retrieve the source code of a method, extract and format the argument list for a function, or get all the information you need to display a detailed traceback.

There are four main kinds of services provided by this module: type checking, getting source code, inspecting classes and functions, and examining the interpreter stack.

### 30.14.1 Types and members

The `getmembers()` function retrieves the members of an object such as a class or module. The functions whose names begin with "is" are mainly provided as convenient choices for the second argument to `getmembers()`. They also help you determine when you can expect to find the following special attributes (see `import-mod-attrs` for module attributes):

Type	屬性	描述
class	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this class was defined
	<code>__qualname__</code>	qualified name
	<code>__module__</code>	name of module in which this class was defined
	<code>__type_params__</code>	A tuple containing the type parameters of a generic class
method	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this method was defined
	<code>__qualname__</code>	qualified name
	<code>__func__</code>	function object containing implementation of method
	<code>__self__</code>	instance to which this method is bound, or <code>None</code>
函式	<code>__module__</code>	name of module in which this method was defined
	<code>__doc__</code>	documentation string
	<code>__name__</code>	name with which this function was defined
	<code>__qualname__</code>	qualified name
	<code>__code__</code>	code object containing compiled function <i>bytecode</i>
	<code>__defaults__</code>	tuple of any default values for positional or keyword parameters
	<code>__kwdefaults__</code>	mapping of any default values for keyword-only parameters
	<code>__globals__</code>	global namespace in which this function was defined
	<code>__builtins__</code>	builtins namespace
	<code>__annotations__</code>	mapping of parameters names to annotations; "return" key is reserved for return annotation
	<code>__type_params__</code>	A tuple containing the type parameters of a generic function
traceback	<code>__module__</code>	name of module in which this function was defined
	<code>tb_frame</code>	frame object at this level
	<code>tb_lasti</code>	index of last attempted instruction in bytecode
	<code>tb_lineno</code>	current line number in Python source code
frame	<code>tb_next</code>	next inner traceback object (called by this level)
	<code>f_back</code>	next outer frame object (this frame's caller)
	<code>f_builtins</code>	builtins namespace seen by this frame
	<code>f_code</code>	code object being executed in this frame
	<code>f_globals</code>	global namespace seen by this frame
	<code>f_lasti</code>	index of last attempted instruction in bytecode
	<code>f_lineno</code>	current line number in Python source code
	<code>f_locals</code>	local namespace seen by this frame
<code>f_trace</code>	tracing function for this frame, or <code>None</code>	
code (程式碼)	<code>co_argcount</code>	number of arguments (not including keyword only arguments, * or ** args)
	<code>co_code</code>	string of raw compiled bytecode
	<code>co_cellvars</code>	tuple of names of cell variables (referenced by containing scopes)
	<code>co_consts</code>	tuple of constants used in the bytecode
	<code>co_filename</code>	name of file in which this code object was created
	<code>co_firstlineno</code>	number of first line in Python source code
	<code>co_flags</code>	bitmap of CO_* flags, read more <a href="#">here</a>
	<code>co_inotab</code>	encoded mapping of line numbers to bytecode indices
	<code>co_freevars</code>	tuple of names of free variables (referenced via a function's closure)
	<code>co_posonlyargcount</code>	number of positional only arguments
	<code>co_kwonlyargcount</code>	number of keyword only arguments (not including ** arg)
	<code>co_name</code>	name with which this code object was defined
	<code>co_qualname</code>	fully qualified name with which this code object was defined
<code>co_names</code>	tuple of names other than arguments and function locals	
<code>co_nlocals</code>	number of local variables	

繼

表格 2 - 繼續上一頁

Type	屬性	描述
	<code>co_stacksize</code>	virtual machine stack space required
	<code>co_varnames</code>	tuple of names of arguments and local variables
generator	<code>__name__</code>	name
	<code>__qualname__</code>	qualified name
	<code>gi_frame</code>	frame
	<code>gi_running</code>	is the generator running?
	<code>gi_code</code>	code (程式碼)
	<code>gi_yieldfrom</code>	object being iterated by <code>yield from</code> , or <code>None</code>
async generator	<code>__name__</code>	name
	<code>__qualname__</code>	qualified name
	<code>ag_await</code>	object being awaited on, or <code>None</code>
	<code>ag_frame</code>	frame
	<code>ag_running</code>	is the generator running?
	<code>ag_code</code>	code (程式碼)
coroutine	<code>__name__</code>	name
	<code>__qualname__</code>	qualified name
	<code>cr_await</code>	object being awaited on, or <code>None</code>
	<code>cr_frame</code>	frame
	<code>cr_running</code>	is the coroutine running?
	<code>cr_code</code>	code (程式碼)
	<code>cr_origin</code>	where coroutine was created, or <code>None</code> . See <code>sys.set_coroutine_origin_tracking_</code>
builtin	<code>__doc__</code>	documentation string
	<code>__name__</code>	original name of this function or method
	<code>__qualname__</code>	qualified name
	<code>__self__</code>	instance to which a method is bound, or <code>None</code>

在 3.5 版的變更: 將 `__qualname__` 和 `gi_yieldfrom` 屬性加到 F 生器。

The `__name__` attribute of generators is now set from the function name, instead of the code name, and it can now be modified.

在 3.7 版的變更: 新增協程的 `cr_origin` 屬性。

在 3.10 版的變更: 新增函式的 `__builtins__` 屬性。

`inspect.getmembers(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name. If the optional *predicate* argument—which will be called with the *value* object of each member—is supplied, only members for which the predicate returns a true value are included.

#### 備 F

`getmembers()` will only return class attributes defined in the metaclass when the argument is a class and those attributes have been listed in the metaclass' custom `__dir__()`.

`inspect.getmembers_static(object[, predicate])`

Return all the members of an object in a list of (name, value) pairs sorted by name without triggering dynamic lookup via the descriptor protocol, `__getattr__` or `__getattribute__`. Optionally, only return members that satisfy a given predicate.

#### 備 F

`getmembers_static()` may not be able to retrieve all members that `getmembers` can fetch (like dynamically created attributes) and may find members that `getmembers` can't (like descriptors that raise `AttributeError`). It can also return descriptor objects instead of instance members in some cases.

在 3.11 版被加入。

`inspect.getmodule`**name** (*path*)

Return the name of the module named by the file *path*, without including the names of enclosing packages. The file extension is checked against all of the entries in `importlib.machinery.all_suffixes()`. If it matches, the final path component is returned with the extension removed. Otherwise, `None` is returned.

Note that this function *only* returns a meaningful name for actual Python modules - paths that potentially refer to Python packages will still return `None`.

在 3.3 版的變更: 此函式直接基於 `importlib`。

`inspect.ismodule` (*object*)

如果物件是模組，則回傳 `True`。

`inspect.isclass` (*object*)

Return `True` if the object is a class, whether built-in or created in Python code.

`inspect.ismethod` (*object*)

Return `True` if the object is a bound method written in Python.

`inspect.isfunction` (*object*)

Return `True` if the object is a Python function, which includes functions created by a *lambda* expression.

`inspect.isgeneratorfunction` (*object*)

如果物件是 Python F生器函式，則回傳 `True`。

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return `True` if the wrapped function is a Python generator function.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return `True` if the wrapped function is a Python generator function.

`inspect.isgenerator` (*object*)

如果物件是F生器，則回傳 `True`。

`inspect.iscoroutinefunction` (*object*)

Return `True` if the object is a *coroutine function* (a function defined with an `async def` syntax), a `functools.partial()` wrapping a *coroutine function*, or a sync function marked with `markcoroutinefunction()`.

在 3.5 版被加入。

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return `True` if the wrapped function is a *coroutine function*.

在 3.12 版的變更: Sync functions marked with `markcoroutinefunction()` now return `True`.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return `True` if the wrapped function is a *coroutine function*.

`inspect.markcoroutinefunction` (*func*)

Decorator to mark a callable as a *coroutine function* if it would not otherwise be detected by `iscoroutinefunction()`.

This may be of use for sync functions that return a *coroutine*, if the function is passed to an API that requires `iscoroutinefunction()`.

When possible, using an `async def` function is preferred. Also acceptable is calling the function and testing the return with `iscoroutine()`.

在 3.12 版被加入。

`inspect.iscoroutine` (*object*)

Return `True` if the object is a *coroutine* created by an `async def` function.

在 3.5 版被加入。

`inspect.isawaitable(object)`

Return True if the object can be used in `await` expression.

Can also be used to distinguish generator-based coroutines from regular generators:

```
import types

def gen():
    yield
@types.coroutine
def gen_coro():
    yield

assert not isawaitable(gen())
assert isawaitable(gen_coro())
```

在 3.5 版被加入。

`inspect.isasyncgenfunction(object)`

Return True if the object is an *asynchronous generator* function, for example:

```
>>> async def agen():
...     yield 1
...
>>> inspect.isasyncgenfunction(agen)
True
```

在 3.6 版被加入。

在 3.8 版的變更: Functions wrapped in `functools.partial()` now return True if the wrapped function is an *asynchronous generator* function.

在 3.13 版的變更: Functions wrapped in `functools.partialmethod()` now return True if the wrapped function is a *coroutine function*.

`inspect.isasyncgen(object)`

Return True if the object is an *asynchronous generator iterator* created by an *asynchronous generator* function.

在 3.6 版被加入。

`inspect.istraceback(object)`

Return True if the object is a traceback.

`inspect.isframe(object)`

Return True if the object is a frame.

`inspect.iscode(object)`

如果物件是程式碼，則回傳 True。

`inspect.isbuiltin(object)`

Return True if the object is a built-in function or a bound built-in method.

`inspect.ismethodwrapper(object)`

Return True if the type of object is a `MethodWrapperType`.

These are instances of `MethodWrapperType`, such as `__str__()`, `__eq__()` and `__repr__()`.

在 3.11 版被加入。

`inspect.isroutine(object)`

如果物件是使用者定義或匯建的函式或方法，則回傳 True。

`inspect.isabstract(object)`

如果物件是抽象基底類，則回傳 True。

`inspect.ismethoddescriptor(object)`

Return True if the object is a method descriptor, but not if `ismethod()`, `isclass()`, `isfunction()` or `isbuiltin()` are true.

This, for example, is true of `int.__add__`. An object passing this test has a `__get__()` method, but not a `__set__()` method or a `__delete__()` method. Beyond that, the set of attributes varies. A `__name__` attribute is usually sensible, and `__doc__` often is.

Methods implemented via descriptors that also pass one of the other tests return False from the `ismethoddescriptor()` test, simply because the other tests promise more -- you can, e.g., count on having the `__func__` attribute (etc) when an object passes `ismethod()`.

在 3.13 版的變更: This function no longer incorrectly reports objects with `__get__()` and `__delete__()`, but not `__set__()`, as being method descriptors (such objects are data descriptors, not method descriptors).

`inspect.isdatadescriptor(object)`

如果物件是資料描述器，則回傳 True。

Data descriptors have a `__set__` or a `__delete__` method. Examples are properties (defined in Python), getsets, and members. The latter two are defined in C and there are more specific tests available for those types, which is robust across Python implementations. Typically, data descriptors will also have `__name__` and `__doc__` attributes (properties, getsets, and members have both of these attributes), but this is not guaranteed.

`inspect.isgetsetdescriptor(object)`

Return True if the object is a getset descriptor.

**CPython 實作細節:** getsets are attributes defined in extension modules via `PyGetSetDef` structures. For Python implementations without such types, this method will always return False.

`inspect.ismemberdescriptor(object)`

如果物件是成員描述器，則回傳 True。

**CPython 實作細節:** Member descriptors are attributes defined in extension modules via `PyMemberDef` structures. For Python implementations without such types, this method will always return False.

### 30.14.2 取得原始碼

`inspect.getdoc(object)`

Get the documentation string for an object, cleaned up with `cleandoc()`. If the documentation string for an object is not provided and the object is a class, a method, a property or a descriptor, retrieve the documentation string from the inheritance hierarchy. Return None if the documentation string is invalid or missing.

在 3.5 版的變更: Documentation strings are now inherited if not overridden.

`inspect.getcomments(object)`

Return in a single string any lines of comments immediately preceding the object's source code (for a class, function, or method), or at the top of the Python source file (if the object is a module). If the object's source code is unavailable, return None. This could happen if the object has been defined in C or the interactive shell.

`inspect.getfile(object)`

Return the name of the (text or binary) file in which an object was defined. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getmodule(object)`

Try to guess which module an object was defined in. Return None if the module cannot be determined.

`inspect.getsourcefile(object)`

Return the name of the Python source file in which an object was defined or None if no way can be identified to get the source. This will fail with a `TypeError` if the object is a built-in module, class, or function.

`inspect.getsourcelines` (*object*)

Return a list of source lines and starting line number for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a list of the lines corresponding to the object and the line number indicates where in the original source file the first line of code was found. An `OSError` is raised if the source code cannot be retrieved. A `TypeError` is raised if the object is a built-in module, class, or function.

在 3.3 版的變更: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.getsource` (*object*)

Return the text of the source code for an object. The argument may be a module, class, method, function, traceback, frame, or code object. The source code is returned as a single string. An `OSError` is raised if the source code cannot be retrieved. A `TypeError` is raised if the object is a built-in module, class, or function.

在 3.3 版的變更: `OSError` is raised instead of `IOError`, now an alias of the former.

`inspect.cleandoc` (*doc*)

Clean up indentation from docstrings that are indented to line up with blocks of code.

All leading whitespace is removed from the first line. Any leading whitespace that can be uniformly removed from the second line onwards is removed. Empty lines at the beginning and end are subsequently removed. Also, all tabs are expanded to spaces.

### 30.14.3 Introspecting callables with the Signature object

在 3.3 版被加入.

The `Signature` object represents the call signature of a callable object and its return annotation. To retrieve a `Signature` object, use the `signature()` function.

`inspect.signature` (*callable*, \*, *follow\_wrapped=True*, *globals=None*, *locals=None*, *eval\_str=False*)

Return a `Signature` object for the given *callable*:

```
>>> from inspect import signature
>>> def foo(a, *, b:int, **kwargs):
...     pass

>>> sig = signature(foo)

>>> str(sig)
'(a, *, b: int, **kwargs)'

>>> str(sig.parameters['b'])
'b: int'

>>> sig.parameters['b'].annotation
<class 'int'>
```

Accepts a wide range of Python callables, from plain functions and classes to `functools.partial()` objects.

For objects defined in modules using stringized annotations (from `__future__` import `annotations`), `signature()` will attempt to automatically un-stringize the annotations using `get_annotations()`. The `globals`, `locals`, and `eval_str` parameters are passed into `get_annotations()` when resolving the annotations; see the documentation for `get_annotations()` for instructions on how to use these parameters.

Raises `ValueError` if no signature can be provided, and `TypeError` if that type of object is not supported. Also, if the annotations are stringized, and `eval_str` is not false, the `eval()` call(s) to un-stringize the annotations in `get_annotations()` could potentially raise any kind of exception.

A slash(/) in the signature of a function denotes that the parameters prior to it are positional-only. For more info, see the FAQ entry on positional-only parameters.

在 3.5 版的變更: The `follow_wrapped` parameter was added. Pass `False` to get a signature of *callable* specifically (`callable.__wrapped__` will not be used to unwrap decorated callables.)

在 3.10 版的變更: The *globals*, *locals*, and *eval\_str* parameters were added.

**備 F**

Some callables may not be introspectable in certain implementations of Python. For example, in CPython, some built-in functions defined in C provide no metadata about their arguments.

**CPython 實作細節:** If the passed object has a `__signature__` attribute, we may use it to create the signature. The exact semantics are an implementation detail and are subject to unannounced changes. Consult the source code for current semantics.

**class** `inspect.Signature` (*parameters=None*, \*, *return\_annotation=Signature.empty*)

A `Signature` object represents the call signature of a function and its return annotation. For each parameter accepted by the function it stores a `Parameter` object in its `parameters` collection.

The optional `parameters` argument is a sequence of `Parameter` objects, which is validated to check that there are no parameters with duplicate names, and that the parameters are in the right order, i.e. positional-only first, then positional-or-keyword, and that parameters with defaults follow parameters without defaults.

The optional `return_annotation` argument can be an arbitrary Python object. It represents the "return" annotation of the callable.

`Signature` objects are *immutable*. Use `Signature.replace()` or `copy.replace()` to make a modified copy.

在 3.5 版的變更: `Signature` objects are now picklable and *hashable*.

**empty**

A special class-level marker to specify absence of a return annotation.

**parameters**

An ordered mapping of parameters' names to the corresponding `Parameter` objects. Parameters appear in strict definition order, including keyword-only parameters.

在 3.7 版的變更: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

**return\_annotation**

The "return" annotation for the callable. If the callable has no "return" annotation, this attribute is set to `Signature.empty`.

**bind** (*\*args*, *\*\*kwargs*)

Create a mapping from positional and keyword arguments to parameters. Returns `BoundArguments` if *\*args* and *\*\*kwargs* match the signature, or raises a `TypeError`.

**bind\_partial** (*\*args*, *\*\*kwargs*)

Works the same way as `Signature.bind()`, but allows the omission of some required arguments (mimics `functools.partial()` behavior.) Returns `BoundArguments`, or raises a `TypeError` if the passed arguments do not match the signature.

**replace** (*\*/, parameters*][, *return\_annotation*])

Create a new `Signature` instance based on the instance `replace()` was invoked on. It is possible to pass different `parameters` and/or `return_annotation` to override the corresponding properties of the base signature. To remove `return_annotation` from the copied `Signature`, pass in `Signature.empty`.

```
>>> def test(a, b):
...     pass
...
>>> sig = signature(test)
>>> new_sig = sig.replace(return_annotation="new return anno")
```

(繼續下一頁)

```
>>> str(new_sig)
"(a, b) -> 'new return anno'"
```

*Signature* objects are also supported by the generic function `copy.replace()`.

**format** (\*, *max\_width=None*)

Create a string representation of the *Signature* object.

If *max\_width* is passed, the method will attempt to fit the signature into lines of at most *max\_width* characters. If the signature is longer than *max\_width*, all parameters will be on separate lines.

在 3.13 版被加入。

**classmethod from\_callable** (*obj*, \*, *follow\_wrapped=True*, *globals=None*, *locals=None*, *eval\_str=False*)

Return a *Signature* (or its subclass) object for a given callable *obj*.

This method simplifies subclassing of *Signature*:

```
class MySignature(Signature):
    pass
sig = MySignature.from_callable(sum)
assert isinstance(sig, MySignature)
```

Its behavior is otherwise identical to that of `signature()`.

在 3.5 版被加入。

在 3.10 版的變更: The *globals*, *locals*, and *eval\_str* parameters were added.

**class inspect.Parameter** (*name*, *kind*, \*, *default=Parameter.empty*, *annotation=Parameter.empty*)

Parameter objects are *immutable*. Instead of modifying a *Parameter* object, you can use `Parameter.replace()` or `copy.replace()` to create a modified copy.

在 3.5 版的變更: Parameter objects are now picklable and *hashable*.

**empty**

A special class-level marker to specify absence of default values and annotations.

**name**

The name of the parameter as a string. The name must be a valid Python identifier.

**CPython 實作細節:** CPython generates implicit parameter names of the form `.0` on the code objects used to implement comprehensions and generator expressions.

在 3.6 版的變更: These parameter names are now exposed by this module as names like `implicit0`.

**default**

The default value for the parameter. If the parameter has no default value, this attribute is set to `Parameter.empty`.

**annotation**

The annotation for the parameter. If the parameter has no annotation, this attribute is set to `Parameter.empty`.

**kind**

Describes how argument values are bound to the parameter. The possible values are accessible via `Parameter` (like `Parameter.KEYWORD_ONLY`), and support comparison and ordering, in the following order:

名徵	意義
<i>POSITIONAL_ONLY</i>	Value must be supplied as a positional argument. Positional only parameters are those which appear before a / entry (if present) in a Python function definition.
<i>POSITIONAL_OR_KEYWORD</i>	Value may be supplied as either a keyword or positional argument (this is the standard binding behaviour for functions implemented in Python.)
<i>VAR_POSITIONAL</i>	A tuple of positional arguments that aren't bound to any other parameter. This corresponds to a *args parameter in a Python function definition.
<i>KEYWORD_ONLY</i>	Value must be supplied as a keyword argument. Keyword only parameters are those which appear after a * or *args entry in a Python function definition.
<i>VAR_KEYWORD</i>	A dict of keyword arguments that aren't bound to any other parameter. This corresponds to a **kwargs parameter in a Python function definition.

Example: print all keyword-only arguments without default values:

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     if (param.kind == param.KEYWORD_ONLY and
...         param.default is param.empty):
...         print('Parameter:', param)
Parameter: c
```

kind.**description**

Describes an enum value of *Parameter.kind*.

在 3.8 版被加入。

範例：列印所有引數的描述：

```
>>> def foo(a, b, *, c, d=10):
...     pass

>>> sig = signature(foo)
>>> for param in sig.parameters.values():
...     print(param.kind.description)
positional or keyword
positional or keyword
keyword-only
keyword-only
```

**replace** (\*[, name][, kind][, default][, annotation])

Create a new *Parameter* instance based on the instance replaced was invoked on. To override a *Parameter* attribute, pass the corresponding argument. To remove a default value or/and an annotation from a *Parameter*, pass *Parameter.empty*.

```
>>> from inspect import Parameter
>>> param = Parameter('foo', Parameter.KEYWORD_ONLY, default=42)
>>> str(param)
'foo=42'

>>> str(param.replace()) # Will create a shallow copy of 'param'
'foo=42'
```

(繼續下一頁)

(繼續上一頁)

```
>>> str(param.replace(default=Parameter.empty, annotation='spam'))
"foo: 'spam'"
```

*Parameter* objects are also supported by the generic function *copy.replace()*.

在 3.4 版的變更: In Python 3.3 *Parameter* objects were allowed to have *name* set to *None* if their *kind* was set to *POSITIONAL\_ONLY*. This is no longer permitted.

#### class inspect.BoundArguments

Result of a *Signature.bind()* or *Signature.bind\_partial()* call. Holds the mapping of arguments to the function's parameters.

##### arguments

A mutable mapping of parameters' names to arguments' values. Contains only explicitly bound arguments. Changes in *arguments* will reflect in *args* and *kwargs*.

Should be used in conjunction with *Signature.parameters* for any argument processing purposes.

#### 備註

Arguments for which *Signature.bind()* or *Signature.bind\_partial()* relied on a default value are skipped. However, if needed, use *BoundArguments.apply\_defaults()* to add them.

在 3.9 版的變更: *arguments* is now of type *dict*. Formerly, it was of type *collections.OrderedDict*.

##### args

A tuple of positional arguments values. Dynamically computed from the *arguments* attribute.

##### kwargs

A dict of keyword arguments values. Dynamically computed from the *arguments* attribute. Arguments that can be passed positionally are included in *args* instead.

##### signature

A reference to the parent *Signature* object.

##### apply\_defaults()

遺漏的引數設定預設值。

For variable-positional arguments (*\*args*) the default is an empty tuple.

For variable-keyword arguments (*\*\*kwargs*) the default is an empty dict.

```
>>> def foo(a, b='ham', *args): pass
>>> ba = inspect.signature(foo).bind('spam')
>>> ba.apply_defaults()
>>> ba.arguments
{'a': 'spam', 'b': 'ham', 'args': ()}
```

在 3.5 版被加入。

The *args* and *kwargs* properties can be used to invoke functions:

```
def test(a, *, b):
    ...

sig = signature(test)
ba = sig.bind(10, b=20)
test(*ba.args, **ba.kwargs)
```

 也參考
**PEP 362 - Function Signature Object.**

The detailed specification, implementation details and examples.

**30.14.4 類 與函式**

`inspect.getclasstree` (*classes*, *unique=False*)

Arrange the given list of classes into a hierarchy of nested lists. Where a nested list appears, it contains classes derived from the class whose entry immediately precedes the list. Each entry is a 2-tuple containing a class and a tuple of its base classes. If the *unique* argument is true, exactly one entry appears in the returned structure for each class in the given list. Otherwise, classes using multiple inheritance and their descendants will appear multiple times.

`inspect.getfullargspec` (*func*)

Get the names and default values of a Python function's parameters. A *named tuple* is returned:

```
FullArgSpec(args, varargs, varkw, defaults, kwoonlyargs, kwoonlydefaults,
            annotations)
```

*args* is a list of the positional parameter names. *varargs* is the name of the \* parameter or *None* if arbitrary positional arguments are not accepted. *varkw* is the name of the \*\* parameter or *None* if arbitrary keyword arguments are not accepted. *defaults* is an *n*-tuple of default argument values corresponding to the last *n* positional parameters, or *None* if there are no such defaults defined. *kwoonlyargs* is a list of keyword-only parameter names in declaration order. *kwoonlydefaults* is a dictionary mapping parameter names from *kwoonlyargs* to the default values used if no argument is supplied. *annotations* is a dictionary mapping parameter names to annotations. The special key "return" is used to report the function return value annotation (if any).

Note that *signature()* and *Signature Object* provide the recommended API for callable introspection, and support additional behaviours (like positional-only arguments) that are sometimes encountered in extension module APIs. This function is retained primarily for use in code that needs to maintain compatibility with the Python 2 *inspect* module API.

在 3.4 版的變更: This function is now based on *signature()*, but still ignores `__wrapped__` attributes and includes the already bound first parameter in the signature output for bound methods.

在 3.6 版的變更: This method was previously documented as deprecated in favour of *signature()* in Python 3.5, but that decision has been reversed in order to restore a clearly supported standard interface for single-source Python 2/3 code migrating away from the legacy *getargspec()* API.

在 3.7 版的變更: Python only explicitly guaranteed that it preserved the declaration order of keyword-only parameters as of version 3.7, although in practice this order had always been preserved in Python 3.

`inspect.getargvalues` (*frame*)

Get information about arguments passed into a particular frame. A *named tuple* `ArgInfo(args, varargs, keywords, locals)` is returned. *args* is a list of the argument names. *varargs* and *keywords* are the names of the \* and \*\* arguments or *None*. *locals* is the locals dictionary of the given frame.

 備

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.formatargvalues` (*args*[, *varargs*, *varkw*, *locals*, *formatarg*, *formatvarargs*, *formatvarkw*, *formatvalue* ])

Format a pretty argument spec from the four values returned by *getargvalues()*. The *format\** arguments are the corresponding optional formatting functions that are called to turn names and values into strings.

## 備 F

This function was inadvertently marked as deprecated in Python 3.5.

`inspect.getmro(cls)`

Return a tuple of class `cls`'s base classes, including `cls`, in method resolution order. No class appears more than once in this tuple. Note that the method resolution order depends on `cls`'s type. Unless a very peculiar user-defined metatype is in use, `cls` will be the first element of the tuple.

`inspect.getcallargs(func, /, *args, **kwargs)`

Bind the `args` and `kwargs` to the argument names of the Python function or method `func`, as if it was called with them. For bound methods, bind also the first argument (typically named `self`) to the associated instance. A dict is returned, mapping the argument names (including the names of the `*` and `**` arguments, if any) to their values from `args` and `kwargs`. In case of invoking `func` incorrectly, i.e. whenever `func(*args, **kwargs)` would raise an exception because of incompatible signature, an exception of the same type and the same or similar message is raised. For example:

```
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
...
>>> getcallargs(f, 1, 2, 3) == {'a': 1, 'named': {}, 'b': 2, 'pos': (3,)}
True
>>> getcallargs(f, a=2, x=4) == {'a': 2, 'named': {'x': 4}, 'b': 1, 'pos': ()}
True
>>> getcallargs(f)
Traceback (most recent call last):
...
TypeError: f() missing 1 required positional argument: 'a'
```

在 3.2 版被加入。

在 3.5 版之後被 F 用: 請改用 `Signature.bind()` 與 `Signature.bind_partial()`。

`inspect.getclosurevars(func)`

Get the mapping of external name references in a Python function or method `func` to their current values. A *named tuple* `ClosureVars(nonlocals, globals, builtins, unbound)` is returned. `nonlocals` maps referenced names to lexical closure variables, `globals` to the function's module globals and `builtins` to the builtins visible from the function body. `unbound` is the set of names referenced in the function that could not be resolved at all given the current module globals and builtins.

如果 `func` 不是 Python 函式或方法, 則引發 `TypeError`。

在 3.3 版被加入。

`inspect.unwrap(func, *, stop=None)`

Get the object wrapped by `func`. It follows the chain of `__wrapped__` attributes returning the last object in the chain.

`stop` is an optional callback accepting an object in the wrapper chain as its sole argument that allows the unwrapping to be terminated early if the callback returns a true value. If the callback never returns a true value, the last object in the chain is returned as usual. For example, `signature()` uses this to stop unwrapping if any object in the chain has a `__signature__` attribute defined.

如果遇到循環, 則引發 `ValueError`。

在 3.4 版被加入。

`inspect.get_annotations(obj, *, globals=None, locals=None, eval_str=False)`

Compute the annotations dict for an object.

`obj` may be a callable, class, or module. Passing in an object of any other type raises `TypeError`.

Returns a dict. `get_annotations()` returns a new dict every time it's called; calling it twice on the same object will return two different but equivalent dicts.

This function handles several details for you:

- If `eval_str` is true, values of type `str` will be un-stringized using `eval()`. This is intended for use with stringized annotations (`from __future__ import annotations`).
- If `obj` doesn't have an annotations dict, returns an empty dict. (Functions and methods always have an annotations dict; classes, modules, and other types of callables may not.)
- Ignores inherited annotations on classes. If a class doesn't have its own annotations dict, returns an empty dict.
- All accesses to object members and dict values are done using `getattr()` and `dict.get()` for safety.
- Always, always, always returns a freshly created dict.

`eval_str` controls whether or not values of type `str` are replaced with the result of calling `eval()` on those values:

- If `eval_str` is true, `eval()` is called on values of type `str`. (Note that `get_annotations` doesn't catch exceptions; if `eval()` raises an exception, it will unwind the stack past the `get_annotations` call.)
- If `eval_str` is false (the default), values of type `str` are unchanged.

`globals` and `locals` are passed in to `eval()`; see the documentation for `eval()` for more information. If `globals` or `locals` is `None`, this function may replace that value with a context-specific default, contingent on `type(obj)`:

- If `obj` is a module, `globals` defaults to `obj.__dict__`.
- If `obj` is a class, `globals` defaults to `sys.modules[obj.__module__].__dict__` and `locals` defaults to the `obj` class namespace.
- If `obj` is a callable, `globals` defaults to `obj.__globals__`, although if `obj` is a wrapped function (using `functools.update_wrapper()`) it is first unwrapped.

Calling `get_annotations` is best practice for accessing the annotations dict of any object. See `annotations-howto` for more information on annotations best practices.

在 3.10 版被加入。

### 30.14.5 直譯器堆 F

Some of the following functions return `FrameInfo` objects. For backwards compatibility these objects allow tuple-like operations on all attributes except `positions`. This behavior is considered deprecated and may be removed in the future.

**class** `inspect.FrameInfo`

**frame**

The frame object that the record corresponds to.

**filename**

The file name associated with the code being executed by the frame this record corresponds to.

**lineno**

The line number of the current line associated with the code being executed by the frame this record corresponds to.

**function**

The function name that is being executed by the frame this record corresponds to.

**code\_context**

A list of lines of context from the source code that's being executed by the frame this record corresponds to.

**index**

The index of the current line being executed in the `code_context` list.

**positions**

A `dis.Positions` object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this record corresponds to.

在 3.5 版的變更: Return a *named tuple* instead of a *tuple*.

在 3.11 版的變更: `FrameInfo` is now a class instance (that is backwards compatible with the previous *named tuple*).

**class inspect.Traceback****filename**

The file name associated with the code being executed by the frame this traceback corresponds to.

**lineno**

The line number of the current line associated with the code being executed by the frame this traceback corresponds to.

**function**

The function name that is being executed by the frame this traceback corresponds to.

**code\_context**

A list of lines of context from the source code that's being executed by the frame this traceback corresponds to.

**index**

The index of the current line being executed in the `code_context` list.

**positions**

A `dis.Positions` object containing the start line number, end line number, start column offset, and end column offset associated with the instruction being executed by the frame this traceback corresponds to.

在 3.11 版的變更: `Traceback` is now a class instance (that is backwards compatible with the previous *named tuple*).

**備 F**

Keeping references to frame objects, as found in the first element of the frame records these functions return, can cause your program to create reference cycles. Once a reference cycle has been created, the lifespan of all objects which can be accessed from the objects which form the cycle can become much longer even if Python's optional cycle detector is enabled. If such cycles must be created, it is important to ensure they are explicitly broken to avoid the delayed destruction of objects and increased memory consumption which occurs.

Though the cycle detector will catch these, destruction of the frames (and local variables) can be made deterministic by removing the cycle in a `finally` clause. This is also important if the cycle detector was disabled when Python was compiled or using `gc.disable()`. For example:

```
def handle_stackframe_without_leak():
    frame = inspect.currentframe()
    try:
        # do something with the frame
    finally:
        del frame
```

If you want to keep the frame around (for example to print a traceback later), you can also break reference cycles by using the `frame.clear()` method.

The optional *context* argument supported by most of these functions specifies the number of lines of context to return, which are centered around the current line.

`inspect.getframeinfo(frame, context=1)`

Get information about a frame or traceback object. A *Traceback* object is returned.

在 3.11 版的變更: A *Traceback* object is returned instead of a named tuple.

`inspect.getouterframes(frame, context=1)`

Get a list of *FrameInfo* objects for a frame and all outer frames. These frames represent the calls that lead to the creation of *frame*. The first entry in the returned list represents *frame*; the last entry represents the outermost call on *frame*'s stack.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 *FrameInfo* 物件串列。

`inspect.getinnerframes(traceback, context=1)`

Get a list of *FrameInfo* objects for a traceback's frame and all inner frames. These frames represent calls made as a consequence of *frame*. The first entry in the list represents *traceback*; the last entry represents where the exception was raised.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 *FrameInfo* 物件串列。

`inspect.currentframe()`

Return the frame object for the caller's stack frame.

**CPython 實作細節:** This function relies on Python stack frame support in the interpreter, which isn't guaranteed to exist in all implementations of Python. If running in an implementation without Python stack frame support this function returns `None`.

`inspect.stack(context=1)`

Return a list of *FrameInfo* objects for the caller's stack. The first entry in the returned list represents the caller; the last entry represents the outermost call on the stack.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 *FrameInfo* 物件串列。

`inspect.trace(context=1)`

Return a list of *FrameInfo* objects for the stack between the current frame and the frame in which an exception currently being handled was raised in. The first entry in the list represents the caller; the last entry represents where the exception was raised.

在 3.5 版的變更: A list of *named tuples* `FrameInfo(frame, filename, lineno, function, code_context, index)` is returned.

在 3.11 版的變更: 回傳一個 *FrameInfo* 物件串列。

### 30.14.6 Fetching attributes statically

Both `getattr()` and `hasattr()` can trigger code execution when fetching or checking for the existence of attributes. Descriptors, like properties, will be invoked and `__getattr__()` and `__getattribute__()` may be called.

For cases where you want passive introspection, like documentation tools, this can be inconvenient. `getattr_static()` has the same signature as `getattr()` but avoids executing code when it fetches attributes.

`inspect.getattr_static(obj, attr, default=None)`

Retrieve attributes without triggering dynamic lookup via the descriptor protocol, `__getattr__()` or `__getattribute__()`.

Note: this function may not be able to retrieve all attributes that `getattr` can fetch (like dynamically created attributes) and may find attributes that `getattr` can't (like descriptors that raise `AttributeError`). It can also return descriptors objects instead of instance members.

If the instance `__dict__` is shadowed by another member (for example a property) then this function will be unable to find instance members.

在 3.2 版被加入。

`getattr_static()` does not resolve descriptors, for example slot descriptors or getset descriptors on objects implemented in C. The descriptor object is returned instead of the underlying attribute.

You can handle these with code like the following. Note that for arbitrary getset descriptors invoking these may trigger code execution:

```
# example code for resolving the builtin descriptor types
class _foo:
    __slots__ = ['foo']

slot_descriptor = type(_foo.foo)
getset_descriptor = type(type(open(__file__)).name)
wrapper_descriptor = type(str.__dict__['__add__'])
descriptor_types = (slot_descriptor, getset_descriptor, wrapper_descriptor)

result = getattr_static(some_object, 'foo')
if type(result) in descriptor_types:
    try:
        result = result.__get__()
    except AttributeError:
        # descriptors can raise AttributeError to
        # indicate there is no underlying value
        # in which case the descriptor itself will
        # have to do
        pass
```

### 30.14.7 Current State of Generators, Coroutines, and Asynchronous Generators

When implementing coroutine schedulers and for other advanced uses of generators, it is useful to determine whether a generator is currently executing, is waiting to start or resume or execution, or has already terminated. `getgeneratorstate()` allows the current state of a generator to be determined easily.

`inspect.getgeneratorstate(generator)`

Get current state of a generator-iterator.

Possible states are:

- `GEN_CREATED`: Waiting to start execution.
- `GEN_RUNNING`: Currently being executed by the interpreter.
- `GEN_SUSPENDED`: Currently suspended at a yield expression.
- `GEN_CLOSED`: Execution has completed.

在 3.2 版被加入。

`inspect.getcoroutinestate(coroutine)`

Get current state of a coroutine object. The function is intended to be used with coroutine objects created by `async def` functions, but will accept any coroutine-like object that has `cr_running` and `cr_frame` attributes.

Possible states are:

- `CORO_CREATED`: Waiting to start execution.
- `CORO_RUNNING`: Currently being executed by the interpreter.
- `CORO_SUSPENDED`: Currently suspended at an await expression.
- `CORO_CLOSED`: Execution has completed.

在 3.5 版被加入。

`inspect.getasyncgenstate(agen)`

Get current state of an asynchronous generator object. The function is intended to be used with asynchronous iterator objects created by `async def` functions which use the `yield` statement, but will accept any asynchronous generator-like object that has `ag_running` and `ag_frame` attributes.

Possible states are:

- `AGEN_CREATED`: 等待開始執行。
- `AGEN_RUNNING`: 目前正在被直譯器執行。
- `AGEN_SUSPENDED`: 目前於 `yield` 運算式暫停。
- `AGEN_CLOSED`: 執行已完成。

在 3.12 版被加入。

The current internal state of the generator can also be queried. This is mostly useful for testing purposes, to ensure that internal state is being updated as expected:

`inspect.getgeneratorlocals(generator)`

Get the mapping of live local variables in *generator* to their current values. A dictionary is returned that maps from variable names to values. This is the equivalent of calling `locals()` in the body of the generator, and all the same caveats apply.

If *generator* is a *generator* with no currently associated frame, then an empty dictionary is returned. `TypeError` is raised if *generator* is not a Python generator object.

**CPython 實作細節：** This function relies on the generator exposing a Python stack frame for introspection, which isn't guaranteed to be the case in all implementations of Python. In such cases, this function will always return an empty dictionary.

在 3.3 版被加入。

`inspect.getcoroutinelocals(coroutine)`

This function is analogous to `getgeneratorlocals()`, but works for coroutine objects created by `async def` functions.

在 3.5 版被加入。

`inspect.getasyncgenlocals(agen)`

This function is analogous to `getgeneratorlocals()`, but works for asynchronous generator objects created by `async def` functions which use the `yield` statement.

在 3.12 版被加入。

### 30.14.8 Code Objects Bit Flags

Python code objects have a `co_flags` attribute, which is a bitmap of the following flags:

`inspect.CO_OPTIMIZED`

The code object is optimized, using fast locals.

`inspect.CO_NEWLOCALS`

If set, a new dict will be created for the frame's `f_locals` when the code object is executed.

`inspect.CO_VARARGS`

The code object has a variable positional parameter (`*args`-like).

`inspect.CO_VARKEYWORDS`

The code object has a variable keyword parameter (\*\*kwargs-like).

`inspect.CO_NESTED`

The flag is set when the code object is a nested function.

`inspect.CO_GENERATOR`

The flag is set when the code object is a generator function, i.e. a generator object is returned when the code object is executed.

`inspect.CO_COROUTINE`

The flag is set when the code object is a coroutine function. When the code object is executed it returns a coroutine object. See [PEP 492](#) for more details.

在 3.5 版被加入.

`inspect.CO_ITERABLE_COROUTINE`

The flag is used to transform generators into generator-based coroutines. Generator objects with this flag can be used in `await` expression, and can `yield` from coroutine objects. See [PEP 492](#) for more details.

在 3.5 版被加入.

`inspect.CO_ASYNC_GENERATOR`

The flag is set when the code object is an asynchronous generator function. When the code object is executed it returns an asynchronous generator object. See [PEP 525](#) for more details.

在 3.6 版被加入.

#### 備註

The flags are specific to CPython, and may not be defined in other Python implementations. Furthermore, the flags are an implementation detail, and can be removed or deprecated in future Python releases. It's recommended to use public APIs from the `inspect` module for any introspection needs.

### 30.14.9 Buffer flags

`class inspect.BufferFlags`

This is an `enum.IntFlag` that represents the flags that can be passed to the `__buffer__()` method of objects implementing the buffer protocol.

The meaning of the flags is explained at [buffer-request-types](#).

`SIMPLE`

`WRITABLE`

`FORMAT`

在 3.12 版被加入。

### 30.14.10 命令列介面

The `inspect` module also provides a basic introspection capability from the command line.

By default, accepts the name of a module and prints the source of that module. A class or function within the module can be printed instead by appended a colon and the qualified name of the target object.

**--details**

Print information about the specified object rather than the source code

## 30.15 `site` --- Site-specific configuration hook

原始碼: `Lib/site.py`

**This module is automatically imported during initialization.** The automatic import can be suppressed using the interpreter's `-S` option.

Importing this module normally appends site-specific paths to the module search path and adds *callable*s, including `help()` to the built-in namespace. However, Python startup option `-S` blocks this and this module can be safely imported with no automatic modifications to the module search path or additions to the builtins. To explicitly trigger the usual site-specific additions, call the `main()` function.

在 3.3 版的變更: Importing the module used to trigger paths manipulation even when using `-S`.

It starts by constructing up to four directories from a head and a tail part. For the head part, it uses `sys.prefix` and `sys.exec_prefix`; empty heads are skipped. For the tail part, it uses the empty string and then `lib/site-packages` (on Windows) or `lib/pythonX.Y[t]/site-packages` (on Unix and macOS). (The optional suffix "t" indicates the *free threading* build, and is appended if "t" is present in the `sys.abiflags` constant.) For each of the distinct head-tail combinations, it sees if it refers to an existing directory, and if so, adds it to `sys.path` and also inspects the newly added path for configuration files.

在 3.5 版的變更: Support for the "site-python" directory has been removed.

在 3.13 版的變更: On Unix, *Free threading* Python installations are identified by the "t" suffix in the version-specific directory name, such as `lib/python3.13t/`.

If a file named "pyenv.cfg" exists one directory above `sys.executable`, `sys.prefix` and `sys.exec_prefix` are set to that directory and it is also checked for site-packages (`sys.base_prefix` and `sys.base_exec_prefix` will always be the "real" prefixes of the Python installation). If "pyenv.cfg" (a bootstrap configuration file) contains the key "include-system-site-packages" set to anything other than "true" (case-insensitive), the system-level prefixes will not be searched for site-packages; otherwise they will.

A path configuration file is a file whose name has the form `name.pth` and exists in one of the four directories mentioned above; its contents are additional items (one per line) to be added to `sys.path`. Non-existing items are never added to `sys.path`, and no check is made that the item refers to a directory rather than a file. No item is added to `sys.path` more than once. Blank lines and lines beginning with `#` are skipped. Lines starting with `import` (followed by space or tab) are executed.

### 備 F

An executable line in a `.pth` file is run at every Python startup, regardless of whether a particular module is actually going to be used. Its impact should thus be kept to a minimum. The primary intended purpose of executable lines is to make the corresponding module(s) importable (load 3rd-party import hooks, adjust `PATH` etc). Any other initialization is supposed to be done upon a module's actual import, if and when it happens. Limiting a code chunk to a single line is a deliberate measure to discourage putting anything more complex here.

在 3.13 版的變更: The `.pth` files are now decoded by UTF-8 at first and then by the *locale encoding* if it fails.

For example, suppose `sys.prefix` and `sys.exec_prefix` are set to `/usr/local`. The Python X.Y library is then installed in `/usr/local/lib/pythonX.Y`. Suppose this has a subdirectory `/usr/local/lib/pythonX.Y/site-packages` with three subsubdirectories, `foo`, `bar` and `spam`, and two path configuration files, `foo.pth` and `bar.pth`. Assume `foo.pth` contains the following:

```
# foo package configuration

foo
bar
bletch
```

and `bar.pth` contains:

```
# bar package configuration

bar
```

Then the following version-specific directories are added to `sys.path`, in this order:

```
/usr/local/lib/pythonX.Y/site-packages/bar
/usr/local/lib/pythonX.Y/site-packages/foo
```

Note that `bletch` is omitted because it doesn't exist; the `bar` directory precedes the `foo` directory because `bar.pth` comes alphabetically before `foo.pth`; and `spam` is omitted because it is not mentioned in either path configuration file.

### 30.15.1 sitecustomize

After these path manipulations, an attempt is made to import a module named `sitecustomize`, which can perform arbitrary site-specific customizations. It is typically created by a system administrator in the `site-packages` directory. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'sitecustomize'`, it is silently ignored. If Python is started without output streams available, as with `pythonw.exe` on Windows (which is used by default to start IDLE), attempted output from `sitecustomize` is ignored. Any other exception causes a silent and perhaps mysterious failure of the process.

### 30.15.2 usercustomize

After this, an attempt is made to import a module named `usercustomize`, which can perform arbitrary user-specific customizations, if `ENABLE_USER_SITE` is true. This file is intended to be created in the user `site-packages` directory (see below), which is part of `sys.path` unless disabled by `-s`. If this import fails with an `ImportError` or its subclass exception, and the exception's `name` attribute equals to `'usercustomize'`, it is silently ignored.

Note that for some non-Unix systems, `sys.prefix` and `sys.exec_prefix` are empty, and the path manipulations are skipped; however the import of `sitecustomize` and `usercustomize` is still attempted.

### 30.15.3 Readline configuration

On systems that support *readline*, this module will also import and configure the *rlcompleter* module, if Python is started in interactive mode and without the `-S` option. The default behavior is enable tab-completion and to use `~/.python_history` as the history save file. To disable it, delete (or override) the `sys.__interactivehook__` attribute in your *sitecustomize* or *usercustomize* module or your `PYTHONSTARTUP` file.

在 3.4 版的變更: Activation of *rlcompleter* and history was made automatic.

### 30.15.4 模組 F 容

#### site.PREFIXES

A list of prefixes for site-packages directories.

#### site.ENABLE\_USER\_SITE

Flag showing the status of the user site-packages directory. `True` means that it is enabled and was added to `sys.path`. `False` means that it was disabled by user request (with `-s` or `PYTHONNOUSERSITE`). `None` means it was disabled for security reasons (mismatch between user or group id and effective id) or by an administrator.

#### site.USER\_SITE

Path to the user site-packages for the running Python. Can be `None` if *getusersitepackages()* hasn't been called yet. Default value is `~/.local/lib/pythonX.Y[t]/site-packages` for UNIX and non-framework macOS builds, `~/Library/Python/X.Y/lib/python/site-packages` for macOS framework builds, and `%APPDATA%\Python\PythonXY\site-packages` on Windows. The optional "t" indicates the free-threaded build. This directory is a site directory, which means that `.pth` files in it will be processed.

#### site.USER\_BASE

Path to the base directory for the user site-packages. Can be `None` if *getuserbase()* hasn't been called yet. Default value is `~/.local` for UNIX and macOS non-framework builds, `~/Library/Python/X.Y` for macOS framework builds, and `%APPDATA%\Python` for Windows. This value is used to compute the installation directories for scripts, data files, Python modules, etc. for the *user installation scheme*. See also `PYTHONUSERBASE`.

#### site.main()

Adds all the standard site-specific directories to the module search path. This function is called automatically when this module is imported, unless the Python interpreter was started with the `-S` flag.

在 3.3 版的變更: This function used to be called unconditionally.

#### site.addsitedir(sitedir, known\_paths=None)

Add a directory to `sys.path` and process its `.pth` files. Typically used in *sitecustomize* or *usercustomize* (see above).

#### site.getsitepackages()

Return a list containing all global site-packages directories.

在 3.2 版被加入.

#### site.getuserbase()

Return the path of the user base directory, `USER_BASE`. If it is not initialized yet, this function will also set it, respecting `PYTHONUSERBASE`.

在 3.2 版被加入.

#### site.getusersitepackages()

Return the path of the user-specific site-packages directory, `USER_SITE`. If it is not initialized yet, this function will also set it, respecting `USER_BASE`. To determine if the user-specific site-packages was added to `sys.path` `ENABLE_USER_SITE` should be used.

在 3.2 版被加入.

### 30.15.5 命令列介面

The `site` module also provides a way to get the user directories from the command line:

```
$ python -m site --user-site
/home/user/.local/lib/python3.11/site-packages
```

If it is called without arguments, it will print the contents of `sys.path` on the standard output, followed by the value of `USER_BASE` and whether the directory exists, then the same thing for `USER_SITE`, and finally the value of `ENABLE_USER_SITE`.

#### **--user-base**

Print the path to the user base directory.

#### **--user-site**

Print the path to the user site-packages directory.

If both options are given, user base and user site will be printed (always in this order), separated by `os.pathsep`.

If any option is given, the script will exit with one of these values: 0 if the user site-packages directory is enabled, 1 if it was disabled by the user, 2 if it is disabled for security reasons or by an administrator, and a value greater than 2 if there is an error.

## 自訂 Python 直譯器

The modules described in this chapter allow writing interfaces similar to Python's interactive interpreter. If you want a Python interpreter that supports some special feature in addition to the Python language, you should look at the `code` module. (The `codeop` module is lower-level, used to support compiling a possibly incomplete chunk of Python code.)

本章節所描述的模組清單<sup>[F]</sup>:

### 31.1 `code` --- 直譯器基底類<sup>[F]</sup>

原始碼: [Lib/code.py](#)

The `code` module provides facilities to implement read-eval-print loops in Python. Two classes and convenience functions are included which can be used to build applications which provide an interactive interpreter prompt.

**class** `code.InteractiveInterpreter` (*locals=None*)

This class deals with parsing and interpreter state (the user's namespace); it does not deal with input buffering or prompting or input file naming (the filename is always passed in explicitly). The optional *locals* argument specifies a mapping to use as the namespace in which code will be executed; it defaults to a newly created dictionary with key `'__name__'` set to `'__console__'` and key `'__doc__'` set to `None`.

**class** `code.InteractiveConsole` (*locals=None, filename='<console>', local\_exit=False*)

Closely emulate the behavior of the interactive Python interpreter. This class builds on `InteractiveInterpreter` and adds prompting using the familiar `sys.ps1` and `sys.ps2`, and input buffering. If *local\_exit* is true, `exit()` and `quit()` in the console will not raise `SystemExit`, but instead return to the calling code.

在 3.13 版的變更: Added *local\_exit* parameter.

**code.interact** (*banner=None, readfunc=None, local=None, exitmsg=None, local\_exit=False*)

Convenience function to run a read-eval-print loop. This creates a new instance of `InteractiveConsole` and sets *readfunc* to be used as the `InteractiveConsole.raw_input()` method, if provided. If *local* is provided, it is passed to the `InteractiveConsole` constructor for use as the default namespace for the interpreter loop. If *local\_exit* is provided, it is passed to the `InteractiveConsole` constructor. The `interact()` method of the instance is then run with *banner* and *exitmsg* passed as the banner and exit message to use, if provided. The console object is discarded after use.

在 3.6 版的變更: 新增 *exitmsg* 參數。

在 3.13 版的變更: Added `local_exit` parameter.

code.`compile_command` (*source*, *filename*='<input>', *symbol*='single')

This function is useful for programs that want to emulate Python's interpreter main loop (a.k.a. the read-eval-print loop). The tricky part is to determine when the user has entered an incomplete command that can be completed by entering more text (as opposed to a complete command or a syntax error). This function *almost* always makes the same decision as the real interpreter main loop.

*source* is the source string; *filename* is the optional filename from which source was read, defaulting to '<input>'; and *symbol* is the optional grammar start symbol, which should be 'single' (the default), 'eval' or 'exec'.

Returns a code object (the same as `compile(source, filename, symbol)`) if the command is complete and valid; `None` if the command is incomplete; raises `SyntaxError` if the command is complete and contains a syntax error, or raises `OverflowError` or `ValueError` if the command contains an invalid literal.

### 31.1.1 Interactive Interpreter Objects

`InteractiveInterpreter.runsource` (*source*, *filename*='<input>', *symbol*='single')

Compile and run some source in the interpreter. Arguments are the same as for `compile_command()`; the default for *filename* is '<input>', and for *symbol* is 'single'. One of several things can happen:

- The input is incorrect; `compile_command()` raised an exception (`SyntaxError` or `OverflowError`). A syntax traceback will be printed by calling the `showsyntaxerror()` method. `runsource()` returns `False`.
- The input is incomplete, and more input is required; `compile_command()` returned `None`. `runsource()` returns `True`.
- The input is complete; `compile_command()` returned a code object. The code is executed by calling the `runcode()` (which also handles run-time exceptions, except for `SystemExit`). `runsource()` returns `False`.

The return value can be used to decide whether to use `sys.ps1` or `sys.ps2` to prompt the next line.

`InteractiveInterpreter.runcode` (*code*)

Execute a code object. When an exception occurs, `showtraceback()` is called to display a traceback. All exceptions are caught except `SystemExit`, which is allowed to propagate.

A note about `KeyboardInterrupt`: this exception may occur elsewhere in this code, and may not always be caught. The caller should be prepared to deal with it.

`InteractiveInterpreter.showsyntaxerror` (*filename*=`None`)

Display the syntax error that just occurred. This does not display a stack trace because there isn't one for syntax errors. If *filename* is given, it is stuffed into the exception instead of the default filename provided by Python's parser, because it always uses '<string>' when reading from a string. The output is written by the `write()` method.

`InteractiveInterpreter.showtraceback` ()

Display the exception that just occurred. We remove the first stack item because it is within the interpreter object implementation. The output is written by the `write()` method.

在 3.5 版的變更: The full chained traceback is displayed instead of just the primary traceback.

`InteractiveInterpreter.write` (*data*)

Write a string to the standard error stream (`sys.stderr`). Derived classes should override this to provide the appropriate output handling as needed.

### 31.1.2 Interactive Console Objects

The `InteractiveConsole` class is a subclass of `InteractiveInterpreter`, and so offers all the methods of the interpreter objects as well as the following additions.

`InteractiveConsole.interact` (*banner=None, exitmsg=None*)

Closely emulate the interactive Python console. The optional *banner* argument specify the banner to print before the first interaction; by default it prints a banner similar to the one printed by the standard Python interpreter, followed by the class name of the console object in parentheses (so as not to confuse this with the real interpreter -- since it's so close!).

The optional *exitmsg* argument specifies an exit message printed when exiting. Pass the empty string to suppress the exit message. If *exitmsg* is not given or `None`, a default message is printed.

在 3.4 版的變更: To suppress printing any banner, pass an empty string.

在 3.6 版的變更: Print an exit message when exiting.

`InteractiveConsole.push` (*line*)

Push a line of source text to the interpreter. The line should not have a trailing newline; it may have internal newlines. The line is appended to a buffer and the interpreter's `runsource()` method is called with the concatenated contents of the buffer as source. If this indicates that the command was executed or invalid, the buffer is reset; otherwise, the command is incomplete, and the buffer is left as it was after the line was appended. The return value is `True` if more input is required, `False` if the line was dealt with in some way (this is the same as `runsource()`).

`InteractiveConsole.resetbuffer` ()

Remove any unhandled source text from the input buffer.

`InteractiveConsole.raw_input` (*prompt=""*)

Write a prompt and read a line. The returned line does not include the trailing newline. When the user enters the EOF key sequence, `EOFError` is raised. The base implementation reads from `sys.stdin`; a subclass may replace this with a different implementation.

## 31.2 codeop --- 編譯 Python 程式碼

原始碼: [Lib/codeop.py](#)

`codeop` 模組提供了可以模擬 Python read-eval-print 循環的工具程式 (utilities), 就像在 `code` 模組中所做的那樣。因此你可能不想直接使用該模組; 如果你想在程式中包含這樣的循環, 你可能需要使用 `code` 模組。

這個任務有兩個部分:

1. 能判斷一列輸入是否完成了一項 Python 陳述式: 簡而言之, 判斷接下來是列印 '>>>' 還是 '...'。
2. 記住使用者輸入了哪些未來陳述式, 以便後續輸入可以在這些陳述式生效的情況下進行編譯。

`codeop` 模組提供了一種完成上述每項任務的方法, 以及同時完成這兩項任務的方法。

只做前者:

`codeop.compile_command` (*source, filename='<input>', symbol='single'*)

嘗試編譯 *source*, 它應該是 Python 程式碼的字串, 如果 *source* 是有效的 Python 程式碼, 則回傳一個程式碼物件 (code object)。在這種情況下, 程式碼物件的檔案名稱屬性將 `filename`, 預設 `'<input>'`。如果 *source* 不是有效的 Python 程式碼, 而是有效 Python 程式碼的前綴, 則回傳 `None`。

如果 *source* 有問題, 就會引發例外。如果存在無效的 Python 語法則會引發 `SyntaxError`; 如果存在無效的文字 (literal), 則會引發 `OverflowError` 或 `ValueError`。

*symbol* 引數 `single` 是否編譯陳述式 ('single', 預設值)、陳述式序列 ('exec') 或運算式 ('eval')。任何其他值都會導致引發 `ValueError`。

**備**

剖析器 (parser) 有可能 (但通常不會) 在到達原始碼的結尾之前停止剖析獲得成功的結果; 在這種情況下, 尾隨符號可能會被忽略而不是導致錯誤。例如, 反斜後面加上兩個行符號後可以是任意的無意義符號。這個問題在未來會因剖析器 API 的改善而被解。

**class** `codeop.Compile`

此類的實例具有 `__call__()` 方法, 其簽名與建函式 `compile()` 相同, 區在於如果實例編譯包含 `__future__` 陳述式的程式文本, 實例會「記住」使用該陳述式開始編譯所有後續程式文本。

**class** `codeop.CommandCompiler`

此類的實例具有 `__call__()` 方法, 其簽名與建函式 `compile_command()` 相同, 區在於如果實例編譯包含 `__future__` 陳述式的程式文本, 實例會「記住」使用該陳述式開始編譯所有後續程式文本。

The modules described in this chapter provide new ways to import other Python modules and hooks for customizing the import process.

The full list of modules described in this chapter is:

## 32.1 `zipimport` --- 從 Zip 封存檔案匯入模組

原始碼: [Lib/zipimport.py](#)

This module adds the ability to import Python modules (`*.py`, `*.pyc`) and packages from ZIP-format archives. It is usually not needed to use the `zipimport` module explicitly; it is automatically used by the built-in `import` mechanism for `sys.path` items that are paths to ZIP archives.

Typically, `sys.path` is a list of directory names as strings. This module also allows an item of `sys.path` to be a string naming a ZIP file archive. The ZIP archive can contain a subdirectory structure to support package imports, and a path within the archive can be specified to only import from a subdirectory. For example, the path `example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

Any files may be present in the ZIP archive, but importers are only invoked for `.py` and `.pyc` files. ZIP import of dynamic modules (`.pyd`, `.so`) is disallowed. Note that if an archive only contains `.py` files, Python will not attempt to modify the archive by adding the corresponding `.pyc` file, meaning that if a ZIP archive doesn't contain `.pyc` files, importing may be rather slow.

在 3.13 版的變更: ZIP64 is supported

在 3.8 版的變更: Previously, ZIP archives with an archive comment were not supported.

Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

#### PEP 273 - Import Modules from Zip Archives

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in [PEP 273](#), but uses an implementation written by Just van Rossum that uses the import hooks described in [PEP 302](#).

***importlib* - The implementation of the import machinery**

Package providing the relevant protocols for all importers to implement.

This module defines an exception:

**exception** `zipimport.ZipImportError`Exception raised by zipimporter objects. It's a subclass of `ImportError`, so it can be caught as `ImportError`, too.**32.1.1 zipimporter 物件**`zipimporter` is the class for importing ZIP files.**class** `zipimport.zipimporter` (*archivepath*)Create a new zipimporter instance. *archivepath* must be a path to a ZIP file, or to a specific path within a ZIP file. For example, an *archivepath* of `foo/bar.zip/lib` will look for modules in the `lib` directory inside the ZIP file `foo/bar.zip` (provided that it exists).`ZipImportError` is raised if *archivepath* doesn't point to a valid ZIP archive.在 3.12 版的變更: Methods `find_loader()` and `find_module()`, deprecated in 3.10 are now removed. Use `find_spec()` instead.**create\_module** (*spec*)Implementation of `importlib.abc.Loader.create_module()` that returns `None` to explicitly request the default semantics.

在 3.10 版被加入。

**exec\_module** (*module*)Implementation of `importlib.abc.Loader.exec_module()`.

在 3.10 版被加入。

**find\_spec** (*fullname*, *target=None*)An implementation of `importlib.abc.PathEntryFinder.find_spec()`.

在 3.10 版被加入。

**get\_code** (*fullname*)Return the code object for the specified module. Raise `ZipImportError` if the module couldn't be imported.**get\_data** (*pathname*)Return the data associated with *pathname*. Raise `OSError` if the file wasn't found.在 3.3 版的變更: `IOError` used to be raised, it is now an alias of `OSError`.**get\_filename** (*fullname*)Return the value `__file__` would be set to if the specified module was imported. Raise `ZipImportError` if the module couldn't be imported.

在 3.1 版被加入。

**get\_source** (*fullname*)Return the source code for the specified module. Raise `ZipImportError` if the module couldn't be found, return `None` if the archive does contain the module, but has no source for it.**is\_package** (*fullname*)Return `True` if the module specified by *fullname* is a package. Raise `ZipImportError` if the module couldn't be found.

**load\_module** (*fullname*)

Load the module specified by *fullname*. *fullname* must be the fully qualified (dotted) module name. Returns the imported module on success, raises *ZipImportError* on failure.

在 3.10 版之後被 用: Use *exec\_module()* instead.

**invalidate\_caches** ()

Clear out the internal cache of information about files found within the ZIP archive.

在 3.10 版被加入.

**archive**

The file name of the importer's associated ZIP file, without a possible subpath.

**prefix**

The subpath within the ZIP file where modules are searched. This is the empty string for *zipimporter* objects which point to the root of the ZIP file.

The *archive* and *prefix* attributes, when combined with a slash, equal the original *archivepath* argument given to the *zipimporter* constructor.

### 32.1.2 范例

Here is an example that imports a module from a ZIP archive - note that the *zipimport* module is not explicitly used.

```
$ unzip -l example.zip
Archive:  example.zip
  Length      Date    Time    Name
-----
   8467   11-26-02  22:30   jwzthreading.py
-----
   8467                   1 file

$ ./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, 'example.zip') # 將 .zip 檔案新增到系統路徑的最前面
>>> import jwzthreading
>>> jwzthreading.__file__
'example.zip/jwzthreading.py'
```

## 32.2 pkgutil --- 套件擴充工具程式

原始碼: `Lib/pkgutil.py`

此模組提供了引入系統 (import system) 的工具程式, 特 是套件相關支援。

**class** `pkgutil.ModuleInfo` (*module\_finder, name, ispkg*)

一個包含模組資訊之簡短摘要的附名元組 (namedtuple)。

在 3.6 版被加入.

`pkgutil.extend_path` (*path, name*)

擴充組成一個套件之模組的搜尋路徑。預期用法是將以下程式碼放入套件的 `__init__.py`:

```
from pkgutil import extend_path
__path__ = extend_path(__path__, __name__)
```

對於 `sys.path` 上具有與套件名稱相符的子目 的每個目，將該子目 新增至套件的 `__path__` 中。如果想要將單一邏輯套件的不同部分給分配到多個目 時，這會非常有用。

它還會尋找 `*.pkg` 檔案，其中開頭的 `*` 與 `name` 引數相符。此功能類似於 `*.pth` 檔案（更多資訊請參 模組），但他不特 處理以 `import` 開頭的行。`*.pkg` 檔案從表面上看是受信任的：除了跳過空行和備 之外，在 `*.pkg` 檔案中找到的所有條目都將新增到路徑中，無論它們是否存在於檔案系統。（這是一個功能。）

如果輸入路徑不是串列（像是凍結套件 (frozen package) 的情 ），它將原封不動地被回傳。輸入路徑不會被修改；而是回傳擴充後的副本。僅將項目附加到副本的尾端。

`sys.path` 被假設是一個序列，`sys.path` 中的項目，若不是代表現存目 的字串則將被忽略。`sys.path` 上用作檔案名稱時導致錯誤的 Unicode 項目可能會導致此函式引發例外（與 `os.path.isdir()` 行 一致）。

`pkgutil.find_loader(fullname)`

取得給定之 `fullname` 的模組 `loader`。

這是一個 `importlib.util.find_spec()` 的向後相容包裝器，它將大多數的失敗轉 `ImportError` 且僅回傳載入器而不是完整的 `importlib.machinery.ModuleSpec`。

在 3.3 版的變更: 更新 直接基於 `importlib`，而不是依賴套件 部 PEP 302 的引入模擬 (import emulation)。

在 3.4 版的變更: 基於 PEP 451 來更新

Deprecated since version 3.12, will be removed in version 3.14: 改用 `importlib.util.find_spec()`。

`pkgutil.get_importer(path_item)`

取得給定之 `path_item` 的 `finder`。

如果回傳的尋檢器 (finder) 是由路徑勾點 (path hook) 所新建立的，則它會被快取在 `sys.path_importer_cache` 中。

如果需要重新掃描 `sys.path_hooks`，可以手動清除快取（或部分快取）。

在 3.3 版的變更: 更新 直接基於 `importlib`，而不是依賴套件 部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.get_loader(module_or_name)`

取得 `module_or_name` 的 `loader` 物件。

如果可以透過正常引入機制存取模組或套件，則回傳該機制相關部分的包裝器。如果找不到或無法引入模組，則回傳 `None`。如果指定的模組尚未被引入，則引入其包含的套件（如有存在）以建立套件 `__path__`。

在 3.3 版的變更: 更新 直接基於 `importlib`，而不是依賴套件 部 PEP 302 的引入模擬 (import emulation)。

在 3.4 版的變更: 基於 PEP 451 來更新

Deprecated since version 3.12, will be removed in version 3.14: 改用 `importlib.util.find_spec()`。

`pkgutil.iter_importers(fullname="")`

yield 給定模組名稱的 `finder` 物件。

如果 `fullname` 包含 `'.'`，則尋檢器將針對包含 `fullname` 的套件，否則它們全部會是在頂層被 的尋檢器（即 `sys.meta_path` 和 `sys.path_hooks` 上的尋檢器）。

如果指定的模組位於套件中，則作 呼叫此函式的副作用 (side effect)，該套件會被引入。

如果未指定模組名稱，則會 生所有頂層尋檢器。

在 3.3 版的變更: 更新 直接基於 `importlib`，而不是依賴套件 部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.iter_modules(path=None, prefix=)`

yield `path` 上所有子模組的 `ModuleInfo`，或者如果 `path` 是 `None`，則生成 `sys.path` 上的所有頂層模組。

`path` 應該是 `None` 或用來尋找模組的路徑串列。

`prefix` 是在輸出的每個模組名稱前面的輸出字串。

#### 備註

僅適用於有定義 `iter_modules()` 方法的 `finder`。此介面非是標準的，因此該模組還提供了 `importlib.machinery.FileFinder` 和 `zipimport.zipimporter` 的實作。

在 3.3 版的變更: 更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.walk_packages(path=None, prefix=, onerror=None)`

在 `path` 上的所有模組遞歸 yield 出 `ModuleInfo`，或如果 `path` 是 `None` 則 yield 所有可存取的模組。

`path` 應該是 `None` 或用來尋找模組的路徑串列。

`prefix` 是在輸出的每個模組名稱前面的輸出字串。

請注意，此函式必須引入給定之 `path` 上的所有套件（不是所有模組！），以便存取 `__path__` 屬性來尋找子模組。

`onerror` 是一個函式，如果在嘗試引入套件時發生任何例外，則使用一個引數（正在引入之套件的名稱）來呼叫函式。如果未提供 `onerror` 函式，則會捕獲並忽略 `ImportError`，同時傳播所有其他例外並終止搜尋。

範例：

```
# list all modules python can access
walk_packages()

# list all submodules of ctypes
walk_packages(ctypes.__path__, ctypes.__name__ + '.')
```

#### 備註

僅適用於有定義 `iter_modules()` 方法的 `finder`。此介面非是標準的，因此該模組還提供了 `importlib.machinery.FileFinder` 和 `zipimport.zipimporter` 的實作。

在 3.3 版的變更: 更新直接基於 `importlib`，而不是依賴套件部 PEP 302 的引入模擬 (import emulation)。

`pkgutil.get_data(package, resource)`

從套件中取得資源。

這是 `loader.get_data` API 的包裝器。`package` 引數應該是標準模組格式 (`foo.bar`) 的套件名稱。`resource` 引數應是相對檔案名稱的形式，使用 `/` 作路徑分隔符號。不允許使用父目錄名稱 `..`，也不允許使用根目錄名稱 (以 `/` 開頭)。

該函式回傳一個二進位字串，它是指定資源的內容。

對於位於檔案系統中且已被引入過的套件，這大致相當於：

```
d = os.path.dirname(sys.modules[package].__file__)
data = open(os.path.join(d, resource), 'rb').read()
```

如果無法定位或載入套件，或者它使用不支援 `get_data` 的 `loader` 則回傳 `None`。特別是命名空間套件的 `loader` 不支援 `get_data`。

`pkgutil.resolve_name(name)`

將名稱解析物件。

標準函式庫中的許多地方都使用了此功能（請參 [bpo-12915](#)），且相同功能也被用於擁有廣大使用者的第三方套件，如 `setuptools`、`Django` 和 `Pyramid`。

`name` 預期要是以下格式之一的字串，其中 `W` 是有效 Python 識字的簡寫，而點 (`dot`) 代表這些正規表示式 (pseudo-regex) 中的字面句點 (literal period)：

- `W(.W)*`
- `W(.W)*:(W(.W)*)?`

第一種形式僅是 `W(.W)*` 了要向後相容。它假設點名稱 (dotted name) 的某些部分是一個套件，其餘部分是該套件某處的物件，其可能巢狀地存在於 (nested) 其他物件。由於無法透過檢查 (inspection) 來推斷出套件停止的位置和物件層次結構的開始位置，因此必須使用此形式來重嘗試引入。

在第二種形式中，呼叫者透過使用一個冒號來明確標明分隔點：冒號左側的點名稱是要引入的套件，右側的點名稱是該套件的物件層次結構。這種形式只需要一次引入。如果它以冒號結尾，則回傳一個模組物件。

此函式會回傳一個物件（可能是一個模組），或引發以下其中一個例外：

`ValueError` -- 如果 `name` 不是可辨識的格式。

`ImportError` -- 如果在不應該失敗的情況下引入失敗。

`AttributeError` -- 如果在遍歷引入套件中的物件層次結構以取得所需物件時發生失敗。

在 3.9 版被加入。

## 32.3 modulefinder --- 搜尋本所使用的模組

原始碼：[Lib/modulefinder.py](#)

此模組提供了一個 `ModuleFinder` 類，可用於確定本引入的模組集合。`modulefinder.py` 也可以作本運行，其將 Python 本的檔案名稱作它的引數，在之後會列印出引入模組的報告。

`modulefinder.AddPackagePath(pkg_name, path)`

記在指定的 `path` 中可以找到名 `pkg_name` 的套件。

`modulefinder.ReplacePackage(oldname, newname)`

允許指定名 `oldname` 的模組實際上是名 `newname` 的套件。

`class modulefinder.ModuleFinder(path=None, debug=0, excludes=[], replace_paths=[])`

此類提供 `run_script()` 和 `report()` 方法來定本引入的模組集合。`path` 可以是搜尋模組的目串列；如果未指定，則使用 `sys.path`。`debug` 設定偵錯等級；較高的值可使類列印有關其即將執行之操作的偵錯訊息。`excludes` 是要從分析中排除的模組名稱串列。`replace_paths` 是將在模組路徑中替的 (`oldpath`, `newpath`) 元組串列。

`report()`

將報告列印到標準輸出，其中列出了本引入的模組及其路徑，以及失或似乎失的模組。

`run_script(pathname)`

分析 `pathname` 檔案的內容，該檔案必須包含 Python 程式碼。

`modules`

將模組名稱對應到模組的字典。請參 [ModuleFinder](#) 的用法範例。

### 32.3.1 ModuleFinder 的用法范例

將被分析的**Python**本 (bacon.py):

```
import re, itertools

try:
    import baconhameggs
except ImportError:
    pass

try:
    import guido.python.ham
except ImportError:
    pass
```

將輸出 bacon.py 報告的**Python**本:

```
from modulefinder import ModuleFinder

finder = ModuleFinder()
finder.run_script('bacon.py')

print('Loaded modules:')
for name, mod in finder.modules.items():
    print('%s: ' % name, end='')
    print(', '.join(list(mod.globalnames.keys())[:3]))

print('-'*50)
print('Modules not imported:')
print('\n'.join(finder.badmodules.keys()))
```

範例輸出 (可能因架構而**Python**):

```
Loaded modules:
_types:
copyreg:  _inverted_registry, _slotnames, __all__
re._compiler:  isstring, _sre, _optimize_unicode
_sre:
re._constants:  REPEAT_ONE, makedict, AT_END_LINE
sys:
re:  __module__, finditer, _expand
itertools:
__main__:  re, itertools, baconhameggs
re._parser:  _PATTERNENDERS, SRE_FLAG_UNICODE
array:
types:  __module__, IntType, TypeType
-----
Modules not imported:
guido.python.ham
baconhameggs
```

## 32.4 runpy --- 定位**Python**執行 Python 模組

原始碼: Lib/runpy.py

The `runpy` module is used to locate and run Python modules without importing them first. Its main use is to implement the `-m` command line switch that allows scripts to be located using the Python module namespace rather than the filesystem.

Note that this is *not* a sandbox module - all code is executed in the current process, and any side effects (such as cached imports of other modules) will remain in place after the functions have returned.

Furthermore, any functions and classes defined by the executed code are not guaranteed to work correctly after a `runpy` function has returned. If that limitation is not acceptable for a given use case, `importlib` is likely to be a more suitable choice than this module.

The `runpy` module provides two functions:

`runpy.run_module(mod_name, init_globals=None, run_name=None, alter_sys=False)`

Execute the code of the specified module and return the resulting module's globals dictionary. The module's code is first located using the standard import mechanism (refer to [PEP 302](#) for details) and then executed in a fresh module namespace.

The `mod_name` argument should be an absolute module name. If the module name refers to a package rather than a normal module, then that package is imported and the `__main__` submodule within that package is then executed and the resulting module globals dictionary returned.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. `init_globals` will not be modified. If any of the special global variables below are defined in `init_globals`, those definitions are overridden by `run_module()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed. (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail.)

`__name__` is set to `run_name` if this optional argument is not `None`, to `mod_name + '__main__'` if the named module is a package and to the `mod_name` argument otherwise.

`__spec__` will be set appropriately for the *actually* imported module (that is, `__spec__.name` will always be `mod_name` or `mod_name + '__main__'`, never `run_name`).

`__file__`, `__cached__`, `__loader__` and `__package__` are set as normal based on the module spec.

If the argument `alter_sys` is supplied and evaluates to `True`, then `sys.argv[0]` is updated with the value of `__file__` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. Both `sys.argv[0]` and `sys.modules[__name__]` are restored to their original values before the function returns.

Note that this manipulation of `sys` is not thread-safe. Other threads may see the partially initialised module, as well as the altered list of arguments. It is recommended that the `sys` module be left alone when invoking this function from threaded code.

### 也參考

The `-m` option offering equivalent functionality from the command line.

在 3.1 版的變更: Added ability to execute packages by looking for a `__main__` submodule.

在 3.2 版的變更: Added `__cached__` global variable (see [PEP 3147](#)).

在 3.4 版的變更: Updated to take advantage of the module spec feature added by [PEP 451](#). This allows `__cached__` to be set correctly for modules run this way, as well as ensuring the real module name is always accessible as `__spec__.name`.

在 3.12 版的變更: The setting of `__cached__`, `__loader__`, and `__package__` are deprecated. See [ModuleSpec](#) for alternatives.

`runpy.run_path(path_name, init_globals=None, run_name=None)`

Execute the code at the named filesystem location and return the resulting module's globals dictionary. As with a script name supplied to the CPython command line, `file_path` may refer to a Python source file, a compiled bytecode file or a valid `sys.path` entry containing a `__main__` module (e.g. a zipfile containing a top-level `__main__.py` file).

For a simple script, the specified code is simply executed in a fresh module namespace. For a valid `sys.path` entry (typically a zipfile or directory), the entry is first added to the beginning of `sys.path`. The function then looks for and executes a `__main__` module using the updated path. Note that there is no special protection against invoking an existing `__main__` entry located elsewhere on `sys.path` if there is no such module at the specified location.

The optional dictionary argument `init_globals` may be used to pre-populate the module's globals dictionary before the code is executed. `init_globals` will not be modified. If any of the special global variables below are defined in `init_globals`, those definitions are overridden by `run_path()`.

The special global variables `__name__`, `__spec__`, `__file__`, `__cached__`, `__loader__` and `__package__` are set in the globals dictionary before the module code is executed. (Note that this is a minimal set of variables - other variables may be set implicitly as an interpreter implementation detail.)

`__name__` is set to `run_name` if this optional argument is not `None` and to `'<run_path>'` otherwise.

If `file_path` directly references a script file (whether as source or as precompiled byte code), then `__file__` will be set to `file_path`, and `__spec__`, `__cached__`, `__loader__` and `__package__` will all be set to `None`.

If `file_path` is a reference to a valid `sys.path` entry, then `__spec__` will be set appropriately for the imported `__main__` module (that is, `__spec__.name` will always be `__main__`). `__file__`, `__cached__`, `__loader__` and `__package__` will be set as normal based on the module spec.

A number of alterations are also made to the `sys` module. Firstly, `sys.path` may be altered as described above. `sys.argv[0]` is updated with the value of `file_path` and `sys.modules[__name__]` is updated with a temporary module object for the module being executed. All modifications to items in `sys` are reverted before the function returns.

Note that, unlike `run_module()`, the alterations made to `sys` are not optional in this function as these adjustments are essential to allowing the execution of `sys.path` entries. As the thread-safety limitations still apply, use of this function in threaded code should be either serialised with the import lock or delegated to a separate process.

## 32.5 importlib --- import 的實作

在 3.1 版被加入。

原始碼: `Lib/importlib/__init__.py`

### 32.5.1 簡介

`importlib` 的目的可分三個部分。

第一是提供 Python 原始碼中 `import` 陳述式的實作（因此，也延伸到 `__import__()` 函式）。這讓 `import` 實作可以移植到任何 Python 直譯器。同時，這也提供了一個比用其他程式語言實作更容易理解的版本。

Two, the components to implement `import` are exposed in this package, making it easier for users to create their own custom objects (known generically as an *importer*) to participate in the import process.

Three, the package contains modules exposing additional functionality for managing aspects of Python packages:

- `importlib.metadata` presents access to metadata from third-party distributions.
- `importlib.resources` provides routines for accessing non-code "resources" from Python packages.

**32.5.2 函式**`importlib.__import__(name, globals=None, locals=None, fromlist=(), level=0)`An implementation of the built-in `__import__()` function.**備 F**Programmatic importing of modules should use `import_module()` instead of this function.`importlib.import_module(name, package=None)`

Import a module. The *name* argument specifies what module to import in absolute or relative terms (e.g. either `pkg.mod` or `..mod`). If the name is specified in relative terms, then the *package* argument must be set to the name of the package which is to act as the anchor for resolving the package name (e.g. `import_module('..mod', 'pkg.subpkg')` will import `pkg.mod`).

The `import_module()` function acts as a simplifying wrapper around `importlib.__import__()`. This means all semantics of the function are derived from `importlib.__import__()`. The most important difference between these two functions is that `import_module()` returns the specified package or module (e.g. `pkg.mod`), while `__import__()` returns the top-level package or module (e.g. `pkg`).

If you are dynamically importing a module that was created since the interpreter began execution (e.g., created a Python source file), you may need to call `invalidate_caches()` in order for the new module to be noticed by the import system.

在 3.3 版的變更: Parent packages are automatically imported.

`importlib.invalidate_caches()`

Invalidate the internal caches of finders stored at `sys.meta_path`. If a finder implements `invalidate_caches()` then it will be called to perform the invalidation. This function should be called if any modules are created/installed while your program is running to guarantee all finders will notice the new module's existence.

在 3.3 版被加入.

在 3.10 版的變更: Namespace packages created/installed in a different `sys.path` location after the same namespace was already imported are noticed.

`importlib.reload(module)`

Reload a previously imported *module*. The argument must be a module object, so it must have been successfully imported before. This is useful if you have edited the module source file using an external editor and want to try out the new version without leaving the Python interpreter. The return value is the module object (which can be different if re-importing causes a different object to be placed in `sys.modules`).

When `reload()` is executed:

- Python module's code is recompiled and the module-level code re-executed, defining a new set of objects which are bound to names in the module's dictionary by reusing the *loader* which originally loaded the module. The `init` function of extension modules is not called a second time.
- As with all other objects in Python the old objects are only reclaimed after their reference counts drop to zero.

- The names in the module namespace are updated to point to any new or changed objects.
- Other references to the old objects (such as names external to the module) are not rebound to refer to the new objects and must be updated in each namespace where they occur if that is desired.

There are a number of other caveats:

When a module is reloaded, its dictionary (containing the module's global variables) is retained. Redefinitions of names will override the old definitions, so this is generally not a problem. If the new version of a module does not define a name that was defined by the old version, the old definition remains. This feature can be used to the module's advantage if it maintains a global table or cache of objects --- with a `try` statement it can test for the table's presence and skip its initialization if desired:

```
try:
    cache
except NameError:
    cache = {}
```

It is generally not very useful to reload built-in or dynamically loaded modules. Reloading `sys`, `__main__`, `builtins` and other key modules is not recommended. In many cases extension modules are not designed to be initialized more than once, and may fail in arbitrary ways when reloaded.

If a module imports objects from another module using `from ... import ...`, calling `reload()` for the other module does not redefine the objects imported from it --- one way around this is to re-execute the `from` statement, another is to use `import` and qualified names (`module.name`) instead.

If a module instantiates instances of a class, reloading the module that defines the class does not affect the method definitions of the instances --- they continue to use the old class definition. The same is true for derived classes.

在 3.4 版被加入。

在 3.7 版的變更: `ModuleNotFoundError` is raised when the module being reloaded lacks a `ModuleSpec`.

### 32.5.3 `importlib.abc` -- Abstract base classes related to import

原始碼: `Lib/importlib/abc.py`

The `importlib.abc` module contains all of the core abstract base classes used by `import`. Some subclasses of the core abstract base classes are also provided to help in implementing the core ABCs.

ABC hierarchy:

```
object
+-- MetaPathFinder
+-- PathEntryFinder
+-- Loader
    +-- ResourceLoader -----+
    +-- InspectLoader          |
        +-- ExecutionLoader ---+
                                +-- FileLoader
                                +-- SourceLoader
```

**class** `importlib.abc.MetaPathFinder`

An abstract base class representing a *meta path finder*.

在 3.3 版被加入。

在 3.10 版的變更: No longer a subclass of `Finder`.

**find\_spec** (*fullname*, *path*, *target=None*)

An abstract method for finding a *spec* for the specified module. If this is a top-level import, *path* will be `None`. Otherwise, this is a search for a subpackage or module and *path* will be the value of `__path__`

from the parent package. If a spec cannot be found, `None` is returned. When passed in, `target` is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `MetaPathFinders`.

在 3.4 版被加入。

#### **invalidate\_caches()**

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `importlib.invalidate_caches()` when invalidating the caches of all finders on `sys.meta_path`.

在 3.4 版的變更: Returns `None` when called instead of `NotImplemented`.

#### **class importlib.abc.PathEntryFinder**

An abstract base class representing a *path entry finder*. Though it bears some similarities to `MetaPathFinder`, `PathEntryFinder` is meant for use only within the path-based import subsystem provided by `importlib.machinery.PathFinder`.

在 3.3 版被加入。

在 3.10 版的變更: No longer a subclass of `Finder`.

#### **find\_spec(fullname, target=None)**

An abstract method for finding a *spec* for the specified module. The finder will search for the module only within the *path entry* to which it is assigned. If a spec cannot be found, `None` is returned. When passed in, `target` is a module object that the finder may use to make a more educated guess about what spec to return. `importlib.util.spec_from_loader()` may be useful for implementing concrete `PathEntryFinders`.

在 3.4 版被加入。

#### **invalidate\_caches()**

An optional method which, when called, should invalidate any internal cache used by the finder. Used by `importlib.machinery.PathFinder.invalidate_caches()` when invalidating the caches of all cached finders.

#### **class importlib.abc.Loader**

An abstract base class for a *loader*. See **PEP 302** for the exact definition for a loader.

Loaders that wish to support resource reading should implement a `get_resource_reader()` method as specified by `importlib.resources.abc.ResourceReader`.

在 3.7 版的變更: Introduced the optional `get_resource_reader()` method.

#### **create\_module(spec)**

A method that returns the module object to use when importing a module. This method may return `None`, indicating that default module creation semantics should take place.

在 3.4 版被加入。

在 3.6 版的變更: This method is no longer optional when `exec_module()` is defined.

#### **exec\_module(module)**

An abstract method that executes the module in its own namespace when a module is imported or reloaded. The module should already be initialized when `exec_module()` is called. When this method exists, `create_module()` must be defined.

在 3.4 版被加入。

在 3.6 版的變更: `create_module()` 也必須被定義。

#### **load\_module(fullname)**

A legacy method for loading a module. If the module cannot be loaded, `ImportError` is raised, otherwise the loaded module is returned.

If the requested module already exists in `sys.modules`, that module should be used and reloaded. Otherwise the loader should create a new module and insert it into `sys.modules` before any loading

begins, to prevent recursion from the import. If the loader inserted a module and the load fails, it must be removed by the loader from `sys.modules`; modules already in `sys.modules` before the loader began execution should be left alone.

The loader should set several attributes on the module (note that some of these attributes can change when a module is reloaded):

- `module.__name__`
- `module.__file__`
- `module.__cached__` (已用)
- `module.__path__`
- `module.__package__` (已用)
- `module.__loader__` (已用)

When `exec_module()` is available then backwards-compatible functionality is provided.

在 3.4 版的變更: Raise `ImportError` when called instead of `NotImplementedError`. Functionality provided when `exec_module()` is available.

Deprecated since version 3.4, will be removed in version 3.15: The recommended API for loading a module is `exec_module()` (and `create_module()`). Loaders should implement it instead of `load_module()`. The import machinery takes care of all the other responsibilities of `load_module()` when `exec_module()` is implemented.

**class** `importlib.abc.ResourceLoader`

*Superseded by `TraversableResources`*

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loading arbitrary resources from the storage back-end.

在 3.7 版之後被用: This ABC is deprecated in favour of supporting resource loading through `importlib.resources.abc.TraversableResources`.

**abstractmethod** `get_data(path)`

An abstract method to return the bytes for the data located at *path*. Loaders that have a file-like storage back-end that allows storing arbitrary data can implement this abstract method to give direct access to the data stored. `OSError` is to be raised if the *path* cannot be found. The *path* is expected to be constructed using a module's `__file__` attribute or an item from a package's `__path__`.

在 3.4 版的變更: Raises `OSError` instead of `NotImplementedError`.

**class** `importlib.abc.InspectLoader`

An abstract base class for a *loader* which implements the optional **PEP 302** protocol for loaders that inspect modules.

**get\_code(fullname)**

Return the code object for a module, or `None` if the module does not have a code object (as would be the case, for example, for a built-in module). Raise an `ImportError` if loader cannot find the requested module.

#### 備

While the method has a default implementation, it is suggested that it be overridden if possible for performance.

在 3.4 版的變更: No longer abstract and a concrete implementation is provided.

**abstractmethod** `get_source(fullname)`

An abstract method to return the source of a module. It is returned as a text string using *universal newlines*, translating all recognized line separators into '\n' characters. Returns `None` if no source is available (e.g. a built-in module). Raises `ImportError` if the loader cannot find the module specified.

在 3.4 版的變更: Raises `ImportError` instead of `NotImplementedError`.

**is\_package** `(fullname)`

An optional method to return a true value if the module is a package, a false value otherwise. `ImportError` is raised if the *loader* cannot find the module.

在 3.4 版的變更: Raises `ImportError` instead of `NotImplementedError`.

**static** `source_to_code(data, path=<string>')`

Create a code object from Python source.

The *data* argument can be whatever the `compile()` function supports (i.e. string or bytes). The *path* argument should be the "path" to where the source code originated from, which can be an abstract concept (e.g. location in a zip file).

With the subsequent code object one can execute it in a module by running `exec(code, module.__dict__)`.

在 3.4 版被加入.

在 3.5 版的變更: Made the method static.

**exec\_module** `(module)`

`Loader.exec_module()` 的實作。

在 3.4 版被加入.

**load\_module** `(fullname)`

`Loader.load_module()` 的實作。

Deprecated since version 3.4, will be removed in version 3.15: 請改用 `exec_module()`。

**class** `importlib.abc.ExecutionLoader`

An abstract base class which inherits from `InspectLoader` that, when implemented, helps a module to be executed as a script. The ABC represents an optional **PEP 302** protocol.

**abstractmethod** `get_filename(fullname)`

An abstract method that is to return the value of `__file__` for the specified module. If no path is available, `ImportError` is raised.

If source code is available, then the method should return the path to the source file, regardless of whether a bytecode was used to load the module.

在 3.4 版的變更: Raises `ImportError` instead of `NotImplementedError`.

**class** `importlib.abc.FileLoader(fullname, path)`

An abstract base class which inherits from `ResourceLoader` and `ExecutionLoader`, providing concrete implementations of `ResourceLoader.get_data()` and `ExecutionLoader.get_filename()`.

The *fullname* argument is a fully resolved name of the module the loader is to handle. The *path* argument is the path to the file for the module.

在 3.3 版被加入.

**name**

The name of the module the loader can handle.

**path**

Path to the file of the module.

**load\_module** (*fullname*)

Calls super's `load_module()`.

Deprecated since version 3.4, will be removed in version 3.15: Use `Loader.exec_module()` instead.

**abstractmethod get\_filename** (*fullname*)

Returns *path*.

**abstractmethod get\_data** (*path*)

Reads *path* as a binary file and returns the bytes from it.

**class** `importlib.abc.SourceLoader`

An abstract base class for implementing source (and optionally bytecode) file loading. The class inherits from both `ResourceLoader` and `ExecutionLoader`, requiring the implementation of:

- `ResourceLoader.get_data()`
- `ExecutionLoader.get_filename()`  
Should only return the path to the source file; sourceless loading is not supported.

The abstract methods defined by this class are to add optional bytecode file support. Not implementing these optional methods (or causing them to raise `NotImplementedError`) causes the loader to only work with source code. Implementing the methods allows the loader to work with source *and* bytecode files; it does not allow for *sourceless* loading where only bytecode is provided. Bytecode files are an optimization to speed up loading by removing the parsing step of Python's compiler, and so no bytecode-specific API is exposed.

**path\_stats** (*path*)

Optional abstract method which returns a *dict* containing metadata about the specified path. Supported dictionary keys are:

- 'mtime' (mandatory): an integer or floating-point number representing the modification time of the source code;
- 'size' (optional): the size in bytes of the source code.

Any other keys in the dictionary are ignored, to allow for future extensions. If the path cannot be handled, `OSError` is raised.

在 3.3 版被加入。

在 3.4 版的變更: Raise `OSError` instead of `NotImplementedError`.

**path\_mtime** (*path*)

Optional abstract method which returns the modification time for the specified path.

在 3.3 版之後被 用: This method is deprecated in favour of `path_stats()`. You don't have to implement it, but it is still available for compatibility purposes. Raise `OSError` if the path cannot be handled.

在 3.4 版的變更: Raise `OSError` instead of `NotImplementedError`.

**set\_data** (*path*, *data*)

Optional abstract method which writes the specified bytes to a file path. Any intermediate directories which do not exist are to be created automatically.

When writing to the path fails because the path is read-only (`errno.EACCES/PermissionError`), do not propagate the exception.

在 3.4 版的變更: No longer raises `NotImplementedError` when called.

**get\_code** (*fullname*)

Concrete implementation of `InspectLoader.get_code()`.

**exec\_module** (*module*)

Concrete implementation of `Loader.exec_module()`.

在 3.4 版被加入。

**load\_module** (*fullname*)

Concrete implementation of `Loader.load_module()`.

Deprecated since version 3.4, will be removed in version 3.15: Use `exec_module()` instead.

**get\_source** (*fullname*)

Concrete implementation of `InspectLoader.get_source()`.

**is\_package** (*fullname*)

Concrete implementation of `InspectLoader.is_package()`. A module is determined to be a package if its file path (as provided by `ExecutionLoader.get_filename()`) is a file named `__init__` when the file extension is removed **and** the module name itself does not end in `__init__`.

**class** `importlib.abc.ResourceReader`

*Superseded by `TraversableResources`*

An *abstract base class* to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored e.g. in a zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a *path-like object* which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by *fullname* is not a package, this method should return `None`. An object compatible with this ABC should only be returned when the specified module is a package.

在 3.7 版被加入。

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.TraversableResources` instead.

**abstractmethod** `open_resource` (*resource*)

Returns an opened, *file-like object* for binary reading of the *resource*.

If the resource cannot be found, `FileNotFoundError` is raised.

**abstractmethod** `resource_path` (*resource*)

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise `FileNotFoundError`.

**abstractmethod** `is_resource` (*name*)

Returns `True` if the named *name* is considered a resource. `FileNotFoundError` is raised if *name* does not exist.

**abstractmethod** `contents` ()

Returns an *iterable* of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which `is_resource()` would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

**class** `importlib.abc.Traversable`

An object with a subset of `pathlib.Path` methods suitable for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

在 3.9 版被加入.

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.Traversable` instead.

**name**

Abstract. The base name of this object without any parent references.

**abstractmethod** `iterdir()`

Yield `Traversable` objects in `self`.

**abstractmethod** `is_dir()`

Return `True` if `self` is a directory.

**abstractmethod** `is_file()`

Return `True` if `self` is a file.

**abstractmethod** `joinpath(child)`

Return `Traversable` child in `self`.

**abstractmethod** `__truediv__(child)`

Return `Traversable` child in `self`.

**abstractmethod** `open(mode='r', *args, **kwargs)`

`mode` may be `'r'` or `'rb'` to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

**read\_bytes()**

Read contents of `self` as bytes.

**read\_text(encoding=None)**

Read contents of `self` as text.

**class** `importlib.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `importlib.resources.abc.ResourceReader` and provides concrete implementations of the `importlib.resources.abc.ResourceReader`'s abstract methods. Therefore, any loader supplying `importlib.abc.TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

在 3.9 版被加入.

Deprecated since version 3.12, will be removed in version 3.14: Use `importlib.resources.abc.TraversableResources` instead.

**abstractmethod** `files()`

Returns a `importlib.resources.abc.Traversable` object for the loaded package.

## 32.5.4 `importlib.machinery` -- Importers and path hooks

原始碼: `Lib/importlib/machinery.py`

---

This module contains the various objects that help `import` find and load modules.

`importlib.machinery.SOURCE_SUFFIXES`

A list of strings representing the recognized file suffixes for source modules.

在 3.3 版被加入。

`importlib.machinery.DEBUG_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for non-optimized bytecode modules.

在 3.3 版被加入。

在 3.5 版之後被~~用~~: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.OPTIMIZED_BYTECODE_SUFFIXES`

A list of strings representing the file suffixes for optimized bytecode modules.

在 3.3 版被加入。

在 3.5 版之後被~~用~~: Use `BYTECODE_SUFFIXES` instead.

`importlib.machinery.BYTECODE_SUFFIXES`

A list of strings representing the recognized file suffixes for bytecode modules (including the leading dot).

在 3.3 版被加入。

在 3.5 版的變更: The value is no longer dependent on `__debug__`.

`importlib.machinery.EXTENSION_SUFFIXES`

A list of strings representing the recognized file suffixes for extension modules.

在 3.3 版被加入。

`importlib.machinery.all_suffixes()`

Returns a combined list of strings representing all file suffixes for modules recognized by the standard import machinery. This is a helper for code which simply needs to know if a filesystem path potentially refers to a module without needing any details on the kind of module (for example, `inspect.getmodulename()`).

在 3.3 版被加入。

**class** `importlib.machinery.BuiltinImporter`

An *importer* for built-in modules. All known built-in modules are listed in `sys.builtin_module_names`. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.5 版的變更: As part of [PEP 489](#), the builtin importer now implements `Loader.create_module()` and `Loader.exec_module()`

**class** `importlib.machinery.FrozenImporter`

An *importer* for frozen modules. This class implements the `importlib.abc.MetaPathFinder` and `importlib.abc.InspectLoader` ABCs.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.4 版的變更: Gained `create_module()` and `exec_module()` methods.

**class** `importlib.machinery.WindowsRegistryFinder`

*Finder* for modules declared in the Windows registry. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

在 3.3 版被加入。

在 3.6 版之後被~~用~~: Use `site` configuration instead. Future versions of Python may not enable this finder by default.

**class** `importlib.machinery.PathFinder`

A *Finder* for `sys.path` and package `__path__` attributes. This class implements the `importlib.abc.MetaPathFinder` ABC.

Only class methods are defined by this class to alleviate the need for instantiation.

**classmethod** `find_spec` (*fullname*, *path=None*, *target=None*)

Class method that attempts to find a *spec* for the module specified by *fullname* on `sys.path` or, if defined, on *path*. For each path entry that is searched, `sys.path_importer_cache` is checked. If a non-`False` object is found then it is used as the *path entry finder* to look for the module being searched for. If no entry is found in `sys.path_importer_cache`, then `sys.path_hooks` is searched for a finder for the path entry and, if found, is stored in `sys.path_importer_cache` along with being queried about the module. If no finder is ever found then `None` is both stored in the cache and returned.

在 3.4 版被加入。

在 3.5 版的變更: If the current working directory -- represented by an empty string -- is no longer valid then `None` is returned but no value is cached in `sys.path_importer_cache`.

**classmethod** `invalidate_caches` ()

Calls `importlib.abc.PathEntryFinder.invalidate_caches()` on all finders stored in `sys.path_importer_cache` that define the method. Otherwise entries in `sys.path_importer_cache` set to `None` are deleted.

在 3.7 版的變更: Entries of `None` in `sys.path_importer_cache` are deleted.

在 3.4 版的變更: Calls objects in `sys.path_hooks` with the current working directory for `' '` (i.e. the empty string).

**class** `importlib.machinery.FileFinder` (*path*, *\*loader\_details*)

A concrete implementation of `importlib.abc.PathEntryFinder` which caches results from the file system.

The *path* argument is the directory for which the finder is in charge of searching.

The *loader\_details* argument is a variable number of 2-item tuples each containing a loader and a sequence of file suffixes the loader recognizes. The loaders are expected to be callables which accept two arguments of the module's name and the path to the file found.

The finder will cache the directory contents as necessary, making stat calls for each module search to verify the cache is not outdated. Because cache staleness relies upon the granularity of the operating system's state information of the file system, there is a potential race condition of searching for a module, creating a new file, and then searching for the module the new file represents. If the operations happen fast enough to fit within the granularity of stat calls, then the module search will fail. To prevent this from happening, when you create a module dynamically, make sure to call `importlib.invalidate_caches()`.

在 3.3 版被加入。

**path**

The path the finder will search in.

**find\_spec** (*fullname*, *target=None*)

Attempt to find the spec to handle *fullname* within *path*.

在 3.4 版被加入。

**invalidate\_caches** ()

Clear out the internal cache.

**classmethod** `path_hook` (*\*loader\_details*)

A class method which returns a closure for use on `sys.path_hooks`. An instance of `FileFinder` is returned by the closure using the path argument given to the closure directly and *loader\_details* indirectly.

If the argument to the closure is not an existing directory, `ImportError` is raised.

**class** `importlib.machinery.SourceFileLoader` (*fullname, path*)

A concrete implementation of `importlib.abc.SourceLoader` by subclassing `importlib.abc.FileLoader` and providing some concrete implementations of other methods.

在 3.3 版被加入。

**name**

The name of the module that this loader will handle.

**path**

The path to the source file.

**is\_package** (*fullname*)

Return `True` if *path* appears to be for a package.

**path\_stats** (*path*)

Concrete implementation of `importlib.abc.SourceLoader.path_stats()`.

**set\_data** (*path, data*)

Concrete implementation of `importlib.abc.SourceLoader.set_data()`.

**load\_module** (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

Deprecated since version 3.6, will be removed in version 3.15: Use `importlib.abc.Loader.exec_module()` instead.

**class** `importlib.machinery.SourcelessFileLoader` (*fullname, path*)

A concrete implementation of `importlib.abc.FileLoader` which can import bytecode files (i.e. no source code files exist).

Please note that direct use of bytecode files (and thus not source code files) inhibits your modules from being usable by all Python implementations or new versions of Python which change the bytecode format.

在 3.3 版被加入。

**name**

The name of the module the loader will handle.

**path**

The path to the bytecode file.

**is\_package** (*fullname*)

Determines if the module is a package based on *path*.

**get\_code** (*fullname*)

Returns the code object for *name* created from *path*.

**get\_source** (*fullname*)

Returns `None` as bytecode files have no source when this loader is used.

**load\_module** (*name=None*)

Concrete implementation of `importlib.abc.Loader.load_module()` where specifying the name of the module to load is optional.

Deprecated since version 3.6, will be removed in version 3.15: Use `importlib.abc.Loader.exec_module()` instead.

**class** `importlib.machinery.ExtensionFileLoader` (*fullname, path*)

A concrete implementation of `importlib.abc.ExecutionLoader` for extension modules.

The *fullname* argument specifies the name of the module the loader is to support. The *path* argument is the path to the extension module's file.

Note that, by default, importing an extension module will fail in subinterpreters if it doesn't implement multi-phase init (see [PEP 489](#)), even if it would otherwise import successfully.

在 3.3 版被加入。

在 3.12 版的變更: Multi-phase init is now required for use in subinterpreters.

**name**

Name of the module the loader supports.

**path**

Path to the extension module.

**create\_module** (*spec*)

Creates the module object from the given specification in accordance with [PEP 489](#).

在 3.5 版被加入。

**exec\_module** (*module*)

Initializes the given module object in accordance with [PEP 489](#).

在 3.5 版被加入。

**is\_package** (*fullname*)

Returns `True` if the file path points to a package's `__init__` module based on `EXTENSION_SUFFIXES`.

**get\_code** (*fullname*)

Returns `None` as extension modules lack a code object.

**get\_source** (*fullname*)

Returns `None` as extension modules do not have source code.

**get\_filename** (*fullname*)

Returns *path*.

在 3.4 版被加入。

**class** `importlib.machinery.NamespaceLoader` (*name, path, path\_finder*)

A concrete implementation of `importlib.abc.InspectLoader` for namespace packages. This is an alias for a private class and is only made public for introspecting the `__loader__` attribute on namespace packages:

```
>>> from importlib.machinery import NamespaceLoader
>>> import my_namespace
>>> isinstance(my_namespace.__loader__, NamespaceLoader)
True
>>> import importlib.abc
>>> isinstance(my_namespace.__loader__, importlib.abc.Loader)
True
```

在 3.11 版被加入。

**class** `importlib.machinery.ModuleSpec` (*name, loader, \*, origin=None, loader\_state=None, is\_package=None*)

A specification for a module's import-system-related state. This is typically exposed as the module's `__spec__` attribute. Many of these attributes are also available directly on a module: for example, `module.__spec__.origin == module.__file__`. Note, however, that while the *values* are usually equivalent, they can differ since there is no synchronization between the two objects. For example, it is possible to update the module's `__file__` at runtime and this will not be automatically reflected in the module's `__spec__.origin`, and vice versa.

在 3.4 版被加入。

**name**

The module's fully qualified name (see `module.__name__`). The *finder* should always set this attribute to a non-empty string.

**loader**

The *loader* used to load the module (see `module.__loader__`). The *finder* should always set this attribute.

**origin**

The location the *loader* should use to load the module (see `module.__file__`). For example, for modules loaded from a `.py` file this is the filename. The *finder* should always set this attribute to a meaningful value for the *loader* to use. In the uncommon case that there is not one (like for namespace packages), it should be set to `None`.

**submodule\_search\_locations**

A (possibly empty) *sequence* of strings enumerating the locations in which a package's submodules will be found (see `module.__path__`). Most of the time there will only be a single directory in this list.

The *finder* should set this attribute to a sequence, even an empty one, to indicate to the import system that the module is a package. It should be set to `None` for non-package modules. It is set automatically later to a special object for namespace packages.

**loader\_state**

The *finder* may set this attribute to an object containing additional, module-specific data to use when loading the module. Otherwise it should be set to `None`.

**cached**

The filename of a compiled version of the module's code (see `module.__cached__`). The *finder* should always set this attribute but it may be `None` for modules that do not need compiled code stored.

**parent**

(Read-only) The fully qualified name of the package the module is in (or the empty string for a top-level module). See `module.__package__`. If the module is a package then this is the same as *name*.

**has\_location**

True if the spec's *origin* refers to a loadable location, False otherwise. This value impacts how *origin* is interpreted and how the module's `__file__` is populated.

**class** `importlib.machinery.AppleFrameworkLoader` (*name*, *path*)

A specialization of `importlib.machinery.ExtensionFileLoader` that is able to load extension modules in Framework format.

For compatibility with the iOS App Store, *all* binary modules in an iOS app must be dynamic libraries, contained in a framework with appropriate metadata, stored in the `Frameworks` folder of the packaged app. There can be only a single binary per framework, and there can be no executable binary material outside the `Frameworks` folder.

To accommodate this requirement, when running on iOS, extension module binaries are *not* packaged as `.so` files on `sys.path`, but as individual standalone frameworks. To discover those frameworks, this loader is registered against the `.framework` file extension, with a `.framework` file acting as a placeholder in the original location of the binary on `sys.path`. The `.framework` file contains the path of the actual binary in the `Frameworks` folder, relative to the app bundle. To allow for resolving a framework-packaged binary back to the original location, the framework is expected to contain a `.origin` file that contains the location of the `.framework` file, relative to the app bundle.

For example, consider the case of an `import from foo.bar import _whiz`, where `_whiz` is implemented with the binary module `sources/foo/bar/_whiz.abi3.so`, with `sources` being the location registered on `sys.path`, relative to the application bundle. This module *must* be distributed as `Frameworks/foo.bar._whiz.framework/foo.bar._whiz` (creating the framework name from the full import path of the module), with an `Info.plist` file in the `.framework` directory identifying the binary as a framework. The `foo.bar._whiz` module would be represented in the original location with a `sources/foo/bar/_whiz.abi3.framework` marker file, containing the path `Frameworks/foo.bar._whiz/foo.bar._whiz`. The framework would also contain `Frameworks/foo.bar._whiz.framework/foo.bar._whiz.origin`, containing the path to the `.framework` file.

When a module is loaded with this loader, the `__file__` for the module will report as the location of the `.framework` file. This allows code to use the `__file__` of a module as an anchor for file system traversal. However, the spec origin will reference the location of the *actual* binary in the `.framework` folder.

The Xcode project building the app is responsible for converting any `.so` files from wherever they exist in the `PYTHONPATH` into frameworks in the `Frameworks` folder (including stripping extensions from the module file, the addition of framework metadata, and signing the resulting framework), and creating the `.framework` and `.origin` files. This will usually be done with a build step in the Xcode project; see the iOS documentation for details on how to construct this build step.

在 3.13 版被加入.

適用: iOS.

#### **name**

Name of the module the loader supports.

#### **path**

Path to the `.framework` file for the extension module.

## 32.5.5 `importlib.util` -- Utility code for importers

原始碼: [Lib/importlib/util.py](#)

This module contains the various objects that help in the construction of an *importer*.

`importlib.util.MAGIC_NUMBER`

The bytes which represent the bytecode version number. If you need help with loading/writing bytecode then consider `importlib.abc.SourceLoader`.

在 3.4 版被加入.

`importlib.util.cache_from_source(path, debug_override=None, *, optimization=None)`

Return the **PEP 3147/PEP 488** path to the byte-compiled file associated with the source *path*. For example, if *path* is `/foo/bar/baz.py` the return value would be `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. The `cpython-32` string comes from the current magic tag (see `get_tag()`; if `sys.implementation.cache_tag` is not defined then `NotImplementedError` will be raised).

The *optimization* parameter is used to specify the optimization level of the bytecode file. An empty string represents no optimization, so `/foo/bar/baz.py` with an *optimization* of `''` will result in a bytecode path of `/foo/bar/__pycache__/baz.cpython-32.pyc`. `None` causes the interpreter's optimization level to be used. Any other value's string representation is used, so `/foo/bar/baz.py` with an *optimization* of `2` will lead to the bytecode path of `/foo/bar/__pycache__/baz.cpython-32.opt-2.pyc`. The string representation of *optimization* can only be alphanumeric, else `ValueError` is raised.

The *debug\_override* parameter is deprecated and can be used to override the system's value for `__debug__`. A `True` value is the equivalent of setting *optimization* to the empty string. A `False` value is the same as setting *optimization* to `1`. If both *debug\_override* and *optimization* are not `None` then `TypeError` is raised.

在 3.4 版被加入.

在 3.5 版的變更: The *optimization* parameter was added and the *debug\_override* parameter was deprecated.

在 3.6 版的變更: Accepts a *path-like object*.

`importlib.util.source_from_cache(path)`

Given the *path* to a **PEP 3147** file name, return the associated source code file path. For example, if *path* is `/foo/bar/__pycache__/baz.cpython-32.pyc` the returned path would be `/foo/bar/baz.py`. *path* need not exist, however if it does not conform to **PEP 3147** or **PEP 488** format, a `ValueError` is raised. If `sys.implementation.cache_tag` is not defined, `NotImplementedError` is raised.

在 3.4 版被加入.

在 3.6 版的變更: Accepts a *path-like object*.

`importlib.util.decode_source(source_bytes)`

Decode the given bytes representing source code and return it as a string with universal newlines (as required by `importlib.abc.InspectLoader.get_source()`).

在 3.4 版被加入。

`importlib.util.resolve_name(name, package)`

Resolve a relative module name to an absolute one.

If **name** has no leading dots, then **name** is simply returned. This allows for usage such as `importlib.util.resolve_name('sys', __spec__.parent)` without doing a check to see if the **package** argument is needed.

`ImportError` is raised if **name** is a relative module name but **package** is a false value (e.g. `None` or the empty string). `ImportError` is also raised if a relative name would escape its containing package (e.g. requesting `..bacon` from within the `spam` package).

在 3.3 版被加入。

在 3.9 版的變更: To improve consistency with import statements, raise `ImportError` instead of `ValueError` for invalid relative import attempts.

`importlib.util.find_spec(name, package=None)`

Find the *spec* for a module, optionally relative to the specified **package** name. If the module is in `sys.modules`, then `sys.modules[name].__spec__` is returned (unless the spec would be `None` or is not set, in which case `ValueError` is raised). Otherwise a search using `sys.meta_path` is done. `None` is returned if no spec is found.

If **name** is for a submodule (contains a dot), the parent module is automatically imported.

**name** and **package** work the same as for `import_module()`.

在 3.4 版被加入。

在 3.7 版的變更: Raises `ModuleNotFoundError` instead of `AttributeError` if **package** is in fact not a package (i.e. lacks a `__path__` attribute).

`importlib.util.module_from_spec(spec)`

Create a new module based on **spec** and `spec.loader.create_module`.

If `spec.loader.create_module` does not return `None`, then any pre-existing attributes will not be reset. Also, no `AttributeError` will be raised if triggered while accessing **spec** or setting an attribute on the module.

This function is preferred over using `types.ModuleType` to create a new module as **spec** is used to set as many import-controlled attributes on the module as possible.

在 3.5 版被加入。

`importlib.util.spec_from_loader(name, loader, *, origin=None, is_package=None)`

A factory function for creating a `ModuleSpec` instance based on a loader. The parameters have the same meaning as they do for `ModuleSpec`. The function uses available *loader* APIs, such as `InspectLoader.is_package()`, to fill in any missing information on the spec.

在 3.4 版被加入。

`importlib.util.spec_from_file_location(name, location, *, loader=None, submodule_search_locations=None)`

A factory function for creating a `ModuleSpec` instance based on the path to a file. Missing information will be filled in on the spec by making use of loader APIs and by the implication that the module will be file-based.

在 3.4 版被加入。

在 3.6 版的變更: Accepts a *path-like object*.

```
importlib.util.source_hash(source_bytes)
```

Return the hash of *source\_bytes* as bytes. A hash-based `.pyc` file embeds the `source_hash()` of the corresponding source file's contents in its header.

在 3.7 版被加入。

```
importlib.util._incompatible_extension_module_restrictions(* , disable_check)
```

A context manager that can temporarily skip the compatibility check for extension modules. By default the check is enabled and will fail when a single-phase init module is imported in a subinterpreter. It will also fail for a multi-phase init module that doesn't explicitly support a per-interpreter GIL, when imported in an interpreter with its own GIL.

Note that this function is meant to accommodate an unusual case; one which is likely to eventually go away. There's a pretty good chance this is not what you were looking for.

You can get the same effect as this function by implementing the basic interface of multi-phase init ([PEP 489](#)) and lying about support for multiple interpreters (or per-interpreter GIL).

 **警告**

Using this function to disable the check can lead to unexpected behavior and even crashes. It should only be used during extension module development.

在 3.12 版被加入。

```
class importlib.util.LazyLoader(loader)
```

A class which postpones the execution of the loader of a module until the module has an attribute accessed.

This class **only** works with loaders that define `exec_module()` as control over what module type is used for the module is required. For those same reasons, the loader's `create_module()` method must return `None` or a type for which its `__class__` attribute can be mutated along with not using `slots`. Finally, modules which substitute the object placed into `sys.modules` will not work as there is no way to properly replace the module references throughout the interpreter safely; `ValueError` is raised if such a substitution is detected.

 **備 F**

For projects where startup time is critical, this class allows for potentially minimizing the cost of loading a module if it is never used. For projects where startup time is not essential then use of this class is **heavily** discouraged due to error messages created during loading being postponed and thus occurring out of context.

在 3.5 版被加入。

在 3.6 版的變更: Began calling `create_module()`, removing the compatibility warning for `importlib.machinery.BuiltinImporter` and `importlib.machinery.ExtensionFileLoader`.

```
classmethod factory(loader)
```

A class method which returns a callable that creates a lazy loader. This is meant to be used in situations where the loader is passed by class instead of by instance.

```
suffixes = importlib.machinery.SOURCE_SUFFIXES
loader = importlib.machinery.SourceFileLoader
lazy_loader = importlib.util.LazyLoader.factory(loader)
finder = importlib.machinery.FileFinder(path, (lazy_loader, suffixes))
```

## 32.5.6 范例

### Importing programmatically

To programmatically import a module, use `importlib.import_module()`.

```
import importlib

itertools = importlib.import_module('itertools')
```

### Checking if a module can be imported

If you need to find out if a module can be imported without actually doing the import, then you should use `importlib.util.find_spec()`.

Note that if `name` is a submodule (contains a dot), `importlib.util.find_spec()` will import the parent module.

```
import importlib.util
import sys

# For illustrative purposes.
name = 'itertools'

if name in sys.modules:
    print(f"{name!r} already in sys.modules")
elif (spec := importlib.util.find_spec(name)) is not None:
    # If you chose to perform the actual import ...
    module = importlib.util.module_from_spec(spec)
    sys.modules[name] = module
    spec.loader.exec_module(module)
    print(f"{name!r} has been imported")
else:
    print(f"can't find the {name!r} module")
```

### Importing a source file directly

This recipe should be used with caution: it is an approximation of an import statement where the file path is specified directly, rather than `sys.path` being searched. Alternatives should first be considered first, such as modifying `sys.path` when a proper module is required, or using `runpy.run_path()` when the global namespace resulting from running a Python file is appropriate.

To import a Python source file directly from a path, use the following recipe:

```
import importlib.util
import sys

def import_from_path(module_name, file_path):
    spec = importlib.util.spec_from_file_location(module_name, file_path)
    module = importlib.util.module_from_spec(spec)
    sys.modules[module_name] = module
    spec.loader.exec_module(module)
    return module

# For illustrative purposes only (use of `json` is arbitrary).
import json
file_path = json.__file__
module_name = json.__name__

# Similar outcome as `import json`.
json = import_from_path(module_name, file_path)
```

## Implementing lazy imports

The example below shows how to implement lazy imports:

```
>>> import importlib.util
>>> import sys
>>> def lazy_import(name):
...     spec = importlib.util.find_spec(name)
...     loader = importlib.util.LazyLoader(spec.loader)
...     spec.loader = loader
...     module = importlib.util.module_from_spec(spec)
...     sys.modules[name] = module
...     loader.exec_module(module)
...     return module
...
>>> lazy_typing = lazy_import("typing")
>>> #lazy_typing is a real module object,
>>> #but it is not loaded in memory yet.
>>> lazy_typing.TYPE_CHECKING
False
```

## Setting up an importer

For deep customizations of import, you typically want to implement an *importer*. This means managing both the *finder* and *loader* side of things. For finders there are two flavours to choose from depending on your needs: a *meta path finder* or a *path entry finder*. The former is what you would put on `sys.meta_path` while the latter is what you create using a *path entry hook* on `sys.path_hooks` which works with `sys.path` entries to potentially create a finder. This example will show you how to register your own importers so that import will use them (for creating an importer for yourself, read the documentation for the appropriate classes defined within this package):

```
import importlib.machinery
import sys

# For illustrative purposes only.
SpamMetaPathFinder = importlib.machinery.PathFinder
SpamPathEntryFinder = importlib.machinery.FileFinder
loader_details = (importlib.machinery.SourceFileLoader,
                  importlib.machinery.SOURCE_SUFFIXES)

# Setting up a meta path finder.
# Make sure to put the finder in the proper location in the list in terms of
# priority.
sys.meta_path.append(SpamMetaPathFinder)

# Setting up a path entry finder.
# Make sure to put the path hook in the proper location in the list in terms
# of priority.
sys.path_hooks.append(SpamPathEntryFinder.path_hook(loader_details))
```

## Approximating `importlib.import_module()`

Import itself is implemented in Python code, making it possible to expose most of the import machinery through `importlib`. The following helps illustrate the various APIs that `importlib` exposes by providing an approximate implementation of `importlib.import_module()`:

```
import importlib.util
import sys

def import_module(name, package=None):
    """An approximate implementation of import."""
    absolute_name = importlib.util.resolve_name(name, package)
```

(繼續下一頁)

(繼續上一頁)

```

try:
    return sys.modules[absolute_name]
except KeyError:
    pass

path = None
if '.' in absolute_name:
    parent_name, _, child_name = absolute_name.rpartition('.')
    parent_module = import_module(parent_name)
    path = parent_module.__spec__.submodule_search_locations
for finder in sys.meta_path:
    spec = finder.find_spec(absolute_name, path)
    if spec is not None:
        break
else:
    msg = f'No module named {absolute_name!r}'
    raise ModuleNotFoundError(msg, name=absolute_name)
module = importlib.util.module_from_spec(spec)
sys.modules[absolute_name] = module
spec.loader.exec_module(module)
if path is not None:
    setattr(parent_module, child_name, module)
return module

```

## 32.6 importlib.resources -- 套件資源的讀取、開 F 與存取

原始碼: `Lib/importlib/resources/__init__.py`

在 3.7 版被加入。

This module leverages Python's import system to provide access to *resources* within *packages*.

”Resources” are file-like resources associated with a module or package in Python. The resources may be contained directly in a package, within a subdirectory contained in that package, or adjacent to modules outside a package. Resources may be text or binary. As a result, Python module sources (.py) of a package and compilation artifacts (pycache) are technically de-facto resources of that package. In practice, however, resources are primarily those non-Python artifacts exposed specifically by the package author.

Resources can be opened or read in either binary or text mode.

Resources are roughly akin to files inside directories, though it's important to keep in mind that this is just a metaphor. Resources and packages **do not** have to exist as physical files and directories on the file system: for example, a package and its resources can be imported from a zip file using `zipimport`.

### 備 F

This module provides functionality similar to `pkg_resources` [Basic Resource Access](#) without the performance overhead of that package. This makes reading resources included in packages easier, with more stable and consistent semantics.

The standalone backport of this module provides more information on [using importlib.resources](#) and [migrating from pkg\\_resources to importlib.resources](#).

*Loaders* that wish to support resource reading should implement a `get_resource_reader(fullname)` method as specified by `importlib.resources.abc.ResourceReader`.

`class` `importlib.resources.Anchor`

Represents an anchor for resources, either a *module object* or a module name as a string. Defined as `Union[str, ModuleType]`.

`importlib.resources.files` (*anchor*: `Anchor` | `None` = `None`)

Returns a *Traversable* object representing the resource container (think directory) and its resources (think files). A *Traversable* may contain other containers (think subdirectories).

*anchor* is an optional *Anchor*. If the anchor is a package, resources are resolved from that package. If a module, resources are resolved adjacent to that module (in the same package or the package root). If the anchor is omitted, the caller's module is used.

在 3.9 版被加入。

在 3.12 版的變更: *package* parameter was renamed to *anchor*. *anchor* can now be a non-package module and if omitted will default to the caller's module. *package* is still accepted for compatibility but will raise a *DeprecationWarning*. Consider passing the anchor positionally or using `importlib_resources >= 5.10` for a compatible interface on older Pythons.

`importlib.resources.as_file` (*traversable*)

Given a *Traversable* object representing a file or directory, typically from `importlib.resources.files()`, return a context manager for use in a `with` statement. The context manager provides a `pathlib.Path` object.

Exiting the context manager cleans up any temporary file or directory created when the resource was extracted from e.g. a zip file.

Use `as_file` when the *Traversable* methods (`read_text`, etc) are insufficient and an actual file or directory on the file system is required.

在 3.9 版被加入。

在 3.12 版的變更: Added support for *traversable* representing a directory.

### 32.6.1 Functional API

A set of simplified, backwards-compatible helpers is available. These allow common operations in a single function call.

For all the following functions:

- *anchor* is an *Anchor*, as in `files()`. Unlike in `files`, it may not be omitted.
- *path\_names* are components of a resource's path name, relative to the anchor. For example, to get the text of resource named `info.txt`, use:

```
importlib.resources.read_text(my_module, "info.txt")
```

Like *Traversable.joinpath*, The individual components should use forward slashes (/) as path separators. For example, the following are equivalent:

```
importlib.resources.read_binary(my_module, "pics/painting.png")
importlib.resources.read_binary(my_module, "pics", "painting.png")
```

For backward compatibility reasons, functions that read text require an explicit *encoding* argument if multiple *path\_names* are given. For example, to get the text of `info/chapter1.txt`, use:

```
importlib.resources.read_text(my_module, "info", "chapter1.txt",
                             encoding='utf-8')
```

`importlib.resources.open_binary` (*anchor*, *\*path\_names*)

Open the named resource for binary reading.

See *the introduction* for details on *anchor* and *path\_names*.

This function returns a *BinaryIO* object, that is, a binary stream open for reading.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).open('rb')
```

在 3.13 版的變更: Multiple *path\_names* are accepted.

```
importlib.resources.open_text(anchor, *path_names, encoding='utf-8', errors='strict')
```

Open the named resource for text reading. By default, the contents are read as strict UTF-8.

See [the introduction](#) for details on *anchor* and *path\_names*. *encoding* and *errors* have the same meaning as in built-in *open()*.

For backward compatibility reasons, the *encoding* argument must be given explicitly if there are multiple *path\_names*. This limitation is scheduled to be removed in Python 3.15.

This function returns a *TextIO* object, that is, a text stream open for reading.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).open('r', encoding=encoding)
```

在 3.13 版的變更: Multiple *path\_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

```
importlib.resources.read_binary(anchor, *path_names)
```

Read and return the contents of the named resource as *bytes*.

See [the introduction](#) for details on *anchor* and *path\_names*.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).read_bytes()
```

在 3.13 版的變更: Multiple *path\_names* are accepted.

```
importlib.resources.read_text(anchor, *path_names, encoding='utf-8', errors='strict')
```

Read and return the contents of the named resource as *str*. By default, the contents are read as strict UTF-8.

See [the introduction](#) for details on *anchor* and *path\_names*. *encoding* and *errors* have the same meaning as in built-in *open()*.

For backward compatibility reasons, the *encoding* argument must be given explicitly if there are multiple *path\_names*. This limitation is scheduled to be removed in Python 3.15.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).read_text(encoding=encoding)
```

在 3.13 版的變更: Multiple *path\_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

```
importlib.resources.path(anchor, *path_names)
```

Provides the path to the *resource* as an actual file system path. This function returns a context manager for use in a *with* statement. The context manager provides a *pathlib.Path* object.

Exiting the context manager cleans up any temporary files created, e.g. when the resource needs to be extracted from a zip file.

For example, the *stat()* method requires an actual file system path; it can be used like this:

```
with importlib.resources.path(anchor, "resource.txt") as fspath:
    result = fspath.stat()
```

See *the introduction* for details on *anchor* and *path\_names*.

This function is roughly equivalent to:

```
as_file(files(anchor).joinpath(*path_names))
```

在 3.13 版的變更: Multiple *path\_names* are accepted. *encoding* and *errors* must be given as keyword arguments.

```
importlib.resources.is_resource(anchor, *path_names)
```

Return `True` if the named resource exists, otherwise `False`. This function does not consider directories to be resources.

See *the introduction* for details on *anchor* and *path\_names*.

This function is roughly equivalent to:

```
files(anchor).joinpath(*path_names).is_file()
```

在 3.13 版的變更: Multiple *path\_names* are accepted.

```
importlib.resources.contents(anchor, *path_names)
```

Return an iterable over the named items within the package or path. The iterable returns names of resources (e.g. files) and non-resources (e.g. directories) as *str*. The iterable does not recurse into subdirectories.

See *the introduction* for details on *anchor* and *path\_names*.

This function is roughly equivalent to:

```
for resource in files(anchor).joinpath(*path_names).iterdir():
    yield resource.name
```

在 3.11 版之後被 F 用: Prefer `iterdir()` as above, which offers more control over the results and richer functionality.

## 32.7 importlib.resources.abc -- 資源的抽象基底類 F

原始碼: `Lib/importlib/resources/abc.py`

在 3.11 版被加入.

```
class importlib.resources.abc.ResourceReader
```

*Superseded by TraversableResources*

An *abstract base class* to provide the ability to read *resources*.

From the perspective of this ABC, a *resource* is a binary artifact that is shipped within a package. Typically this is something like a data file that lives next to the `__init__.py` file of the package. The purpose of this class is to help abstract out the accessing of such data files so that it does not matter if the package and its data file(s) are stored e.g. in a zip file versus on the file system.

For any of methods of this class, a *resource* argument is expected to be a *path-like object* which represents conceptually just a file name. This means that no subdirectory paths should be included in the *resource* argument. This is because the location of the package the reader is for, acts as the "directory". Hence the metaphor for directories and file names is packages and resources, respectively. This is also why instances of this class are expected to directly correlate to a specific package (instead of potentially representing multiple packages or a module).

Loaders that wish to support resource reading are expected to provide a method called `get_resource_reader(fullname)` which returns an object implementing this ABC's interface. If the module specified by `fullname` is not a package, this method should return `None`. An object compatible with this ABC should only be returned when the specified module is a package.

在 3.12 版之後被 F 用: Use `importlib.resources.abc.TraversableResources` instead.

**abstractmethod** `open_resource(resource)`

Returns an opened, *file-like object* for binary reading of the *resource*.

If the resource cannot be found, `FileNotFoundError` is raised.

**abstractmethod** `resource_path(resource)`

Returns the file system path to the *resource*.

If the resource does not concretely exist on the file system, raise `FileNotFoundError`.

**abstractmethod** `is_resource(name)`

Returns `True` if the named *name* is considered a resource. `FileNotFoundError` is raised if *name* does not exist.

**abstractmethod** `contents()`

Returns an *iterable* of strings over the contents of the package. Do note that it is not required that all names returned by the iterator be actual resources, e.g. it is acceptable to return names for which `is_resource()` would be false.

Allowing non-resource names to be returned is to allow for situations where how a package and its resources are stored are known a priori and the non-resource names would be useful. For instance, returning subdirectory names is allowed so that when it is known that the package and resources are stored on the file system then those subdirectory names can be used directly.

The abstract method returns an iterable of no items.

**class** `importlib.resources.abc.Traversable`

An object with a subset of `pathlib.Path` methods suitable for traversing directories and opening files.

For a representation of the object on the file-system, use `importlib.resources.as_file()`.

**name**

Abstract. The base name of this object without any parent references.

**abstractmethod** `iterdir()`

Yield `Traversable` objects in self.

**abstractmethod** `is_dir()`

Return `True` if self is a directory.

**abstractmethod** `is_file()`

Return `True` if self is a file.

**abstractmethod** `joinpath(*pathsegments)`

Traverse directories according to *pathsegments* and return the result as `Traversable`.

Each *pathsegments* argument may contain multiple names separated by forward slashes (`/`, `posixpath.sep`). For example, the following are equivalent:

```
files.joinpath('subdir', 'subsudir', 'file.txt')
files.joinpath('subdir/subsudir/file.txt')
```

Note that some `Traversable` implementations might not be updated to the latest version of the protocol. For compatibility with such implementations, provide a single argument without path separators to each call to `joinpath`. For example:

```
files.joinpath('subdir').joinpath('subsudir').joinpath('file.txt')
```

在 3.11 版的變更: `joinpath` accepts multiple *pathsegments*, and these segments may contain forward slashes as path separators. Previously, only a single *child* argument was accepted.

**abstractmethod** `__truediv__(child)`

Return Traversable child in self. Equivalent to `joinpath(child)`.

**abstractmethod** `open(mode='r', *args, **kwargs)`

`mode` may be 'r' or 'rb' to open as text or binary. Return a handle suitable for reading (same as `pathlib.Path.open`).

When opening as text, accepts encoding parameters such as those accepted by `io.TextIOWrapper`.

**read\_bytes()**

Read contents of self as bytes.

**read\_text(encoding=None)**

Read contents of self as text.

**class** `importlib.resources.abc.TraversableResources`

An abstract base class for resource readers capable of serving the `importlib.resources.files()` interface. Subclasses `ResourceReader` and provides concrete implementations of the `ResourceReader`'s abstract methods. Therefore, any loader supplying `TraversableResources` also supplies `ResourceReader`.

Loaders that wish to support resource reading are expected to implement this interface.

**abstractmethod** `files()`

Returns a `importlib.resources.abc.Traversable` object for the loaded package.

## 32.8 importlib.metadata -- 存取套件的元資料

在 3.8 版被加入。

在 3.10 版的變更: `importlib.metadata` is no longer provisional.

原始碼: `Lib/importlib/metadata/__init__.py`

`importlib.metadata` is a library that provides access to the metadata of an installed **Distribution Package**, such as its entry points or its top-level names (**Import Packages**, modules, if any). Built in part on Python's import system, this library intends to replace similar functionality in the **entry point API** and **metadata API** of `pkg_resources`. Along with `importlib.resources`, this package can eliminate the need to use the older and less efficient `pkg_resources` package.

`importlib.metadata` operates on third-party *distribution packages* installed into Python's `site-packages` directory via tools such as `pip`. Specifically, it works with distributions with discoverable `dist-info` or `egg-info` directories, and metadata defined by the **Core metadata specifications**.

### 重要

These are *not* necessarily equivalent to or correspond 1:1 with the top-level *import package* names that can be imported inside Python code. One *distribution package* can contain multiple *import packages* (and single modules), and one top-level *import package* may map to multiple *distribution packages* if it is a namespace package. You can use `packages_distributions()` to get a mapping between them.

By default, distribution metadata can live on the file system or in zip archives on `sys.path`. Through an extension mechanism, the metadata can live almost anywhere.

### 也參考

<https://importlib-metadata.readthedocs.io/>

The documentation for `importlib_metadata`, which supplies a backport of `importlib.metadata`. This includes an **API reference** for this module's classes and functions, as well as a **migration guide** for existing users of `pkg_resources`.

### 32.8.1 Overview

Let's say you wanted to get the version string for a [Distribution Package](#) you've installed using `pip`. We start by creating a virtual environment and installing something into it:

```
$ python -m venv example
$ source example/bin/activate
(example) $ python -m pip install wheel
```

You can get the version string for `wheel` by running the following:

```
(example) $ python
>>> from importlib.metadata import version
>>> version('wheel')
'0.32.3'
```

You can also get a collection of entry points selectable by properties of the `EntryPoint` (typically `'group'` or `'name'`), such as `console_scripts`, `distutils.commands` and others. Each group contains a collection of [EntryPoint](#) objects.

You can get the *metadata for a distribution*:

```
>>> list(metadata('wheel'))
['Metadata-Version', 'Name', 'Version', 'Summary', 'Home-page', 'Author', 'Author-email',
↪ 'Maintainer', 'Maintainer-email', 'License', 'Project-URL', 'Project-URL', 'Project-URL',
↪ 'Keywords', 'Platform', 'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier',
↪ 'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier', 'Classifier',
↪ 'Classifier', 'Requires-Python', 'Provides-Extra', 'Requires-Dist', 'Requires-Dist']
```

You can also get a *distribution's version number*, list its *constituent files*, and get a list of the distribution's *Distribution requirements*.

**exception** `importlib.metadata.PackageNotFoundError`

Subclass of `ModuleNotFoundError` raised by several functions in this module when queried for a distribution package which is not installed in the current Python environment.

### 32.8.2 Functional API

This package provides the following functionality via its public API.

#### Entry points

`importlib.metadata.entry_points(**select_params)`

Returns a `EntryPoints` instance describing entry points for the current environment. Any given keyword parameters are passed to the `select()` method for comparison to the attributes of the individual entry point definitions.

Note: it is not currently possible to query for entry points based on their `EntryPoint.dist` attribute (as different `Distribution` instances do not currently compare equal, even if they have the same attributes)

**class** `importlib.metadata.EntryPoints`

Details of a collection of installed entry points.

Also provides a `.groups` attribute that reports all identified entry point groups, and a `.names` attribute that reports all identified entry point names.

**class** `importlib.metadata.EntryPoint`

Details of an installed entry point.

Each `EntryPoint` instance has `.name`, `.group`, and `.value` attributes and a `.load()` method to resolve the value. There are also `.module`, `.attr`, and `.extras` attributes for getting the components of the `.value` attribute, and `.dist` for obtaining information regarding the distribution package that provides the entry point.

Query all entry points:

```
>>> eps = entry_points()
```

The `entry_points()` function returns a `EntryPoint` object, a collection of all `EntryPoint` objects with `names` and `groups` attributes for convenience:

```
>>> sorted(eps.groups)
['console_scripts', 'distutils.commands', 'distutils.setup_keywords', 'egg_info.writers',
↪ 'setuptools.installation']
```

`EntryPoint` has a `select()` method to select entry points matching specific properties. Select entry points in the `console_scripts` group:

```
>>> scripts = eps.select(group='console_scripts')
```

Equivalently, since `entry_points()` passes keyword arguments through to `select`:

```
>>> scripts = entry_points(group='console_scripts')
```

Pick out a specific script named "wheel" (found in the wheel project):

```
>>> 'wheel' in scripts.names
True
>>> wheel = scripts['wheel']
```

Equivalently, query for that entry point during selection:

```
>>> (wheel,) = entry_points(group='console_scripts', name='wheel')
>>> (wheel,) = entry_points().select(group='console_scripts', name='wheel')
```

Inspect the resolved entry point:

```
>>> wheel
EntryPoint(name='wheel', value='wheel.cli:main', group='console_scripts')
>>> wheel.module
'wheel.cli'
>>> wheel.attr
'main'
>>> wheel.extras
[]
>>> main = wheel.load()
>>> main
<function main at 0x103528488>
```

The `group` and `name` are arbitrary values defined by the package author and usually a client will wish to resolve all entry points for a particular group. Read [the setuptools docs](#) for more information on entry points, their definition, and usage.

在 3.12 版的變更: The "selectable" entry points were introduced in `importlib_metadata` 3.6 and Python 3.10. Prior to those changes, `entry_points` accepted no parameters and always returned a dictionary of entry points, keyed by group. With `importlib_metadata` 5.0 and Python 3.12, `entry_points` always returns an `EntryPoint` object. See [backports.entry\\_points\\_selectable](#) for compatibility options.

在 3.13 版的變更: `EntryPoint` objects no longer present a tuple-like interface (`__getitem__()`).

### Distribution metadata

`importlib.metadata.metadata` (*distribution\_name*)

Return the distribution metadata corresponding to the named distribution package as a `PackageMetadata` instance.

Raises `PackageNotFoundError` if the named distribution package is not installed in the current Python environment.

**class** `importlib.metadata.PackageMetadata`

A concrete implementation of the `PackageMetadata` protocol.

In addition to providing the defined protocol methods and attributes, subscripting the instance is equivalent to calling the `get()` method.

Every `Distribution Package` includes some metadata, which you can extract using the `metadata()` function:

```
>>> wheel_metadata = metadata('wheel')
```

The keys of the returned data structure name the metadata keywords, and the values are returned unparsed from the distribution metadata:

```
>>> wheel_metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

`PackageMetadata` also presents a `json` attribute that returns all the metadata in a JSON-compatible form per [PEP 566](#):

```
>>> wheel_metadata.json['requires_python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
```

The full set of available metadata is not described here. See the [PyPA Core metadata specification](#) for additional details.

在 3.10 版的變更: `The Description` is now included in the metadata when presented through the payload. Line continuation characters have been removed.

新增 `json` 屬性。

## Distribution versions

`importlib.metadata.version(distribution_name)`

Return the installed distribution package `version` for the named distribution package.

Raises `PackageNotFoundError` if the named distribution package is not installed in the current Python environment.

The `version()` function is the quickest way to get a `Distribution Package`'s version number, as a string:

```
>>> version('wheel')
'0.32.3'
```

## Distribution files

`importlib.metadata.files(distribution_name)`

Return the full set of files contained within the named distribution package.

Raises `PackageNotFoundError` if the named distribution package is not installed in the current Python environment.

Returns `None` if the distribution is found but the installation database records reporting the files associated with the distribution package are missing.

**class** `importlib.metadata.PackagePath`

A `pathlib.PurePath` derived object with additional `dist`, `size`, and `hash` properties corresponding to the distribution package's installation metadata for that file.

The `files()` function takes a `Distribution Package` name and returns all of the files installed by this distribution. Each file is reported as a `PackagePath` instance. For example:

```
>>> util = [p for p in files('wheel') if 'util.py' in str(p)][0]
>>> util
PackagePath('wheel/util.py')
>>> util.size
859
>>> util.dist
<importlib.metadata._hooks.PathDistribution object at 0x101e0cef0>
>>> util.hash
<FileHash mode: sha256 value: bYkw5oMccfazVCoYQwKkemoVyMAFoR34mmKBx8R1NI>
```

Once you have the file, you can also read its contents:

```
>>> print(util.read_text())
import base64
import sys
...
def as_bytes(s):
    if isinstance(s, text_type):
        return s.encode('utf-8')
    return s
```

You can also use the `locate()` method to get the absolute path to the file:

```
>>> util.locate()
PosixPath('/home/gustav/example/lib/site-packages/wheel/util.py')
```

In the case where the metadata file listing files (`RECORD` or `SOURCES.txt`) is missing, `files()` will return `None`. The caller may wish to wrap calls to `files()` in [always\\_iterable](#) or otherwise guard against this condition if the target distribution is not known to have the metadata present.

## Distribution requirements

`importlib.metadata.requires(distribution_name)`

Return the declared dependency specifiers for the named distribution package.

Raises `PackageNotFoundError` if the named distribution package is not installed in the current Python environment.

To get the full set of requirements for a [Distribution Package](#), use the `requires()` function:

```
>>> requires('wheel')
["pytest (>=3.0.0) ; extra == 'test'", "pytest-cov ; extra == 'test'"]
```

## Mapping import to distribution packages

`importlib.metadata.packages_distributions()`

Return a mapping from the top level module and import package names found via `sys.meta_path` to the names of the distribution packages (if any) that provide the corresponding files.

To allow for namespace packages (which may have members provided by multiple distribution packages), each top level import name maps to a list of distribution names rather than mapping directly to a single name.

A convenience method to resolve the [Distribution Package](#) name (or names, in the case of a namespace package) that provide each importable top-level Python module or [Import Package](#):

```
>>> packages_distributions()
{'importlib_metadata': ['importlib-metadata'], 'yaml': ['PyYAML'], 'jaraco': ['jaraco.classes',
↪', 'jaraco.functools'], ...}
```

Some editable installs, [do not supply top-level names](#), and thus this function is not reliable with such installs.

在 3.10 版被加入。

### 32.8.3 Distributions

`importlib.metadata.distribution(distribution_name)`

Return a *Distribution* instance describing the named distribution package.

Raises *PackageNotFoundError* if the named distribution package is not installed in the current Python environment.

**class** `importlib.metadata.Distribution`

Details of an installed distribution package.

Note: different *Distribution* instances do not currently compare equal, even if they relate to the same installed distribution and accordingly have the same attributes.

While the module level API described above is the most common and convenient usage, you can get all of that information from the *Distribution* class. *Distribution* is an abstract object that represents the metadata for a Python Distribution Package. You can get the concrete *Distribution* subclass instance for an installed distribution package by calling the *distribution()* function:

```
>>> from importlib.metadata import distribution
>>> dist = distribution('wheel')
>>> type(dist)
<class 'importlib.metadata.PathDistribution'>
```

Thus, an alternative way to get the version number is through the *Distribution* instance:

```
>>> dist.version
'0.32.3'
```

There are all kinds of additional metadata available on *Distribution* instances:

```
>>> dist.metadata['Requires-Python']
'>=2.7, !=3.0.*, !=3.1.*, !=3.2.*, !=3.3.*'
>>> dist.metadata['License']
'MIT'
```

For editable packages, an *origin* property may present [PEP 610](#) metadata:

```
>>> dist.origin.url
'file:///path/to/wheel-0.32.3.editable-py3-none-any.whl'
```

The full set of available metadata is not described here. See the [PyPA Core metadata specification](#) for additional details.

在 3.13 版被加入: 新增 `.origin` 屬性 (property)。

### 32.8.4 Distribution Discovery

By default, this package provides built-in support for discovery of metadata for file system and zip file *Distribution Packages*. This metadata finder search defaults to `sys.path`, but varies slightly in how it interprets those values from how other import machinery does. In particular:

- `importlib.metadata` does not honor *bytes* objects on `sys.path`.
- `importlib.metadata` will incidentally honor *pathlib.Path* objects on `sys.path` even though such values will be ignored for imports.

### 32.8.5 Extending the search algorithm

Because *Distribution Package* metadata is not available through *sys.path* searches, or package loaders directly, the metadata for a distribution is found through import system finders. To find a distribution package's metadata, `importlib.metadata` queries the list of *meta path finders* on `sys.meta_path`.

By default `importlib.metadata` installs a finder for distribution packages found on the file system. This finder doesn't actually find any *distributions*, but it can find their metadata.

The abstract class `importlib.abc.MetaPathFinder` defines the interface expected of finders by Python's import system. `importlib.metadata` extends this protocol by looking for an optional `find_distributions` callable on the finders from `sys.meta_path` and presents this extended interface as the `DistributionFinder` abstract base class, which defines this abstract method:

```
@abc.abstractmethod
def find_distributions(context=DistributionFinder.Context()):
    """Return an iterable of all Distribution instances capable of
    loading the metadata for packages for the indicated ``context``.
    """
```

The `DistributionFinder.Context` object provides `.path` and `.name` properties indicating the path to search and name to match and may supply other relevant context.

What this means in practice is that to support finding distribution package metadata in locations other than the file system, subclass `DistributionFinder` and implement the abstract methods. Then from a custom finder, return instances of this derived `Distribution` in the `find_distributions()` method.

## Example

Consider for example a custom finder that loads Python modules from a database:

```
class DatabaseImporter(importlib.abc.MetaPathFinder):
    def __init__(self, db):
        self.db = db

    def find_spec(self, fullname, target=None) -> ModuleSpec:
        return self.db.spec_from_name(fullname)

sys.meta_path.append(DatabaseImporter(connect_db(...)))
```

That importer now presumably provides importable modules from a database, but it provides no metadata or entry points. For this custom importer to provide metadata, it would also need to implement `DistributionFinder`:

```
from importlib.metadata import DistributionFinder

class DatabaseImporter(DistributionFinder):
    ...

    def find_distributions(self, context=DistributionFinder.Context()):
        query = dict(name=context.name) if context.name else {}
        for dist_record in self.db.query_distributions(query):
            yield DatabaseDistribution(dist_record)
```

In this way, `query_distributions` would return records for each distribution served by the database matching the query. For example, if `requests-1.0` is in the database, `find_distributions` would yield a `DatabaseDistribution` for `Context(name='requests')` or `Context(name=None)`.

For the sake of simplicity, this example ignores `context.path`. The `path` attribute defaults to `sys.path` and is the set of import paths to be considered in the search. A `DatabaseImporter` could potentially function without any concern for a search path. Assuming the importer does no partitioning, the "path" would be irrelevant. In order to illustrate the purpose of `path`, the example would need to illustrate a more complex `DatabaseImporter` whose behavior varied depending on `sys.path/PYTHONPATH`. In that case, the `find_distributions` should honor the `context.path` and only yield `Distributions` pertinent to that path.

`DatabaseDistribution`, then, would look something like:

```
class DatabaseDistribution(importlib.metadata.Distribution):
    def __init__(self, record):
```

(繼續下一頁)

(繼續上一頁)

```

self.record = record

def read_text(self, filename):
    """
    Read a file like "METADATA" for the current distribution.
    """
    if filename == "METADATA":
        return f"""Name: {self.record.name}
Version: {self.record.version}
"""
    if filename == "entry_points.txt":
        return "\n".join(
            f"[{ep.group}]\n{ep.name}={ep.value}"
            for ep in self.record.entry_points)

def locate_file(self, path):
    raise RuntimeError("This distribution has no file system")

```

This basic implementation should provide metadata and entry points for packages served by the DatabaseImporter, assuming that the record supplies suitable `.name`, `.version`, and `.entry_points` attributes.

The DatabaseDistribution may also provide other metadata files, like RECORD (required for Distribution.files) or override the implementation of Distribution.files. See the source for more inspiration.

## 32.9 sys.path 模組搜尋路徑的初始化

A module search path is initialized when Python starts. This module search path may be accessed at `sys.path`.

The first entry in the module search path is the directory that contains the input script, if there is one. Otherwise, the first entry is the current directory, which is the case when executing the interactive shell, a `-c` command, or `-m` module.

The PYTHONPATH environment variable is often used to add directories to the search path. If this environment variable is found then the contents are added to the module search path.

### 備 F

PYTHONPATH will affect all installed Python versions/environments. Be wary of setting this in your shell profile or global environment variables. The `site` module offers more nuanced techniques as mentioned below.

The next items added are the directories containing standard Python modules as well as any *extension modules* that these modules depend on. Extension modules are `.pyd` files on Windows and `.so` files on other platforms. The directory with the platform-independent Python modules is called `prefix`. The directory with the extension modules is called `exec_prefix`.

The PYTHONHOME environment variable may be used to set the `prefix` and `exec_prefix` locations. Otherwise these directories are found by using the Python executable as a starting point and then looking for various 'landmark' files and directories. Note that any symbolic links are followed so the real Python executable location is used as the search starting point. The Python executable location is called `home`.

Once `home` is determined, the `prefix` directory is found by first looking for `pythonmajorversionminorversion.zip` (`python311.zip`). On Windows the zip archive is searched for in `home` and on Unix the archive is expected to be in `lib`. Note that the expected zip archive location is added to the module search path even if the archive does not exist. If no archive was found, Python on Windows will continue the search for `prefix` by looking for `Lib\os.py`. Python on Unix will look for `lib/pythonmajorversion.minorversion/os.py` (`lib/python3.11/os.py`). On Windows `prefix` and `exec_prefix` are the same, however on other platforms `lib/pythonmajorversion.minorversion/lib-dynload` (`lib/python3.11/lib-dynload`) is searched for and used as an anchor for `exec_prefix`. On some platforms `lib` may be `lib64`

or another value, see `sys.platlibdir` and `PYTHONPLATLIBDIR`.

Once found, `prefix` and `exec_prefix` are available at `sys.prefix` and `sys.exec_prefix` respectively.

Finally, the `site` module is processed and `site-packages` directories are added to the module search path. A common way to customize the search path is to create `sitecustomize` or `usercustomize` modules as described in the `site` module documentation.

 備 F

Certain command line options may further affect path calculations. See `-E`, `-I`, `-s` and `-S` for further details.

### 32.9.1 F 擬環境

If Python is run in a virtual environment (as described at `tut-venv`) then `prefix` and `exec_prefix` are specific to the virtual environment.

If a `pyenv.config` file is found alongside the main executable, or in the directory one level above the executable, the following variations apply:

- If `home` is an absolute path and `PYTHONHOME` is not set, this path is used instead of the path to the main executable when deducing `prefix` and `exec_prefix`.

### 32.9.2 .pth 檔案

To completely override `sys.path` create a `._pth` file with the same name as the shared library or executable (`python._pth` or `python311._pth`). The shared library path is always known on Windows, however it may not be available on other platforms. In the `._pth` file specify one line for each path to add to `sys.path`. The file based on the shared library name overrides the one based on the executable, which allows paths to be restricted for any program loading the runtime if desired.

When the file exists, all registry and environment variables are ignored, isolated mode is enabled, and `site` is not imported unless one line in the file specifies `import site`. Blank paths and lines starting with `#` are ignored. Each path may be absolute or relative to the location of the file. Import statements other than `to site` are not permitted, and arbitrary code cannot be specified.

Note that `._pth` files (without leading underscore) will be processed normally by the `site` module when `import site` has been specified.

### 32.9.3 Embedded Python

If Python is embedded within another application `Py_InitializeFromConfig()` and the `PyConfig` structure can be used to initialize Python. The path specific details are described at `init-path-config`.

 也參考

- `windows_finding_modules` 有關於 Windows 的詳細資訊。
- `using-on-unix` 有關於 Unix 的詳細資訊。

Python provides a number of modules to assist in working with the Python language. These modules support tokenizing, parsing, syntax analysis, bytecode disassembly, and various other facilities.

這些模組包括：

### 33.1 ast --- 抽象語法樹 (Abstract Syntax Trees)

原始碼：Lib/ast.py

`ast` 模組可以幫助 Python 應用程式處理 Python 抽象語法文法 (abstract syntax grammar) 樹狀資料結構。抽象語法本身可能會隨著每個 Python 版本發布而改變；此模組有助於以程式化的方式來得知當前文法的面貌。

要生成抽象語法樹，可以透過將 `ast.PyCF_ONLY_AST` 作旗標傳遞給 `compile()` 或使用此模組所提供的 `parse()` 輔助函式。結果將會是一個物件的樹，其類都繼承自 `ast.AST`。可以使用 `compile()` 函式將抽象語法樹編譯成 Python 程式碼物件。

#### 33.1.1 抽象文法 (Abstract Grammar)

抽象文法目前定義如下：

```
-- ASDL's 4 builtin types are:
-- identifier, int, string, constant

module Python
{
    mod = Module(stmt* body, type_ignore* type_ignores)
        | Interactive(stmt* body)
        | Expression(expr body)
        | FunctionType(expr* argtypes, expr returns)

    stmt = FunctionDef(identifier name, arguments args,
                      stmt* body, expr* decorator_list, expr? returns,
                      string? type_comment, type_param* type_params)
        | AsyncFunctionDef(identifier name, arguments args,
                           stmt* body, expr* decorator_list, expr? returns,
```

(繼續下一頁)

```

        string? type_comment, type_param* type_params)

| ClassDef(identifier name,
  expr* bases,
  keyword* keywords,
  stmt* body,
  expr* decorator_list,
  type_param* type_params)
| Return(expr? value)

| Delete(expr* targets)
| Assign(expr* targets, expr value, string? type_comment)
| TypeAlias(expr name, type_param* type_params, expr value)
| AugAssign(expr target, operator op, expr value)
-- 'simple' indicates that we annotate simple name without parens
| AnnAssign(expr target, expr annotation, expr? value, int simple)

-- use 'orelse' because else is a keyword in target languages
| For(expr target, expr iter, stmt* body, stmt* orelse, string? type_comment)
| AsyncFor(expr target, expr iter, stmt* body, stmt* orelse, string? type_comment)
| While(expr test, stmt* body, stmt* orelse)
| If(expr test, stmt* body, stmt* orelse)
| With(withitem* items, stmt* body, string? type_comment)
| AsyncWith(withitem* items, stmt* body, string? type_comment)

| Match(expr subject, match_case* cases)

| Raise(expr? exc, expr? cause)
| Try(stmt* body, excepthandler* handlers, stmt* orelse, stmt* finalbody)
| TryStar(stmt* body, excepthandler* handlers, stmt* orelse, stmt* finalbody)
| Assert(expr test, expr? msg)

}

```

### 33.1.2 節點 (Node) 類

**class ast.AST**

這是所有 AST 節點類的基礎。實際的節點類是衍生自 `Parser/Python.asdl` 檔案，該檔案在上方重現。它們被定義於 `_ast` 的 C 模組中，於 `ast` 中重新匯出。

抽象文法中每個左側符號定義了一個類（例如 `ast.stmt` 或 `ast.expr`）。此外，也每個右側的建構函式 (constructor) 定義了一個類；這些類繼承自左側樹的類。例如，`ast.BinOp` 繼承自 `ast.expr`。對於具有替代方案（即「和 (sums)」) 的生規則，左側類是抽象的：僅有特定建構函式節點的實例會被建立。

#### `_fields`

每個具體類都有一個屬性 `_fields`，它會給出所有子節點的名稱。

具體類的每個實例對於每個子節點都有一個屬性，其型如文法中所定義。例如，`ast.BinOp` 實例具有型 `ast.expr` 的屬性 `left`。

如果這些屬性在文法中被標記可選（使用問號），則該值可能 `None`。如果屬性可以有零個或多個值（用星號標記），則這些值將表示 Python 串列。使用 `compile()` 編譯 AST 時，所有可能的屬性都必須存在且具有有效值。

#### `_field_types`

每個具體類上的 `_field_types` 屬性是將欄位名稱（也在 `_fields` 中列出）對映到其型的字典。

```

>>> ast.TypeVar._field_types
{'name': <class 'str'>, 'bound': ast.expr | None, 'default_value': ast.expr | None}

```

在 3.13 版被加入。

#### `lineno`

#### `col_offset`

#### `end_lineno`

#### `end_col_offset`

`ast.expr` 和 `ast.stmt` 子類的實例具有 `lineno`、`col_offset`、`end_lineno` 和 `end_col_offset` 屬性。`lineno` 和 `end_lineno` 是原始文本跨度 (source text span) 的第一個和最後一個列號 (1-indexed, 因此第一列號是 1) 以及 `col_offset` 和 `end_col_offset` 是生成節點的第一個和最後一個標記對應的 UTF-8 位元組偏移量。會記 UTF-8 偏移量是因剖析器 (parser) 部使用 UTF-8。

請注意，編譯器不需要結束位置，因此其可選的。結束偏移量在最後一個符號之後，例如可以使用 `source_line[node.col_offset : node.end_col_offset]` 來獲取單列運算式節點 (expression node) 的原始片段。

`ast.T` 類型的建構函式按以下方式剖析其引數：

- 如果有位置引數，則必須與 `T._fields` 中的項目一樣多；它們將被賦這些名稱的屬性。
- 如果有關鍵字引數，它們會將相同名稱的屬性設定給定值。

例如，要建立填充 (populate) `ast.UnaryOp` 節點，你可以使用：

```
node = ast.UnaryOp(ast.USub(), ast.Constant(5, lineno=0, col_offset=0),
                  lineno=0, col_offset=0)
```

如果建構函式中省略了语法中可選的欄位，則它預設 `None`。如果省略串列欄位，則預設空串列。如果省略 `ast.expr_context` 型欄位，則預設 `Load()`。如果省略任何其他欄位，則會引發 `DeprecationWarning`，且 AST 節點將有此欄位。在 Python 3.15 中，這種情況會引發錯誤。

在 3.8 版的變更：`ast.Constant` 類現在用於所有常數。

在 3.9 版的變更：以它們的值表示簡單索引，擴充切片 (slice) 則以元組 (tuple) 表示。

在 3.8 版之後被用：舊的類 `ast.Num`、`ast.Str`、`ast.Bytes`、`ast.NameConstant` 和 `ast.Ellipsis` 仍然可用，但它們將在未來的 Python 釋出版本中移除。與此同時，實例化它們將回傳不同類型的實例。

在 3.9 版之後被用：舊的類 `ast.Index` 和 `ast.ExtSlice` 仍然可用，但它們將在未來的 Python 版本中刪除。同時，實例化它們會回傳不同類型的實例。

Deprecated since version 3.13, will be removed in version 3.15: 先前版本的 Python 允許建立缺少必填欄位的 AST 節點。同樣地，AST 節點建構函式允許將任意關鍵字引數設為 AST 節點的屬性，即使它們與 AST 節點的任何欄位都不匹配。此行已被用，將在 Python 3.15 中刪除。

### 備

這顯示的特定節點類型的描述最初是從出色的 [Green Tree Snakes](#) 專案和所有貢獻者那改編而來的。

## 根節點

**class** `ast.Module` (*body*, *type\_ignores*)

一個 Python 模組，與檔案輸入一樣。由 `ast.parse()` 在預設的 "exec" mode 下生成的節點型。

*body* 是模組的陳述式的一個 *list*。

*type\_ignores* 是模組的忽略型解的 *list*；有關更多詳細資訊，請參 `ast.parse()`。

```
>>> print(ast.dump(ast.parse('x = 1'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Name(id='x', ctx=Store())],
      value=Constant(value=1))])
```

**class** `ast.Expression` (*body*)

單個 Python 運算式輸入。當 mode 是 "eval" 時節點型由 `ast.parse()` 生成。

*body* 是單個節點，是運算式型的其中之一。

```
>>> print(ast.dump(ast.parse('123', mode='eval'), indent=4))
Expression(
  body=Constant(value=123))
```

**class** `ast.Interactive` (*body*)

單個互動式輸入，和 `tut-interac` 中所述的相似。當 `mode` 是 "single" 時節點型由 `ast.parse()` 生成。

`body` 是陳述式節點 (*statement nodes*) 的 *list*。

```
>>> print(ast.dump(ast.parse('x = 1; y = 2', mode='single'), indent=4))
Interactive(
  body=[
    Assign(
      targets=[
        Name(id='x', ctx=Store())],
      value=Constant(value=1)),
    Assign(
      targets=[
        Name(id='y', ctx=Store())],
      value=Constant(value=2))])
```

**class** `ast.FunctionType` (*argtypes, returns*)

函式的舊式型解的表示法，因 3.5 之前的 Python 版本不支援 [PEP 484](#) 釋。當 `mode` 是 "func\_type" 時節點型由 `ast.parse()` 生成。

這種型的解看起來像這樣：

```
def sum_two_number(a, b):
    # type: (int, int) -> int
    return a + b
```

`argtypes` 是運算式節點的 *list*。

`returns` 是單個運算式節點。

```
>>> print(ast.dump(ast.parse('(int, str) -> List[int]', mode='func_type'), indent=4))
FunctionType(
  argtypes=[
    Name(id='int', ctx=Load()),
    Name(id='str', ctx=Load())],
  returns=Subscript(
    value=Name(id='List', ctx=Load()),
    slice=Name(id='int', ctx=Load()),
    ctx=Load()))
```

在 3.8 版被加入。

## 文本 (Literals)

**class** `ast.Constant` (*value*)

一個常數值。Constant 文本的 `value` 屬性包含它所代表的 Python 物件。表示的值可以是簡單型，例如數字、字串或 `None`，但如果它們的所有元素都是常數，也可以是不可變的 (immutable) 容器型 (元組和凍結集合 (frozensets))。

```
>>> print(ast.dump(ast.parse('123', mode='eval'), indent=4))
Expression(
  body=Constant(value=123))
```

**class** `ast.FormattedValue` (*value, conversion, format\_spec*)

表示 f 字串 (f-string) 中的單個格式化欄位的節點。如果字串包含單個格式欄位且有其他內容，則可以隔離 (isolate) 該節點，否則它將出現在 `JoinedStr` 中。

- `value` 任何運算式節點 (例如文字、變數或函式呼叫)。
- `conversion` 是一個整數：
  - -1: 無格式化

- 115: !s 字串格式化
  - 114: !r 重 F 格式化化
  - 97: ! a ascii 格式化
- `format_spec` 是一個 *JoinedStr* 節點，表示值的格式，若未指定格式則 F None。conversion 和 `format_spec` 可以同時設定。

**class** `ast.JoinedStr` (*values*)

一個 f 字串，包含一系列 *FormattedValue* 和 *Constant* 節點。

```
>>> print(ast.dump(ast.parse('f"sin({a}) is {sin(a):.3}"', mode='eval'), indent=4))
Expression(
  body=JoinedStr(
    values=[
      Constant(value='sin('),
      FormattedValue(
        value=Name(id='a', ctx=Load()),
        conversion=-1),
      Constant(value=') is '),
      FormattedValue(
        value=Call(
          func=Name(id='sin', ctx=Load()),
          args=[
            Name(id='a', ctx=Load())]),
          conversion=-1,
          format_spec=JoinedStr(
            values=[
              Constant(value='.3')])))])])
```

**class** `ast.List` (*elts, ctx*)

**class** `ast.Tuple` (*elts, ctx*)

串列或元組。`elts` 保存表示元素的節點串列。如果容器是賦值目標（即 `(x,y)=something`），則 `ctx` 是 *Store*，否則是 *Load*。

```
>>> print(ast.dump(ast.parse('[1, 2, 3]', mode='eval'), indent=4))
Expression(
  body=List(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)],
    ctx=Load())
>>> print(ast.dump(ast.parse('(1, 2, 3)', mode='eval'), indent=4))
Expression(
  body=Tuple(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)],
    ctx=Load())
```

**class** `ast.Set` (*elts*)

一個集合。`elts` 保存表示集合之元素的節點串列。

```
>>> print(ast.dump(ast.parse('{1, 2, 3}', mode='eval'), indent=4))
Expression(
  body=Set(
    elts=[
      Constant(value=1),
      Constant(value=2),
      Constant(value=3)]))
```

**class** `ast.Dict` (*keys, values*)

一個字典 (dictionary)。keys 和 values 分別按匹配順序保存表示鍵和值的節點串列 (呼叫 `dictionary.keys()` 和 `dictionary.values()` 時將回傳的內容)。

當使用字典文本進行字典解包 (unpack) 時, 要擴充的運算式位於 values 串列中, 在 keys 中的相應位置有一個 None。

```
>>> print(ast.dump(ast.parse('{ "a":1, **d}', mode='eval'), indent=4))
Expression(
  body=Dict(
    keys=[
      Constant(value='a'),
      None],
    values=[
      Constant(value=1),
      Name(id='d', ctx=Load())])])
```

## 變數

**class** `ast.Name` (*id, ctx*)

一個變數名稱。id 將名稱以字串形式保存, 且 ctx 是以下型之一。

**class** `ast.Load`

**class** `ast.Store`

**class** `ast.Del`

變數參照可用於載入變數的值、其分配新值或除它。變數參照被賦予情境 (context) 來區分這些情。

```
>>> print(ast.dump(ast.parse('a'), indent=4))
Module(
  body=[
    Expr(
      value=Name(id='a', ctx=Load()))])

>>> print(ast.dump(ast.parse('a = 1'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Name(id='a', ctx=Store())],
      value=Constant(value=1))])

>>> print(ast.dump(ast.parse('del a'), indent=4))
Module(
  body=[
    Delete(
      targets=[
        Name(id='a', ctx=Del())])])
```

**class** `ast.Starred` (*value, ctx*)

一個 \*var 變數參照。value 保存變數, 通常是一個 `Name` 節點。在使用 \*args 建置 `Call` 節點時必須使用此型。

```
>>> print(ast.dump(ast.parse('a, *b = it'), indent=4))
Module(
  body=[
    Assign(
      targets=[
        Tuple(
          elts=[
```

(繼續下一頁)

(繼續上一頁)

```

        Name(id='a', ctx=Store()),
        Starred(
            value=Name(id='b', ctx=Store()),
            ctx=Store()),
        ctx=Store()),
        value=Name(id='it', ctx=Load()))])

```

## 運算式

**class** `ast.Expr` (*value*)

當運算式 (例如函式呼叫) 本身作為陳述式出現且未使用或儲存其回傳值時, 它將被包裝在此容器中。value 保存此區段 (section) 中的一個其他節點: *Constant*、*Name*、*Lambda*、*Yield* 或 *YieldFrom*

```

>>> print(ast.dump(ast.parse('-a'), indent=4))
Module(
  body=[
    Expr(
      value=UnaryOp(
        op=USub(),
        operand=Name(id='a', ctx=Load())))]

```

**class** `ast.UnaryOp` (*op*, *operand*)

一元運算 (unary operation)。op 是運算子, operand 是任何運算式節點。

**class** `ast.UAdd`

**class** `ast.USub`

**class** `ast.Not`

**class** `ast.Invert`

一元運算子標記。Not 是 not 關鍵字、Invert 是 ~ 運算子。

```

>>> print(ast.dump(ast.parse('not x', mode='eval'), indent=4))
Expression(
  body=UnaryOp(
    op=Not(),
    operand=Name(id='x', ctx=Load()))

```

**class** `ast.BinOp` (*left*, *op*, *right*)

二元運算 (binary operation) (如加法或除法)。op 是運算子、left 和 right 是任意運算式節點。

```

>>> print(ast.dump(ast.parse('x + y', mode='eval'), indent=4))
Expression(
  body=BinOp(
    left=Name(id='x', ctx=Load()),
    op=Add(),
    right=Name(id='y', ctx=Load()))

```

**class** `ast.Add`

**class** `ast.Sub`

**class** `ast.Mult`

**class** `ast.Div`

**class** `ast.FloorDiv`

**class** `ast.Mod`

**class** `ast.Pow`

**class** `ast.LShift`

**class** `ast.RShift`

**class** `ast.BitOr`

```
class ast.BitXor
```

```
class ast.BitAnd
```

```
class ast.MatMult
```

二元運算子 token。

```
class ast.BoolOp(op, values)
```

布林運算 'or' 或 'and'。op 是 *Or* 或 *And*。values 是有所涉及的值。使用同一運算子的連續操作（例如 a or b or c）會被折成具有多個值的一個節點。

這不包括 not，它是一個 *UnaryOp*。

```
>>> print(ast.dump(ast.parse('x or y', mode='eval'), indent=4))
Expression(
  body=BoolOp(
    op=Or(),
    values=[
      Name(id='x', ctx=Load()),
      Name(id='y', ctx=Load())])
```

```
class ast.And
```

```
class ast.Or
```

布林運算子 token。

```
class ast.Compare(left, ops, comparators)
```

兩個或多個值的比較。left 是比較中的第一個值、ops 是運算子串列、comparators 是要比較的第一個元素之後值的串列。

```
>>> print(ast.dump(ast.parse('1 <= a < 10', mode='eval'), indent=4))
Expression(
  body=Compare(
    left=Constant(value=1),
    ops=[
      LtE(),
      Lt()],
    comparators=[
      Name(id='a', ctx=Load()),
      Constant(value=10)])
```

```
class ast.Eq
```

```
class ast.NotEq
```

```
class ast.Lt
```

```
class ast.LtE
```

```
class ast.Gt
```

```
class ast.GtE
```

```
class ast.Is
```

```
class ast.IsNot
```

```
class ast.In
```

```
class ast.NotIn
```

比較運算子 token。

```
class ast.Call(func, args, keywords)
```

一個函式呼叫。func 是該函式，通常是一個 *Name* 或 *Attribute* 物件。而在引數中：

- args 保存按位置傳遞的引數串列。
- keywords 保存一個 *keyword* 物件串列，表示透過關鍵字傳遞的引數。

args 和 keywords 引數是可選的，預設為空串列。

```
>>> print(ast.dump(ast.parse('func(a, b=c, *d, **e)', mode='eval'), indent=4))
Expression(
  body=Call(
    func=Name(id='func', ctx=Load()),
    args=[
      Name(id='a', ctx=Load()),
      Starred(
        value=Name(id='d', ctx=Load()),
        ctx=Load()),
    ],
    keywords=[
      keyword(
        arg='b',
        value=Name(id='c', ctx=Load())),
      keyword(
        value=Name(id='e', ctx=Load()))])])
```

**class** `ast.keyword` (*arg, value*)

函式呼叫或類定義的關鍵字引數。arg 是參數名稱的原始字串，value 是要傳入的節點。

**class** `ast.IfExp` (*test, body, orelse*)

像是 `a if b else c` 之類的運算式。每個欄位都保存一個節點，因此在以下範例中，所有三個都是 `Name` 節點。

```
>>> print(ast.dump(ast.parse('a if b else c', mode='eval'), indent=4))
Expression(
  body=IfExp(
    test=Name(id='b', ctx=Load()),
    body=Name(id='a', ctx=Load()),
    orelse=Name(id='c', ctx=Load())))
```

**class** `ast.Attribute` (*value, attr, ctx*)

屬性的存取，例如 `d.keys`。value 是一個節點，通常是一個 `Name`。attr 是一個屬性名稱的字串，ctx 根據屬性的作用方式可能是 `Load`、`Store` 或 `Del`。

```
>>> print(ast.dump(ast.parse('snake.colour', mode='eval'), indent=4))
Expression(
  body=Attribute(
    value=Name(id='snake', ctx=Load()),
    attr='colour',
    ctx=Load()))
```

**class** `ast.NamedExpr` (*target, value*)

一個命名運算式 (named expression)。該 AST 節點由賦值運算式運算子 (也稱海象運算子) 生成。相對於 `Assign` 節點之第一個引數可多個節點，在這種情況下 target 和 value 都必須是單個節點。

```
>>> print(ast.dump(ast.parse('(x := 4)', mode='eval'), indent=4))
Expression(
  body=NamedExpr(
    target=Name(id='x', ctx=Store()),
    value=Constant(value=4)))
```

在 3.8 版被加入。

## 下標 (Subscripting)

**class** `ast.Subscript` (*value, slice, ctx*)

一個下標，例如 `l[1]`。value 是下標物件 (通常是序列或對映)。slice 是索引、切片或鍵。它可以是一個 `tuple` 包含一個 `Slice`。根據下標執行的操作不同，ctx 可以是 `Load`、`Store` 或 `Del`。

```
>>> print(ast.dump(ast.parse('l[1:2, 3]', mode='eval'), indent=4))
Expression(
  body=Subscript(
    value=Name(id='l', ctx=Load()),
    slice=Tuple(
      elts=[
        Slice(
          lower=Constant(value=1),
          upper=Constant(value=2)),
        Constant(value=3)],
      ctx=Load()),
    ctx=Load())
```

**class** `ast.Slice` (*lower, upper, step*)

常規切片 (形式 `lower:upper` 或 `lower:upper:step`)。只能直接或者或者作 `Tuple` 的元素出現在 `Subscript` 的 `slice` 欄位。

```
>>> print(ast.dump(ast.parse('l[1:2]', mode='eval'), indent=4))
Expression(
  body=Subscript(
    value=Name(id='l', ctx=Load()),
    slice=Slice(
      lower=Constant(value=1),
      upper=Constant(value=2)),
    ctx=Load())
```

### 綜合運算式 (comprehensions)

**class** `ast.ListComp` (*elt, generators*)

**class** `ast.SetComp` (*elt, generators*)

**class** `ast.GeneratorExp` (*elt, generators*)

**class** `ast.DictComp` (*key, value, generators*)

串列和集合綜合運算、生成器運算式和字典綜合運算。`elt` (或 `key` 和 `value`) 是單個節點，表示各個項目會被求值 (`evaluate`) 的部分。

`generators` 是一個 *comprehension* 節點的串列。

```
>>> print(ast.dump(
...     ast.parse('[x for x in numbers]', mode='eval'),
...     indent=4,
... ))
Expression(
  body=ListComp(
    elt=Name(id='x', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        is_async=0)])
>>> print(ast.dump(
...     ast.parse('{x: x**2 for x in numbers}', mode='eval'),
...     indent=4,
... ))
Expression(
  body=DictComp(
    key=Name(id='x', ctx=Load()),
    value=BinOp(
      left=Name(id='x', ctx=Load()),
      op=Pow(),
      right=Constant(value=2)),
```

(繼續下一頁)

(繼續上一頁)

```

        generators=[
            comprehension(
                target=Name(id='x', ctx=Store()),
                iter=Name(id='numbers', ctx=Load()),
                is_async=0)))
>>> print(ast.dump(
...     ast.parse('{x for x in numbers}', mode='eval'),
...     indent=4,
... ))
Expression(
  body=SetComp(
    elt=Name(id='x', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='x', ctx=Store()),
        iter=Name(id='numbers', ctx=Load()),
        is_async=0)))

```

**class** `ast.comprehension` (*target, iter, ifs, is\_async*)

綜合運算中的一個 for 子句。target 是用於每個元素的參照 - 通常是 *Name* 或 *Tuple* 節點。iter 是要取代的物件。ifs 是測試運算式的串列：每個 for 子句可以有多个 ifs。

is\_async 表示綜合運算式是非同步的（使用 `async for` 而不是 `for`）。該值為整數（0 或 1）。

```

>>> print(ast.dump(ast.parse('[ord(c) for line in file for c in line]', mode='eval'),
...                 indent=4)) # Multiple comprehensions in one.
Expression(
  body=ListComp(
    elt=Call(
      func=Name(id='ord', ctx=Load()),
      args=[
        Name(id='c', ctx=Load())]),
    generators=[
      comprehension(
        target=Name(id='line', ctx=Store()),
        iter=Name(id='file', ctx=Load()),
        is_async=0),
      comprehension(
        target=Name(id='c', ctx=Store()),
        iter=Name(id='line', ctx=Load()),
        is_async=0)))

>>> print(ast.dump(ast.parse('(n**2 for n in it if n>5 if n<10)', mode='eval'),
...                 indent=4)) # generator comprehension
Expression(
  body=GeneratorExp(
    elt=BinOp(
      left=Name(id='n', ctx=Load()),
      op=Pow(),
      right=Constant(value=2)),
    generators=[
      comprehension(
        target=Name(id='n', ctx=Store()),
        iter=Name(id='it', ctx=Load()),
        ifs=[
          Compare(
            left=Name(id='n', ctx=Load()),
            ops=[
              Gt()],
            comparators=[
              Constant(value=5)]),

```

(繼續下一頁)

```

        Compare (
            left=Name(id='n', ctx=Load()),
            ops=[
                Lt()],
            comparators=[
                Constant(value=10)]],
            is_async=0)))

>>> print(ast.dump(ast.parse('[i async for i in soc]', mode='eval'),
...                    indent=4)) # Async comprehension
Expression(
  body=ListComp(
    elt=Name(id='i', ctx=Load()),
    generators=[
      comprehension(
        target=Name(id='i', ctx=Store()),
        iter=Name(id='soc', ctx=Load()),
        is_async=1)])])

```

## 陳述式

**class** `ast.Assign(targets, value, type_comment)`

一個賦值。targets 是節點串列，value 是單個節點。

targets 中的多個節點表示每個節點分配相同的值。解包是透過在 targets 中放置一個 *Tuple* 或 *List* 來表示的。

**type\_comment**

type\_comment 是一個可選字串，其中的解包型解釋。

```

>>> print(ast.dump(ast.parse('a = b = 1'), indent=4)) # Multiple assignment
Module(
  body=[
    Assign(
      targets=[
        Name(id='a', ctx=Store()),
        Name(id='b', ctx=Store())],
      value=Constant(value=1))]])

>>> print(ast.dump(ast.parse('a,b = c'), indent=4)) # Unpacking
Module(
  body=[
    Assign(
      targets=[
        Tuple(
          elts=[
            Name(id='a', ctx=Store()),
            Name(id='b', ctx=Store())],
          ctx=Store())],
      value=Name(id='c', ctx=Load()))])

```

**class** `ast.AnnAssign(target, annotation, value, simple)`

帶有型解釋的賦值。target 是單個節點，可以是 *Name*、*Attribute* 或 *Subscript*。annotation 是解釋，例如 *Constant* 或 *Name* 節點。value 是單個可選節點。

simple 總會是 0 (表示一個「雜」目標) 或 1 (表示一個「簡單」目標)。一個「簡單」目標僅包含一個 *Name* 節點，且不出現在括號之間；所有其他目標都被視是雜的。只有簡單目標會出現在模組和類的 `__annotations__` 字典中。

```

>>> print(ast.dump(ast.parse('c: int'), indent=4))
Module(
  body=[
    AnnAssign(
      target=Name(id='c', ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=1))

>>> print(ast.dump(ast.parse('(a): int = 1'), indent=4)) # Annotation with parenthesis
Module(
  body=[
    AnnAssign(
      target=Name(id='a', ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      value=Constant(value=1),
      simple=0))

>>> print(ast.dump(ast.parse('a.b: int'), indent=4)) # Attribute annotation
Module(
  body=[
    AnnAssign(
      target=Attribute(
        value=Name(id='a', ctx=Load()),
        attr='b',
        ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=0))

>>> print(ast.dump(ast.parse('a[1]: int'), indent=4)) # Subscript annotation
Module(
  body=[
    AnnAssign(
      target=Subscript(
        value=Name(id='a', ctx=Load()),
        slice=Constant(value=1),
        ctx=Store()),
      annotation=Name(id='int', ctx=Load()),
      simple=0))

```

**class** `ast.AugAssign` (*target, op, value*)

增加賦值 (augmented assignment), 例如 `a += 1`。在下面的範例中, `target` 是 `x` 的 `Name` 節點 (帶有 `Store` 情境), `op` 是 `Add`, `value` 是一個值 1 的 `Constant`。

與 `Assign` 的目標不同, `target` 屬性不能屬於 `Tuple` 或 `List` 類。

```

>>> print(ast.dump(ast.parse('x += 2'), indent=4))
Module(
  body=[
    AugAssign(
      target=Name(id='x', ctx=Store()),
      op=Add(),
      value=Constant(value=2))])

```

**class** `ast.Raise` (*exc, cause*)

一個 `raise` 陳述式。 `exc` 是要引發的例外物件, 通常是 `Call` 或 `Name`, 若是獨立的 `raise` 則 `None`。 `cause` 是 `raise x from y` 中的可選部分 `y`。

```

>>> print(ast.dump(ast.parse('raise x from y'), indent=4))
Module(
  body=[
    Raise(

```

(繼續下一頁)

(繼續上一頁)

```
exc=Name(id='x', ctx=Load()),
cause=Name(id='y', ctx=Load()))]])
```

**class ast.Assert** (*test, msg*)

一個斷言 (assertion)。test 保存條件，例如 *Compare* 節點。msg 保存失敗訊息。

```
>>> print(ast.dump(ast.parse('assert x,y'), indent=4))
Module(
  body=[
    Assert(
      test=Name(id='x', ctx=Load()),
      msg=Name(id='y', ctx=Load()))]])
```

**class ast.Delete** (*targets*)

代表一個 del 陳述式。targets 是節點串列，例如 *Name*、*Attribute* 或 *Subscript* 節點。

```
>>> print(ast.dump(ast.parse('del x,y,z'), indent=4))
Module(
  body=[
    Delete(
      targets=[
        Name(id='x', ctx=Del()),
        Name(id='y', ctx=Del()),
        Name(id='z', ctx=Del())]])])
```

**class ast.Pass**

一個 pass 陳述式。

```
>>> print(ast.dump(ast.parse('pass'), indent=4))
Module(
  body=[
    Pass()]])
```

**class ast.TypeAlias** (*name, type\_params, value*)

透過 type 陳述式建立的型別名 (*type alias*)。name 是型別名的名稱、type\_params 是型別參數 (*type parameter*) 的串列、value 是型別名的值。

```
>>> print(ast.dump(ast.parse('type Alias = int'), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      value=Name(id='int', ctx=Load()))]])
```

在 3.12 版被加入。

其他僅適用於函式或圈部的陳述式將在其他部分中描述。

## 引入 (imports)

**class ast.Import** (*names*)

一個 import 陳述式。names 是 *alias* 節點的串列。

```
>>> print(ast.dump(ast.parse('import x,y,z'), indent=4))
Module(
  body=[
    Import(
      names=[
        alias(name='x'),
```

(繼續下一頁)

(繼續上一頁)

```
alias(name='y'),
alias(name='z')]]])
```

**class** `ast.ImportFrom` (*module, names, level*)

代表 `from x import y`。 `module` 是 'from' 名稱的原始字串，前面有任意的點 (dot)，或者對於諸如 `from . import foo` 之類的陳述式則為 `None`。 `level` 是一個整數，保存相對引入的級數 (0 表示對引入)。

```
>>> print(ast.dump(ast.parse('from y import x,y,z'), indent=4))
Module(
  body=[
    ImportFrom(
      module='y',
      names=[
        alias(name='x'),
        alias(name='y'),
        alias(name='z')],
      level=0)])
```

**class** `ast.alias` (*name, asname*)

這兩個參數都是名稱的原始字串。如果要使用常規名稱， `asname` 可以為 `None`。

```
>>> print(ast.dump(ast.parse('from ..foo.bar import a as b, c'), indent=4))
Module(
  body=[
    ImportFrom(
      module='foo.bar',
      names=[
        alias(name='a', asname='b'),
        alias(name='c')],
      level=2)])
```

## 流程控制

### 備註

諸如 `else` 之類的可選子句如果不存在，則將被儲存為空串列。

**class** `ast.If` (*test, body, orelse*)

一個 `if` 陳述式。 `test` 保存單個節點，例如 `Compare` 節點。 `body` 和 `orelse` 各自保存一個節點串列。 `elif` 子句在 AST 中有特殊表示，而是在前一個子句的 `orelse` 部分中作為額外的 `If` 節點出現。

```
>>> print(ast.dump(ast.parse("""
... if x:
...     ...
... elif y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    If(
      test=Name(id='x', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis))],
      orelse=...
```

(繼續下一頁)

```

    orelse=[
        If(
            test=Name(id='y', ctx=Load()),
            body=[
                Expr(
                    value=Constant(value=Ellipsis)],
            orelse=[
                Expr(
                    value=Constant(value=Ellipsis))]]))]]))

```

**class** `ast.For`(*target*, *iter*, *body*, *orelse*, *type\_comment*)

一個 for 圈。target 保存圈賦予的變數，單個 *Name*、*Tuple*、*List*、*Attribute* 或 *Subscript* 節點。iter 保存要圈跑過的項目，也單個節點。body 和 orelse 包含要執行的節點串列。如果圈正常完成，則執行 orelse 中的內容，而不是透過 break 陳述式執行。

**type\_comment**

type\_comment 是一個可選字串，其中的解型釋。

```

>>> print(ast.dump(ast.parse("""
... for x in y:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    For(
      target=Name(id='x', ctx=Store()),
      iter=Name(id='y', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis)],
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))]]))

```

**class** `ast.While`(*test*, *body*, *orelse*)

一個 while 圈。test 保存條件，例如 *Compare* 節點。

```

>> print(ast.dump(ast.parse("""
... while x:
...     ...
... else:
...     ...
... """), indent=4))
Module(
  body=[
    While(
      test=Name(id='x', ctx=Load()),
      body=[
        Expr(
          value=Constant(value=Ellipsis)],
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))]]))

```

**class** `ast.Break`

**class** `ast.Continue`

break 和 continue 陳述式。

```

>>> print(ast.dump(ast.parse("""\
... for a in b:
...     if a > 5:
...         break
...     else:
...         continue
... """), indent=4))
Module(
  body=[
    For(
      target=Name(id='a', ctx=Store()),
      iter=Name(id='b', ctx=Load()),
      body=[
        If(
          test=Compare(
            left=Name(id='a', ctx=Load()),
            ops=[
              Gt()],
            comparators=[
              Constant(value=5)]),
          body=[
            Break()],
          orelse=[
            Continue()])))])

```

**class** `ast.Try`(*body, handlers, orelse, finalbody*)

try 區塊。除 `handlers` 是 `ExceptionHandler` 節點的串列外，其他所有屬性都是要執行之節點的串列。

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except Exception:
...     ...
... except OtherException as e:
...     ...
... else:
...     ...
... finally:
...     ...
... """), indent=4))
Module(
  body=[
    Try(
      body=[
        Expr(
          value=Constant(value=Ellipsis))],
      handlers=[
        ExceptionHandler(
          type=Name(id='Exception', ctx=Load()),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        ExceptionHandler(
          type=Name(id='OtherException', ctx=Load()),
          name='e',
          body=[
            Expr(
              value=Constant(value=Ellipsis))])]),
      orelse=[
        Expr(
          value=Constant(value=Ellipsis))],

```

(繼續下一頁)

(繼續上一頁)

```

finalbody=[
    Expr (
        value=Constant (value=Ellipsis))]]])

```

**class** `ast.TryStar` (*body, handlers, or\_else, finalbody*)

try 區塊，後面跟著 `except*` 子句。這些屬性與 `Try` 相同，但是 `handlers` 中的 `ExceptionHandler` 節點被直譯 (interpret) `except*` 區塊而不是 `except`。

```

>>> print(ast.dump(ast.parse("""
... try:
...     ...
... except* Exception:
...     ...
... """), indent=4))
Module(
  body=[
    TryStar(
      body=[
        Expr(
          value=Constant(value=Ellipsis))],
      handlers=[
        ExceptionHandler(
          type=Name(id='Exception', ctx=Load()),
          body=[
            Expr(
              value=Constant(value=Ellipsis))])])])

```

在 3.11 版被加入。

**class** `ast.ExceptionHandler` (*type, name, body*)

單個 `except` 子句。 `type` 是會被匹配的例外型，通常是一個 `Name` 節點 (或者 `None` 表示會捕捉到所有例外的 `except:` 子句)。 `name` 是用於保存例外的名稱之原始字串，如果子句有 `as foo`，則 `None`。 `body` 是節點串列。

```

>>> print(ast.dump(ast.parse("""\
... try:
...     a + 1
... except TypeError:
...     pass
... """), indent=4))
Module(
  body=[
    Try(
      body=[
        Expr(
          value=BinOp(
            left=Name(id='a', ctx=Load()),
            op=Add(),
            right=Constant(value=1)))]],
      handlers=[
        ExceptionHandler(
          type=Name(id='TypeError', ctx=Load()),
          body=[
            Pass()])])])

```

**class** `ast.With` (*items, body, type\_comment*)

一個 `with` 區塊。 `items` 是表示情境管理器的 `withitem` 節點串列， `body` 是情境的縮進區塊。

**type\_comment**

`type_comment` 是一個可選字串，其中的解型釋。

**class** `ast.withitem` (*context\_expr, optional\_vars*)

`with` 區塊中的單個情境管理器。`context_expr` 是情境管理器，通常是一個 `Call` 節點。`Optional_vars` 是 `as foo` 部分的 `Name`、`Tuple` 或 `List`，或者如果不使用則 `None`。

```
>>> print(ast.dump(ast.parse("""\
... with a as b, c as d:
...     something(b, d)
... """), indent=4))
Module(
  body=[
    With(
      items=[
        withitem(
          context_expr=Name(id='a', ctx=Load()),
          optional_vars=Name(id='b', ctx=Store()),
        withitem(
          context_expr=Name(id='c', ctx=Load()),
          optional_vars=Name(id='d', ctx=Store()))],
      body=[
        Expr(
          value=Call(
            func=Name(id='something', ctx=Load()),
            args=[
              Name(id='b', ctx=Load()),
              Name(id='d', ctx=Load())])])])])]
```

### 模式匹配 (pattern matching)

**class** `ast.Match` (*subject, cases*)

一個 `match` 陳述式。`subject` 保存匹配的主題（與案例匹配的物件），`cases` 包含具有不同案例的 `match_case` 節點的可代物件。

在 3.10 版被加入。

**class** `ast.match_case` (*pattern, guard, body*)

`match` 陳述式中的單個案例模式。`pattern` 包含主題將與之匹配的匹配模式。請注意，模式生成的 `AST` 節點與運算式生成的節點不同，即使它們共享相同的語法。

`guard` 屬性包含一個運算式，如果模式與主題匹配，則將對該運算式求值。

`body` 包含一個節點串列，如果模式匹配且防護運算式 (`guard expression`) 的求值 (`evaluate`) 結果為真，則會執行該節點串列。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] if x>0:
...         ...
...     case tuple():
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchAs(name='x')]),
          guard=Compare(
            left=Name(id='x', ctx=Load()),
            ops=[
```

(繼續下一頁)

(繼續上一頁)

```

        Gt()),
        comparators=[
            Constant(value=0)],
        body=[
            Expr(
                value=Constant(value=Ellipsis))]),
        match_case(
            pattern=MatchClass(
                cls=Name(id='tuple', ctx=Load())),
            body=[
                Expr(
                    value=Constant(value=Ellipsis))]]))]]))

```

在 3.10 版被加入。

**class** `ast.MatchValue` (*value*)

以相等性進行比較的匹配文本或值的模式。`value` 是一個運算式節點。允許值節點受到匹配陳述式文件中所述的限制。如果匹配主題等於求出值，則此模式成功。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case "Relevant":
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchValue(
            value=Constant(value='Relevant')),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]]))]]))

```

在 3.10 版被加入。

**class** `ast.MatchSingleton` (*value*)

按識別性 (identity) 進行比較的匹配文本模式。`value` 是要與 `None`、`True` 或 `False` 進行比較的單例 (singleton)。如果匹配主題是給定的常數，則此模式成功。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case None:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSingleton(value=None),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]]))]]))

```

在 3.10 版被加入。

**class** `ast.MatchSequence` (*patterns*)

匹配序列模式。如果主題是一個序列，`patterns` 包含與主題元素匹配的模式。如果子模式之一是

MatchStar 節點，則匹配可變長度序列，否則匹配固定長度序列。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2]:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchValue(
                value=Constant(value=1)),
              MatchValue(
                value=Constant(value=2))]),
          body=[
            Expr(
              value=Constant(value=Ellipsis)))]])])])])
```

在 3.10 版被加入。

**class** `ast.MatchStar` (*name*)

以可變長度匹配序列模式匹配序列的其余部分。如果 *name* 不是 `None`，則如果整體序列模式成功，則包含其余序列元素的串列將綁定到該名稱。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [1, 2, *rest]:
...         ...
...     case [*_]:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchValue(
                value=Constant(value=1)),
              MatchValue(
                value=Constant(value=2)),
              MatchStar(name='rest')]),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        match_case(
          pattern=MatchSequence(
            patterns=[
              MatchStar()]),
          body=[
            Expr(
              value=Constant(value=Ellipsis)))]])])])])
```

在 3.10 版被加入。

**class** `ast.MatchMapping` (*keys*, *patterns*, *rest*)

匹配對映模式。keys 是運算式節點的序列。patterns 是相應的模式節點序列。rest 是一個可選名稱，可以指定它來捕獲剩余的對映元素。允許的鍵運算式受到匹配陳述式文件中所述的限制。

如果主題是對映，所有求值出的鍵運算式都存在於對映中，且與每個鍵對應的值與相應的子模式匹配，則此模式成功。如果 rest 不是 None，則如果整體對映模式成功，則包含其余對映元素的字典將綁定到該名稱。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case {1: _, 2: _}:
...         ...
...     case {**rest}:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchMapping(
            keys=[
              Constant(value=1),
              Constant(value=2)],
            patterns=[
              MatchAs(),
              MatchAs()]
          ),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]
        ),
        match_case(
          pattern=MatchMapping(rest='rest'),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]
          )
        ]
      )
  ]
)
```

在 3.10 版被加入。

**class** `ast.MatchClass` (*cls, patterns, kwd\_attrs, kwd\_patterns*)

匹配類模式。cls 是一個給定要匹配的名義類 (nominal class) 的運算式。patterns 是要與類定義的模式匹配屬性序列進行匹配的模式節點序列。kwd\_attrs 是要匹配的附加屬性序列 (在類模式中指定關鍵字引數)，kwd\_patterns 是相應的模式 (在類模式中指定關鍵字的值)。

如果主題是指定類的實例，所有位置模式都與相應的類定義屬性匹配，且任何指定的關鍵字屬性與其相應模式匹配，則此模式成功。

注意：類可以定義一個回傳 self 的特性 (property)，以便將模式節點與正在匹配的實例進行匹配。一些建型也以這種方式匹配，如同匹配陳述式文件中所述。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case Point2D(0, 0):
...         ...
...     case Point3D(x=0, y=0, z=0):
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchClass(
```

(繼續下一頁)

(繼續上一頁)

```

cls=Name(id='Point2D', ctx=Load()),
patterns=[
    MatchValue(
        value=Constant(value=0)),
    MatchValue(
        value=Constant(value=0))],
body=[
    Expr(
        value=Constant(value=Ellipsis))],
match_case(
    pattern=MatchClass(
        cls=Name(id='Point3D', ctx=Load()),
        kwd_attrs=[
            'x',
            'y',
            'z'],
        kwd_patterns=[
            MatchValue(
                value=Constant(value=0)),
            MatchValue(
                value=Constant(value=0)),
            MatchValue(
                value=Constant(value=0))],
        body=[
            Expr(
                value=Constant(value=Ellipsis))]]))]]))

```

在 3.10 版被加入。

**class** `ast.MatchAs` (*pattern, name*)

匹配的「as 模式 (as-pattern)」，`pattern` 捕獲模式 (capture pattern) 或通配模式 (wildcard pattern)。包含主題將與之匹配的匹配模式。如果模式是 `None`，則該節點代表捕獲模式 (即裸名 (bare name)) 且始終會成功。

`name` 屬性包含模式成功時將綁定的名稱。如果 `name` 是 `None`，則 `pattern` 也必須是 `None`，且節點代表通配模式。

```

>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] as y:
...         ...
...     case _:
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchAs(
            pattern=MatchSequence(
              patterns=[
                MatchAs(name='x')]),
            name='y'),
          body=[
            Expr(
              value=Constant(value=Ellipsis))]),
        match_case(
          pattern=MatchAs(),
          body=[

```

(繼續下一頁)

```
Expr(
  value=Constant(value=Ellipsis))))))
```

在 3.10 版被加入。

**class** `ast.MatchOr` (*patterns*)

匹配的「or 模式 (or-pattern)」。or 模式依次將其每個子模式與主題進行匹配，直到成功為止，然後 or 模式就會被認為是成功的。如果有一個子模式成功，則 or 模式將失敗。patterns 屬性包含將與主題進行匹配的匹配模式節點串列。

```
>>> print(ast.dump(ast.parse("""
... match x:
...     case [x] | (y):
...         ...
... """), indent=4))
Module(
  body=[
    Match(
      subject=Name(id='x', ctx=Load()),
      cases=[
        match_case(
          pattern=MatchOr(
            patterns=[
              MatchSequence(
                patterns=[
                  MatchAs(name='x')]),
              MatchAs(name='y')]),
          body=[
            Expr(
              value=Constant(value=Ellipsis))))))
```

在 3.10 版被加入。

### 型參數 (type parameters)

型參數可以存在於類、函式和型名上。

**class** `ast.TypeVar` (*name, bound, default\_value*)

一個 `typing.TypeVar`。name 是型變數的名稱。bound 是（如果有存在的）界限 (bound) 或約束 (constraint)。如果 bound 是一個 `Tuple`，它代表約束；否則它代表界限。default\_value 預設值；如果 `TypeVar` 有預設值，那此屬性會被設為 `None`。

```
>>> print(ast.dump(ast.parse("type Alias[T: int = bool] = list[T]"), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[
        TypeVar(
          name='T',
          bound=Name(id='int', ctx=Load()),
          default_value=Name(id='bool', ctx=Load()))],
      value=Subscript(
        value=Name(id='list', ctx=Load()),
        slice=Name(id='T', ctx=Load()),
        ctx=Load()))]
```

在 3.12 版被加入。

在 3.13 版的變更: 新增 `default_value` 參數。

**class** `ast.ParamSpec` (*name*, *default\_value*)

一個 `typing.ParamSpec`。 *name* 是參數規範的名稱。 *default\_value* 是預設值；如果 `ParamSpec` 有預設值，則該屬性將設定為 `None`。

```
>>> print(ast.dump(ast.parse("type Alias[*P = [int, str]] = Callable[P, int]"),
↳indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[
        ParamSpec(
          name='P',
          default_value=List(
            elts=[
              Name(id='int', ctx=Load()),
              Name(id='str', ctx=Load())],
            ctx=Load())],
          value=Subscript(
            value=Name(id='Callable', ctx=Load()),
            slice=Tuple(
              elts=[
                Name(id='P', ctx=Load()),
                Name(id='int', ctx=Load())],
              ctx=Load()),
            ctx=Load()))])])
```

在 3.12 版被加入。

在 3.13 版的變更: 新增 `default_value` 參數。

**class** `ast.TypeVarTuple` (*name*, *default\_value*)

一個 `typing.TypeVarTuple`。 *name* 是型變數元組的名稱。 *default\_value* 預設值；如果 `TypeVarTuple` 有預設值，那此屬性會被設定為 `None`。

```
>>> print(ast.dump(ast.parse("type Alias[*Ts = ()] = tuple[*Ts]"), indent=4))
Module(
  body=[
    TypeAlias(
      name=Name(id='Alias', ctx=Store()),
      type_params=[
        TypeVarTuple(
          name='Ts',
          default_value=Tuple(ctx=Load())],
          value=Subscript(
            value=Name(id='tuple', ctx=Load()),
            slice=Tuple(
              elts=[
                Starred(
                  value=Name(id='Ts', ctx=Load()),
                  ctx=Load())],
              ctx=Load()),
            ctx=Load()))])])
```

在 3.12 版被加入。

在 3.13 版的變更: 新增 `default_value` 參數。

## 函式和類定義

**class** `ast.FunctionDef` (*name, args, body, decorator\_list, returns, type\_comment, type\_params*)

一個函式定義。

- `name` 是函式名稱的原始字串。
- `args` 是一個 *arguments* 節點。
- `body` 是函式節點的串列。
- `decorator_list` 是要應用的裝飾器串列，在最外層者會被儲存在首位（即串列中首位將會是最後一個被應用的那個）。
- `returns` 是回傳釋。
- `type_params` 是型參數的串列。

**type\_comment**

`type_comment` 是一個可選字串，其中的解型釋。

在 3.12 版的變更: 新增了 `type_params`。

**class** `ast.Lambda` (*args, body*)

`lambda` 是可以在運算式使用的最小函式定義。與 `FunctionDef` 不同, `body` 保存單個節點。

```
>>> print(ast.dump(ast.parse('lambda x,y: ...'), indent=4))
Module(
  body=[
    Expr(
      value=Lambda(
        args=arguments(
          args=[
            arg(arg='x'),
            arg(arg='y')]
          ),
        body=Constant(value=Ellipsis)))])
```

**class** `ast.arguments` (*posonlyargs, args, vararg, kwonlyargs, kw\_defaults, kwarg, defaults*)

函式的引數。

- `posonlyargs`、`args` 和 `kwonlyargs` 是 *arg* 節點的串列。
- `vararg` 和 `kwarg` 是單個 *arg* 節點，指的是 `*args`, `**kwargs` 參數。
- `kw_defaults` 是僅限關鍵字引數的預設值串列。如果其中某個 `None`，則相應參數就會是必要的。
- `defaults` 是可以按位置傳遞的引數的預設值串列。如果預設值較少，則它們對應於最後 `n` 個引數。

**class** `ast.arg` (*arg, annotation, type\_comment*)

串列中的單個引數。`arg` 是引數名稱的原始字串，`annotation` 是它的釋，例如 `Name` 節點。

**type\_comment**

`type_comment` 是一個可選字串，其解型釋

```
>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... def f(a: 'annotation', b=1, c=2, *d, e, f=3, **g) -> 'return annotation':
...     pass
... """), indent=4))
Module(
  body=[
    FunctionDef(
      name='f',
```

(繼續下一頁)

(繼續上一頁)

```

args=arguments(
    args=[
        arg(
            arg='a',
            annotation=Constant(value='annotation')),
        arg(arg='b'),
        arg(arg='c')],
    vararg=arg(arg='d'),
    kwonlyargs=[
        arg(arg='e'),
        arg(arg='f')],
    kw_defaults=[
        None,
        Constant(value=3)],
    kwarg=arg(arg='g'),
    defaults=[
        Constant(value=1),
        Constant(value=2)],
    body=[
        Pass()],
    decorator_list=[
        Name(id='decorator1', ctx=Load()),
        Name(id='decorator2', ctx=Load())],
    returns=Constant(value='return annotation'))

```

**class** `ast.Return` (*value*)一個 `return` 陳述式。

```

>>> print(ast.dump(ast.parse('return 4'), indent=4))
Module(
  body=[
    Return(
      value=Constant(value=4))])

```

**class** `ast.Yield` (*value*)**class** `ast.YieldFrom` (*value*)一個 `yield` 或 `yield from` 運算式。因 F 這些是運算式，所以如果不使用發送回來的值，則必須將它們包裝在 `Expr` 節點中。

```

>>> print(ast.dump(ast.parse('yield x'), indent=4))
Module(
  body=[
    Expr(
      value=Yield(
        value=Name(id='x', ctx=Load()))))]

>>> print(ast.dump(ast.parse('yield from x'), indent=4))
Module(
  body=[
    Expr(
      value=YieldFrom(
        value=Name(id='x', ctx=Load()))))]

```

**class** `ast.Global` (*names*)**class** `ast.Nonlocal` (*names*)`global` 和 `nonlocal` 陳述式。names 是原始字串的串列。

```

>>> print(ast.dump(ast.parse('global x,y,z'), indent=4))
Module(

```

(繼續下一頁)

```

body=[
    Global(
        names=[
            'x',
            'y',
            'z'])])

>>> print(ast.dump(ast.parse('nonlocal x,y,z'), indent=4))
Module(
  body=[
    Nonlocal(
      names=[
        'x',
        'y',
        'z'])])

```

**class** `ast.ClassDef` (*name, bases, keywords, body, decorator\_list, type\_params*)

一個類定義。

- `name` 是類名的原始字串
- `bases` 是被顯式指定的基底類節點串列。
- `keywords` 是一個 *keyword* 節點的串列，主要用於 `metaclass` (元類)。如 [PEP 3115](#) 所述，其他關鍵字將被傳遞到 `metaclass`。
- `body` 是表示類定義中程式碼的節點串列。
- `decorator_list` 是一個節點串列，如 `FunctionDef` 中所示。
- `type_params` 是型參數的串列。

```

>>> print(ast.dump(ast.parse("""\
... @decorator1
... @decorator2
... class Foo(base1, base2, metaclass=meta):
...     pass
... """), indent=4))
Module(
  body=[
    ClassDef(
      name='Foo',
      bases=[
        Name(id='base1', ctx=Load()),
        Name(id='base2', ctx=Load())],
      keywords=[
        keyword(
          arg='metaclass',
          value=Name(id='meta', ctx=Load()))],
      body=[
        Pass()],
      decorator_list=[
        Name(id='decorator1', ctx=Load()),
        Name(id='decorator2', ctx=Load())])])

```

在 3.12 版的變更: 新增了 `type_params`。

## async 和 await

**class** `ast.AsyncFunctionDef` (*name, args, body, decorator\_list, returns, type\_comment, type\_params*)

一個 `async def` 函式定義。與 `FunctionDef` 具有相同的欄位。

在 3.12 版的變更: 新增了 `type_params`。

**class** `ast.Await` (*value*)

一個 `await` 運算式。 `value` 是它等待的東西。僅在 `AsyncFunctionDef` 主體 (body) 中有效。

```
>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4))
Module (
  body=[
    AsyncFunctionDef (
      name='f',
      args=arguments(),
      body=[
        Expr (
          value=Await (
            value=Call (
              func=Name(id='other_func', ctx=Load())))))]])
```

**class** `ast.AsyncFor` (*target, iter, body, or\_else, type\_comment*)

**class** `ast.AsyncWith` (*items, body, type\_comment*)

`async for` 和 `async with` 情境管理器。它們分具有與 `For` 和 `With` 相同的欄位。僅在 `AsyncFunctionDef` 主體中有效。

#### 備

當字串被 `ast.parse()` 剖析時，回傳樹的運算子節點 (`ast.operator`、`ast.unaryop`、`ast.cmpop`、`ast.boolop` 和 `ast.expr_context`) 將是單例。對其中之一的更改將反映在所有其他出現的相同值中 (例如 `ast.Add`)。

### 33.1.3 ast 輔助程式

除了節點類之外，`ast` 模組還定義了這些用於遍歷 (traverse) 抽象語法樹的實用函式和類：

`ast.parse` (*source, filename='<unknown>', mode='exec', \*, type\_comments=False, feature\_version=None, optimize=-1*)

將原始碼剖析 AST 節點，相當於 `compile(source, filename, mode, flags=FLAGS_VALUE, optimize=optimize)`，其中 `FLAGS_VALUE` 在 `optimize <= 0` 時 `ast.PyCF_ONLY_AST`，否則 `ast.PyCF_OPTIMIZED_AST`。

如果給定 `type_comments=True`，剖析器將被修改檢查回傳 **PEP 484** 和 **PEP 526** 指定的型釋。這相當於將 `ast.PyCF_TYPE_COMMENTS` 新增到傳遞給 `compile()` 的旗標中。這將報告錯誤型釋的語法錯誤。如果有此旗標，型釋將被忽略，且所選 AST 節點上的 `type_comment` 欄位將始終 `None`。此外，`# type: ignore` 的位置將作 `Module` 的 `type_ignores` 屬性回傳 (否則它始終是一個空串列)。

此外，如果 `mode` 是 `'func_type'`，則輸入語法將會依據 **PEP 484** 「簽名型解 (signature type comments)」而被修改，例如 `(str, int) -> List[str]`。

將 `feature_version` 設定元組 (major, minor) 將「盡可能」嘗試使用該 Python 版本的文法進行剖析。當前 major 必須等於 3。例如，設定 `feature_version=(3, 9)` 將嘗試禁止剖析 `match` 陳述式。目前 major 必須 3、支援的最低版本 (3, 7) (這在未來的 Python 版本中可能會增加)；最高的是 `sys.version_info[0:2]`。「盡可能」嘗試意味著不能保證剖析 (或剖析的成功) 與在與 `feature_version` 對應的 Python 版本上運行時相同。

如果來源包含 `null` 字元 (`\0`)，則會引發 `ValueError`。

#### 警告

請注意，成功將原始碼剖析成 AST 物件不能保證提供的原始碼是可以執行的有效 Python 程式碼，因為編譯步驟可能會引發進一步的 `SyntaxError` 例外。例如，原始的 `return 42` 會生成一個有效的 AST 節點，但它不能單獨編譯（它需要位於函式節點中）。

特別是 `ast.parse()` 不會執行任何範圍檢查，而編譯步驟才會執行此操作。

#### 警告

由於 Python AST 編譯器中的堆 (stack) 深度限制，太大或太複雜的字串可能會導致 Python 直譯器崩潰。

在 3.8 版的變更：新增 `type_comments`、`mode='func_type'` 與 `feature_version`。

在 3.13 版的變更：`feature_version` 的最低支援版本現在是 (3, 7)。新增了 `optimize` 引數。

`ast.unparse(ast_obj)`

反剖析 `ast.AST` 物件生成一個帶有程式碼的字串，如果使用 `ast.parse()` 剖析回來，該程式碼將生成等效的 `ast.AST` 物件。

#### 警告

生成的程式碼字串不一定等於生成 `ast.AST` 物件的原始程式碼（沒有任何編譯器最佳化，例如常數元組/凍結集合）。

#### 警告

嘗試剖析高度複雜的運算式會導致 `RecursionError`。

在 3.9 版被加入。

`ast.literal_eval(node_or_string)`

僅包含 Python 文本或容器之顯示的運算式節點或字串來求值。提供的字串或節點只能包含以下 Python 文本結構：字串、位元組、數字、元組、串列、字典、集合、布林值、None 和 Ellipsis。

這可用於包含 Python 值的字串求值，而無需自己剖析這些值。它無法計算任意複雜的運算式，例如涉及運算子或索引。

該函式過去被記為「安全」，但它有定義其含義，這有點誤導讀者，它是特別設計不去執行 Python 程式碼，與更通用的 `eval()` 不同。它有命名空間、有名稱查找、也有呼叫的能力。但它也不能免受攻擊：相對較小的輸入可能會導致記憶體耗盡或 C 堆耗盡，從而導致行程崩潰。某些輸入也可能會出現 CPU 消耗過多而導致拒絕服務的情況。因此不建議在不受信任的資料上呼叫它。

#### 警告

由於 Python AST 編譯器的堆深度限制，Python 直譯器可能會崩潰。

它可能會引發 `ValueError`、`TypeError`、`SyntaxError`、`MemoryError` 和 `RecursionError`，具體取決於格式錯誤的輸入。

在 3.2 版的變更：現在允許位元組和集合文本 (set literal)。

在 3.9 版的變更：現在支援使用 `'set()'` 建立空集合。

在 3.10 版的變更：對於字串輸入，前導空格和定位字元 (tab) 現在已被去除。

`ast.get_docstring(node, clean=True)`

回傳給定 `node` 的文件字串 (docstring) (必須是 `FunctionDef`、`AsyncFunctionDef`、`ClassDef` 或 `Module` 節點) 或如果它沒有文件字串則 `None`。如果 `clean` 為 `true`，則使用 `inspect.cleandoc()` 清理文件字串的縮排。

在 3.5 版的變更: 目前已支援 `AsyncFunctionDef`。

`ast.get_source_segment(source, node, *, padded=False)`

獲取生成 `node` 的 `source` 的原始碼片段。如果某些位置資訊 (`lineno`、`end_lineno`、`col_offset` 或 `end_col_offset`) 遺漏，則回傳 `None`。

如果 `padded` 為 `True`，則多列陳述式的第一列將用空格填充 (`padded`) 以匹配其原始位置。

在 3.8 版被加入。

`ast.fix_missing_locations(node)`

當你使用 `compile()` 編譯節點樹時，對於每個有支援 `lineno` 和 `col_offset` 屬性之節點，編譯器預期他們的這些屬性都要存在。填入生成的節點相當繁瑣，因此該輔助工具透過將這些屬性設定為父節點的值，在尚未設定的地方遞增地新增這些屬性。它從 `node` 開始遞增地作用。

`ast.increment_lineno(node, n=1)`

將樹中從 `node` 開始的每個節點的列號和結束列號增加 `n`。這對於「移動程式碼」到檔案中的不同位置很有用。

`ast.copy_location(new_node, old_node)`

如果可行，將原始位置 (`lineno`、`col_offset`、`end_lineno` 和 `end_col_offset`) 從 `old_node` 复制到 `new_node`，回傳 `new_node`。

`ast.iter_fields(node)`

在 `node` 上存在的 `node._fields` 中的每個欄位生成一個 (`fieldname`, `value`) 元組。

`ast.iter_child_nodes(node)`

生成 `node` 的所有直接子節點，即作節點的所有欄位以及作節點串列欄位的所有項目。

`ast.walk(node)`

遞增地生成樹中從 `node` 開始的所有後代節點 (包括 `node` 本身)，不按指定順序。如果你只想就地修改節點而不關心情境，這非常有用。

**class** `ast.NodeVisitor`

節點訪問者基底類，它遍歷抽象語法樹找到的每個節點呼叫訪問者函式。該函式可能會回傳一個由 `visit()` 方法轉發的值。

這個類應該被子類化，子類新增訪問者方法。

**visit** (`node`)

訪問一個節點。預設實作呼叫名 `self.visit_classname` 的方法，其中 `classname` 是節點類的名稱，或者在該方法不存在時呼叫 `generic_visit()`。

**generic\_visit** (`node`)

該訪問者對該節點的所有子節點呼叫 `visit()`。

請注意，除非訪問者呼叫 `generic_visit()` 或訪問它們本身，否則不會訪問具有自定義訪問者方法的節點之子節點。

**visit\_Constant** (`node`)

處理所有常數節點。

如果你想在遍歷期間將變更應用 (apply) 於節點，請不要使用 `NodeVisitor`。此，有個允許修改的特殊遍歷訪問者工具 `NodeTransformer`。

在 3.8 版之後被用: `visit_Num()`、`visit_Str()`、`visit_Bytes()`、`visit_NameConstant()` 和 `visit_Ellipsis()` 方法現已用，且不會在未來的 Python 版本中被呼叫。新增 `visit_Constant()` 方法來處理所有常數節點。

**class** `ast.NodeTransformer`

一個 `NodeVisitor` 子類，它會遍歷抽象語法樹允許修改節點。

`NodeTransformer` 將遍歷 AST 使用訪問者方法的回傳值來替或除舊節點。如果訪問者方法的回傳值 `None`，則該節點將從其位置中除，否則將被替回傳值。回傳值可能是原始節點，在這種情況下不會發生替。

下面是一個示範用的 transformer，它將查找所有出現名稱 (`foo`) 改寫 `data['foo']`：

```
class RewriteName(NodeTransformer):

    def visit_Name(self, node):
        return Subscript(
            value=Name(id='data', ctx=Load()),
            slice=Constant(value=node.id),
            ctx=node.ctx
        )
```

請記住，如果你正在操作的節點有子節點，你必須自己轉子節點或先呼叫該節點的 `generic_visit()` 方法。

對於屬於陳述式總集 (collection) 一部分的節點 (適用於所有陳述式節點)，訪問者還可以回傳節點串列，而不僅僅是單個節點。

如果 `NodeTransformer` 引進了新節點 (不屬於原始樹的一部分)，但有給它們提供位置資訊 (例如 `lineno`)，則應使用新的子樹呼叫 `fix_missing_locations()` 以重新計算位置資訊：

```
tree = ast.parse('foo', mode='eval')
new_tree = fix_missing_locations(RewriteName().visit(tree))
```

你通常會像這樣使用 transformer：

```
node = YourTransformer().visit(node)
```

**ast.dump** (`node`, `annotate_fields=True`, `include_attributes=False`, \*, `indent=None`, `show_empty=False`)

回傳 `node` 中樹的格式化傾印 (formatted dump)，這主要用於除錯。如果 `annotate_fields` `True` (預設值)，則回傳的字串將顯示欄位的名稱和值。如果 `annotate_fields` `False`，則透過省略明確的欄位名稱，結果字串將更加縮簡潔。預設情況下，不會傾印列號和行偏移量等屬性。如果需要，可以設定 `include_attributes` `True`。

如果 `indent` 是非負整數或字串，那樹將使用該縮排級來做漂亮印出 (pretty-print)。縮排級 `0`、負數或 `""` 只會插入列符號 (newlines)。`None` (預設值) 代表選擇單列表示。使用正整數縮排可以在每個級縮排相同數量的空格。如果 `indent` 是一個字串 (例如 `"\t"`)，則該字串用於縮排每個級。

如果 `show_empty` `False` (預設值)，則輸出中將省略 `False` 的空串列和欄位。

在 3.9 版的變更: 新增 `indent` 選項。

在 3.13 版的變更: 新增 `show_empty` 選項。

```
>>> print(ast.dump(ast.parse("""\
... async def f():
...     await other_func()
... """), indent=4, show_empty=True))
Module(
  body=[
    AsyncFunctionDef(
      name='f',
      args=arguments(
        posonlyargs=[],
        args=[],
        kwonlyargs=[],
        kw_defaults=[],
```

(繼續下一頁)

(繼續上一頁)

```

        defaults=[],
        body=[
            Expr (
                value=Await (
                    value=Call (
                        func=Name (id='other_func', ctx=Load()),
                        args=[],
                        keywords=[])))),
            decorator_list=[],
            type_params=[]],
        type_ignores=[])

```

### 33.1.4 編譯器旗標

可以將以下旗標傳遞給 `compile()` 以變更對程式的編譯效果：

`ast.PyCF_ALLOW_TOP_LEVEL_AWAIT`

☑️ 用對最高階 `await`、`async for`、`async with` 和非同步綜合運算的支援。

在 3.8 版被加入。

`ast.PyCF_ONLY_AST`

生成☑️回傳抽象語法樹，而不是回傳已編譯的程式碼物件。

`ast.PyCF_OPTIMIZED_AST`

回傳的 AST 會根據 `compile()` 或 `ast.parse()` 中的 `optimize` 引數進行最佳化。

在 3.13 版被加入。

`ast.PyCF_TYPE_COMMENTS`

☑️ 用對 [PEP 484](#) 和 [PEP 526](#) 樣式型☑️☑️釋的支援 (`# type: <type>`, `# type: ignore <stuff>`)。

在 3.8 版被加入。

### 33.1.5 命令列用法

在 3.9 版被加入。

`ast` 模組可以作☑️☑️本從命令列執行，可以像這樣簡單地做到：

```
python -m ast [-m <mode>] [-a] [infile]
```

以下選項可被接受：

`-h`, `--help`

顯示幫助訊息☑️退出。

`-m <mode>`

`--mode <mode>`

指定必須編譯哪種類型的程式碼，像是 `parse()` 中的 `mode` 引數。

`--no-type-comments`

不要剖析型☑️☑️解。

`-a`, `--include-attributes`

包括列號和行偏移量等屬性。

`-i <indent>`

`--indent <indent>`

AST 中節點的縮進（空格數）。

如果指定了 `infile`，則其內容將被剖析 AST 傾印 (dump) 到 `stdout`。否則會從 `stdin` 讀取內容。

### 也參考

[Green Tree Snakes](#) 是一個外部文件資源，提供了有關使用 Python AST 的詳細資訊。

[ASTTokens](#) 使用生成它們的原始碼中的標記和文本的位置來解釋 Python AST。這對於進行原始碼轉換的工具很有幫助。

[leoAst.py](#) 透過在 `token` 和 `ast` 節點之間插入雙向鏈結，統一了 python 程式的基於 `token` 和基於剖析樹的視圖。

[LibCST](#) 將程式碼剖析具體語法樹 (Concrete Syntax Tree)，看起來像 `ast` 樹保留所有格式詳細資訊。它對於建置自動重構 (codemod) 應用程式和 linter 非常有用。

[Parso](#) 是一個 Python 剖析器，支援不同 Python 版本的錯誤復原和往返剖析。Parso 還能列出 Python 檔案中的多個語法錯誤。

## 33.2 `symtable` --- 存取編譯器的符號表

原始碼：[Lib/symtable.py](#)

符號表 (symbol table) 是在生成位元組碼 (bytecode) 之前由編譯器從 AST 生成的。符號表負責計算程式碼中每個識別器 (identifier) 的作用域。`symtable` 提供了一個介面來檢查這些表。

### 33.2.1 生符號表

`symtable.symtable` (*code*, *filename*, *compile\_type*)

回傳 Python 原始 *code* 的頂層 `SymbolTable`。*filename* 是包含程式碼之檔案之名稱。*compile\_type* 類似於 `compile()` 的 *mode* 引數。

### 33.2.2 檢查符號表

`class symtable.SymbolTableType`

表明 `SymbolTable` 物件型的列舉。

`MODULE = "module"`

用於模組的符號表。

`FUNCTION = "function"`

用於函式的符號表。

`CLASS = "class"`

用於類的符號表。

以下成員代表不同風格的解釋作用域。

`ANNOTATION = "annotation"`

如果 `from __future__ import annotations` 處於活動狀態，則用於解。

`TYPE_ALIAS = "type alias"`

用於 `type` 結構的符號表。

`TYPE_PARAMETERS = "type parameters"`

用於泛型函式 (generic functions) 或泛型類 (generic classes) 的符號表。

```
TYPE_VARIABLE = "type variable"
```

用於形式意義上 (formal sense) 的結、約束元組 (constraint tuple) 或單一型變數的預設值的符號表，即 `TypeVar`、`TypeVarTuple` 或 `ParamSpec` 物件（後兩者不支援結或約束元組）。

在 3.13 版被加入。

```
class symtable.SymbolTable
```

一個區塊 (block) 的命名空間表 (namespace table)。建構函式 (constructor) 不公開。

```
get_type()
```

回傳符號表的類型。可能的值 `SymbolTableType` 列舉的成員。

在 3.12 版的變更: 新增了 'annotation'、'TypeVar bound'、'type alias' 和 'type parameter' 作可能的回傳值。

在 3.13 版的變更: 回傳值是 `SymbolTableType` 列舉的成員。

回傳字串的確切值在未來可能會發生變化，因此建議使用 `SymbolTableType` 成員而不是寫死 (hard-coded) 字串。

```
get_id()
```

回傳表的識別器。

```
get_name()
```

回傳表的名稱。如果表用於類，則這是類的名稱；如果表用於函式，則這是函式的名稱；如果表是全域的，則 'top' (`get_type()` 會回傳 'module')。對於型參數作用域 (用於泛型類、函式和型名)，它是底層類、函式或型名的名稱。對於型名作用域，它是型名的名稱。對於 `TypeVar` 綁定作用域，它會是 `TypeVar` 的名稱。

```
get_lineno()
```

回傳此表所代表的區塊中第一行的編號。

```
is_optimized()
```

如果可以最佳化該表中的區域變數，則回傳 `True`。

```
is_nested()
```

如果區塊是巢狀類或函式，則回傳 `True`。

```
has_children()
```

如果區塊有巢狀命名空間，則回傳 `True`。這些可以透過 `get_children()` 獲得。

```
get_identifiers()
```

回傳包含表中符號之名稱的視圖物件 (view object)。請參視圖物件的文件。

```
lookup(name)
```

在表中查找 `name` 回傳一個 `Symbol` 實例。

```
get_symbols()
```

回傳表中名稱的 `Symbol` 實例串列。

```
get_children()
```

回傳巢狀符號表的串列。

```
class symtable.Function
```

一個函式或方法的命名空間。該類繼承自 `SymbolTable`。

```
get_parameters()
```

回傳一個包含此函式參數名稱的元組 (tuple)。

```
get_locals()
```

回傳一個包含此函式中區域變數 (locals) 名稱的元組。

```
get_globals()
```

回傳一個包含此函式中全域變數 (globals) 名稱的元組。

`get_nonlocals()`

回傳一個包含此函式中明確宣告的非區域變數 (nonlocals) 名稱的元組。

`get_frees()`

回傳一個包含此函式自由 (閉包) 變數 (*free (closure) variables*) 名稱的元組。

`class` `syntable.Class`

一個類 `Class` 的命名空間。該類繼承自 `SymbolTable`。

`get_methods()`

回傳一個包含類 `Class` 中聲明的類似方法之函式名稱的元組。

在這 `Class`，術語「方法 (method)」表示透過 `def` 或 `async def` 在類 `Class` 主體中定義的任何函式。

`get_methods()` 不會取得更深作用域 `Class` 定義的函式 (例如在 `Class` 內部類 `Class` 中)。

舉例來 `Class`：

```
>>> import syntable
>>> st = syntable.syntable('')
... def outer(): pass
...
... class A:
...     def f():
...         def w(): pass
...
...     def g(self): pass
...
...     @classmethod
...     async def h(cls): pass
...
...     global outer
...     def outer(self): pass
...     '', 'test', 'exec')
>>> class_A = st.get_children()[1]
>>> class_A.get_methods()
('f', 'g', 'h')
```

儘管 `A().f()` 會在 runtime 引發 `TypeError`，但 `A.f` 仍然被視 `Class` 類似方法的函式。

`class` `syntable.Symbol`

`SymbolTable` 中的條目對應於來源中的識 `Symbol` 器。建構函式不是公開的。

`get_name()`

回傳符號的名稱。

`is_referenced()`

如果該符號在其區塊中使用，則回傳 `True`。

`is_imported()`

如果符號是從 `import` 陳述式建立的，則回傳 `True`。

`is_parameter()`

如果符號是一個參數，則回傳 `True`。

`is_global()`

如果符號是全域的，則回傳 `True`。

`is_nonlocal()`

如果符號是非區域的，則回傳 `True`。

`is_declared_global()`

如果使用全域陳述式將符號聲明 `Class` 全域的，則回傳 `True`。

**is\_local()**

如果符號是其區塊的區域符號，則回傳 True。

**is\_annotated()**

如果符號有被釋，則回傳 True。

在 3.6 版被加入。

**is\_free()**

如果該符號在其區塊中被參照 (referenced) 但未被賦值 (assigned)，則回傳 True。

**is\_assigned()**

如果該符號被賦值到其區塊中，則回傳 True。

**is\_namespace()**

如果名稱綁定引入 (introduce) 新的命名空間，則回傳 True。

如果名稱用作函式或類陳述式的目標，則這將會是 true。

舉例來：

```
>>> table = symtable.symtable("def some_func(): pass", "string", "exec")
>>> table.lookup("some_func").is_namespace()
True
```

請注意，單個名稱可以綁定到多個物件。如果結果 True，則該名稱也可能被綁定到其他物件，例如 int 或 list，而不會引入新的命名空間。

**get\_namespaces()**

回傳綁定到該名稱的命名空間的串列。

**get\_namespace()**

回傳綁定到該名稱的命名空間。如果該名稱綁定了多個命名空間或有命名空間，則會引發 *ValueError*。

### 33.2.3 命令列用法

在 3.13 版被加入。

`symtable` 模組可以從命令列作本執行。

```
python -m symtable [infile...]
```

指定的 Python 原始檔生符號表轉儲 (dump) 到 stdout。如果未指定輸入檔案，則從 stdin 讀取內容。

## 33.3 token --- 與 Python 剖析樹一起使用的常數

原始碼：[Lib/token.py](#)

This module provides constants which represent the numeric values of leaf nodes of the parse tree (terminal tokens). Refer to the file `Grammar/Tokens` in the Python distribution for the definitions of the names in the context of the language grammar. The specific numeric values which the names map to may change between Python versions.

The module also provides a mapping from numeric codes to names and some functions. The functions mirror definitions in the Python C header files.

`token.tok_name`

Dictionary mapping the numeric values of the constants defined in this module back to name strings, allowing more human-readable representation of parse trees to be generated.

`token.ISTERMINAL` (*x*)

Return `True` for terminal token values.

`token.ISNONTERMINAL` (*x*)

Return `True` for non-terminal token values.

`token.ISEOF` (*x*)

Return `True` if *x* is the marker indicating the end of input.

The token constants are:

`token.ENDMARKER`

`token.NAME`

`token.NUMBER`

`token.STRING`

`token.NEWLINE`

`token.INDENT`

`token.DEDENT`

`token.LPAR`

Token value for "(".

`token.RPAR`

Token value for ")".

`token.LSQB`

Token value for "[".

`token.RSQB`

Token value for "]".

`token.COLON`

Token value for ":".

`token.COMMA`

Token value for ",".

`token.SEMI`

Token value for ";".

`token.PLUS`

Token value for "+".

`token.MINUS`

Token value for "-".

`token.STAR`

Token value for "\*".

`token.SLASH`

Token value for "/".

`token.VBAR`

Token value for "|".

`token.AMPER`

Token value for "&".

`token.LESS`  
Token value for "<".

`token.GREATER`  
Token value for ">".

`token.EQUAL`  
Token value for "=".

`token.DOT`  
Token value for ".".

`token.PERCENT`  
Token value for "%".

`token.LBRACE`  
Token value for "{".

`token.RBRACE`  
Token value for "}".

`token.EQEQUAL`  
Token value for "==".

`token.NOTEQUAL`  
Token value for "!=".

`token.LESSEQUAL`  
Token value for "<=".

`token.GREATEREQUAL`  
Token value for ">=".

`token.TILDE`  
Token value for "~".

`token.CIRCUMFLEX`  
Token value for "^".

`token.LEFTSHIFT`  
Token value for "<<".

`token.RIGHTSHIFT`  
Token value for ">>".

`token.DOUBLESTAR`  
Token value for "\*\*".

`token.PLUSEQUAL`  
Token value for "+=".

`token.MINEQUAL`  
Token value for "-=".

`token.STAREQUAL`  
Token value for "\*=".

`token.SLASHEQUAL`  
Token value for "/=".

`token.PERCENTEQUAL`  
Token value for "%=".

token.**AMPEREQUAL**

Token value for "&=".

token.**VBAREQUAL**

Token value for "|=".

token.**CIRCUMFLEXEQUAL**

Token value for "^=".

token.**LEFTSHIFTEQUAL**

Token value for "<<=".

token.**RIGHTSHIFTEQUAL**

Token value for ">>=".

token.**DOUBLESTAREQUAL**

Token value for "\*\*\*=".

token.**DOUBLES LASH**

Token value for "//".

token.**DOUBLES LASH EQUAL**

Token value for "//=".

token.**AT**

Token value for "@".

token.**ATEQUAL**

Token value for "@=".

token.**RARROW**

Token value for "->".

token.**ELLIPSIS**

Token value for "...".

token.**COLONEQUAL**

Token value for ":=".

token.**EXCLAMATION**

Token value for "!".

token.**OP**

token.**TYPE\_IGNORE**

token.**TYPE\_COMMENT**

token.**SOFT\_KEYWORD**

token.**FSTRING\_START**

token.**FSTRING\_MIDDLE**

token.**FSTRING\_END**

token.**COMMENT**

token.**NL**

token.**ERRORTOKEN**

token.**N\_TOKENS**

`token.NT_OFFSET`

The following token type values aren't used by the C tokenizer but are needed for the `tokenize` module.

`token.COMMENT`

Token value used to indicate a comment.

`token.NL`

Token value used to indicate a non-terminating newline. The `NEWLINE` token indicates the end of a logical line of Python code; `NL` tokens are generated when a logical line of code is continued over multiple physical lines.

`token.ENCODING`

Token value that indicates the encoding used to decode the source bytes into text. The first token returned by `tokenize.tokenize()` will always be an `ENCODING` token.

`token.TYPE_COMMENT`

Token value indicating that a type comment was recognized. Such tokens are only produced when `ast.parse()` is invoked with `type_comments=True`.

`token.EXACT_TOKEN_TYPES`

A dictionary mapping the string representation of a token to its numeric code.

在 3.8 版被加入。

在 3.5 版的變更: Added `AWAIT` and `ASYNC` tokens.

在 3.7 版的變更: Added `COMMENT`, `NL` and `ENCODING` tokens.

在 3.7 版的變更: Removed `AWAIT` and `ASYNC` tokens. "async" and "await" are now tokenized as `NAME` tokens.

在 3.8 版的變更: Added `TYPE_COMMENT`, `TYPE_IGNORE`, `COLONEQUAL`. Added `AWAIT` and `ASYNC` tokens back (they're needed to support parsing older Python versions for `ast.parse()` with `feature_version` set to 6 or lower).

在 3.13 版的變更: Removed `AWAIT` and `ASYNC` tokens again.

## 33.4 keyword --- 檢驗 Python 關鍵字

原始碼: `Lib/keyword.py`

此模組允許 Python 程式確定某個字串是否 是 關鍵字或軟關鍵字 (soft keyword)。

`keyword.iskeyword(s)`

如果 `s` 是一個 Python 關鍵字則回傳 `True`。

`keyword.kwlist`

包含直譯器定義的所有 關鍵字的序列。如果所定義的任何關鍵字僅在特定 `__future__` 陳述式生效時被 用，它們也將被包含在 。

`keyword.issoftkeyword(s)`

如果 `s` 是一個 Python 軟關鍵字則回傳 `True`。

在 3.9 版被加入。

`keyword.softkwlist`

包含直譯器定義的所有 軟關鍵字的序列。如果所定義的任何軟關鍵字僅在特定 `__future__` 陳述式生效時被 用，它們也將被包含在 。

在 3.9 版被加入。

## 33.5 tokenize --- Tokenizer for Python source

原始碼: `Lib/tokenize.py`

The `tokenize` module provides a lexical scanner for Python source code, implemented in Python. The scanner in this module returns comments as tokens as well, making it useful for implementing “pretty-printers”, including colorizers for on-screen displays.

To simplify token stream handling, all operator and delimiter tokens and `Ellipsis` are returned using the generic `OP` token type. The exact type can be determined by checking the `exact_type` property on the `named tuple` returned from `tokenize.tokenize()`.

警告

Note that the functions in this module are only designed to parse syntactically valid Python code (code that does not raise when parsed using `ast.parse()`). The behavior of the functions in this module is **undefined** when providing invalid Python code and it can change at any point.

### 33.5.1 Tokenizing Input

The primary entry point is a *generator*:

`tokenize.tokenize(readline)`

The `tokenize()` generator requires one argument, `readline`, which must be a callable object which provides the same interface as the `io.IOBase.readline()` method of file objects. Each call to the function should return one line of input as bytes.

The generator produces 5-tuples with these members: the token type; the token string; a 2-tuple (`srow`, `scol`) of ints specifying the row and column where the token begins in the source; a 2-tuple (`erow`, `ecol`) of ints specifying the row and column where the token ends in the source; and the line on which the token was found. The line passed (the last tuple item) is the *physical* line. The 5 tuple is returned as a `named tuple` with the field names: `type string start end line`.

The returned `named tuple` has an additional property named `exact_type` that contains the exact operator type for `OP` tokens. For all other token types `exact_type` equals the named tuple `type` field.

在 3.1 版的變更: 新增附名元組 (named tuple) 的支援。

在 3.3 版的變更: 新增 `exact_type` 的支援。

`tokenize()` determines the source encoding of the file by looking for a UTF-8 BOM or encoding cookie, according to [PEP 263](#).

`tokenize.generate_tokens(readline)`

Tokenize a source reading unicode strings instead of bytes.

Like `tokenize()`, the `readline` argument is a callable returning a single line of input. However, `generate_tokens()` expects `readline` to return a str object rather than bytes.

The result is an iterator yielding named tuples, exactly like `tokenize()`. It does not yield an `ENCODING` token.

All constants from the `token` module are also exported from `tokenize`.

Another function is provided to reverse the tokenization process. This is useful for creating tools that tokenize a script, modify the token stream, and write back the modified script.

`tokenize.untokenize(iterable)`

Converts tokens back into Python source code. The `iterable` must return sequences with at least two elements, the token type and the token string. Any additional sequence elements are ignored.

The result is guaranteed to tokenize back to match the input so that the conversion is lossless and round-trips are assured. The guarantee applies only to the token type and token string as the spacing between tokens (column positions) may change.

It returns bytes, encoded using the `ENCODING` token, which is the first token sequence output by `tokenize()`. If there is no encoding token in the input, it returns a str instead.

`tokenize()` needs to detect the encoding of source files it tokenizes. The function it uses to do this is available:

`tokenize.detect_encoding(readline)`

The `detect_encoding()` function is used to detect the encoding that should be used to decode a Python source file. It requires one argument, `readline`, in the same way as the `tokenize()` generator.

It will call `readline` a maximum of twice, and return the encoding used (as a string) and a list of any lines (not decoded from bytes) it has read in.

It detects the encoding from the presence of a UTF-8 BOM or an encoding cookie as specified in [PEP 263](#). If both a BOM and a cookie are present, but disagree, a `SyntaxError` will be raised. Note that if the BOM is found, `'utf-8-sig'` will be returned as an encoding.

If no encoding is specified, then the default of `'utf-8'` will be returned.

Use `open()` to open Python source files: it uses `detect_encoding()` to detect the file encoding.

`tokenize.open(filename)`

Open a file in read only mode using the encoding detected by `detect_encoding()`.

在 3.2 版被加入。

**exception** `tokenize.TokenError`

Raised when either a docstring or expression that may be split over several lines is not completed anywhere in the file, for example:

```
"""Beginning of
docstring
```

或是：

```
[1,
 2,
 3
```

### 33.5.2 Command-Line Usage

在 3.3 版被加入。

The `tokenize` module can be executed as a script from the command line. It is as simple as:

```
python -m tokenize [-e] [filename.py]
```

The following options are accepted:

**-h, --help**

show this help message and exit

**-e, --exact**

display token names using the exact type

If `filename.py` is specified its contents are tokenized to stdout. Otherwise, tokenization is performed on stdin.

### 33.5.3 范例

Example of a script rewriter that transforms float literals into Decimal objects:

```

from tokenize import tokenize, untokenize, NUMBER, STRING, NAME, OP
from io import BytesIO

def decistmt(s):
    """Substitute Decimals for floats in a string of statements.

    >>> from decimal import Decimal
    >>> s = 'print(+21.3e-5*-.1234/81.7)'
    >>> decistmt(s)
    "print (+Decimal ('21.3e-5')*-Decimal ('.1234')/Decimal ('81.7'))"

    The format of the exponent is inherited from the platform C library.
    Known cases are "e-007" (Windows) and "e-07" (not Windows). Since
    we're only showing 12 digits, and the 13th isn't close to 5, the
    rest of the output should be platform-independent.

    >>> exec(s) #doctest: +ELLIPSIS
    -3.21716034272e-0...7

    Output from calculations with Decimal should be identical across all
    platforms.

    >>> exec(decistmt(s))
    -3.217160342717258261933904529E-7
    """
    result = []
    g = tokenize(BytesIO(s.encode('utf-8')).readline) # tokenize the string
    for toknum, tokval, _, _, _ in g:
        if toknum == NUMBER and '.' in tokval: # replace NUMBER tokens
            result.extend([
                (NAME, 'Decimal'),
                (OP, '('),
                (STRING, repr(tokval)),
                (OP, ')')
            ])
        else:
            result.append((toknum, tokval))
    return untokenize(result).decode('utf-8')

```

Example of tokenizing from the command line. The script:

```

def say_hello():
    print("Hello, World!")

say_hello()

```

will be tokenized to the following output where the first column is the range of the line/column coordinates where the token is found, the second column is the name of the token, and the final column is the value of the token (if any)

```

$ python -m tokenize hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME          'def'
1,4-1,13:     NAME          'say_hello'
1,13-1,14:    OP            '('
1,14-1,15:    OP            ')'
1,15-1,16:    OP            ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT       '    '
2,4-2,9:      NAME          'print'

```

(繼續下一頁)

(繼續上一頁)

```

2,9-2,10:      OP           '('
2,10-2,25:     STRING        '"Hello, World!'"
2,25-2,26:     OP           ')'
2,26-2,27:     NEWLINE      '\n'
3,0-3,1:       NL           '\n'
4,0-4,0:       DEDENT       ''
4,0-4,9:       NAME         'say_hello'
4,9-4,10:      OP           '('
4,10-4,11:     OP           ')'
4,11-4,12:     NEWLINE      '\n'
5,0-5,0:       ENDMARKER   ''

```

The exact token type names can be displayed using the `-e` option:

```

$ python -m tokenize -e hello.py
0,0-0,0:      ENCODING      'utf-8'
1,0-1,3:      NAME         'def'
1,4-1,13:     NAME         'say_hello'
1,13-1,14:    LPAR         '('
1,14-1,15:    RPAR         ')'
1,15-1,16:    COLON        ':'
1,16-1,17:    NEWLINE      '\n'
2,0-2,4:      INDENT       '    '
2,4-2,9:      NAME         'print'
2,9-2,10:     LPAR         '('
2,10-2,25:    STRING        '"Hello, World!'"
2,25-2,26:    RPAR         ')'
2,26-2,27:    NEWLINE      '\n'
3,0-3,1:      NL           '\n'
4,0-4,0:      DEDENT       ''
4,0-4,9:      NAME         'say_hello'
4,9-4,10:     LPAR         '('
4,10-4,11:    RPAR         ')'
4,11-4,12:    NEWLINE      '\n'
5,0-5,0:      ENDMARKER   ''

```

Example of tokenizing a file programmatically, reading unicode strings instead of bytes with `generate_tokens()`:

```

import tokenize

with tokenize.open('hello.py') as f:
    tokens = tokenize.generate_tokens(f.readline)
    for token in tokens:
        print(token)

```

Or reading bytes directly with `tokenize()`:

```

import tokenize

with open('hello.py', 'rb') as f:
    tokens = tokenize.tokenize(f.readline)
    for token in tokens:
        print(token)

```

## 33.6 tabnanny --- 偵測不良縮排

原始碼: `Lib/tabnanny.py`

目前現 是此模組打算以 本方式被呼叫使用，但也可以將其引入於 IDE 中 使用下方 述的 `check()` 函式。

#### 備

此模組所提供的 API 很有可能會在未來的發 版本中有所變更，且有可能不具有向後相容性。

`tabnanny.check(file_or_dir)`

如果 `file_or_dir` 是個目 且 非符號鏈接 (symbolic link)，則會遞 地在名 `file_or_dir` 的目 樹 (directory tree) 中不斷下行檢查所有 `.py` 檔案。如果 `file_or_dir` 是個一般 Python 原始檔案，則 其檢查空格相關問題。診斷訊息會以 `print()` 函式輸出至標準輸出 (standard output) 當中。

`tabnanny.verbose`

標示是否要印出詳細訊息 (verbose message) 的旗標，若是以 本方式呼叫的話則可以用 `-v` 選項來增加。

`tabnanny.filename_only`

標示是否要只印出那些有空白相關問題檔案之檔名的旗標，若是以 本方式呼叫的話則可以用 `-q` 選項來設 真值。

**exception** `tabnanny.NannyNag`

當偵測到不良縮排時，此例外會被 `process_tokens()` 引發，會在 `check()` 中捕獲與處理。

`tabnanny.process_tokens(tokens)`

此函式被 `check()` 用來處理由 `tokenize` 生的標記 (token)。

#### 也參考

`tokenize` 模組

Python 原始程式碼的詞 掃描器 (lexical scanner)。

## 33.7 pyc1br --- Python 模組 覽器支援

原始碼：Lib/pyc1br.py

The `pyc1br` module provides limited information about the functions, classes, and methods defined in a Python-coded module. The information is sufficient to implement a module browser. The information is extracted from the Python source code rather than by importing the module, so this module is safe to use with untrusted code. This restriction makes it impossible to use this module with modules not implemented in Python, including all standard and optional extension modules.

`pyc1br.readmodule(module, path=None)`

Return a dictionary mapping module-level class names to class descriptors. If possible, descriptors for imported base classes are included. Parameter `module` is a string with the name of the module to read; it may be the name of a module within a package. If given, `path` is a sequence of directory paths prepended to `sys.path`, which is used to locate the module source code.

This function is the original interface and is only kept for back compatibility. It returns a filtered version of the following.

`pyc1br.readmodule_ex(module, path=None)`

Return a dictionary-based tree containing a function or class descriptors for each function and class defined in the module with a `def` or `class` statement. The returned dictionary maps module-level function and class names to their descriptors. Nested objects are entered into the children dictionary of their parent. As with `readmodule`, `module` names the module to be read and `path` is prepended to `sys.path`. If the module being read

is a package, the returned dictionary has a key '`__path__`' whose value is a list containing the package search path.

在 3.7 版被加入: Descriptors for nested definitions. They are accessed through the new `children` attribute. Each has a new `parent` attribute.

The descriptors returned by these functions are instances of `Function` and `Class` classes. Users are not expected to create instances of these classes.

### 33.7.1 函式物件

**class** `pyclbr.Function`

Class `Function` instances describe functions defined by `def` statements. They have the following attributes:

**file**

Name of the file in which the function is defined.

**module**

The name of the module defining the function described.

**name**

The name of the function.

**lineno**

The line number in the file where the definition starts.

**parent**

For top-level functions, `None`. For nested functions, the parent.

在 3.7 版被加入.

**children**

A *dictionary* mapping names to descriptors for nested functions and classes.

在 3.7 版被加入.

**is\_async**

`True` for functions that are defined with the `async` prefix, `False` otherwise.

在 3.10 版被加入.

### 33.7.2 Class Objects

**class** `pyclbr.Class`

Class `Class` instances describe classes defined by class statements. They have the same attributes as *Functions* and two more.

**file**

Name of the file in which the class is defined.

**module**

The name of the module defining the class described.

**name**

The name of the class.

**lineno**

The line number in the file where the definition starts.

**parent**

For top-level classes, `None`. For nested classes, the parent.

在 3.7 版被加入.

**children**

A dictionary mapping names to descriptors for nested functions and classes.

在 3.7 版被加入。

**super**

A list of `Class` objects which describe the immediate base classes of the class being described. Classes which are named as superclasses but which are not discoverable by `readmodule_ex()` are listed as a string with the class name instead of as `Class` objects.

**methods**

A *dictionary* mapping method names to line numbers. This can be derived from the newer `children` dictionary, but remains for back-compatibility.

## 33.8 py\_compile — 編譯 Python 來源檔案

原始碼: `Lib/py_compile.py`

The `py_compile` module provides a function to generate a byte-code file from a source file, and another function used when the module source file is invoked as a script.

Though not often needed, this function can be useful when installing modules for shared use, especially if some of the users may not have permission to write the byte-code cache files in the directory containing the source code.

**exception** `py_compile.PyCompileError`

Exception raised when an error occurs while attempting to compile the file.

`py_compile.compile(file, cfile=None, dfile=None, doraise=False, optimize=-1, invalidation_mode=PycInvalidationMode.TIMESTAMP, quiet=0)`

Compile a source file to byte-code and write out the byte-code cache file. The source code is loaded from the file named `file`. The byte-code is written to `cfile`, which defaults to the [PEP 3147/PEP 488](#) path, ending in `.pyc`. For example, if `file` is `/foo/bar/baz.py` `cfile` will default to `/foo/bar/__pycache__/baz.cpython-32.pyc` for Python 3.2. If `dfile` is specified, it is used instead of `file` as the name of the source file from which source lines are obtained for display in exception tracebacks. If `doraise` is true, a `PyCompileError` is raised when an error is encountered while compiling `file`. If `doraise` is false (the default), an error string is written to `sys.stderr`, but no exception is raised. This function returns the path to byte-compiled file, i.e. whatever `cfile` value was used.

The `doraise` and `quiet` arguments determine how errors are handled while compiling file. If `quiet` is 0 or 1, and `doraise` is false, the default behaviour is enabled: an error string is written to `sys.stderr`, and the function returns `None` instead of a path. If `doraise` is true, a `PyCompileError` is raised instead. However if `quiet` is 2, no message is written, and `doraise` has no effect.

If the path that `cfile` becomes (either explicitly specified or computed) is a symlink or non-regular file, `FileExistsError` will be raised. This is to act as a warning that import will turn those paths into regular files if it is allowed to write byte-compiled files to those paths. This is a side-effect of import using file renaming to place the final byte-compiled file into place to prevent concurrent file writing issues.

`optimize` controls the optimization level and is passed to the built-in `compile()` function. The default of `-1` selects the optimization level of the current interpreter.

`invalidation_mode` should be a member of the `PycInvalidationMode` enum and controls how the generated bytecode cache is invalidated at runtime. The default is `PycInvalidationMode.CHECKED_HASH` if the `SOURCE_DATE_EPOCH` environment variable is set, otherwise the default is `PycInvalidationMode.TIMESTAMP`.

在 3.2 版的變更: Changed default value of `cfile` to be [PEP 3147](#)-compliant. Previous default was `file + '.c'` ('o' if optimization was enabled). Also added the `optimize` parameter.

在 3.4 版的變更: Changed code to use `importlib` for the byte-code cache file writing. This means file creation/writing semantics now match what `importlib` does, e.g. permissions, write-and-move semantics, etc. Also added the caveat that `FileExistsError` is raised if `cfile` is a symlink or non-regular file.

在 3.7 版的變更: The `invalidation_mode` parameter was added as specified in [PEP 552](#). If the `SOURCE_DATE_EPOCH` environment variable is set, `invalidation_mode` will be forced to `PycInvalidationMode.CHECKED_HASH`.

在 3.7.2 版的變更: The `SOURCE_DATE_EPOCH` environment variable no longer overrides the value of the `invalidation_mode` argument, and determines its default value instead.

在 3.8 版的變更: 新增 `quiet` 參數。

**class** `py_compile.PycInvalidationMode`

An enumeration of possible methods the interpreter can use to determine whether a bytecode file is up to date with a source file. The `.pyc` file indicates the desired invalidation mode in its header. See `pyc-invalidation` for more information on how Python invalidates `.pyc` files at runtime.

在 3.7 版被加入.

#### **TIMESTAMP**

The `.pyc` file includes the timestamp and size of the source file, which Python will compare against the metadata of the source file at runtime to determine if the `.pyc` file needs to be regenerated.

#### **CHECKED\_HASH**

The `.pyc` file includes a hash of the source file content, which Python will compare against the source at runtime to determine if the `.pyc` file needs to be regenerated.

#### **UNCHECKED\_HASH**

Like `CHECKED_HASH`, the `.pyc` file includes a hash of the source file content. However, Python will at runtime assume the `.pyc` file is up to date and not validate the `.pyc` against the source file at all.

This option is useful when the `.pycs` are kept up to date by some system external to Python like a build system.

## 33.8.1 Command-Line Interface

This module can be invoked as a script to compile several source files. The files named in `filenames` are compiled and the resulting bytecode is cached in the normal manner. This program does not search a directory structure to locate source files; it only compiles files named explicitly. The exit status is nonzero if one of the files could not be compiled.

```
<file> ... <fileN>
```

```
-
```

Positional arguments are files to compile. If `-` is the only parameter, the list of files is taken from standard input.

```
-q, --quiet
```

Suppress errors output.

在 3.2 版的變更: 新增對 `-` 的支援。

在 3.10 版的變更: 新增對 `-q` 的支援。

### 也參考

`compileall` 模組

Utilities to compile all Python source files in a directory tree.

## 33.9 compileall --- 位元組編譯 Python 函式庫

原始碼: [Lib/compileall.py](#)

This module provides some utility functions to support installing Python libraries. These functions compile Python source files in a directory tree. This module can be used to create the cached byte-code files at library installation time, which makes them available for use even by users who don't have write permission to the library directories.

適用: not WASI.

此模組在 WebAssembly 平台上不起作用或無法使用。更多資訊請參 [F](#) [WebAssembly](#) 平台。

### 33.9.1 Command-line use

This module can work as a script (using `python -m compileall`) to compile Python sources.

`directory ...`

`file ...`

Positional arguments are files to compile or directories that contain source files, traversed recursively. If no argument is given, behave as if the command line was `-l <directories from sys.path>`.

`-l`

Do not recurse into subdirectories, only compile source code files directly contained in the named or implied directories.

`-f`

Force rebuild even if timestamps are up-to-date.

`-q`

Do not print the list of files compiled. If passed once, error messages will still be printed. If passed twice (`-qq`), all output is suppressed.

`-d destdir`

Directory prepended to the path to each file being compiled. This will appear in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

`-s strip_prefix`

`-p prepend_prefix`

Remove (`-s`) or append (`-p`) the given prefix of paths recorded in the `.pyc` files. Cannot be combined with `-d`.

`-x regex`

`regex` is used to search the full path to each file considered for compilation, and if the regex produces a match, the file is skipped.

`-i list`

Read the file `list` and add each line that it contains to the list of files and directories to compile. If `list` is `-`, read lines from `stdin`.

`-b`

Write the byte-code files to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

`-r`

Control the maximum recursion level for subdirectories. If this is given, then `-l` option will not be taken into account. `python -m compileall <directory> -r 0` is equivalent to `python -m compileall <directory> -l`.

`-j N`

Use *N* workers to compile the files within the given directory. If 0 is used, then the result of `os.process_cpu_count()` will be used.

`--invalidation-mode [timestamp|checked-hash|unchecked-hash]`

Control how the generated byte-code files are invalidated at runtime. The `timestamp` value, means that `.pyc` files with the source timestamp and size embedded will be generated. The `checked-hash` and `unchecked-hash` values cause hash-based pycs to be generated. Hash-based pycs embed a hash of the source file contents rather than a timestamp. See `pyc-invalidation` for more information on how Python validates bytecode cache files at runtime. The default is `timestamp` if the `SOURCE_DATE_EPOCH` environment variable is not set, and `checked-hash` if the `SOURCE_DATE_EPOCH` environment variable is set.

`-o level`

Compile with the given optimization level. May be used multiple times to compile for multiple levels at a time (for example, `compileall -o 1 -o 2`).

`-e dir`

Ignore symlinks pointing outside the given directory.

`--hardlink-dupes`

If two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版的變更: 新增選項 `-i`、`-b` 與 `-h`。

在 3.5 版的變更: Added the `-j`, `-r`, and `-qq` options. `-q` option was changed to a multilevel value. `-b` will always produce a byte-code file ending in `.pyc`, never `.pyo`.

在 3.7 版的變更: 新增選項 `--invalidation-mode`。

在 3.9 版的變更: Added the `-s`, `-p`, `-e` and `--hardlink-dupes` options. Raised the default recursion limit from 10 to `sys.getrecursionlimit()`. Added the possibility to specify the `-o` option multiple times.

There is no command-line option to control the optimization level used by the `compile()` function, because the Python interpreter itself already provides the option: `python -O -m compileall`.

Similarly, the `compile()` function respects the `sys.pycache_prefix` setting. The generated bytecode cache will only be useful if `compile()` is run with the same `sys.pycache_prefix` (if any) that will be used at runtime.

## 33.9.2 Public functions

`compileall.compile_dir` (*dir*, *maxlevels*=`sys.getrecursionlimit()`, *ddir*=`None`, *force*=`False`, *rx*=`None`, *quiet*=`0`, *legacy*=`False`, *optimize*=`-1`, *workers*=`1`, *invalidation\_mode*=`None`, \*, *stripdir*=`None`, *prependdir*=`None`, *limit\_sl\_dest*=`None`, *hardlink\_dupes*=`False`)

Recursively descend the directory tree named by *dir*, compiling all `.py` files along the way. Return a true value if all the files compiled successfully, and a false value otherwise.

The *maxlevels* parameter is used to limit the depth of the recursion; it defaults to `sys.getrecursionlimit()`.

If *ddir* is given, it is prepended to the path to each file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *force* is true, modules are re-compiled even if the timestamps are up to date.

If *rx* is given, its `search` method is called on the complete path to each file considered for compilation, and if it returns a true value, the file is skipped. This can be used to exclude files matching a regular expression, given as a `re.Pattern` object.

If *quiet* is `False` or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

The argument *workers* specifies how many workers are used to compile files in parallel. The default is to not use multiple workers. If the platform can't use multiple workers and *workers* argument is given, then sequential compilation will be used as a fallback. If *workers* is 0, the number of cores in the system is used. If *workers* is lower than 0, a `ValueError` will be raised.

*invalidation\_mode* should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit\_sl\_dest* arguments correspond to the `-s`, `-p` and `-e` options described above. They may be specified as `str` or `os.PathLike`.

If *hardlink\_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版的變更: 新增 *legacy* 與 *optimize* 參數。

在 3.5 版的變更: 新增 *workers* 參數。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.6 版的變更: Accepts a *path-like object*.

在 3.7 版的變更: 新增 *invalidation\_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation\_mode* 參數的預設值被更新 `None`。

在 3.8 版的變更: Setting *workers* to 0 now chooses the optimal number of cores.

在 3.9 版的變更: Added *stripdir*, *prependdir*, *limit\_sl\_dest* and *hardlink\_dupes* arguments. Default value of *maxlevels* was changed from 10 to `sys.getrecursionlimit()`

```
compileall.compile_file(fullname, ddir=None, force=False, rx=None, quiet=0, legacy=False, optimize=-1,
                        invalidation_mode=None, *, stripdir=None, prependdir=None, limit_sl_dest=None,
                        hardlink_dupes=False)
```

Compile the file with path *fullname*. Return a true value if the file compiled successfully, and a false value otherwise.

If *ddir* is given, it is prepended to the path to the file being compiled for use in compilation time tracebacks, and is also compiled in to the byte-code file, where it will be used in tracebacks and other messages in cases where the source file does not exist at the time the byte-code file is executed.

If *rx* is given, its `search` method is passed the full path name to the file being compiled, and if it returns a true value, the file is not compiled and `True` is returned. This can be used to exclude files matching a regular expression, given as a `re.Pattern` object.

If *quiet* is `False` or 0 (the default), the filenames and other information are printed to standard out. Set to 1, only errors are printed. Set to 2, all output is suppressed.

If *legacy* is true, byte-code files are written to their legacy locations and names, which may overwrite byte-code files created by another version of Python. The default is to write files to their [PEP 3147](#) locations and names, which allows byte-code files from multiple versions of Python to coexist.

*optimize* specifies the optimization level for the compiler. It is passed to the built-in `compile()` function. Accepts also a sequence of optimization levels which lead to multiple compilations of one `.py` file in one call.

*invalidation\_mode* should be a member of the `py_compile.PycInvalidationMode` enum and controls how the generated pycs are invalidated at runtime.

The *stripdir*, *prependdir* and *limit\_sl\_dest* arguments correspond to the *-s*, *-p* and *-e* options described above. They may be specified as `str` or `os.PathLike`.

If *hardlink\_dupes* is true and two `.pyc` files with different optimization level have the same content, use hard links to consolidate duplicate files.

在 3.2 版被加入。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.7 版的變更: 新增 *invalidation\_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation\_mode* 參數的預設值被更新  `None`。

在 3.9 版的變更: Added *stripdir*, *prependdir*, *limit\_sl\_dest* and *hardlink\_dupes* arguments.

```
compileall.compile_path(skip_curdir=True, maxlevels=0, force=False, quiet=0, legacy=False, optimize=-1,
                        invalidation_mode=None)
```

Byte-compile all the `.py` files found along `sys.path`. Return a true value if all the files compiled successfully, and a false value otherwise.

If *skip\_curdir* is true (the default), the current directory is not included in the search. All other parameters are passed to the `compile_dir()` function. Note that unlike the other compile functions, `maxlevels` defaults to 0.

在 3.2 版的變更: 新增 *legacy* 與 *optimize* 參數。

在 3.5 版的變更: *quiet* parameter was changed to a multilevel value.

在 3.5 版的變更: The *legacy* parameter only writes out `.pyc` files, not `.pyo` files no matter what the value of *optimize* is.

在 3.7 版的變更: 新增 *invalidation\_mode* 參數。

在 3.7.2 版的變更: 新增 *invalidation\_mode* 參數的預設值被更新  `None`。

To force a recompile of all the `.py` files in the `Lib/` subdirectory and all its subdirectories:

```
import compileall

compileall.compile_dir('Lib/', force=True)

# Perform same compilation, excluding files in .svn directories.
import re
compileall.compile_dir('Lib/', rx=re.compile(r'[/\\][.]svn'), force=True)

# pathlib.Path objects can also be used.
import pathlib
compileall.compile_dir(pathlib.Path('Lib/'), force=True)
```

### 也參考

#### `py_compile` 模組

Byte-compile a single source file.

## 33.10 `dis` --- Python bytecode 的反組譯器

原始碼: `Lib/dis.py`

`dis` 模組支援反組譯分析 CPython *bytecode*。CPython *bytecode* 作輸入的模組被定義於 `Include/opcode.h` 且被編譯器和直譯器所使用。

**CPython 實作細節：** Bytecode is an implementation detail of the CPython interpreter. No guarantees are made that bytecode will not be added, removed, or changed between versions of Python. Use of this module should not be considered to work across Python VMs or Python releases.

在 3.6 版的變更: Use 2 bytes for each instruction. Previously the number of bytes varied by instruction.

在 3.10 版的變更: The argument of `jump`, `exception handling` and `loop instructions` is now the instruction offset rather than the byte offset.

在 3.11 版的變更: Some instructions are accompanied by one or more inline cache entries, which take the form of `CACHE` instructions. These instructions are hidden by default, but can be shown by passing `show_caches=True` to any `dis` utility. Furthermore, the interpreter now adapts the bytecode to specialize it for different runtime conditions. The adaptive bytecode can be shown by passing `adaptive=True`.

在 3.12 版的變更: The argument of a `jump` is the offset of the target instruction relative to the instruction that appears immediately after the `jump` instruction's `CACHE` entries.

As a consequence, the presence of the `CACHE` instructions is transparent for forward jumps but needs to be taken into account when reasoning about backward jumps.

在 3.13 版的變更: The output shows logical labels rather than instruction offsets for jump targets and exception handlers. The `-O` command line option and the `show_offsets` argument were added.

Example: Given the function `myfunc()`:

```
def myfunc(alist):
    return len(alist)
```

the following command can be used to display the disassembly of `myfunc()`:

```
>>> dis.dis(myfunc)
2          RESUME                0

3          LOAD_GLOBAL           1 (len + NULL)
          LOAD_FAST              0 (alist)
          CALL                   1
          RETURN_VALUE
```

(The "2" is a line number).

### 33.10.1 Command-line interface

The `dis` module can be invoked as a script from the command line:

```
python -m dis [-h] [-C] [-O] [infile]
```

The following options are accepted:

**-h, --help**  
Display usage and exit.

**-C, --show-caches**  
Show inline caches.  
在 3.13 版被加入。

**-O, --show-offsets**  
Show offsets of instructions.  
在 3.13 版被加入。

If `infile` is specified, its disassembled code will be written to stdout. Otherwise, disassembly is performed on compiled source code received from stdin.

### 33.10.2 Bytecode analysis

在 3.4 版被加入。

The bytecode analysis API allows pieces of Python code to be wrapped in a *Bytecode* object that provides easy access to details of the compiled code.

```
class dis.Bytecode(x, *, first_line=None, current_offset=None, show_caches=False, adaptive=False,
                    show_offsets=False)
```

Analyse the bytecode corresponding to a function, generator, asynchronous generator, coroutine, method, string of source code, or a code object (as returned by *compile()*).

This is a convenience wrapper around many of the functions listed below, most notably *get\_instructions()*, as iterating over a *Bytecode* instance yields the bytecode operations as *Instruction* instances.

If *first\_line* is not *None*, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

If *current\_offset* is not *None*, it refers to an instruction offset in the disassembled code. Setting this means *dis()* will display a "current instruction" marker against the specified opcode.

If *show\_caches* is *True*, *dis()* will display inline cache entries used by the interpreter to specialize the bytecode.

If *adaptive* is *True*, *dis()* will display specialized bytecode that may be different from the original bytecode.

If *show\_offsets* is *True*, *dis()* will include instruction offsets in the output.

```
classmethod from_traceback(tb, *, show_caches=False)
```

Construct a *Bytecode* instance from the given traceback, setting *current\_offset* to the instruction responsible for the exception.

**codeobj**

The compiled code object.

**first\_line**

The first source line of the code object (if available)

**dis()**

Return a formatted view of the bytecode operations (the same as printed by *dis.dis()*, but returned as a multi-line string).

**info()**

Return a formatted multi-line string with detailed information about the code object, like *code\_info()*.

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

在 3.11 版的變更: 新增 *show\_caches* 與 *adaptive* 參數。

範例:

```
>>> bytecode = dis.Bytecode(myfunc)
>>> for instr in bytecode:
...     print(instr.opname)
...
RESUME
LOAD_GLOBAL
LOAD_FAST
CALL
RETURN_VALUE
```

### 33.10.3 Analysis functions

The `dis` module also defines the following analysis functions that convert the input directly to the desired output. They can be useful if only a single operation is being performed, so the intermediate analysis object isn't useful:

`dis.code_info(x)`

Return a formatted multi-line string with detailed code object information for the supplied function, generator, asynchronous generator, coroutine, method, source code string or code object.

Note that the exact contents of code info strings are highly implementation dependent and they may change arbitrarily across Python VMs or Python releases.

在 3.2 版被加入。

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

`dis.show_code(x, *, file=None)`

Print detailed code object information for the supplied function, method, source code string or code object to `file` (or `sys.stdout` if `file` is not specified).

This is a convenient shorthand for `print(code_info(x), file=file)`, intended for interactive exploration at the interpreter prompt.

在 3.2 版被加入。

在 3.4 版的變更: 新增 `file` 參數。

`dis.dis(x=None, *, file=None, depth=None, show_caches=False, adaptive=False)`

Disassemble the `x` object. `x` can denote either a module, a class, a method, a function, a generator, an asynchronous generator, a coroutine, a code object, a string of source code or a byte sequence of raw bytecode. For a module, it disassembles all functions. For a class, it disassembles all methods (including class and static methods). For a code object or sequence of raw bytecode, it prints one line per bytecode instruction. It also recursively disassembles nested code objects. These can include generator expressions, nested functions, the bodies of nested classes, and the code objects used for annotation scopes. Strings are first compiled to code objects with the `compile()` built-in function before being disassembled. If no object is provided, this function disassembles the last traceback.

The disassembly is written as text to the supplied `file` argument if provided and to `sys.stdout` otherwise.

The maximal depth of recursion is limited by `depth` unless it is `None`. `depth=0` means no recursion.

If `show_caches` is `True`, this function will display inline cache entries used by the interpreter to specialize the bytecode.

If `adaptive` is `True`, this function will display specialized bytecode that may be different from the original bytecode.

在 3.4 版的變更: 新增 `file` 參數。

在 3.7 版的變更: Implemented recursive disassembling and added `depth` parameter.

在 3.7 版的變更: This can now handle coroutine and asynchronous generator objects.

在 3.11 版的變更: 新增 `show_caches` 與 `adaptive` 參數。

`distb(tb=None, *, file=None, show_caches=False, adaptive=False, show_offset=False)`

Disassemble the top-of-stack function of a traceback, using the last traceback if none was passed. The instruction causing the exception is indicated.

The disassembly is written as text to the supplied `file` argument if provided and to `sys.stdout` otherwise.

在 3.4 版的變更: 新增 `file` 參數。

在 3.11 版的變更: 新增 `show_caches` 與 `adaptive` 參數。

在 3.13 版的變更: 新增 `show_offsets` 參數。

`dis.disassemble(code, lasti=-1, *, file=None, show_caches=False, adaptive=False)`

`disco(code, lasti=-1, *, file=None, show_caches=False, adaptive=False, show_offsets=False)`

Disassemble a code object, indicating the last instruction if *lasti* was provided. The output is divided in the following columns:

1. the line number, for the first instruction of each line
2. the current instruction, indicated as `-->`,
3. a labelled instruction, indicated with `>>`,
4. the address of the instruction,
5. the operation code name,
6. operation parameters, and
7. interpretation of the parameters in parentheses.

The parameter interpretation recognizes local and global variable names, constant values, branch targets, and compare operators.

The disassembly is written as text to the supplied *file* argument if provided and to `sys.stdout` otherwise.

在 3.4 版的變更: 新增 *file* 參數。

在 3.11 版的變更: 新增 *show\_caches* 與 *adaptive* 參數。

在 3.13 版的變更: 新增 *show\_offsets* 參數。

`dis.get_instructions(x, *, first_line=None, show_caches=False, adaptive=False)`

Return an iterator over the instructions in the supplied function, method, source code string or code object.

The iterator generates a series of *Instruction* named tuples giving the details of each operation in the supplied code.

If *first\_line* is not `None`, it indicates the line number that should be reported for the first source line in the disassembled code. Otherwise, the source line information (if any) is taken directly from the disassembled code object.

The *adaptive* parameter works as it does in `dis()`.

在 3.4 版被加入。

在 3.11 版的變更: 新增 *show\_caches* 與 *adaptive* 參數。

在 3.13 版的變更: The *show\_caches* parameter is deprecated and has no effect. The iterator generates the *Instruction* instances with the *cache\_info* field populated (regardless of the value of *show\_caches*) and it no longer generates separate items for the cache entries.

`dis.findlinestarts(code)`

This generator function uses the `co_lines()` method of the code object *code* to find the offsets which are starts of lines in the source code. They are generated as `(offset, lineno)` pairs.

在 3.6 版的變更: Line numbers can be decreasing. Before, they were always increasing.

在 3.10 版的變更: The [PEP 626](#) `co_lines()` method is used instead of the `co_firstlineno` and `co_notab` attributes of the code object.

在 3.13 版的變更: Line numbers can be `None` for bytecode that does not map to source lines.

`dis.findlabels(code)`

Detect all offsets in the raw compiled bytecode string *code* which are jump targets, and return a list of these offsets.

`dis.stack_effect (opcode, oparg=None, *, jump=None)`

Compute the stack effect of *opcode* with argument *oparg*.

If the code has a jump target and *jump* is `True`, `stack_effect()` will return the stack effect of jumping. If *jump* is `False`, it will return the stack effect of not jumping. And if *jump* is `None` (default), it will return the maximal stack effect of both cases.

在 3.4 版被加入。

在 3.8 版的變更: 新增 *jump* 參數。

在 3.13 版的變更: If *oparg* is omitted (or `None`), the stack effect is now returned for *oparg*=0. Previously this was an error for opcodes that use their arg. It is also no longer an error to pass an integer *oparg* when the *opcode* does not use it; the *oparg* in this case is ignored.

### 33.10.4 Python Bytecode Instructions

The `get_instructions()` function and `Bytecode` class provide details of bytecode instructions as `Instruction` instances:

**class** `dis.Instruction`

Details for a bytecode operation

**opcode**

numeric code for operation, corresponding to the opcode values listed below and the bytecode values in the *Opcode collections*.

**opname**

human readable name for operation

**baseopcode**

numeric code for the base operation if operation is specialized; otherwise equal to *opcode*

**baseopname**

human readable name for the base operation if operation is specialized; otherwise equal to *opname*

**arg**

numeric argument to operation (if any), otherwise `None`

**oparg**

alias for *arg*

**argval**

resolved arg value (if any), otherwise `None`

**argrepr**

human readable description of operation argument (if any), otherwise an empty string.

**offset**

start index of operation within bytecode sequence

**start\_offset**

start index of operation within bytecode sequence, including prefixed `EXTENDED_ARG` operations if present; otherwise equal to *offset*

**cache\_offset**

start index of the cache entries following the operation

**end\_offset**

end index of the cache entries following the operation

**starts\_line**

`True` if this opcode starts a source line, otherwise `False`

**line\_number**

source line number associated with this opcode (if any), otherwise `None`

**is\_jump\_target**

True if other code jumps to here, otherwise `False`

**jump\_target**

bytecode index of the jump target if this is a jump operation, otherwise `None`

**positions**

`dis.Positions` object holding the start and end locations that are covered by this instruction.

在 3.4 版被加入.

在 3.11 版的變更: Field `positions` is added.

在 3.13 版的變更: Changed field `starts_line`.

Added fields `start_offset`, `cache_offset`, `end_offset`, `baseopname`, `baseopcode`, `jump_target`, `oparg`, `line_number` and `cache_info`.

**class** `dis.Positions`

In case the information is not available, some fields might be `None`.

**lineno****end\_lineno****col\_offset****end\_col\_offset**

在 3.11 版被加入.

The Python compiler currently generates the following bytecode instructions.

**General instructions**

In the following, We will refer to the interpreter stack as `STACK` and describe operations on it as if it was a Python list. The top of the stack corresponds to `STACK[-1]` in this language.

**NOP**

Do nothing code. Used as a placeholder by the bytecode optimizer, and to generate line tracing events.

**POP\_TOP**

Removes the top-of-stack item:

```
STACK.pop()
```

**END\_FOR**

Removes the top-of-stack item. Equivalent to `POP_TOP`. Used to clean up at the end of loops, hence the name.

在 3.12 版被加入.

**END\_SEND**

Implements `del STACK[-2]`. Used to clean up when a generator exits.

在 3.12 版被加入.

**COPY** (*i*)

Push the *i*-th item to the top of the stack without removing it from its original location:

```
assert i > 0
STACK.append(STACK[-i])
```

在 3.11 版被加入.

**SWAP** (*i*)

Swap the top of the stack with the *i*-th element:

```
STACK[-i], STACK[-1] = STACK[-1], STACK[-i]
```

在 3.11 版被加入。

**CACHE**

Rather than being an actual instruction, this opcode is used to mark extra space for the interpreter to cache useful data directly in the bytecode itself. It is automatically hidden by all `dis` utilities, but can be viewed with `show_caches=True`.

Logically, this space is part of the preceding instruction. Many opcodes expect to be followed by an exact number of caches, and will instruct the interpreter to skip over them at runtime.

Populated caches can look like arbitrary instructions, so great care should be taken when reading or modifying raw, adaptive bytecode containing quickened data.

在 3.11 版被加入。

**Unary operations**

Unary operations take the top of the stack, apply the operation, and push the result back on the stack.

**UNARY\_NEGATIVE**

Implements `STACK[-1] = -STACK[-1]`.

**UNARY\_NOT**

Implements `STACK[-1] = not STACK[-1]`.

在 3.13 版的變更: This instruction now requires an exact `bool` operand.

**UNARY\_INVERT**

Implements `STACK[-1] = ~STACK[-1]`.

**GET\_ITER**

Implements `STACK[-1] = iter(STACK[-1])`.

**GET\_YIELD\_FROM\_ITER**

If `STACK[-1]` is a *generator iterator* or *coroutine* object it is left as is. Otherwise, implements `STACK[-1] = iter(STACK[-1])`.

在 3.5 版被加入。

**TO\_BOOL**

Implements `STACK[-1] = bool(STACK[-1])`.

在 3.13 版被加入。

**Binary and in-place operations**

Binary operations remove the top two items from the stack (`STACK[-1]` and `STACK[-2]`). They perform the operation, then put the result back on the stack.

In-place operations are like binary operations, but the operation is done in-place when `STACK[-2]` supports it, and the resulting `STACK[-1]` may be (but does not have to be) the original `STACK[-2]`.

**BINARY\_OP** (*op*)

Implements the binary and in-place operators (depending on the value of *op*):

```
rhs = STACK.pop()
lhs = STACK.pop()
STACK.append(lhs op rhs)
```

在 3.11 版被加入。

**BINARY\_SUBSCR**

Implements:

```
key = STACK.pop()
container = STACK.pop()
STACK.append(container[key])
```

**STORE\_SUBSCR**

Implements:

```
key = STACK.pop()
container = STACK.pop()
value = STACK.pop()
container[key] = value
```

**DELETE\_SUBSCR**

Implements:

```
key = STACK.pop()
container = STACK.pop()
del container[key]
```

**BINARY\_SLICE**

Implements:

```
end = STACK.pop()
start = STACK.pop()
container = STACK.pop()
STACK.append(container[start:end])
```

在 3.12 版被加入。

**STORE\_SLICE**

Implements:

```
end = STACK.pop()
start = STACK.pop()
container = STACK.pop()
values = STACK.pop()
container[start:end] = value
```

在 3.12 版被加入。

**Coroutine opcodes****GET\_AWAITABLE** (*where*)

Implements `STACK[-1] = get_awaitable(STACK[-1])`, where `get_awaitable(o)` returns `o` if `o` is a coroutine object or a generator object with the `CO_ITERABLE_COROUTINE` flag, or resolves `o.__await__`.

If the `where` operand is nonzero, it indicates where the instruction occurs:

- 1: After a call to `__aenter__`
- 2: After a call to `__aexit__`

在 3.5 版被加入。

在 3.11 版的變更: Previously, this instruction did not have an `oparg`.

**GET\_AITER**

Implements `STACK[-1] = STACK[-1].__aiter__()`.

在 3.5 版被加入。

在 3.7 版的變更: Returning awaitable objects from `__aiter__` is no longer supported.

**GET\_ANEXT**

Implement `STACK.append(get_awaitable(STACK[-1].__anext__()))` to the stack. See `GET_AWAITABLE` for details about `get_awaitable`.

在 3.5 版被加入。

**END\_ASYNC\_FOR**

Terminates an `async for` loop. Handles an exception raised when awaiting a next item. The stack contains the `async iterable` in `STACK[-2]` and the raised exception in `STACK[-1]`. Both are popped. If the exception is not `StopAsyncIteration`, it is re-raised.

在 3.8 版被加入。

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

**CLEANUP\_THROW**

Handles an exception raised during a `throw()` or `close()` call through the current frame. If `STACK[-1]` is an instance of `StopIteration`, pop three values from the stack and push its `value` member. Otherwise, re-raise `STACK[-1]`.

在 3.12 版被加入。

**BEFORE\_ASYNC\_WITH**

Resolves `__aenter__` and `__aexit__` from `STACK[-1]`. Pushes `__aexit__` and result of `__aenter__()` to the stack:

```
STACK.extend((__aexit__, __aenter__()))
```

在 3.5 版被加入。

**Miscellaneous opcodes****SET\_ADD** (*i*)

Implements:

```
item = STACK.pop()
set.add(STACK[-i], item)
```

Used to implement set comprehensions.

**LIST\_APPEND** (*i*)

Implements:

```
item = STACK.pop()
list.append(STACK[-i], item)
```

Used to implement list comprehensions.

**MAP\_ADD** (*i*)

Implements:

```
value = STACK.pop()
key = STACK.pop()
dict.__setitem__(STACK[-i], key, value)
```

Used to implement dict comprehensions.

在 3.1 版被加入。

在 3.8 版的變更: Map value is `STACK[-1]` and map key is `STACK[-2]`. Before, those were reversed.

For all of the `SET_ADD`, `LIST_APPEND` and `MAP_ADD` instructions, while the added value or key/value pair is popped off, the container object remains on the stack so that it is available for further iterations of the loop.

**RETURN\_VALUE**

Returns with `STACK[-1]` to the caller of the function.

**RETURN\_CONST** (*consti*)

Returns with `co_consts[consti]` to the caller of the function.

在 3.12 版被加入。

**YIELD\_VALUE**

Yields `STACK.pop()` from a *generator*.

在 3.11 版的變更: `oparg` set to be the stack depth.

在 3.12 版的變更: `oparg` set to be the exception block depth, for efficient closing of generators.

在 3.13 版的變更: `oparg` is 1 if this instruction is part of a `yield-from` or `await`, and 0 otherwise.

**SETUP\_ANNOTATIONS**

Checks whether `__annotations__` is defined in `locals()`, if not it is set up to an empty `dict`. This opcode is only emitted if a class or module body contains *variable annotations* statically.

在 3.6 版被加入。

**POP\_EXCEPT**

Pops a value from the stack, which is used to restore the exception state.

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

**RERAISE**

Re-raises the exception currently on top of the stack. If `oparg` is non-zero, pops an additional value from the stack which is used to set `f_lasti` of the current frame.

在 3.9 版被加入。

在 3.11 版的變更: Exception representation on the stack now consist of one, not three, items.

**PUSH\_EXC\_INFO**

Pops a value from the stack. Pushes the current exception to the top of the stack. Pushes the value originally popped back to the stack. Used in exception handlers.

在 3.11 版被加入。

**CHECK\_EXC\_MATCH**

Performs exception matching for `except`. Tests whether the `STACK[-2]` is an exception matching `STACK[-1]`. Pops `STACK[-1]` and pushes the boolean result of the test.

在 3.11 版被加入。

**CHECK\_EG\_MATCH**

Performs exception matching for `except*`. Applies `split(STACK[-1])` on the exception group representing `STACK[-2]`.

In case of a match, pops two items from the stack and pushes the non-matching subgroup (`None` in case of full match) followed by the matching subgroup. When there is no match, pops one item (the match type) and pushes `None`.

在 3.11 版被加入。

**WITH\_EXCEPT\_START**

Calls the function in position 4 on the stack with arguments (type, val, tb) representing the exception at the top of the stack. Used to implement the call `context_manager.__exit__(*exc_info())` when an exception has occurred in a `with` statement.

在 3.9 版被加入。

在 3.11 版的變更: The `__exit__` function is in position 4 of the stack rather than 7. Exception representation on the stack now consist of one, not three, items.

**LOAD\_ASSERTION\_ERROR**

Pushes `AssertionError` onto the stack. Used by the `assert` statement.

在 3.9 版被加入。

**LOAD\_BUILD\_CLASS**

Pushes `builtins.__build_class__()` onto the stack. It is later called to construct a class.

**BEFORE\_WITH**

This opcode performs several operations before a `with` block starts. First, it loads `__exit__()` from the context manager and pushes it onto the stack for later use by `WITH_EXCEPT_START`. Then, `__enter__()` is called. Finally, the result of calling the `__enter__()` method is pushed onto the stack.

在 3.11 版被加入。

**GET\_LEN**

Perform `STACK.append(len(STACK[-1]))`. Used in `match` statements where comparison with structure of pattern is needed.

在 3.10 版被加入。

**MATCH\_MAPPING**

If `STACK[-1]` is an instance of `collections.abc.Mapping` (or, more technically: if it has the `Py_TPFLAGS_MAPPING` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

在 3.10 版被加入。

**MATCH\_SEQUENCE**

If `STACK[-1]` is an instance of `collections.abc.Sequence` and is *not* an instance of `str/bytes/bytearray` (or, more technically: if it has the `Py_TPFLAGS_SEQUENCE` flag set in its `tp_flags`), push `True` onto the stack. Otherwise, push `False`.

在 3.10 版被加入。

**MATCH\_KEYS**

`STACK[-1]` is a tuple of mapping keys, and `STACK[-2]` is the match subject. If `STACK[-2]` contains all of the keys in `STACK[-1]`, push a `tuple` containing the corresponding values. Otherwise, push `None`.

在 3.10 版被加入。

在 3.11 版的變更: Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

**STORE\_NAME (namei)**

Implements `name = STACK.pop()`. `namei` is the index of `name` in the attribute `co_names` of the code object. The compiler tries to use `STORE_FAST` or `STORE_GLOBAL` if possible.

**DELETE\_NAME (namei)**

Implements `del name`, where `namei` is the index into `co_names` attribute of the code object.

**UNPACK\_SEQUENCE (count)**

Unpacks `STACK[-1]` into `count` individual values, which are put onto the stack right-to-left. Require there to be exactly `count` values.:

```
assert (len(STACK[-1]) == count)
STACK.extend(STACK.pop()[:-count-1:-1])
```

**UNPACK\_EX (counts)**

Implements assignment with a starred target: Unpacks an iterable in `STACK[-1]` into individual values, where the total number of values can be smaller than the number of items in the iterable: one of the new values will be a list of all leftover items.

The number of values before and after the list value is limited to 255.

The number of values before the list value is encoded in the argument of the opcode. The number of values after the list if any is encoded using an `EXTENDED_ARG`. As a consequence, the argument can be seen as a two bytes values where the low byte of `counts` is the number of values before the list value, the high byte of `counts` the number of values after it.

The extracted values are put onto the stack right-to-left, i.e. `a, *b, c = d` will be stored after execution as `STACK.extend((a, b, c))`.

**STORE\_ATTR** (*namei*)

Implements:

```
obj = STACK.pop()
value = STACK.pop()
obj.name = value
```

where *namei* is the index of name in `co_names` of the code object.

**DELETE\_ATTR** (*namei*)

Implements:

```
obj = STACK.pop()
del obj.name
```

where *namei* is the index of name into `co_names` of the code object.

**STORE\_GLOBAL** (*namei*)

Works as `STORE_NAME`, but stores the name as a global.

**DELETE\_GLOBAL** (*namei*)

Works as `DELETE_NAME`, but deletes a global name.

**LOAD\_CONST** (*consti*)

Pushes `co_consts[consti]` onto the stack.

**LOAD\_NAME** (*namei*)

Pushes the value associated with `co_names[namei]` onto the stack. The name is looked up within the locals, then the globals, then the builtins.

**LOAD\_LOCALS**

Pushes a reference to the locals dictionary onto the stack. This is used to prepare namespace dictionaries for `LOAD_FROM_DICT_OR_DEREF` and `LOAD_FROM_DICT_OR_GLOBALS`.

在 3.12 版被加入。

**LOAD\_FROM\_DICT\_OR\_GLOBALS** (*i*)

Pops a mapping off the stack and looks up the value for `co_names[namei]`. If the name is not found there, looks it up in the globals and then the builtins, similar to `LOAD_GLOBAL`. This is used for loading global variables in annotation scopes within class bodies.

在 3.12 版被加入。

**BUILD\_TUPLE** (*count*)

Creates a tuple consuming *count* items from the stack, and pushes the resulting tuple onto the stack:

```
if count == 0:
    value = ()
else:
    value = tuple(STACK[-count:])
    STACK = STACK[:-count]

STACK.append(value)
```

**BUILD\_LIST** (*count*)

Works as *BUILD\_TUPLE*, but creates a list.

**BUILD\_SET** (*count*)

Works as *BUILD\_TUPLE*, but creates a set.

**BUILD\_MAP** (*count*)

Pushes a new dictionary object onto the stack. Pops  $2 * \text{count}$  items so that the dictionary holds *count* entries: `{..., STACK[-4]: STACK[-3], STACK[-2]: STACK[-1]}`.

在 3.5 版的變更: The dictionary is created from stack items instead of creating an empty dictionary pre-sized to hold *count* items.

**BUILD\_CONST\_KEY\_MAP** (*count*)

The version of *BUILD\_MAP* specialized for constant keys. Pops the top element on the stack which contains a tuple of keys, then starting from `STACK[-2]`, pops *count* values to form values in the built dictionary.

在 3.6 版被加入.

**BUILD\_STRING** (*count*)

Concatenates *count* strings from the stack and pushes the resulting string onto the stack.

在 3.6 版被加入.

**LIST\_EXTEND** (*i*)

Implements:

```
seq = STACK.pop()
list.extend(STACK[-i], seq)
```

Used to build lists.

在 3.9 版被加入.

**SET\_UPDATE** (*i*)

Implements:

```
seq = STACK.pop()
set.update(STACK[-i], seq)
```

Used to build sets.

在 3.9 版被加入.

**DICT\_UPDATE** (*i*)

Implements:

```
map = STACK.pop()
dict.update(STACK[-i], map)
```

Used to build dicts.

在 3.9 版被加入.

**DICT\_MERGE** (*i*)

Like *DICT\_UPDATE* but raises an exception for duplicate keys.

在 3.9 版被加入.

**LOAD\_ATTR** (*namei*)

If the low bit of *namei* is not set, this replaces `STACK[-1]` with `getattr(STACK[-1], co_names[namei>>1])`.

If the low bit of *namei* is set, this will attempt to load a method named `co_names[namei>>1]` from the `STACK[-1]` object. `STACK[-1]` is popped. This bytecode distinguishes two cases: if `STACK[-1]` has a

method with the correct name, the bytecode pushes the unbound method and `STACK[-1]`. `STACK[-1]` will be used as the first argument (`self`) by `CALL` or `CALL_KW` when calling the unbound method. Otherwise, `NULL` and the object returned by the attribute lookup are pushed.

在 3.12 版的變更: If the low bit of `namei` is set, then a `NULL` or `self` is pushed to the stack before the attribute or unbound method respectively.

#### **LOAD\_SUPER\_ATTR** (*namei*)

This opcode implements `super()`, both in its zero-argument and two-argument forms (e.g. `super().method()`, `super().attr` and `super(cls, self).method()`, `super(cls, self).attr`).

It pops three values from the stack (from top of stack down):

- `self`: the first argument to the current method
- `cls`: the class within which the current method was defined
- the global `super`

With respect to its argument, it works similarly to `LOAD_ATTR`, except that `namei` is shifted left by 2 bits instead of 1.

The low bit of `namei` signals to attempt a method load, as with `LOAD_ATTR`, which results in pushing `NULL` and the loaded method. When it is unset a single value is pushed to the stack.

The second-low bit of `namei`, if set, means that this was a two-argument call to `super()` (unset means zero-argument).

在 3.12 版被加入.

#### **COMPARE\_OP** (*opname*)

Performs a Boolean operation. The operation name can be found in `cmp_op[opname >> 5]`. If the fifth-lowest bit of `opname` is set (`opname & 16`), the result should be coerced to `bool`.

在 3.13 版的變更: The fifth-lowest bit of the `oparg` now indicates a forced conversion to `bool`.

#### **IS\_OP** (*invert*)

Performs `is` comparison, or `is not` if `invert` is 1.

在 3.9 版被加入.

#### **CONTAINS\_OP** (*invert*)

Performs `in` comparison, or `not in` if `invert` is 1.

在 3.9 版被加入.

#### **IMPORT\_NAME** (*namei*)

Imports the module `co_names[namei]`. `STACK[-1]` and `STACK[-2]` are popped and provide the *fromlist* and *level* arguments of `__import__()`. The module object is pushed onto the stack. The current namespace is not affected: for a proper import statement, a subsequent `STORE_FAST` instruction modifies the namespace.

#### **IMPORT\_FROM** (*namei*)

Loads the attribute `co_names[namei]` from the module found in `STACK[-1]`. The resulting object is pushed onto the stack, to be subsequently stored by a `STORE_FAST` instruction.

#### **JUMP\_FORWARD** (*delta*)

Increments bytecode counter by *delta*.

#### **JUMP\_BACKWARD** (*delta*)

Decrements bytecode counter by *delta*. Checks for interrupts.

在 3.11 版被加入.

#### **JUMP\_BACKWARD\_NO\_INTERRUPT** (*delta*)

Decrements bytecode counter by *delta*. Does not check for interrupts.

在 3.11 版被加入.

**POP\_JUMP\_IF\_TRUE** (*delta*)

If `STACK[-1]` is true, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

在 3.11 版的變更: The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.12 版的變更: This is no longer a pseudo-instruction.

在 3.13 版的變更: This instruction now requires an exact *bool* operand.

**POP\_JUMP\_IF\_FALSE** (*delta*)

If `STACK[-1]` is false, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

在 3.11 版的變更: The oparg is now a relative delta rather than an absolute target. This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.12 版的變更: This is no longer a pseudo-instruction.

在 3.13 版的變更: This instruction now requires an exact *bool* operand.

**POP\_JUMP\_IF\_NOT\_NONE** (*delta*)

If `STACK[-1]` is not `None`, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.11 版被加入.

在 3.12 版的變更: This is no longer a pseudo-instruction.

**POP\_JUMP\_IF\_NONE** (*delta*)

If `STACK[-1]` is `None`, increments the bytecode counter by *delta*. `STACK[-1]` is popped.

This opcode is a pseudo-instruction, replaced in final bytecode by the directed versions (forward/backward).

在 3.11 版被加入.

在 3.12 版的變更: This is no longer a pseudo-instruction.

**FOR\_ITER** (*delta*)

`STACK[-1]` is an *iterator*. Call its `__next__()` method. If this yields a new value, push it on the stack (leaving the iterator below it). If the iterator indicates it is exhausted then the byte code counter is incremented by *delta*.

在 3.12 版的變更: Up until 3.11 the iterator was popped when it was exhausted.

**LOAD\_GLOBAL** (*namei*)

Loads the global named `co_names[namei >> 1]` onto the stack.

在 3.11 版的變更: If the low bit of *namei* is set, then a `NULL` is pushed to the stack before the global variable.

**LOAD\_FAST** (*var\_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack.

在 3.12 版的變更: This opcode is now only used in situations where the local variable is guaranteed to be initialized. It cannot raise `UnboundLocalError`.

**LOAD\_FAST\_LOAD\_FAST** (*var\_nums*)

Pushes references to `co_varnames[var_nums >> 4]` and `co_varnames[var_nums & 15]` onto the stack.

在 3.13 版被加入.

**LOAD\_FAST\_CHECK** (*var\_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack, raising an `UnboundLocalError` if the local variable has not been initialized.

在 3.12 版被加入.

**LOAD\_FAST\_AND\_CLEAR** (*var\_num*)

Pushes a reference to the local `co_varnames[var_num]` onto the stack (or pushes `NULL` onto the stack if the local variable has not been initialized) and sets `co_varnames[var_num]` to `NULL`.

在 3.12 版被加入。

**STORE\_FAST** (*var\_num*)

Stores `STACK.pop()` into the local `co_varnames[var_num]`.

**STORE\_FAST\_STORE\_FAST** (*var\_nums*)

Stores `STACK[-1]` into `co_varnames[var_nums >> 4]` and `STACK[-2]` into `co_varnames[var_nums & 15]`.

在 3.13 版被加入。

**STORE\_FAST\_LOAD\_FAST** (*var\_nums*)

Stores `STACK.pop()` into the local `co_varnames[var_nums >> 4]` and pushes a reference to the local `co_varnames[var_nums & 15]` onto the stack.

在 3.13 版被加入。

**DELETE\_FAST** (*var\_num*)

Deletes local `co_varnames[var_num]`.

**MAKE\_CELL** (*i*)

Creates a new cell in slot *i*. If that slot is nonempty then that value is stored into the new cell.

在 3.11 版被加入。

**LOAD\_DEREF** (*i*)

Loads the cell contained in slot *i* of the "fast locals" storage. Pushes a reference to the object the cell contains on the stack.

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

**LOAD\_FROM\_DICT\_OR\_DEREF** (*i*)

Pops a mapping off the stack and looks up the name associated with slot *i* of the "fast locals" storage in this mapping. If the name is not found there, loads it from the cell contained in slot *i*, similar to `LOAD_DEREF`. This is used for loading *closure variables* in class bodies (which previously used `LOAD_CLASSDEREF`) and in annotation scopes within class bodies.

在 3.12 版被加入。

**STORE\_DEREF** (*i*)

Stores `STACK.pop()` into the cell contained in slot *i* of the "fast locals" storage.

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

**DELETE\_DEREF** (*i*)

Empties the cell contained in slot *i* of the "fast locals" storage. Used by the `del` statement.

在 3.2 版被加入。

在 3.11 版的變更: *i* is no longer offset by the length of `co_varnames`.

**COPY\_FREE\_VARS** (*n*)

Copies the *n* *free (closure) variables* from the closure into the frame. Removes the need for special code on the caller's side when calling closures.

在 3.11 版被加入。

**RAISE\_VARARGS** (*argc*)

Raises an exception using one of the 3 forms of the `raise` statement, depending on the value of *argc*:

- 0: `raise` (re-raise previous exception)
- 1: `raise STACK[-1]` (raise exception instance or type at `STACK[-1]`)

- 2: raise STACK[-2] from STACK[-1] (raise exception instance or type at STACK[-2] with `__cause__` set to STACK[-1])

**CALL** (*argc*)

Calls a callable object with the number of arguments specified by *argc*. On the stack are (in ascending order):

- The callable
- `self` or `NULL`
- The remaining positional arguments

*argc* is the total of the positional arguments, excluding `self`.

`CALL` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.11 版被加入。

在 3.13 版的變更: The callable now always appears at the same position on the stack.

在 3.13 版的變更: Calls with keyword arguments are now handled by `CALL_KW`.

**CALL\_KW** (*argc*)

Calls a callable object with the number of arguments specified by *argc*, including one or more named arguments. On the stack are (in ascending order):

- The callable
- `self` or `NULL`
- The remaining positional arguments
- The named arguments
- A *tuple* of keyword argument names

*argc* is the total of the positional and named arguments, excluding `self`. The length of the tuple of keyword argument names is the number of named arguments.

`CALL_KW` pops all arguments, the keyword names, and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.13 版被加入。

**CALL\_FUNCTION\_EX** (*flags*)

Calls a callable object with variable set of positional and keyword arguments. If the lowest bit of *flags* is set, the top of the stack contains a mapping object containing additional keyword arguments. Before the callable is called, the mapping object and iterable object are each “unpacked” and their contents passed in as keyword and positional arguments respectively. `CALL_FUNCTION_EX` pops all arguments and the callable object off the stack, calls the callable object with those arguments, and pushes the return value returned by the callable object.

在 3.6 版被加入。

**PUSH\_NULL**

Pushes a `NULL` to the stack. Used in the call sequence to match the `NULL` pushed by `LOAD_METHOD` for non-method calls.

在 3.11 版被加入。

**MAKE\_FUNCTION**

Pushes a new function object on the stack built from the code object at `STACK[-1]`.

在 3.10 版的變更: Flag value `0x04` is a tuple of strings instead of dictionary

在 3.11 版的變更: Qualified name at `STACK[-1]` was removed.

在 3.13 版的變更: Extra function attributes on the stack, signaled by `oparg` flags, were removed. They now use `SET_FUNCTION_ATTRIBUTE`.

**SET\_FUNCTION\_ATTRIBUTE** (*flag*)

Sets an attribute on a function object. Expects the function at `STACK[-1]` and the attribute value to set at `STACK[-2]`; consumes both and leaves the function at `STACK[-1]`. The flag determines which attribute to set:

- `0x01` a tuple of default values for positional-only and positional-or-keyword parameters in positional order
- `0x02` a dictionary of keyword-only parameters' default values
- `0x04` a tuple of strings containing parameters' annotations
- `0x08` a tuple containing cells for free variables, making a closure

在 3.13 版被加入。

**BUILD\_SLICE** (*argc*)

Pushes a slice object on the stack. *argc* must be 2 or 3. If it is 2, implements:

```
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, end))
```

if it is 3, implements:

```
step = STACK.pop()
end = STACK.pop()
start = STACK.pop()
STACK.append(slice(start, end, step))
```

See the `slice()` built-in function for more information.

**EXTENDED\_ARG** (*ext*)

Prefixes any opcode which has an argument too big to fit into the default one byte. *ext* holds an additional byte which act as higher bits in the argument. For each opcode, at most three prefixal `EXTENDED_ARG` are allowed, forming an argument from two-byte to four-byte.

**CONVERT\_VALUE** (*oparg*)

Convert value to a string, depending on *oparg*:

```
value = STACK.pop()
result = func(value)
STACK.append(result)
```

- *oparg* == 1: call `str()` on *value*
- *oparg* == 2: call `repr()` on *value*
- *oparg* == 3: call `ascii()` on *value*

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入。

**FORMAT\_SIMPLE**

Formats the value on top of stack:

```
value = STACK.pop()
result = value.__format__("")
STACK.append(result)
```

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入。

**FORMAT\_WITH\_SPEC**

Formats the given value with the given format spec:

```
spec = STACK.pop()
value = STACK.pop()
result = value.__format__(spec)
STACK.append(result)
```

Used for implementing formatted literal strings (f-strings).

在 3.13 版被加入。

**MATCH\_CLASS** (*count*)

`STACK[-1]` is a tuple of keyword attribute names, `STACK[-2]` is the class being matched against, and `STACK[-3]` is the match subject. *count* is the number of positional sub-patterns.

Pop `STACK[-1]`, `STACK[-2]`, and `STACK[-3]`. If `STACK[-3]` is an instance of `STACK[-2]` and has the positional and keyword attributes required by *count* and `STACK[-1]`, push a tuple of extracted attributes. Otherwise, push `None`.

在 3.10 版被加入。

在 3.11 版的變更: Previously, this instruction also pushed a boolean value indicating success (`True`) or failure (`False`).

**RESUME** (*context*)

A no-op. Performs internal tracing, debugging and optimization checks.

The *context* operand consists of two parts. The lowest two bits indicate where the **RESUME** occurs:

- 0 The start of a function, which is neither a generator, coroutine nor an async generator
- 1 After a `yield` expression
- 2 After a `yield from` expression
- 3 After an `await` expression

The next bit is 1 if the **RESUME** is at except-depth 1, and 0 otherwise.

在 3.11 版被加入。

在 3.13 版的變更: The *oparg* value changed to include information about except-depth

**RETURN\_GENERATOR**

Create a generator, coroutine, or async generator from the current frame. Used as first opcode of in code object for the above mentioned callables. Clear the current frame and return the newly created generator.

在 3.11 版被加入。

**SEND** (*delta*)

Equivalent to `STACK[-1] = STACK[-2].send(STACK[-1])`. Used in `yield from` and `await` statements.

If the call raises `StopIteration`, pop the top value from the stack, push the exception's `value` attribute, and increment the bytecode counter by *delta*.

在 3.11 版被加入。

**HAVE\_ARGUMENT**

This is not really an opcode. It identifies the dividing line between opcodes in the range `[0,255]` which don't use their argument and those that do (`< HAVE_ARGUMENT` and `>= HAVE_ARGUMENT`, respectively).

If your application uses pseudo instructions or specialized instructions, use the `hasarg` collection instead.

在 3.6 版的變更: Now every instruction has an argument, but opcodes `< HAVE_ARGUMENT` ignore it. Before, only opcodes `>= HAVE_ARGUMENT` had an argument.

在 3.12 版的變更: Pseudo instructions were added to the `dis` module, and for them it is not true that comparison with `HAVE_ARGUMENT` indicates whether they use their arg.

在 3.13 版之後被用: Use `hasarg` instead.

#### CALL\_INTRINSIC\_1

Calls an intrinsic function with one argument. Passes `STACK[-1]` as the argument and sets `STACK[-1]` to the result. Used to implement functionality that is not performance critical.

The operand determines which intrinsic function is called:

運算元	描述
<code>INTRINSIC_1_INVALID</code>	Not valid
<code>INTRINSIC_PRINT</code>	Prints the argument to standard out. Used in the REPL.
<code>INTRINSIC_IMPORT_!</code>	Performs <code>import *</code> for the named module.
<code>INTRINSIC_STOPITE!</code>	Extracts the return value from a <code>StopIteration</code> exception.
<code>INTRINSIC_ASYNC_G!</code>	Wraps an async generator value
<code>INTRINSIC_UNARY_P!</code>	Performs the unary <code>+</code> operation
<code>INTRINSIC_LIST_TO.</code>	Converts a list to a tuple
<code>INTRINSIC_TYPEVAR</code>	Creates a <code>typing.TypeVar</code>
<code>INTRINSIC_PARAMSP!</code>	Creates a <code>typing.ParamSpec</code>
<code>INTRINSIC_TYPEVAR.</code>	Creates a <code>typing.TypeVarTuple</code>
<code>INTRINSIC_SUBSCRI!</code>	Returns <code>typing.Generic</code> subscripted with the argument
<code>INTRINSIC_TYPEALI!</code>	Creates a <code>typing.TypeAliasType</code> ; used in the <code>type</code> statement. The argument is a tuple of the type alias's name, type parameters, and value.

在 3.12 版被加入.

#### CALL\_INTRINSIC\_2

Calls an intrinsic function with two arguments. Used to implement functionality that is not performance critical:

```
arg2 = STACK.pop()
arg1 = STACK.pop()
result = intrinsic2(arg1, arg2)
STACK.append(result)
```

The operand determines which intrinsic function is called:

運算元	描述
<code>INTRINSIC_2_INVALID</code>	Not valid
<code>INTRINSIC_PREP_RERAISE_STAR</code>	Calculates the <code>ExceptionGroup</code> to raise from a <code>try-except*</code> .
<code>INTRINSIC_TYPEVAR_WITH_BOUND</code>	Creates a <code>typing.TypeVar</code> with a bound.
<code>INTRINSIC_TYPEVAR_WITH_CONSTRAIN'</code>	Creates a <code>typing.TypeVar</code> with constraints.
<code>INTRINSIC_SET_FUNCTION_TYPE_PARAI</code>	Sets the <code>__type_params__</code> attribute of a function.

在 3.12 版被加入.

#### Pseudo-instructions

These opcodes do not appear in Python bytecode. They are used by the compiler but are replaced by real opcodes or removed before bytecode is generated.

##### SETUP\_FINALLY (*target*)

Set up an exception handler for the following code block. If an exception occurs, the value stack level is restored to its current state and control is transferred to the exception handler at `target`.

**SETUP\_CLEANUP** (*target*)

Like `SETUP_FINALLY`, but in case of an exception also pushes the last instruction (`lasti`) to the stack so that `RE_RAISE` can restore it. If an exception occurs, the value stack level and the last instruction on the frame are restored to their current state, and control is transferred to the exception handler at `target`.

**SETUP\_WITH** (*target*)

Like `SETUP_CLEANUP`, but in case of an exception one more item is popped from the stack before control is transferred to the exception handler at `target`.

This variant is used in `with` and `async with` constructs, which push the return value of the context manager's `__enter__()` or `__aenter__()` to the stack.

**POP\_BLOCK**

Marks the end of the code block associated with the last `SETUP_FINALLY`, `SETUP_CLEANUP` or `SETUP_WITH`.

**JUMP****JUMP\_NO\_INTERRUPT**

Undirected relative jump instructions which are replaced by their directed (forward/backward) counterparts by the assembler.

**LOAD\_CLOSURE** (*i*)

Pushes a reference to the cell contained in slot `i` of the "fast locals" storage.

Note that `LOAD_CLOSURE` is replaced with `LOAD_FAST` in the assembler.

在 3.13 版的變更: This opcode is now a pseudo-instruction.

**LOAD\_METHOD**

Optimized unbound method lookup. Emitted as a `LOAD_ATTR` opcode with a flag set in the arg.

### 33.10.5 Opcode collections

These collections are provided for automatic introspection of bytecode instructions:

在 3.12 版的變更: The collections now contain pseudo instructions and instrumented instructions as well. These are opcodes with values `>= MIN_PSEUDO_OPCODE` and `>= MIN_INSTRUMENTED_OPCODE`.

**dis.opname**

Sequence of operation names, indexable using the bytecode.

**dis.opmap**

Dictionary mapping operation names to bytecodes.

**dis.cmp\_op**

Sequence of all compare operation names.

**dis.hasarg**

Sequence of bytecodes that use their argument.

在 3.12 版被加入.

**dis.hasconst**

Sequence of bytecodes that access a constant.

**dis.hasfree**

Sequence of bytecodes that access a *free (closure) variable*. 'free' in this context refers to names in the current scope that are referenced by inner scopes or names in outer scopes that are referenced from this scope. It does *not* include references to global or builtin scopes.

**dis.hasname**

Sequence of bytecodes that access an attribute by name.

**dis.hasjump**

Sequence of bytecodes that have a jump target. All jumps are relative.

在 3.13 版被加入。

**dis.haslocal**

Sequence of bytecodes that access a local variable.

**dis.hascompare**

Sequence of bytecodes of Boolean operations.

**dis.hasexc**

Sequence of bytecodes that set an exception handler.

在 3.12 版被加入。

**dis.hasjrel**

Sequence of bytecodes that have a relative jump target.

在 3.13 版之後被用: All jumps are now relative. Use *hasjump*.

**dis.hasjabs**

Sequence of bytecodes that have an absolute jump target.

在 3.13 版之後被用: All jumps are now relative. This list is empty.

## 33.11 pickletools --- pickle 開發者的工具

原始碼: [Lib/pickletools.py](#)

該模組包含與 *pickle* 模組的詳細資訊相關的各種常數、一些有關實作的冗長釋以及一些用於分析已 *pickle* 資料的有用函式。該模組的內容對於有 *pickle* 相關工作的 Python 核心開發人員很有用; *pickle* 模組的一般使用者可能不會發現 *pickletools* 模組。

### 33.11.1 命令列用法

在 3.2 版被加入。

當從命令列呼叫時, `python -m pickletools` 將拆解 (disassemble) 一個或多個 *pickle* 檔案的內容。請注意, 如果你想查看儲存在 *pickle* 中的 Python 物件而不是 *pickle* 格式的詳細資訊, 你可能需要使用 `-m pickle`。但是, 當你要檢查的 *pickle* 檔案來自不受信任的來源時, `-m pickletools` 是一個更安全的選項, 因它不執行 *pickle* 位元組碼。

例如, *pickle* 於檔案 `x.pickle` 中的元組 (1, 2):

```
$ python -m pickle x.pickle
(1, 2)

$ python -m pickletools x.pickle
0: \x80 PROTO      3
2: K   BININT1    1
4: K   BININT1    2
6: \x86 TUPLE2
7: q   BININPUT   0
9: .   STOP
highest protocol among opcodes = 2
```

**命令列選項**

- a, --annotate**  
用簡短的操作碼 (opcode) 描述每一行。
- o, --output=<file>**  
應將輸出結果寫入之檔案的名稱。
- l, --indentlevel=<num>**  
新 MARK 級縮進的空格數。
- m, --memo**  
當拆解多個物件時，會在拆解間保留備忘。
- p, --preamble=<preamble>**  
當指定多個 pickle 檔案時，會在每次拆解之前印出給定的一段序言 (preamble)。

**33.11.2 程式化介面**

`pickletools.dis` (*pickle*, *out=None*, *memo=None*, *indentlevel=4*, *annotate=0*)

將 pickle 的符號拆解 (symbolic disassembly) 輸出到類檔案物件 *out*，預設 `sys.stdout`。*pickle* 可以是字串或類檔案物件。*memo* 可以是一個 Python 字典，將用作 pickle 的備忘；它可用於對同一 pickler 建立的多個 pickle 執行拆解。串流中由 MARK 操作碼指示的連續級由 *indentlevel* 空格縮進。如果 *annotate* 指定非零值，則輸出中的每個操作碼都會用簡短的描述進行解釋。*annotate* 的值用作解釋之起始行提示。

在 3.2 版的變更: 新增 *annotate* 參數。

`pickletools.genops` (*pickle*)

提供 pickle 中所有操作碼的一個 *iterator*，回傳形式 (*opcode*, *arg*, *pos*) 三元組序列。*opcode* 是 `OpcodeInfo` 類的實例；*arg* 是操作碼引數的解碼值 (作 Python 物件)；*pos* 是該操作碼所在的位置。*pickle* 可以是字串或類檔案物件。

`pickletools.optimize` (*picklestring*)

消除未使用的 PUT 操作碼後回傳一個新的等效 pickle 字串。最佳化後的 pickle 更短、傳輸時間更少、需要更小的儲存空間，且 `unpickle` 效率也更高。

此章節描述僅在 MS Windows 系統上可用的模組 (module)。

## 34.1 msvcrt --- MS VC++ runtime 提供的有用例程

These functions provide access to some useful capabilities on Windows platforms. Some higher-level modules use these functions to build the Windows implementations of their services. For example, the *getpass* module uses this in the implementation of the *getpass()* function.

Further documentation on these functions can be found in the Platform API documentation.

The module implements both the normal and wide char variants of the console I/O api. The normal API deals only with ASCII characters and is of limited use for internationalized applications. The wide char API should be used where ever possible.

在 3.3 版的變更: Operations in this module now raise *OSError* where *IOError* was raised.

### 34.1.1 File Operations

`msvcrt.locking` (*fd*, *mode*, *nbytes*)

Lock part of a file based on file descriptor *fd* from the C runtime. Raises *OSError* on failure. The locked region of the file extends from the current file position for *nbytes* bytes, and may continue beyond the end of the file. *mode* must be one of the `LK_*` constants listed below. Multiple regions in a file may be locked at the same time, but may not overlap. Adjacent regions are not merged; they must be unlocked individually.

引發一個附帶引數 *fd*、*mode*、*nbytes* 的稽核事件 `msvcrt.locking`。

`msvcrt.LK_LOCK`

`msvcrt.LK_RLCK`

Locks the specified bytes. If the bytes cannot be locked, the program immediately tries again after 1 second. If, after 10 attempts, the bytes cannot be locked, *OSError* is raised.

`msvcrt.LK_NBLCK`

`msvcrt.LK_NBRLCK`

Locks the specified bytes. If the bytes cannot be locked, *OSError* is raised.

`msvcrt.LK_UNLCK`

Unlocks the specified bytes, which must have been previously locked.

`msvcrt.setmode(fd, flags)`

Set the line-end translation mode for the file descriptor *fd*. To set it to text mode, *flags* should be `os.O_TEXT`; for binary, it should be `os.O_BINARY`.

`msvcrt.open_osfhandle(handle, flags)`

Create a C runtime file descriptor from the file handle *handle*. The *flags* parameter should be a bitwise OR of `os.O_APPEND`, `os.O_RDONLY`, `os.O_TEXT` and `os.O_NOINHERIT`. The returned file descriptor may be used as a parameter to `os.fdupen()` to create a file object.

The file descriptor is inheritable by default. Pass `os.O_NOINHERIT` flag to make it non inheritable.

引發一個附帶引數 *handle*、*flags* 的稽核事件 `msvcrt.open_osfhandle`。

`msvcrt.get_osfhandle(fd)`

Return the file handle for the file descriptor *fd*. Raises `OSError` if *fd* is not recognized.

引發一個附帶引數 *fd* 的稽核事件 `msvcrt.get_osfhandle`。

### 34.1.2 Console I/O

`msvcrt.kbhit()`

Returns a nonzero value if a keypress is waiting to be read. Otherwise, return 0.

`msvcrt.getch()`

Read a keypress and return the resulting character as a byte string. Nothing is echoed to the console. This call will block if a keypress is not already available, but will not wait for `Enter` to be pressed. If the pressed key was a special function key, this will return `'\000'` or `'\xe0'`; the next call will return the keycode. The `Control-C` keypress cannot be read with this function.

`msvcrt.getwch()`

Wide char variant of `getch()`, returning a Unicode value.

`msvcrt.getche()`

Similar to `getch()`, but the keypress will be echoed if it represents a printable character.

`msvcrt.getwche()`

Wide char variant of `getche()`, returning a Unicode value.

`msvcrt.putch(char)`

Print the byte string *char* to the console without buffering.

`msvcrt.putwch(unicode_char)`

Wide char variant of `putch()`, accepting a Unicode value.

`msvcrt.ungetch(char)`

Cause the byte string *char* to be "pushed back" into the console buffer; it will be the next character read by `getch()` or `getche()`.

`msvcrt.ungetwch(unicode_char)`

Wide char variant of `ungetch()`, accepting a Unicode value.

### 34.1.3 Other Functions

`msvcrt.heapmin()`

Force the `malloc()` heap to clean itself up and return unused blocks to the operating system. On failure, this raises `OSError`.

`msvcrt.set_error_mode(mode)`

Changes the location where the C runtime writes an error message for an error that might end the program. *mode* must be one of the `OUT_*` constants listed below or `REPORT_ERRMODE`. Returns the old setting or -1 if an error occurs. Only available in debug build of Python.

`msvcrt.OUT_TO_DEFAULT`

Error sink is determined by the app's type. Only available in debug build of Python.

`msvcrt.OUT_TO_STDERR`

Error sink is a standard error. Only available in debug build of Python.

`msvcrt.OUT_TO_MSGBOX`

Error sink is a message box. Only available in debug build of Python.

`msvcrt.REPORT_ERRMODE`

Report the current error mode value. Only available in debug build of Python.

`msvcrt.CrtSetReportMode(type, mode)`

Specifies the destination or destinations for a specific report type generated by `_CrtDbgReport()` in the MS VC++ runtime. *type* must be one of the `CRT_*` constants listed below. *mode* must be one of the `CRTDBG_*` constants listed below. Only available in debug build of Python.

`msvcrt.CrtSetReportFile(type, file)`

After you use `CrtSetReportMode()` to specify `CRTDBG_MODE_FILE`, you can specify the file handle to receive the message text. *type* must be one of the `CRT_*` constants listed below. *file* should be the file handle you want specified. Only available in debug build of Python.

`msvcrt.CRT_WARN`

Warnings, messages, and information that doesn't need immediate attention.

`msvcrt.CRT_ERROR`

Errors, unrecoverable problems, and issues that require immediate attention.

`msvcrt.CRT_ASSERT`

Assertion failures.

`msvcrt.CRTDBG_MODE_DEBUG`

Writes the message to the debugger's output window.

`msvcrt.CRTDBG_MODE_FILE`

Writes the message to a user-supplied file handle. `CrtSetReportFile()` should be called to define the specific file or stream to use as the destination.

`msvcrt.CRTDBG_MODE_WNDW`

Creates a message box to display the message along with the Abort, Retry, and Ignore buttons.

`msvcrt.CRTDBG_REPORT_MODE`

Returns current *mode* for the specified *type*.

`msvcrt.CRT_ASSEMBLY_VERSION`

The CRT Assembly version, from the `crtassem.h` header file.

`msvcrt.VC_ASSEMBLY_PUBLICKEYTOKEN`

The VC Assembly public key token, from the `crtassem.h` header file.

`msvcrt.LIBRARIES_ASSEMBLY_NAME_PREFIX`

The Libraries Assembly name prefix, from the `crtassem.h` header file.

## 34.2 winreg --- Windows F F 表存取

These functions expose the Windows registry API to Python. Instead of using an integer as the registry handle, a *handle object* is used to ensure that the handles are closed correctly, even if the programmer neglects to explicitly close them.

在 3.3 版的變更: Several functions in this module used to raise a *WindowsError*, which is now an alias of *OSError*.

### 34.2.1 函式

This module offers the following functions:

`winreg.CloseKey(hkey)`

Closes a previously opened registry key. The *hkey* argument specifies a previously opened key.

#### 備 F

If *hkey* is not closed using this method (or via *hkey.Close()*), it is closed when the *hkey* object is destroyed by Python.

`winreg.ConnectRegistry(computer_name, key)`

Establishes a connection to a predefined registry handle on another computer, and returns a *handle object*.

*computer\_name* is the name of the remote computer, of the form `r"\\computername"`. If `None`, the local computer is used.

*key* is the predefined handle to connect to.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

引發一個附帶引數 *computer\_name*、*key* 的稽核事件 `winreg.ConnectRegistry`。

在 3.3 版的變更: See *above*.

`winreg.CreateKey(key, sub_key)`

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that names the key this method opens or creates.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an *OSError* exception is raised.

引發一個附帶引數 *key*、*sub\_key*、*access* 的稽核事件 `winreg.CreateKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.3 版的變更: See *above*.

`winreg.CreateKeyEx(key, sub_key, reserved=0, access=KEY_WRITE)`

Creates or opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*sub\_key* is a string that names the key this method opens or creates.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is *KEY\_WRITE*. See *Access Rights* for other allowed values.

If *key* is one of the predefined keys, *sub\_key* may be `None`. In that case, the handle returned is the same key handle passed in to the function.

If the key already exists, this function opens the existing key.

The return value is the handle of the opened key. If the function fails, an `OSError` exception is raised.

引發一個附帶引數 *key*、*sub\_key*、*access* 的稽核事件 `winreg.CreateKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.2 版被加入。

在 3.3 版的變更: See *above*.

`winreg.DeleteKey` (*key*, *sub\_key*)

Deletes the specified key.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

引發一個附帶引數 *key*、*sub\_key*、*access* 的稽核事件 `winreg.DeleteKey`。

在 3.3 版的變更: See *above*.

`winreg.DeleteKeyEx` (*key*, *sub\_key*, *access=KEY\_WOW64\_64KEY*, *reserved=0*)

Deletes the specified key.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

*sub\_key* is a string that must be a subkey of the key identified by the *key* parameter. This value must not be `None`, and the key may not have subkeys.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_WOW64_64KEY`. On 32-bit Windows, the WOW64 constants are ignored. See *Access Rights* for other allowed values.

*This method can not delete keys with subkeys.*

If the method succeeds, the entire key, including all of its values, is removed. If the method fails, an `OSError` exception is raised.

On unsupported Windows versions, `NotImplementedError` is raised.

引發一個附帶引數 *key*、*sub\_key*、*access* 的稽核事件 `winreg.DeleteKey`。

在 3.2 版被加入。

在 3.3 版的變更: See *above*.

`winreg.DeleteValue` (*key*, *value*)

Removes a named value from a registry key.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

*value* is a string that identifies the value to remove.

引發一個附帶引數 *key*、*value* 的稽核事件 `winreg.DeleteValue`。

`winreg.EnumKey(key, index)`

Enumerates subkeys of an open registry key, returning a string.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*index* is an integer that identifies the index of the key to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly until an *OSError* exception is raised, indicating, no more values are available.

引發一個附帶引數 *key*、*index* 的稽核事件 `winreg.EnumKey`。

在 3.3 版的變更: See *above*.

`winreg.EnumValue(key, index)`

Enumerates values of an open registry key, returning a tuple.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

*index* is an integer that identifies the index of the value to retrieve.

The function retrieves the name of one subkey each time it is called. It is typically called repeatedly, until an *OSError* exception is raised, indicating no more values.

The result is a tuple of 3 items:

Index	含義
0	A string that identifies the value name
1	An object that holds the value data, and whose type depends on the underlying registry type
2	An integer that identifies the type of the value data (see table in docs for <i>SetValueEx()</i> )

引發一個附帶引數 *key*、*index* 的稽核事件 `winreg.EnumValue`。

在 3.3 版的變更: See *above*.

`winreg.ExpandEnvironmentStrings(str)`

Expands environment variable placeholders *%NAME%* in strings like *REG\_EXPAND\_SZ*:

```
>>> ExpandEnvironmentStrings('%windir%')
'C:\\Windows'
```

引發一個附帶引數 *str* 的稽核事件 `winreg.ExpandEnvironmentStrings`。

`winreg.FlushKey(key)`

Writes all the attributes of a key to the registry.

*key* is an already open key, or one of the predefined *HKEY\_\* constants*.

It is not necessary to call *FlushKey()* to change a key. Registry changes are flushed to disk by the registry using its lazy flusher. Registry changes are also flushed to disk at system shutdown. Unlike *CloseKey()*, the *FlushKey()* method returns only when all the data has been written to the registry. An application should only call *FlushKey()* if it requires absolute certainty that registry changes are on disk.

#### 備 F

If you don't know whether a *FlushKey()* call is required, it probably isn't.

`winreg.LoadKey(key, sub_key, file_name)`

Creates a subkey under the specified key and stores registration information from a specified file into that subkey.

*key* is a handle returned by *ConnectRegistry()* or one of the constants *HKEY\_USERS* or *HKEY\_LOCAL\_MACHINE*.

*sub\_key* is a string that identifies the subkey to load.

*file\_name* is the name of the file to load registry data from. This file must have been created with the `SaveKey()` function. Under the file allocation table (FAT) file system, the filename may not have an extension.

A call to `LoadKey()` fails if the calling process does not have the `SE_RESTORE_PRIVILEGE` privilege. Note that privileges are different from permissions -- see the [RegLoadKey documentation](#) for more details.

If *key* is a handle returned by `ConnectRegistry()`, then the path specified in *file\_name* is relative to the remote computer.

引發一個附帶引數 *key*、*sub\_key*、*file\_name* 的稽核事件 `winreg.LoadKey`。

`winreg.OpenKey(key, sub_key, reserved=0, access=KEY_READ)`

`winreg.OpenKeyEx(key, sub_key, reserved=0, access=KEY_READ)`

Opens the specified key, returning a *handle object*.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

*sub\_key* is a string that identifies the sub\_key to open.

*reserved* is a reserved integer, and must be zero. The default is zero.

*access* is an integer that specifies an access mask that describes the desired security access for the key. Default is `KEY_READ`. See [Access Rights](#) for other allowed values.

The result is a new handle to the specified key.

If the function fails, `OSError` is raised.

引發一個附帶引數 *key*、*sub\_key*、*access* 的稽核事件 `winreg.OpenKey`。

引發一個附帶引數 *key* 的稽核事件 `winreg.OpenKey/result`。

在 3.2 版的變更: Allow the use of named arguments.

在 3.3 版的變更: See [above](#).

`winreg.QueryInfoKey(key)`

Returns information about a key, as a tuple.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

The result is a tuple of 3 items:

In- dex	含義
0	An integer giving the number of sub keys this key has.
1	An integer giving the number of values this key has.
2	An integer giving when the key was last modified (if available) as 100's of nanoseconds since Jan 1, 1601.

引發一個附帶引數 *key* 的稽核事件 `winreg.QueryInfoKey`。

`winreg.QueryValue(key, sub_key)`

Retrieves the unnamed value for a key, as a string.

*key* is an already open key, or one of the predefined `HKEY_* constants`.

*sub\_key* is a string that holds the name of the subkey with which the value is associated. If this parameter is `None` or empty, the function retrieves the value set by the `SetValue()` method for the key identified by *key*.

Values in the registry have name, type, and data components. This method retrieves the data for a key's first value that has a `NULL` name. But the underlying API call doesn't return the type, so always use `QueryValueEx()` if possible.

引發一個附帶引數 `key`、`sub_key`、`value_name` 的稽核事件 `winreg.QueryKey`。

`winreg.QueryValueEx` (`key`, `value_name`)

Retrieves the type and data for a specified value name associated with an open registry key.

`key` is an already open key, or one of the predefined *HKEY\_\* constants*.

`value_name` is a string indicating the value to query.

The result is a tuple of 2 items:

Index	含義
0	The value of the registry item.
1	An integer giving the registry type for this value (see table in docs for <code>SetValueEx()</code> )

引發一個附帶引數 `key`、`sub_key`、`value_name` 的稽核事件 `winreg.QueryKey`。

`winreg.SaveKey` (`key`, `file_name`)

Saves the specified key, and all its subkeys to the specified file.

`key` is an already open key, or one of the predefined *HKEY\_\* constants*.

`file_name` is the name of the file to save registry data to. This file cannot already exist. If this filename includes an extension, it cannot be used on file allocation table (FAT) file systems by the `LoadKey()` method.

If `key` represents a key on a remote computer, the path described by `file_name` is relative to the remote computer. The caller of this method must possess the **SeBackupPrivilege** security privilege. Note that privileges are different than permissions -- see the [Conflicts Between User Rights and Permissions](#) documentation for more details.

This function passes `NULL` for `security_attributes` to the API.

引發一個附帶引數 `key`、`file_name` 的稽核事件 `winreg.SaveKey`。

`winreg.SetValue` (`key`, `sub_key`, `type`, `value`)

Associates a value with a specified key.

`key` is an already open key, or one of the predefined *HKEY\_\* constants*.

`sub_key` is a string that names the subkey with which the value is associated.

`type` is an integer that specifies the type of the data. Currently this must be `REG_SZ`, meaning only strings are supported. Use the `SetValueEx()` function for support for other data types.

`value` is a string that specifies the new value.

If the key specified by the `sub_key` parameter does not exist, the `SetValue` function creates it.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

The key identified by the `key` parameter must have been opened with `KEY_SET_VALUE` access.

引發一個附帶引數 `key`、`sub_key`、`type`、`value` 的稽核事件 `winreg.SetValue`。

`winreg.SetValueEx` (`key`, `value_name`, `reserved`, `type`, `value`)

Stores data in the value field of an open registry key.

`key` is an already open key, or one of the predefined *HKEY\_\* constants*.

`value_name` is a string that names the subkey with which the value is associated.

`reserved` can be anything -- zero is always passed to the API.

`type` is an integer that specifies the type of the data. See *Value Types* for the available types.

`value` is a string that specifies the new value.

This method can also set additional value and type information for the specified key. The key identified by the key parameter must have been opened with `KEY_SET_VALUE` access.

To open the key, use the `CreateKey()` or `OpenKey()` methods.

Value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as files with the filenames stored in the configuration registry. This helps the registry perform efficiently.

引發一個附帶引數 `key`、`sub_key`、`type`、`value` 的稽核事件 `winreg.SetValue`。

`winreg.DisableReflectionKey(key)`

Disables registry reflection for 32-bit processes running on a 64-bit operating system.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

If the key is not on the reflection list, the function succeeds but has no effect. Disabling reflection for a key does not affect reflection of any subkeys.

引發一個附帶引數 `key` 的稽核事件 `winreg.DisableReflectionKey`。

`winreg.EnableReflectionKey(key)`

Restores registry reflection for the specified disabled key.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

Restoring reflection for a key does not affect reflection of any subkeys.

引發一個附帶引數 `key` 的稽核事件 `winreg.EnableReflectionKey`。

`winreg.QueryReflectionKey(key)`

Determines the reflection state for the specified key.

`key` is an already open key, or one of the predefined `HKEY_* constants`.

Returns `True` if reflection is disabled.

Will generally raise `NotImplementedError` if executed on a 32-bit operating system.

引發一個附帶引數 `key` 的稽核事件 `winreg.QueryReflectionKey`。

## 34.2.2 常數

The following constants are defined for use in many `winreg` functions.

### HKEY\_\* Constants

`winreg.HKEY_CLASSES_ROOT`

Registry entries subordinate to this key define types (or classes) of documents and the properties associated with those types. Shell and COM applications use the information stored under this key.

`winreg.HKEY_CURRENT_USER`

Registry entries subordinate to this key define the preferences of the current user. These preferences include the settings of environment variables, data about program groups, colors, printers, network connections, and application preferences.

`winreg.HKEY_LOCAL_MACHINE`

Registry entries subordinate to this key define the physical state of the computer, including data about the bus type, system memory, and installed hardware and software.

`winreg.HKEY_USERS`

Registry entries subordinate to this key define the default user configuration for new users on the local computer and the user configuration for the current user.

`winreg.HKEY_PERFORMANCE_DATA`

Registry entries subordinate to this key allow you to access performance data. The data is not actually stored in the registry; the registry functions cause the system to collect the data from its source.

`winreg.HKEY_CURRENT_CONFIG`

Contains information about the current hardware profile of the local computer system.

`winreg.HKEY_DYN_DATA`

This key is not used in versions of Windows after 98.

## Access Rights

For more information, see [Registry Key Security and Access](#).

`winreg.KEY_ALL_ACCESS`

Combines the `STANDARD_RIGHTS_REQUIRED`, `KEY_QUERY_VALUE`, `KEY_SET_VALUE`, `KEY_CREATE_SUB_KEY`, `KEY_ENUMERATE_SUB_KEYS`, `KEY_NOTIFY`, and `KEY_CREATE_LINK` access rights.

`winreg.KEY_WRITE`

Combines the `STANDARD_RIGHTS_WRITE`, `KEY_SET_VALUE`, and `KEY_CREATE_SUB_KEY` access rights.

`winreg.KEY_READ`

Combines the `STANDARD_RIGHTS_READ`, `KEY_QUERY_VALUE`, `KEY_ENUMERATE_SUB_KEYS`, and `KEY_NOTIFY` values.

`winreg.KEY_EXECUTE`

Equivalent to `KEY_READ`.

`winreg.KEY_QUERY_VALUE`

Required to query the values of a registry key.

`winreg.KEY_SET_VALUE`

Required to create, delete, or set a registry value.

`winreg.KEY_CREATE_SUB_KEY`

Required to create a subkey of a registry key.

`winreg.KEY_ENUMERATE_SUB_KEYS`

Required to enumerate the subkeys of a registry key.

`winreg.KEY_NOTIFY`

Required to request change notifications for a registry key or for subkeys of a registry key.

`winreg.KEY_CREATE_LINK`

Reserved for system use.

## 64-bit Specific

For more information, see [Accessing an Alternate Registry View](#).

`winreg.KEY_WOW64_64KEY`

Indicates that an application on 64-bit Windows should operate on the 64-bit registry view. On 32-bit Windows, this constant is ignored.

`winreg.KEY_WOW64_32KEY`

Indicates that an application on 64-bit Windows should operate on the 32-bit registry view. On 32-bit Windows, this constant is ignored.

## Value Types

For more information, see [Registry Value Types](#).

`winreg.REG_BINARY`

Binary data in any form.

`winreg.REG_DWORD`

32-bit number.

`winreg.REG_DWORD_LITTLE_ENDIAN`

A 32-bit number in little-endian format. Equivalent to `REG_DWORD`.

`winreg.REG_DWORD_BIG_ENDIAN`

A 32-bit number in big-endian format.

`winreg.REG_EXPAND_SZ`

Null-terminated string containing references to environment variables (`%PATH%`).

`winreg.REG_LINK`

A Unicode symbolic link.

`winreg.REG_MULTI_SZ`

A sequence of null-terminated strings, terminated by two null characters. (Python handles this termination automatically.)

`winreg.REG_NONE`

No defined value type.

`winreg.REG_QWORD`

A 64-bit number.

在 3.6 版被加入.

`winreg.REG_QWORD_LITTLE_ENDIAN`

A 64-bit number in little-endian format. Equivalent to `REG_QWORD`.

在 3.6 版被加入.

`winreg.REG_RESOURCE_LIST`

A device-driver resource list.

`winreg.REG_FULL_RESOURCE_DESCRIPTOR`

A hardware setting.

`winreg.REG_RESOURCE_REQUIREMENTS_LIST`

A hardware resource list.

`winreg.REG_SZ`

A null-terminated string.

### 34.2.3 Registry Handle Objects

This object wraps a Windows HKEY object, automatically closing it when the object is destroyed. To guarantee cleanup, you can call either the `Close()` method on the object, or the `CloseKey()` function.

All registry functions in this module return one of these objects.

All registry functions in this module which accept a handle object also accept an integer, however, use of the handle object is encouraged.

Handle objects provide semantics for `__bool__()` -- thus

```
if handle:
    print("Yes")
```

will print `Yes` if the handle is currently valid (has not been closed or detached).

The object also support comparison semantics, so handle objects will compare true if they both reference the same underlying Windows handle value.

Handle objects can be converted to an integer (e.g., using the built-in `int()` function), in which case the underlying Windows handle value is returned. You can also use the `Detach()` method to return the integer handle, and also disconnect the Windows handle from the handle object.

`PyHKEY.Close()`

Closes the underlying Windows handle.

If the handle is already closed, no error is raised.

`PyHKEY.Detach()`

Detaches the Windows handle from the handle object.

The result is an integer that holds the value of the handle before it is detached. If the handle is already detached or closed, this will return zero.

After calling this function, the handle is effectively invalidated, but the handle is not closed. You would call this function when you need the underlying Win32 handle to exist beyond the lifetime of the handle object.

引發一個附帶引數 `key` 的稽核事件 `winreg.PyHKEY.Detach`。

`PyHKEY.__enter__()`

`PyHKEY.__exit__(*exc_info)`

The `HKEY` object implements `__enter__()` and `__exit__()` and thus supports the context protocol for the `with` statement:

```
with OpenKey(HKEY_LOCAL_MACHINE, "foo") as key:
    ... # work with key
```

will automatically close `key` when control leaves the `with` block.

### 34.3 winsound --- Windows 的聲音播放介面

The `winsound` module provides access to the basic sound-playing machinery provided by Windows platforms. It includes functions and several constants.

`winsound.Beep(frequency, duration)`

Beep the PC's speaker. The `frequency` parameter specifies frequency, in hertz, of the sound, and must be in the range 37 through 32,767. The `duration` parameter specifies the number of milliseconds the sound should last. If the system is not able to beep the speaker, `RuntimeError` is raised.

`winsound.PlaySound(sound, flags)`

Call the underlying `PlaySound()` function from the Platform API. The `sound` parameter may be a filename, a system sound alias, audio data as a *bytes-like object*, or `None`. Its interpretation depends on the value of `flags`, which can be a bitwise ORed combination of the constants described below. If the `sound` parameter is `None`, any currently playing waveform sound is stopped. If the system indicates an error, `RuntimeError` is raised.

`winsound.MessageBeep(type=MB_OK)`

Call the underlying `MessageBeep()` function from the Platform API. This plays a sound as specified in the registry. The `type` argument specifies which sound to play; possible values are `-1`, `MB_ICONASTERISK`, `MB_ICONEXCLAMATION`, `MB_ICONHAND`, `MB_ICONQUESTION`, and `MB_OK`, all described below. The value `-1` produces a "simple beep"; this is the final fallback if a sound cannot be played otherwise. If the system indicates an error, `RuntimeError` is raised.

`winsound.SND_FILENAME`

The `sound` parameter is the name of a WAV file. Do not use with `SND_ALIAS`.

**winsound.SND\_ALIAS**

The *sound* parameter is a sound association name from the registry. If the registry contains no such name, play the system default sound unless *SND\_NODEFAULT* is also specified. If no default sound is registered, raise *RuntimeError*. Do not use with *SND\_FILENAME*.

All Win32 systems support at least the following; most systems support many more:

<i>PlaySound()</i> name	Corresponding Control Panel Sound name
'SystemAsterisk'	Asterisk
'SystemExclamation'	Exclamation
'SystemExit'	Exit Windows
'SystemHand'	Critical Stop
'SystemQuestion'	Question

例如:

```
import winsound
# Play Windows exit sound.
winsound.PlaySound("SystemExit", winsound.SND_ALIAS)

# Probably play Windows default sound, if any is registered (because
# "*" probably isn't the registered name of any sound).
winsound.PlaySound("*", winsound.SND_ALIAS)
```

**winsound.SND\_LOOP**

Play the sound repeatedly. The *SND\_ASYNC* flag must also be used to avoid blocking. Cannot be used with *SND\_MEMORY*.

**winsound.SND\_MEMORY**

The *sound* parameter to *PlaySound()* is a memory image of a WAV file, as a *bytes-like object*.

**備**

This module does not support playing from a memory image asynchronously, so a combination of this flag and *SND\_ASYNC* will raise *RuntimeError*.

**winsound.SND\_PURGE**

Stop playing all instances of the specified sound.

**備**

This flag is not supported on modern Windows platforms.

**winsound.SND\_ASYNC**

Return immediately, allowing sounds to play asynchronously.

**winsound.SND\_NODEFAULT**

If the specified sound cannot be found, do not play the system default sound.

**winsound.SND\_NOSTOP**

Do not interrupt sounds currently playing.

**winsound.SND\_NOWAIT**

Return immediately if the sound driver is busy.

 備 F

This flag is not supported on modern Windows platforms.

`winsound.MB_ICONASTERISK`

播放 SystemDefault 聲音。

`winsound.MB_ICONEXCLAMATION`

播放 SystemExclamation 聲音。

`winsound.MB_ICONHAND`

播放 SystemHand 聲音。

`winsound.MB_ICONQUESTION`

播放 SystemQuestion 聲音。

`winsound.MB_OK`

播放 SystemDefault 聲音。

此章節所描述的模組 (module) 提供了針對 Unix 作業系統獨有特性的介面，或在某些情況下可用於其他 Unix 變形版本。以下概述：

## 35.1 `posix` --- 最常見的 POSIX 系統呼叫

該模組提供對由 C 標準和 POSIX 標準（一種包裝的 Unix 介面）所標準化的作業系統功能的存取。

適用：Unix。

**不要直接引入此模組。**請改用引入 `os` 模組，它提供了此介面的可移植 (*portable*) 版本。在 Unix 上，`os` 模組提供了 `posix` 介面的超集 (superset)。在非 Unix 作業系統上，`posix` 模組不可用，但始終可以通過 `os` 介面使用一個子集。一旦 `os` 有被引入，使用它代替 `posix` 不會有性能損失。此外，`os` 提供了一些額外的功能，例如當 `os.environ` 中的條目更改時自動呼叫 `putenv()`。

錯誤會以例外的形式被回報；常見的例外是因型錯誤而給出的，而系統呼叫回報的錯誤會引發 `OSError`。

### 35.1.1 對大檔案 (Large File) 的支援

一些作業系統（包括 AIX 和 Solaris）支援來自 C 程式模型且大於 2 GiB 的檔案，其中 `int` 和 `long` 是 32-bit (32 位元) 的值。這通常透過將相關大小和偏移量 (offset) 種類定義 64-bit 值來實作。此類檔案有時被稱「大檔案 (*large files*)」。

當 `off_t` 的大小大於 `long` 且 `long long` 的大小至少與 `off_t` 相同時，對大檔案的支援會被啟用。可能需要使用某些編譯器旗標來配置和編譯 Python 以用此模式。例如，對於 Solaris 2.6 和 2.7，你需要執行如下操作：

```
CFLAGS="`getconf LFS_CFLAGS`" OPT="-g -O2 $CFLAGS" \  
./configure
```

在支援大檔案的 Linux 系統上，這可能有效：

```
CFLAGS='-D_LARGEFILE64_SOURCE -D_FILE_OFFSET_BITS=64' OPT="-g -O2 $CFLAGS" \  
./configure
```

### 35.1.2 值得注意的模組內容

除了 `os` 模組明文件中描述的許多函式外, `posix` 還定義了以下資料項目:

#### `posix.envIRON`

表示直譯器動時的字串環境的字典。鍵和值在 Unix 上是位元組, 在 Windows 上是 `str`。例如, `environ[b'HOME']` (Windows 上 `environ['HOME']`) 是你的主目的路徑名, 等同於 C 語言中的 `getenv("HOME")`。

修改這個字典不會影響由 `execv()`、`popen()` 或 `system()` 傳遞的字串環境; 如果你需要更改環境, 請將 `environ` 傳遞給 `execve()` 或將變數賦值和匯出陳述句新增到 `system()` 或 `popen()` 的指令字串中。

在 3.2 版的變更: 在 Unix 上, 鍵和值是位元組。

#### 備

`os` 模組提供了 `environ` 的替代實作, 會在修改時更新環境。另請注意, 更新 `os.envIRON` 將使該字典變成過時的。建議使用 `os` 模組版本, 而不是直接存取 `posix` 模組。

## 35.2 pwd --- 密碼資料庫

此模組提供對 Unix 使用者帳和密碼資料庫的存取介面。它適用於所有 Unix 版本。

適用: Unix, not WASI, not iOS.

密碼資料庫條目被報告類似元組的物件 (tuple-like object), 其屬性會對應於 `passwd` 結構的成員 (屬性欄位請見下面的 `<pwd.h>`):

索引	屬性	意義
0	<code>pw_name</code>	登入名
1	<code>pw_passwd</code>	可選的加密碼
2	<code>pw_uid</code>	數值的使用者 ID
3	<code>pw_gid</code>	數值的群組 ID
4	<code>pw_gecos</code>	使用者名稱或解欄位
5	<code>pw_dir</code>	使用者主目的 (home directory)
6	<code>pw_shell</code>	使用者命令直譯器

`uid` 和 `gid` 項目是整數, 其他項目都是字串。如果找不到請求的條目, 則會引發 `KeyError`。

#### 備

In traditional Unix the field `pw_passwd` usually contains a password encrypted with a DES derived algorithm. However most modern unices use a so-called *shadow password* system. On those unices the `pw_passwd` field only contains an asterisk (`'*'`) or the letter `'x'` where the encrypted password is stored in a file `/etc/shadow` which is not world readable. Whether the `pw_passwd` field contains anything useful is system-dependent.

它定義了以下項目:

#### `pwd.getpwnuid(uid)`

回傳給定數值使用者 ID 的密碼資料庫條目。

#### `pwd.getpwnam(name)`

回傳給定使用者名稱的密碼資料庫條目。

`pwd.getpwall()`

以任意順序回傳所有可用密碼資料庫條目的 `list`。

#### 也參考

##### `grp` 模組

群組資料庫的介面，與此模組類似。

## 35.3 `grp` --- 群組資料庫

This module provides access to the Unix group database. It is available on all Unix versions.

適用: Unix, not WASI, not Android, not iOS.

Group database entries are reported as a tuple-like object, whose attributes correspond to the members of the `group` structure (Attribute field below, see `<grp.h>`):

Index	屬性	含義
0	<code>gr_name</code>	the name of the group
1	<code>gr_passwd</code>	the (encrypted) group password; often empty
2	<code>gr_gid</code>	the numerical group ID
3	<code>gr_mem</code>	all the group member's user names

The `gid` is an integer, name and password are strings, and the member list is a list of strings. (Note that most users are not explicitly listed as members of the group they are in according to the password database. Check both databases to get complete membership information. Also note that a `gr_name` that starts with a `+` or `-` is likely to be a YP/NIS reference and may not be accessible via `getgrnam()` or `getgrgid()`.)

It defines the following items:

`grp.getgrgid(id)`

Return the group database entry for the given numeric group ID. `KeyError` is raised if the entry asked for cannot be found.

在 3.10 版的變更: `TypeError` is raised for non-integer arguments like floats or strings.

`grp.getgrnam(name)`

Return the group database entry for the given group name. `KeyError` is raised if the entry asked for cannot be found.

`grp.getgrall()`

Return a list of all available group entries, in arbitrary order.

#### 也參考

##### `pwd` 模組

An interface to the user database, similar to this.

## 35.4 `termios` --- POSIX 風格 tty 控制

This module provides an interface to the POSIX calls for tty I/O control. For a complete description of these calls, see `termios(3)` Unix manual page. It is only available for those Unix versions that support POSIX `termios` style tty I/O control configured during installation.

適用: Unix.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by `sys.stdin.fileno()`, or a *file object*, such as `sys.stdin` itself.

This module also defines all the constants needed to work with the functions provided here; these have the same name as their counterparts in C. Please refer to your system documentation for more information on using these terminal control interfaces.

The module defines the following functions:

`termios.tcgetattr(fd)`

Return a list containing the tty attributes for file descriptor *fd*, as follows: [*iflag*, *oflag*, *cflag*, *lflag*, *ispeed*, *ospeed*, *cc*] where *cc* is a list of the tty special characters (each a string of length 1, except the items with indices `VMIN` and `VTIME`, which are integers when these fields are defined). The interpretation of the flags and the speeds as well as the indexing in the *cc* array must be done using the symbolic constants defined in the `termios` module.

`termios.tcsetattr(fd, when, attributes)`

Set the tty attributes for file descriptor *fd* from the *attributes*, which is a list like the one returned by `tcgetattr()`. The *when* argument determines when the attributes are changed:

`termios.TCSANOW`

Change attributes immediately.

`termios.TCSADRAIN`

Change attributes after transmitting all queued output.

`termios.TCSAFLUSH`

Change attributes after transmitting all queued output and discarding all queued input.

`termios.tcsendbreak(fd, duration)`

Send a break on file descriptor *fd*. A zero *duration* sends a break for 0.25--0.5 seconds; a nonzero *duration* has a system dependent meaning.

`termios.tcdrain(fd)`

Wait until all output written to file descriptor *fd* has been transmitted.

`termios.tcflush(fd, queue)`

Discard queued data on file descriptor *fd*. The *queue* selector specifies which queue: `TCIFLUSH` for the input queue, `TCOFLUSH` for the output queue, or `TCIOFLUSH` for both queues.

`termios.tcflow(fd, action)`

Suspend or resume input or output on file descriptor *fd*. The *action* argument can be `TCOOFF` to suspend output, `TCOON` to restart output, `TCIOFF` to suspend input, or `TCION` to restart input.

`termios.tcgetwinsize(fd)`

Return a tuple (*ws\_row*, *ws\_col*) containing the tty window size for file descriptor *fd*. Requires `termios.TIOCGWINSZ` or `termios.TIOCGSIZE`.

在 3.11 版被加入。

`termios.tcsetwinsize(fd, winsize)`

Set the tty window size for file descriptor *fd* from *winsize*, which is a two-item tuple (*ws\_row*, *ws\_col*) like the one returned by `tcgetwinsize()`. Requires at least one of the pairs (`termios.TIOCGWINSZ`, `termios.TIOCSWINSZ`); (`termios.TIOCGSIZE`, `termios.TIOCSSIZE`) to be defined.

在 3.11 版被加入。

### 也參考

#### `tty` 模組

Convenience functions for common terminal control operations.

### 35.4.1 范例

Here's a function that prompts for a password with echoing turned off. Note the technique using a separate `tcgetattr()` call and a `try ... finally` statement to ensure that the old tty attributes are restored exactly no matter what happens:

```
def getpass(prompt="Password: "):
    import termios, sys
    fd = sys.stdin.fileno()
    old = termios.tcgetattr(fd)
    new = termios.tcgetattr(fd)
    new[3] = new[3] & ~termios.ECHO          # lflags
    try:
        termios.tcsetattr(fd, termios.TCSADRAIN, new)
        passwd = input(prompt)
    finally:
        termios.tcsetattr(fd, termios.TCSADRAIN, old)
    return passwd
```

## 35.5 tty --- 終端機控制函式

原始碼: `Lib/tty.py`

`tty` 模組定義了將 tty 放入 `cbreak` 和 `raw` 模式的函式。

適用: Unix.

因它需要 `termios` 模組，所以只能在 Unix 上執行。

`tty` 模組定義了以下函式：

`tty.cfmakeraw(mode)`

Convert the tty attribute list *mode*, which is a list like the one returned by `termios.tcgetattr()`, to that of a tty in raw mode.

在 3.12 版被加入。

`tty.cfmakecbreak(mode)`

Convert the tty attribute list *mode*, which is a list like the one returned by `termios.tcgetattr()`, to that of a tty in cbreak mode.

This clears the `ECHO` and `ICANON` local mode flags in *mode* as well as setting the minimum input to 1 byte with no delay.

在 3.12 版被加入。

在 3.12.2 版的變更: The `ICRNLC` flag is no longer cleared. This matches Linux and macOS `stty cbreak` behavior and what `setcbreak()` historically did.

`tty.setraw(fd, when=termios.TCSAFLUSH)`

將檔案描述器 *fd* 的模式更改為 `raw`。如果 *when* 被省略，則預設為 `termios.TCSAFLUSH`，傳遞給 `termios.tcsetattr()`。`termios.tcgetattr()` 的回傳值會在設定 *fd* 模式為 `raw` 之前先儲存起來。此函式回傳這個值。

在 3.12 版的變更: 現在的回傳值是原本的 tty 屬性，而不是 `None`。

`tty.setcbreak(fd, when=termios.TCSAFLUSH)`

將檔案描述器 *fd* 的模式更改為 `cbreak`。如果 *when* 被省略，則預設為 `termios.TCSAFLUSH`，傳遞給 `termios.tcsetattr()`。`termios.tcgetattr()` 的回傳值會在設定 *fd* 模式為 `raw` 之前先儲存起來。此函式回傳這個值。

This clears the `ECHO` and `ICANON` local mode flags as well as setting the minimum input to 1 byte with no delay.

在 3.12 版的變更: 現在的回傳值回原本的 `tty` 屬性, 而不是 `None`。

在 3.12.2 版的變更: The `ICRNL` flag is no longer cleared. This restores the behavior of Python 3.11 and earlier as well as matching what Linux, macOS, & BSDs describe in their `stty(1)` man pages regarding `cbreak` mode.

#### `termios` 模組

低階終端機控制介面。

## 35.6 `pty` --- F 終端工具

原始碼: `Lib/pty.py`

The `pty` module defines operations for handling the pseudo-terminal concept: starting another process and being able to write to and read from its controlling terminal programmatically.

適用: Unix.

Pseudo-terminal handling is highly platform dependent. This code is mainly tested on Linux, FreeBSD, and macOS (it is supposed to work on other POSIX platforms but it's not been thoroughly tested).

The `pty` module defines the following functions:

`pty.fork()`

Fork. Connect the child's controlling terminal to a pseudo-terminal. Return value is `(pid, fd)`. Note that the child gets `pid 0`, and the `fd` is *invalid*. The parent's return value is the `pid` of the child, and `fd` is a file descriptor connected to the child's controlling terminal (and also to the child's standard input and output).

### 警告

On macOS the use of this function is unsafe when mixed with using higher-level system APIs, and that includes using `urllib.request`.

`pty.openpty()`

Open a new pseudo-terminal pair, using `os.openpty()` if possible, or emulation code for generic Unix systems. Return a pair of file descriptors (`master, slave`), for the master and the slave end, respectively.

`pty.spawn(argv[, master_read[, stdin_read]])`

Spawn a process, and connect its controlling terminal with the current process's standard io. This is often used to baffle programs which insist on reading from the controlling terminal. It is expected that the process spawned behind the `pty` will eventually terminate, and when it does `spawn` will return.

A loop copies STDIN of the current process to the child and data received from the child to STDOUT of the current process. It is not signaled to the child if STDIN of the current process closes down.

The functions `master_read` and `stdin_read` are passed a file descriptor which they should read from, and they should always return a byte string. In order to force `spawn` to return before the child process exits an empty byte array should be returned to signal end of file.

The default implementation for both functions will read and return up to 1024 bytes each time the function is called. The `master_read` callback is passed the pseudoterminal's master file descriptor to read output from the child process, and `stdin_read` is passed file descriptor 0, to read from the parent process's standard input.

Returning an empty byte string from either callback is interpreted as an end-of-file (EOF) condition, and that callback will not be called after that. If `stdin_read` signals EOF the controlling terminal can no longer

communicate with the parent process OR the child process. Unless the child process will quit without any input, *spawn* will then loop forever. If *master\_read* signals EOF the same behavior results (on linux at least).

Return the exit status value from *os.waitpid()* on the child process.

*os.waitstatus\_to\_exitcode()* can be used to convert the exit status into an exit code.

引發一個附帶引數 *argv* 的稽核事件 *pty.spawn*。

在 3.4 版的變更: *spawn()* now returns the status value from *os.waitpid()* on the child process.

### 35.6.1 范例

The following program acts like the Unix command *script(1)*, using a pseudo-terminal to record all input and output of a terminal session in a "typescript".

```
import argparse
import os
import pty
import sys
import time

parser = argparse.ArgumentParser()
parser.add_argument('-a', dest='append', action='store_true')
parser.add_argument('-p', dest='use_python', action='store_true')
parser.add_argument('filename', nargs='?', default='typescript')
options = parser.parse_args()

shell = sys.executable if options.use_python else os.environ.get('SHELL', 'sh')
filename = options.filename
mode = 'ab' if options.append else 'wb'

with open(filename, mode) as script:
    def read(fd):
        data = os.read(fd, 1024)
        script.write(data)
        return data

    print('Script started, file is', filename)
    script.write(('Script started on %s\n' % time.asctime()).encode())

    pty.spawn(shell, read)

    script.write(('Script done on %s\n' % time.asctime()).encode())
    print('Script done, file is', filename)
```

## 35.7 fcntl --- fcntl 和 ioctl 系統呼叫

This module performs file and I/O control on file descriptors. It is an interface to the *fcntl()* and *ioctl()* Unix routines. See the *fcntl(2)* and *ioctl(2)* Unix manual pages for full details.

適用: Unix, not WASI.

All functions in this module take a file descriptor *fd* as their first argument. This can be an integer file descriptor, such as returned by *sys.stdin\_FILENO()*, or an *io.IOBase* object, such as *sys.stdin* itself, which provides a *fileno()* that returns a genuine file descriptor.

在 3.3 版的變更: Operations in this module used to raise an *IOError* where they now raise an *OSError*.

在 3.8 版的變更: The *fcntl* module now contains *F\_ADD\_SEALS*, *F\_GET\_SEALS*, and *F\_SEAL\_\** constants for sealing of *os.memfd\_create()* file descriptors.

在 3.9 版的變更: On macOS, the `fcntl` module exposes the `F_GETPATH` constant, which obtains the path of a file from a file descriptor. On Linux (>=3.15), the `fcntl` module exposes the `F_OFD_GETLK`, `F_OFD_SETLK` and `F_OFD_SETLKW` constants, which are used when working with open file description locks.

在 3.10 版的變更: On Linux >= 2.6.11, the `fcntl` module exposes the `F_GETPIPE_SZ` and `F_SETPIPE_SZ` constants, which allow to check and modify a pipe's size respectively.

在 3.11 版的變更: On FreeBSD, the `fcntl` module exposes the `F_DUP2FD` and `F_DUP2FD_CLOEXEC` constants, which allow to duplicate a file descriptor, the latter setting `FD_CLOEXEC` flag in addition.

在 3.12 版的變更: On Linux >= 4.5, the `fcntl` module exposes the `FICLONE` and `FICLONERANGE` constants, which allow to share some data of one file with another file by reflinking on some filesystems (e.g., btrfs, OCFS2, and XFS). This behavior is commonly referred to as "copy-on-write".

在 3.13 版的變更: On Linux >= 2.6.32, the `fcntl` module exposes the `F_GETOWN_EX`, `F_SETOWN_EX`, `F_OWNER_TID`, `F_OWNER_PID`, `F_OWNER_PGRP` constants, which allow to direct I/O availability signals to a specific thread, process, or process group. On Linux >= 4.13, the `fcntl` module exposes the `F_GET_RW_HINT`, `F_SET_RW_HINT`, `F_GET_FILE_RW_HINT`, `F_SET_FILE_RW_HINT`, and `RWH_WRITE_LIFE_*` constants, which allow to inform the kernel about the relative expected lifetime of writes on a given inode or via a particular open file description. On Linux >= 5.1 and NetBSD, the `fcntl` module exposes the `F_SEAL_FUTURE_WRITE` constant for use with `F_ADD_SEALS` and `F_GET_SEALS` operations. On FreeBSD, the `fcntl` module exposes the `F_READAHEAD`, `F_ISUNIONSTACK`, and `F_KINFO` constants. On macOS and FreeBSD, the `fcntl` module exposes the `F_RDADHEAD` constant. On NetBSD and AIX, the `fcntl` module exposes the `F_CLOSEM` constant. On NetBSD, the `fcntl` module exposes the `F_MAXFD` constant. On macOS and NetBSD, the `fcntl` module exposes the `F_GETNOSIGPIPE` and `F_SETNOSIGPIPE` constant.

The module defines the following functions:

`fcntl.fcntl` (*fd*, *cmd*, *arg*=0)

Perform the operation *cmd* on file descriptor *fd* (file objects providing a `fileno()` method are accepted as well). The values used for *cmd* are operating system dependent, and are available as constants in the `fcntl` module, using the same names as used in the relevant C header files. The argument *arg* can either be an integer value, or a `bytes` object. With an integer value, the return value of this function is the integer return value of the C `fcntl()` call. When the argument is bytes it represents a binary structure, e.g. created by `struct.pack()`. The binary data is copied to a buffer whose address is passed to the C `fcntl()` call. The return value after a successful call is the contents of the buffer, converted to a `bytes` object. The length of the returned object will be the same as the length of the *arg* argument. This is limited to 1024 bytes. If the information returned in the buffer by the operating system is larger than 1024 bytes, this is most likely to result in a segmentation violation or a more subtle data corruption.

If the `fcntl()` call fails, an `OSError` is raised.

引發一個附帶引數 *fd*、*cmd*、*arg* 的稽核事件 `fcntl.fcntl`。

`fcntl.ioctl` (*fd*, *request*, *arg*=0, *mutate\_flag*=True)

This function is identical to the `fcntl()` function, except that the argument handling is even more complicated.

The *request* parameter is limited to values that can fit in 32-bits. Additional constants of interest for use as the *request* argument can be found in the `termios` module, under the same names as used in the relevant C header files.

The parameter *arg* can be one of an integer, an object supporting the read-only buffer interface (like `bytes`) or an object supporting the read-write buffer interface (like `bytearray`).

In all but the last case, behaviour is as for the `fcntl()` function.

If a mutable buffer is passed, then the behaviour is determined by the value of the *mutate\_flag* parameter.

If it is false, the buffer's mutability is ignored and behaviour is as for a read-only buffer, except that the 1024 byte limit mentioned above is avoided -- so long as the buffer you pass is at least as long as what the operating system wants to put there, things should work.

If *mutate\_flag* is true (the default), then the buffer is (in effect) passed to the underlying `ioctl()` system call, the latter's return code is passed back to the calling Python, and the buffer's new contents reflect the action of the `ioctl()`. This is a slight simplification, because if the supplied buffer is less than 1024 bytes long it is first

copied into a static buffer 1024 bytes long which is then passed to `ioctl()` and copied back into the supplied buffer.

If the `ioctl()` call fails, an `OSError` exception is raised.

範例：

```
>>> import array, fcntl, struct, termios, os
>>> os.getpgrp()
13341
>>> struct.unpack('h', fcntl.ioctl(0, termios.TIOCGPRG, " "))[0]
13341
>>> buf = array.array('h', [0])
>>> fcntl.ioctl(0, termios.TIOCGPRG, buf, 1)
0
>>> buf
array('h', [13341])
```

引發一個附帶引數 `fd`、`request`、`arg` 的稽核事件 `fcntl.ioctl`。

`fcntl.flock(fd, operation)`

Perform the lock operation *operation* on file descriptor *fd* (file objects providing a `fileno()` method are accepted as well). See the Unix manual `flock(2)` for details. (On some systems, this function is emulated using `fcntl()`.)

If the `flock()` call fails, an `OSError` exception is raised.

引發一個附帶引數 `fd`、`operation` 的稽核事件 `fcntl.flock`。

`fcntl.lockf(fd, cmd, len=0, start=0, whence=0)`

This is essentially a wrapper around the `fcntl()` locking calls. *fd* is the file descriptor (file objects providing a `fileno()` method are accepted as well) of the file to lock or unlock, and *cmd* is one of the following values:

`fcntl.LOCK_UN`

Release an existing lock.

`fcntl.LOCK_SH`

Acquire a shared lock.

`fcntl.LOCK_EX`

Acquire an exclusive lock.

`fcntl.LOCK_NB`

Bitwise OR with any of the other three `LOCK_*` constants to make the request non-blocking.

If `LOCK_NB` is used and the lock cannot be acquired, an `OSError` will be raised and the exception will have an `errno` attribute set to `EACCES` or `EAGAIN` (depending on the operating system; for portability, check for both values). On at least some systems, `LOCK_EX` can only be used if the file descriptor refers to a file opened for writing.

*len* is the number of bytes to lock, *start* is the byte offset at which the lock starts, relative to *whence*, and *whence* is as with `io.IOBase.seek()`, specifically:

- 0 -- relative to the start of the file (`os.SEEK_SET`)
- 1 -- relative to the current buffer position (`os.SEEK_CUR`)
- 2 -- relative to the end of the file (`os.SEEK_END`)

The default for *start* is 0, which means to start at the beginning of the file. The default for *len* is 0 which means to lock to the end of the file. The default for *whence* is also 0.

引發一個附帶引數 `fd`、`cmd`、`len`、`start`、`whence` 的稽核事件 `fcntl.lockf`。

Examples (all on a SVR4 compliant system):

```
import struct, fcntl, os

f = open(...)
rv = fcntl.fcntl(f, fcntl.F_SETFL, os.O_NDELAY)

lockdata = struct.pack('hhllhh', fcntl.F_WRLCK, 0, 0, 0, 0, 0)
rv = fcntl.fcntl(f, fcntl.F_SETLKW, lockdata)
```

Note that in the first example the return value variable *rv* will hold an integer value; in the second example it will hold a *bytes* object. The structure lay-out for the *lockdata* variable is system dependent --- therefore using the *flock()* call may be better.

### 也參考

#### os 模組

If the locking flags *O\_SHLOCK* and *O\_EXLOCK* are present in the *os* module (on BSD only), the *os.open()* function provides an alternative to the *lockf()* and *flock()* functions.

## 35.8 resource --- 資源使用資訊

This module provides basic mechanisms for measuring and controlling system resources utilized by a program.

適用: Unix, not WASI.

Symbolic constants are used to specify particular system resources and to request usage information about either the current process or its children.

An *OSError* is raised on syscall failure.

#### exception resource.error

A deprecated alias of *OSError*.

在 3.3 版的變更: Following [PEP 3151](#), this class was made an alias of *OSError*.

### 35.8.1 Resource Limits

Resources usage can be limited using the *setrlimit()* function described below. Each resource is controlled by a pair of limits: a soft limit and a hard limit. The soft limit is the current limit, and may be lowered or raised by a process over time. The soft limit can never exceed the hard limit. The hard limit can be lowered to any value greater than the soft limit, but not raised. (Only processes with the effective UID of the super-user can raise a hard limit.)

The specific resources that can be limited are system dependent. They are described in the *getrlimit(2)* man page. The resources listed below are supported when the underlying operating system supports them; resources which cannot be checked or controlled by the operating system are not defined in this module for those platforms.

#### resource.RLIM\_INFINITY

Constant used to represent the limit for an unlimited resource.

#### resource.getrlimit(resource)

Returns a tuple (soft, hard) with the current soft and hard limits of *resource*. Raises *ValueError* if an invalid resource is specified, or *error* if the underlying system call fails unexpectedly.

#### resource.setrlimit(resource, limits)

Sets new limits of consumption of *resource*. The *limits* argument must be a tuple (soft, hard) of two integers describing the new limits. A value of *RLIM\_INFINITY* can be used to request a limit that is unlimited.

Raises *ValueError* if an invalid resource is specified, if the new soft limit exceeds the hard limit, or if a process tries to raise its hard limit. Specifying a limit of *RLIM\_INFINITY* when the hard or system limit for

that resource is not unlimited will result in a `ValueError`. A process with the effective UID of super-user can request any valid limit value, including unlimited, but `ValueError` will still be raised if the requested limit exceeds the system imposed limit.

`setrlimit` may also raise `error` if the underlying system call fails.

VxWorks only supports setting `RLIMIT_NOFILE`.

引發一個附帶引數 `resource`、`limits` 的稽核事件 `resource.setrlimit`。

`resource.prlimit(pid, resource[, limits])`

Combines `setrlimit()` and `getrlimit()` in one function and supports to get and set the resources limits of an arbitrary process. If `pid` is 0, then the call applies to the current process. `resource` and `limits` have the same meaning as in `setrlimit()`, except that `limits` is optional.

When `limits` is not given the function returns the `resource` limit of the process `pid`. When `limits` is given the `resource` limit of the process is set and the former resource limit is returned.

Raises `ProcessLookupError` when `pid` can't be found and `PermissionError` when the user doesn't have `CAP_SYS_RESOURCE` for the process.

引發一個附帶引數 `pid`、`resource`、`limits` 的稽核事件 `resource.prlimit`。

適用: Linux >= 2.6.36 with glibc >= 2.13.

在 3.4 版被加入。

These symbols define resources whose consumption can be controlled using the `setrlimit()` and `getrlimit()` functions described below. The values of these symbols are exactly the constants used by C programs.

The Unix man page for `getrlimit(2)` lists the available resources. Note that not all systems use the same symbol or same value to denote the same resource. This module does not attempt to mask platform differences --- symbols not defined for a platform will not be available from this module on that platform.

`resource.RLIMIT_CORE`

The maximum size (in bytes) of a core file that the current process can create. This may result in the creation of a partial core file if a larger core would be required to contain the entire process image.

`resource.RLIMIT_CPU`

The maximum amount of processor time (in seconds) that a process can use. If this limit is exceeded, a `SIGXCPU` signal is sent to the process. (See the `signal` module documentation for information about how to catch this signal and do something useful, e.g. flush open files to disk.)

`resource.RLIMIT_FSIZE`

The maximum size of a file which the process may create.

`resource.RLIMIT_DATA`

The maximum size (in bytes) of the process's heap.

`resource.RLIMIT_STACK`

The maximum size (in bytes) of the call stack for the current process. This only affects the stack of the main thread in a multi-threaded process.

`resource.RLIMIT_RSS`

The maximum resident set size that should be made available to the process.

`resource.RLIMIT_NPROC`

The maximum number of processes the current process may create.

`resource.RLIMIT_NOFILE`

The maximum number of open file descriptors for the current process.

`resource.RLIMIT_OFILE`

The BSD name for `RLIMIT_NOFILE`.

`resource.RLIMIT_MEMLOCK`

The maximum address space which may be locked in memory.

`resource.RLIMIT_VMEM`

The largest area of mapped memory which the process may occupy.

適用: FreeBSD >= 11.

`resource.RLIMIT_AS`

The maximum area (in bytes) of address space which may be taken by the process.

`resource.RLIMIT_MSGQUEUE`

The number of bytes that can be allocated for POSIX message queues.

適用: Linux >= 2.6.8.

在 3.4 版被加入.

`resource.RLIMIT_NICE`

The ceiling for the process's nice level (calculated as 20 - rlim\_cur).

適用: Linux >= 2.6.12.

在 3.4 版被加入.

`resource.RLIMIT_RTPRIO`

The ceiling of the real-time priority.

適用: Linux >= 2.6.12.

在 3.4 版被加入.

`resource.RLIMIT_RTTIME`

The time limit (in microseconds) on CPU time that a process can spend under real-time scheduling without making a blocking syscall.

適用: Linux >= 2.6.25.

在 3.4 版被加入.

`resource.RLIMIT_SIGPENDING`

The number of signals which the process may queue.

適用: Linux >= 2.6.8.

在 3.4 版被加入.

`resource.RLIMIT_SBSIZE`

The maximum size (in bytes) of socket buffer usage for this user. This limits the amount of network memory, and hence the amount of mbufs, that this user may hold at any time.

適用: FreeBSD.

在 3.4 版被加入.

`resource.RLIMIT_SWAP`

The maximum size (in bytes) of the swap space that may be reserved or used by all of this user id's processes. This limit is enforced only if bit 1 of the `vm.overcommit` sysctl is set. Please see [tuning\(7\)](#) for a complete description of this sysctl.

適用: FreeBSD.

在 3.4 版被加入.

`resource.RLIMIT_NPTS`

The maximum number of pseudo-terminals created by this user id.

適用: FreeBSD.

在 3.4 版被加入.

`resource.RLIMIT_KQUEUES`

The maximum number of kqueues this user id is allowed to create.

適用: FreeBSD >= 11.

在 3.10 版被加入.

## 35.8.2 Resource Usage

These functions are used to retrieve resource usage information:

`resource.getrusage(who)`

This function returns an object that describes the resources consumed by either the current process or its children, as specified by the *who* parameter. The *who* parameter should be specified using one of the `RUSAGE_*` constants described below.

一個簡單範例:

```
from resource import *
import time

# a non CPU-bound task
time.sleep(3)
print(getrusage(RUSAGE_SELF))

# a CPU-bound task
for i in range(10 ** 8):
    _ = 1 + 1
print(getrusage(RUSAGE_SELF))
```

The fields of the return value each describe how a particular system resource has been used, e.g. amount of time spent running in user mode or number of times the process was swapped out of main memory. Some values are dependent on the clock tick interval, e.g. the amount of memory the process is using.

For backward compatibility, the return value is also accessible as a tuple of 16 elements.

The fields `ru_utime` and `ru_stime` of the return value are floating-point values representing the amount of time spent executing in user mode and the amount of time spent executing in system mode, respectively. The remaining values are integers. Consult the `getrusage(2)` man page for detailed information about these values. A brief summary is presented here:

Index	Field	Resource
0	<code>ru_utime</code>	time in user mode (float seconds)
1	<code>ru_stime</code>	time in system mode (float seconds)
2	<code>ru_maxrss</code>	maximum resident set size
3	<code>ru_ixrss</code>	shared memory size
4	<code>ru_idrss</code>	unshared memory size
5	<code>ru_isrss</code>	unshared stack size
6	<code>ru_minflt</code>	page faults not requiring I/O
7	<code>ru_majflt</code>	page faults requiring I/O
8	<code>ru_nswap</code>	number of swap outs
9	<code>ru_inblock</code>	block input operations
10	<code>ru_oublock</code>	block output operations
11	<code>ru_msgsnd</code>	messages sent
12	<code>ru_msgrcv</code>	messages received
13	<code>ru_nsignals</code>	signals received
14	<code>ru_nvcsw</code>	voluntary context switches
15	<code>ru_nivcsw</code>	involuntary context switches

This function will raise a `ValueError` if an invalid `who` parameter is specified. It may also raise `error` exception in unusual circumstances.

`resource.getpagesize()`

Returns the number of bytes in a system page. (This need not be the same as the hardware page size.)

The following `RUSAGE_*` symbols are passed to the `getrusage()` function to specify which processes information should be provided for.

`resource.RUSAGE_SELF`

Pass to `getrusage()` to request resources consumed by the calling process, which is the sum of resources used by all threads in the process.

`resource.RUSAGE_CHILDREN`

Pass to `getrusage()` to request resources consumed by child processes of the calling process which have been terminated and waited for.

`resource.RUSAGE_BOTH`

Pass to `getrusage()` to request resources consumed by both the current process and child processes. May not be available on all systems.

`resource.RUSAGE_THREAD`

Pass to `getrusage()` to request resources consumed by the current thread. May not be available on all systems.

在 3.2 版被加入。

## 35.9 syslog --- Unix syslog 函式庫例程

This module provides an interface to the Unix `syslog` library routines. Refer to the Unix manual pages for a detailed description of the `syslog` facility.

適用: Unix, not WASI, not iOS.

This module wraps the system `syslog` family of routines. A pure Python library that can speak to a syslog server is available in the `logging.handlers` module as `SysLogHandler`.

該模組定義了以下函式:

`syslog.syslog(message)`

`syslog.syslog(priority, message)`

Send the string *message* to the system logger. A trailing newline is added if necessary. Each message is tagged with a priority composed of a *facility* and a *level*. The optional *priority* argument, which defaults to `LOG_INFO`, determines the message priority. If the facility is not encoded in *priority* using logical-or (`LOG_INFO | LOG_USER`), the value given in the `openlog()` call is used.

If `openlog()` has not been called prior to the call to `syslog()`, `openlog()` will be called with no arguments.

引發一個附帶引數 `priority`、`message` 的稽核事件 `syslog.syslog`。

在 3.2 版的變更: In previous versions, `openlog()` would not be called automatically if it wasn't called prior to the call to `syslog()`, deferring to the `syslog` implementation to call `openlog()`.

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) `openlog()` must be called in the main interpreter before `syslog()` may be used in a subinterpreter. Otherwise it will raise `RuntimeError`.

`syslog.openlog([ident[, logoption[, facility]])]`

Logging options of subsequent `syslog()` calls can be set by calling `openlog()`. `syslog()` will call `openlog()` with no arguments if the log is not currently open.

The optional *ident* keyword argument is a string which is prepended to every message, and defaults to `sys.argv[0]` with leading path components stripped. The optional *logoption* keyword argument (default is 0) is a bit field -- see below for possible values to combine. The optional *facility* keyword argument (default is `LOG_USER`) sets the default facility for messages which do not have a facility explicitly encoded.

引發一個附帶引數 `ident`、`logoption`、`facility` 的稽核事件 `syslog.openlog`。

在 3.2 版的變更: In previous versions, keyword arguments were not allowed, and *ident* was required.

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise `RuntimeError` if called in a subinterpreter.

`syslog.closelog()`

Reset the `syslog` module values and call the system library `closelog()`.

This causes the module to behave as it does when initially imported. For example, `openlog()` will be called on the first `syslog()` call (if `openlog()` hasn't already been called), and *ident* and other `openlog()` parameters are reset to defaults.

引發一個不附帶引數的稽核事件 `syslog.closelog`。

在 3.12 版的變更: This function is restricted in subinterpreters. (Only code that runs in multiple interpreters is affected and the restriction is not relevant for most users.) This may only be called in the main interpreter. It will raise `RuntimeError` if called in a subinterpreter.

`syslog.setlogmask(maskpri)`

Set the priority mask to *maskpri* and return the previous mask value. Calls to `syslog()` with a priority level not set in *maskpri* are ignored. The default is to log all priorities. The function `LOG_MASK(pri)` calculates the mask for the individual priority *pri*. The function `LOG_UPTO(pri)` calculates the mask for all priorities up to and including *pri*.

引發一個附帶引數 `maskpri` 的稽核事件 `syslog.setlogmask`。

The module defines the following constants:

`syslog.LOG_EMERG`

`syslog.LOG_ALERT`

`syslog.LOG_CRIT`

`syslog.LOG_ERR`

`syslog.LOG_WARNING`

`syslog.LOG_NOTICE`

`syslog.LOG_INFO`

`syslog.LOG_DEBUG`

Priority levels (high to low).

`syslog.LOG_AUTH`

`syslog.LOG_AUTHPRIV`

`syslog.LOG_CRON`

`syslog.LOG_DAEMON`

`syslog.LOG_FTP`

`syslog.LOG_INSTALL`

`syslog.LOG_KERN`

`syslog.LOG_LAUNCHD`

`syslog.LOG_LPR`

`syslog.LOG_MAIL`

`syslog.LOG_NETINFO`

`syslog.LOG_NEWS`

`syslog.LOG_RAS`

`syslog.LOG_REMOTEAUTH`

`syslog.LOG_SYSLOG`

`syslog.LOG_USER`

`syslog.LOG_UUCP`

`syslog.LOG_LOCAL0`

`syslog.LOG_LOCAL1`

`syslog.LOG_LOCAL2`

`syslog.LOG_LOCAL3`

`syslog.LOG_LOCAL4`

`syslog.LOG_LOCAL5`

`syslog.LOG_LOCAL6`

`syslog.LOG_LOCAL7`

Facilities, depending on availability in `<syslog.h>` for `LOG_AUTHPRIV`, `LOG_FTP`, `LOG_NETINFO`, `LOG_REMOTEAUTH`, `LOG_INSTALL` and `LOG_RAS`.

在 3.13 版的變更: Added `LOG_FTP`, `LOG_NETINFO`, `LOG_REMOTEAUTH`, `LOG_INSTALL`, `LOG_RAS`, and `LOG_LAUNCHD`.

`syslog.LOG_PID`

`syslog.LOG_CONS`

`syslog.LOG_NDELAY`

`syslog.LOG_ODELAY`

`syslog.LOG_NOWAIT`

`syslog.LOG_PERROR`

Log options, depending on availability in `<syslog.h>` for `LOG_ODELAY`, `LOG_NOWAIT` and `LOG_PERROR`.

## 35.9.1 范例

### 簡單范例

一組簡單範例:

```
import syslog

syslog.syslog('Processing started')
if error:
    syslog.syslog(syslog.LOG_ERR, 'Processing started')
```

An example of setting some log options, these would include the process ID in logged messages, and write the messages to the destination facility used for mail logging:

```
syslog.openlog(logoption=syslog.LOG_PID, facility=syslog.LOG_MAIL)
syslog.syslog('E-mail processing initiated...')
```

## 已被取代的模組

---

此章節所描述的模組在大多數使用情況下已被其他模組取代，僅為了向後相容性而被保留下來。

Modules may appear in this chapter because they only cover a limited subset of a problem space, and a more generally applicable solution is available elsewhere in the standard library (for example, `getopt` covers the very specific task of “mimic the C `getopt()` API in Python”, rather than the broader command line option parsing and argument parsing capabilities offered by `optparse` and `argparse`).

Alternatively, modules may appear in this chapter because they are deprecated outright, and awaiting removal in a future release, or they are *soft deprecated* and their use is actively discouraged in new projects. With the removal of various obsolete modules through [PEP 594](#), there are currently no modules in this latter category.

### 37.1 `getopt` --- 用於命令列選項的 C 風格剖析器

原始碼: `Lib/getopt.py`

#### 備註

This module is considered feature complete. A more declarative and extensible alternative to this API is provided in the `optparse` module. Further functional enhancements for command line parameter processing are provided either as third party modules on PyPI, or else as features in the `argparse` module.

---

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form `'-'` and `'--'`). Long options similar to those supported by GNU software may be used as well via an optional third argument.

Users who are unfamiliar with the Unix `getopt()` function should consider using the `argparse` module instead. Users who are familiar with the Unix `getopt()` function, but would like to get equivalent behavior while writing less code and getting better help and error messages should consider using the `optparse` module. See [選擇一個命令列參數剖析函式庫](#) for additional details.

這個模組提供兩個函式和一個例外：

`getopt.getopt(args, shortopts, longopts=[])`

Parses command line options and parameter list. `args` is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. `shortopts` is the string of option

letters that the script wants to recognize, with options that require an argument followed by a colon (':'); i.e., the same format that Unix `getopt()` uses).

**備**

Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

`longopts`, if specified, must be a list of strings with the names of the long options which should be supported. The leading '--' characters should not be included in the option name. Long options which require an argument should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, `shortopts` should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if `longopts` is ['foo', 'frob'], the option `--fo` will match as `--foo`, but `--f` will not match uniquely, so `GetoptError` will be raised.

The return value consists of two elements: the first is a list of (`option`, `value`) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of `args`). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt(args, shortopts, longopts=[])`

This function works like `getopt()`, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The `getopt()` function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

**exception** `getopt.GetoptError`

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

**exception** `getopt.error`

為了向後相容性而設的 `GetoptError` 名。

一個僅使用 Unix 風格選項的範例：

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

使用長選項名稱同樣容易：

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
```

(繼續下一頁)

(繼續上一頁)

```

...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']

```

在圖本中，典型的用法如下：

```

import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # 印出幫助訊息並退出：
        print(err) # 會印出像是 "option -a not recognized" 的訊息
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    process(args, output=output, verbose=verbose)

if __name__ == "__main__":
    main()

```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the `optparse` module:

```

import optparse

if __name__ == '__main__':
    parser = optparse.OptionParser()
    parser.add_option('-o', '--output')
    parser.add_option('-v', dest='verbose', action='store_true')
    opts, args = parser.parse_args()
    process(args, output=opts.output, verbose=opts.verbose)

```

A roughly equivalent command line interface for this case can also be produced by using the `argparse` module:

```

import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    parser.add_argument('rest', nargs='*')
    args = parser.parse_args()
    process(args.rest, output=args.output, verbose=args.verbose)

```

參見選擇一個命令列參數剖析函式庫以圖解這段程式碼的 `argparse` 版本與 `optparse` (以及 `getopt`) 版本在行圖上的差圖。

---

## 已移除的模組

---

本章描述的模組已從 Python 標準函式庫中移除。這提供文件以協助尋找替代方案。

### 38.1 `aifc` --- 讀寫 AIFF 與 AIFC 檔案

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定的。

最後提供 `aifc` 模組的 Python 版本是 [Python 3.12](#)。

### 38.2 `asynchat` --- 非同步 socket 指令/回應處理函式

Deprecated since version 3.6, removed in version 3.12.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.6 中被用，已在 Python 3.12 中被移除。它的移除是在 [PEP 594](#) 中定的。

應用程式應改用 `asyncio` 模組。

最後提供 `asynchat` 模組的 Python 版本是 [Python 3.11](#)。

### 38.3 `asyncore` --- 非同步 socket 處理函式

Deprecated since version 3.6, removed in version 3.12.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.6 中被用，已在 Python 3.12 中被移除。它的移除是在 [PEP 594](#) 中定的。

應用程式應改用 `asyncio` 模組。

最後提供 `asyncore` 模組的 Python 版本是 [Python 3.11](#)。

## 38.4 audiopop --- 操作原始聲音檔案

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 PEP 594 中定义的。

最後提供 audiopop 模組的 Python 版本是 Python 3.12。

## 38.5 cgi --- 通用閘道器介面支援

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 PEP 594 中定义的。

可以改用 PyPI 上的模組 fork: `legacy-cgi`。這是 `cgi` 模組的一個副本，不再由 Python 核心團隊維護或支援。

最後提供 `cgi` 模組的 Python 版本是 Python 3.12。

## 38.6 cgitb --- CGI 本的回溯管理器 (traceback manager)

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 PEP 594 中定义的。

可以改用 PyPI 上的模組 fork: `legacy-cgi`。這是 `cgi` 模組的一個副本，不再由 Python 核心團隊維護或支援。

最後提供 `cgitb` 模組的 Python 版本是 Python 3.12。

## 38.7 chunk --- 讀取 IFF 分塊資料

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 PEP 594 中定义的。

最後提供 `chunk` 模組的 Python 版本是 Python 3.12。

## 38.8 crypt --- 用於檢查 Unix 密碼的函式

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 PEP 594 中定义的。

應用程式可以改用標準函式庫中的 `hashlib` 模組。其他可能的替代方案是 PyPI 上的第三方庫: `legacycrypt`、`bcrypt`、`argon2-cffi` 或 `passlib`。這些函式庫不受 Python 核心團隊支援或維護。

最後提供 `crypt` 模組的 Python 版本是 Python 3.12。

## 38.9 distutils --- 建置與安裝 Python 模組

Deprecated since version 3.10, removed in version 3.12.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.10 中被廢用，已在 Python 3.12 中被移除。它的移除是在 PEP 632 中定义的，該 PEP 附有遷移建議。

最後提供 `distutils` 模組的 Python 版本是 Python 3.11。

## 38.10 `imghdr` --- 判定圖片種類

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

可能的替代方案是 PyPI 上的第三方函式庫：`filetype`、`puremagic` 或 `python-magic`。它們不受 Python 核心團隊支援或維護。

最後提供 `imghdr` 模組的 Python 版本是 Python 3.12。

## 38.11 `imp` --- 存取引入系統層

Deprecated since version 3.4, removed in version 3.12.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.4 中被廢用，已在 Python 3.12 中被移除。其移除通知包含了從 `imp` 遷移至 `importlib` 的指引。

最後提供 `imp` 模組的 Python 版本是 Python 3.11。

## 38.12 `mailcap` --- Mailcap 檔案處理

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `mailcap` 模組的 Python 版本是 Python 3.12。

## 38.13 `msilib` --- 讀寫 Microsoft Installer 檔案

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `msilib` 模組的 Python 版本是 Python 3.12。

## 38.14 `nis` --- Sun NIS (Yellow Pages) 介面

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `nis` 模組的 Python 版本是 Python 3.12。

## 38.15 `nntplib` --- NNTP 協定客戶端

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `nntplib` 模組的 Python 版本是 Python 3.12。

## 38.16 `ossaudiodev` --- 對 OSS 相容聲音裝置的存取

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `ossaudiodev` 模組的 Python 版本是 Python 3.12。

## 38.17 `pipes` --- shell pipelines 介面

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

應用程式應改用 `subprocess` 模組。

最後提供 `pipes` 模組的 Python 版本是 Python 3.12。

## 38.18 `smtplib` --- SMTP 伺服器

Deprecated since version 3.6, removed in version 3.12.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.6 中被廢用，已在 Python 3.12 中被移除。它的移除是在 [PEP 594](#) 中定义的。

一個可能的替代方案是第三方 `aiosmtp` 函式庫。這個函式庫不是由 Python 核心團隊維護或支援。

最後提供 `smtplib` 模組的 Python 版本是 Python 3.11。

## 38.19 `sndhdr` --- 判定聲音檔案的種類

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

可能的替代方案是 PyPI 上的第三方模組：`filetype`、`puremagic` 或 `python-magic`。它們不受 Python 核心團隊支援或維護。

最後提供 `sndhdr` 模組的 Python 版本是 Python 3.12。

## 38.20 `spwd` --- shadow 密碼資料庫

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

可能的替代方案是 PyPI 上的第三方函式庫：`python-pam`。這不受 Python 核心團隊支援或維護。

最後提供 `spwd` 模組的 Python 版本是 Python 3.12。

## 38.21 `sunau` --- 讀寫 Sun AU 檔案

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被廢用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定义的。

最後提供 `sunau` 模組的 Python 版本是 Python 3.12。

## 38.22 telnetlib --- Telnet 客端

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定的。

可能的替代方案是 PyPI 上的第三方函式庫：[telnetlib3](#) 或 [Exscript](#)。它們不受 Python 核心團隊支援或維護。

最後提供 `telnetlib` 模組的 Python 版本是 [Python 3.12](#)。

## 38.23 uu --- uuencode 檔案的編碼與解碼

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定的。

最後提供 `uu` 模組的 Python 版本是 [Python 3.12](#)。

## 38.24 xdrlib --- XDR 資料的編碼與解碼

Deprecated since version 3.11, removed in version 3.13.

這個模組已不再是 Python 標準函式庫的一部分。它在 Python 3.11 中被用，已在 Python 3.13 中被移除。它的移除是在 [PEP 594](#) 中定的。

最後提供 `xdrlib` 模組的 Python 版本是 [Python 3.12](#)。

---

## 安全性注意事項

---

以下模組具有特定的安全性注意事項：

- *base64*: *base64* 安全性注意事項在 **RFC 4648**
- *hashlib*: 所有建構函式都禁用 "usedforsecurity" 僅限關鍵字引數，禁用已知的不安全與被阻擋的演算法
- *http.server* 不適合在正式環境使用，因其僅實作基本的安全檢查。請參閱安全注意事項。
- *logging*: 日誌配置使用 *eval()*
- *multiprocessing*: *Connection.recv()* 使用 *pickle*
- *pickle*: 限制 *pickle* 中的全域變數
- *random* 不該用於安全性相關用途，請改用 *secrets*
- *shelve*: *shelve* 基於 *pickle*，因此不適合用來處理不受信任的來源
- *ssl*: *SSL/TLS* 安全性注意事項
- *subprocess*: 子行程安全性注意事項
- *tempfile*: *mktemp* 由於存在競態條件 (*race condition*) 漏洞而被禁用
- *xml*: *XML* 漏洞
- *zipfile*: 惡意準備的 *.zip* 檔案可能會導致硬碟空間耗盡

`-I` 命令列選項可用於在隔離模式下運行 Python。若其無法使用，可以改用 `-P` 選項或 `PYTHONSAFEPATH` 環境變數，避免 `sys.path` 新增在的不安全路徑，例如當前目錄、本目錄或空字串。

&gt;&gt;&gt;

互動式 shell 的預設 Python 提示字元。常見於能在直譯器中以互動方式被執行的程式碼範例。

...

可以表示：

- 在一個被縮排的程式碼區塊、在一對匹配的左右定界符 (delimiter, 例如括號、方括號、花括號或三引號) 內部, 或是在指定一個裝飾器 (decorator) 之後, 要輸入程式碼時, 互動式 shell 顯示的預設 Python 提示字元。
- 建立常數 *Ellipsis*。

### abstract base class (抽象基底類)

抽象基底類 (又稱 ABC) 提供了一種定義界面的方法, 作 *duck-typing* (鴨子型) 的補充。其他類似的技術, 像是 `hasattr()`, 則顯得笨拙或是帶有細微的錯誤 (例如使用魔術方法 (magic method))。ABC 用擬的 subclass (子類), 它們不繼承自另一個 class (類), 但仍可被 `isinstance()` 及 `issubclass()` 辨識; 請參 `abc` 模組的說明文件。Python 有許多建立的 ABC, 用於資料結構 (在 `collections.abc` 模組)、數字 (在 `numbers` 模組)、串流 (在 `io` 模組) 及 import 尋檢器和載入器 (在 `importlib.abc` 模組)。你可以使用 `abc` 模組建立自己的 ABC。

### annotation (釋)

一個與變數、class 屬性、函式的參數或回傳值相關聯的標。照慣例, 它被用來作 *type hint* (型提示)。

在執行環境 (runtime), 區域變數的釋無法被存取, 但全域變數、class 屬性和函式的解, 會分被儲存在模組、class 和函式的 `__annotations__` 特殊屬性中。

請參 *variable annotation*、*function annotation*、**PEP 484** 和 **PEP 526**, 這些章節皆有此功能的。關於釋的最佳實踐方法也請參 `annotations-howto`。

### argument (引數)

呼叫函式時被傳遞給 *function* (或 *method*) 的值。引數有兩種：

- 關鍵字引數 (*keyword argument*): 在函式呼叫中, 以識字 (identifier, 例如 `name=`) 開頭的引數, 或是以 `**` 後面 dictionary (字典) 的值被傳遞的引數。例如, 3 和 5 都是以下 `complex()` 呼叫中的關鍵字引數：

```
complex(real=3, imag=5)
complex(**{'real': 3, 'imag': 5})
```

- 位置引數 (*positional argument*): 不是關鍵字引數的引數。位置引數可在一個引數列表的起始處出現, 和 (或) 作 `*` 之後的 *iterable* (可代物件) 中的元素被傳遞。例如, 3 和 5 都是以下呼叫中的位置引數:

```
complex(3, 5)
complex(*(3, 5))
```

引數會被指定給函式主體中的附名區域變數。關於支配這個指定過程的規則, 請參 [calls](#) 章節。在語法上, 任何運算式都可以被用來表示一個引數; 其評估值會被指定給區域變數。

另請參 [術語表的parameter](#) (參數) 條目、常見問題中的引數和參數之間的差, 以及 [PEP 362](#)。

### asynchronous context manager (非同步情境管理器)

一個可以控制 `async with` 陳述式中所見環境的物件, 而它是透過定義 `__aenter__()` 和 `__aexit__()` method (方法) 來控制的。由 [PEP 492](#) 引入。

### asynchronous generator (非同步生成器)

一個會回傳 *asynchronous generator iterator* (非同步生成器代器) 的函式。它看起來像一個以 `async def` 定義的協程函式 (coroutine function), 但不同的是它包含了 `yield` 運算式, 能生成一系列可用於 `async for` 圈的值。

這個術語通常用來表示一個非同步生成器函式, 但在某些情境中, 也可能是表示非同步生成器代器 (*asynchronous generator iterator*)。萬一想表達的意思不清晰, 那就使用完整的術語, 以避免歧義。

一個非同步生成器函式可能包含 `await` 運算式, 以及 `async for` 和 `async with` 陳述式。

### asynchronous generator iterator (非同步生成器代器)

一個由 *asynchronous generator* (非同步生成器) 函式所建立的物件。

這是一個 *asynchronous iterator* (非同步代器), 當它以 `__anext__()` method 被呼叫時, 會回傳一個可等待物件 (awaitable object), 該物件將執行非同步生成器的函式主體, 直到遇到下一個 `yield` 運算式。

每個 `yield` 會暫停處理程序, 記住執行狀態 (包括區域變數及擱置中的 `try` 陳述式)。當非同步生成器代器以另一個被 `__anext__()` 回傳的可等待物件有效地回復時, 它會從停止的地方繼續執行。請參 [PEP 492](#) 和 [PEP 525](#)。

### asynchronous iterable (非同步可代物件)

一個物件, 它可以在 `async for` 陳述式中被使用。必須從它的 `__aiter__()` method 回傳一個 *asynchronous iterator* (非同步代器)。由 [PEP 492](#) 引入。

### asynchronous iterator (非同步代器)

一個實作 `__aiter__()` 和 `__anext__()` method 的物件。`__anext__()` 必須回傳一個 *awaitable* (可等待物件)。`async for` 會解析非同步代器的 `__anext__()` method 所回傳的可等待物件, 直到它引發 `StopAsyncIteration` 例外。由 [PEP 492](#) 引入。

### attribute (屬性)

一個與某物件相關聯的值, 該值大多能透過使用點分隔運算式 (dotted expression) 的名稱被參照。例如, 如果物件 `o` 有一個屬性 `a`, 則該屬性能以 `o.a` 被參照。

如果一個物件允許, 給予該物件一個名稱不是由 `identifiers` 所定義之識符 (identifier) 的屬性是有可能的, 例如使用 `setattr()`。像這樣的屬性將無法使用點分隔運算式來存取, 而是需要使用 `getattr()` 來取得它。

### awaitable (可等待物件)

一個可以在 `await` 運算式中被使用的物件。它可以是一個 *coroutine* (協程), 或是一個有 `__await__()` method 的物件。另請參 [PEP 492](#)。

### BDFL

Benevolent Dictator For Life (終身仁慈獨裁者), 又名 [Guido van Rossum](#), Python 的創造者。

### binary file (二進位檔案)

一個能讀取和寫入 *bytes-like objects* (類位元組串物件) 的 *file object* (檔案物件)。二進位檔案的例子有: 以二進位模式 ('rb'、'wb' 或 'rb+') 開的檔案、`sys.stdin.buffer`、`sys.stdout.buffer`, 以及 `io.BytesIO` 和 `gzip.GzipFile` 實例。

另請參閱 `text file` (文字檔案)，它是一個能讀取和寫入 `str` 物件的檔案物件。

### borrowed reference (借用參照)

在 Python 的 C API 中，借用參照是一個對物件的參照，其中使用該物件的程式碼不擁有這個參照。如果該物件被銷毀，它會成爲一個迷途指標 (dangling pointer)。例如，一次垃圾回收 (garbage collection) 可以移除對物件的最後一個 *strong reference* (參照)，而將該物件銷毀。

對 *borrowed reference* 呼叫 `Py_INCREF()` 以將它原地 (in-place) 轉成 *strong reference* 是被建議的做法，除非該物件不能在最後一次使用借用參照之前被銷毀。`Py_NewRef()` 函式可用於建立一個新的 *strong reference*。

### bytes-like object (類位元組串物件)

一個支援 `bufferobjects` 且能匯出 *C-contiguous* 緩衝區的物件。這包括所有的 `bytes`、`bytearray` 和 `array.array` 物件，以及許多常見的 `memoryview` 物件。類位元組串物件可用於處理二進位資料的各種運算；這些運算包括壓縮、儲存至二進位檔案和透過 `socket` (插座) 發送。

有些運算需要二進位資料是可變的。明文文件通常會將這些物件稱爲「可讀寫的類位元組串物件」。可變緩衝區的物件包括 `bytearray`，以及 `bytearray` 的 `memoryview`。其他的運算需要讓二進位資料被儲存在不可變物件 (「唯讀的類位元組串物件」) 中；這些物件包括 `bytes`，以及 `bytes` 物件的 `memoryview`。

### bytecode (位元組碼)

Python 的原始碼會被編譯成位元組碼，它是 Python 程式在 CPython 直譯器中的內部表示法。該位元組碼也會被暫存在 `.pyc` 檔案中，以便第二次執行同一個檔案時能更快速 (可以不用從原始碼重新編譯位元組碼)。這種「中間語言 (intermediate language)」據說是運行在一個 *virtual machine* (擬機器) 上，該擬機器會執行與每個位元組碼對應的機器碼 (machine code)。要注意的是，位元組碼理論上是無法在不同的 Python 擬機器之間運作的，也不能在不同版本的 Python 之間保持穩定。

位元組碼的指令列表可以在 `dis` 模組的明文文件中找到。

### callable (可呼叫物件)

一個 callable 是可以被呼叫的物件，呼叫時可能以下列形式帶有一組引數 (請見 `argument`):

```
callable(argument1, argument2, argumentN)
```

一個 `function` 與其延伸的 `method` 都是 callable。一個有實作 `__call__()` 方法的 `class` 之實例也是個 callable。

### callback (回呼)

作引數被傳遞的一個副程式 (subroutine) 函式，會在未來的某個時間點被執行。

### class (類)

一個用於建立使用者定義物件的模板。Class 的定義通常會包含 `method` 的定義，這些 `method` 可以在 `class` 的實例上進行操作。

### class variable (類變數)

一個在 `class` 中被定義，且應該只能在 `class` 層次 (意即不是在 `class` 的實例中) 被修改的變數。

### closure variable (閉包變數)

從外部作用域中定義且從巢狀作用域參照的自由變數，不是於 `runtime` 從全域或建命名空間解析。可以使用 `nonlocal` 關鍵字明確定義以允許寫入存取，或者如果僅需讀取變數則隱式定義即可。

例如在下面程式碼中的 `inner` 函式中，`x` 和 `print` 都是自由變數，但只有 `x` 是閉包變數：

```
def outer():
    x = 0
    def inner():
        nonlocal x
        x += 1
        print(x)
    return inner
```

由於 `codeobject.co_freevars` 屬性 (管名稱如此，但它僅包含閉包變數的名稱，而不是列出所有參照的自由變數)，當預期含義是特指閉包變數時，有時候甚至也會使用更通用的自由變數一詞。

**complex number (複數)**

一個我們熟悉的實數系統的擴充，在此所有數字都會被表示成一個實部和一個虛部之和。複數就是實數單位（-1 的平方根）的實數倍，此單位通常在數學中被寫成  $i$ ，在工程學中被寫成  $j$ 。Python 建了對複數的支援，它是用後者的記法來表示複數；虛部會帶著一個後綴的  $j$  被編寫，例如  $3+1j$ 。若要將 `math` 模組的工具等效地用於複數，請使用 `cmath` 模組。複數的使用是一個相當進階的數學功能。如果你有察覺到對它們的需求，那你幾乎能確定你可以安全地忽略它們。

**context (情境)**

This term has different meanings depending on where and how it is used. Some common meanings:

- The temporary state or environment established by a *context manager* via a `with` statement.
- The collection of keyvalue bindings associated with a particular `contextvars.Context` object and accessed via `ContextVar` objects. Also see *context variable*.
- 一個 `contextvars.Context` 物件。另請參閱 *current context*。

**context management protocol (情境管理協定)**

由 `with` 陳述式所呼叫的 `__enter__()` 和 `__exit__()` 方法。另請參閱 [PEP 343](#)。

**context manager (情境管理器)**

An object which implements the *context management protocol* and controls the environment seen in a `with` statement. See [PEP 343](#).

**context variable (情境變數)**

A variable whose value depends on which context is the *current context*. Values are accessed via `contextvars.ContextVar` objects. Context variables are primarily used to isolate state between concurrent asynchronous tasks.

**contiguous (連續的)**

如果一個緩衝區是 *C-contiguous* 或是 *Fortran contiguous*，則它會確切地被視作是連續的。零維 (zero-dimensional) 的緩衝區都是 C 及 Fortran contiguous。在一維 (one-dimensional) 陣列中，各項目必須在記憶體中彼此相鄰地排列，而其索引順序是從零開始遞增。在多維的 (multidimensional) C-contiguous 陣列中，按記憶體位址的順序訪問各個項目時，最後一個索引的變化最快。然而，在 Fortran contiguous 陣列中，第一個索引的變化最快。

**coroutine (協程)**

協程是副程式 (subroutine) 的一種更廣義的形式。副程式是在某個時間點被進入並在另一個時間點被退出。協程可以在許多不同的時間點被進入、退出和回復。它們能以 `async def` 陳述式被實作。另請參閱 [PEP 492](#)。

**coroutine function (協程函式)**

一個回傳 *coroutine* (協程) 物件的函式。一個協程函式能以 `async def` 陳述式被定義，可能包含 `await`、`async for` 和 `async with` 關鍵字。這些關鍵字由 [PEP 492](#) 引入。

**CPython**

Python 程式語言的標準實作 (canonical implementation)，被發布在 [python.org](#) 上。「CPython」這個術語在必要時被使用，以區分此實作與其它語言的實作，例如 Jython 或 IronPython。

**current context**

The *context* (`contextvars.Context` object) that is currently used by `ContextVar` objects to access (get or set) the values of *context variables*. Each thread has its own current context. Frameworks for executing asynchronous tasks (see *asyncio*) associate each task with a context which becomes the current context whenever the task starts or resumes execution.

**decorator (裝飾器)**

一個函式，它會回傳另一個函式，通常它會使用 `@wrapper` 語法，被應用一種函式的變換 (function transformation)。裝飾器的常見範例是 `classmethod()` 和 `staticmethod()`。

裝飾器語法只是語法糖。以下兩個函式定義在語義上是等效的：

```
def f(arg):
    ...
f = staticmethod(f)
```

(繼續下一頁)

(繼續上一頁)

```
@staticmethod
def f(arg):
    ...
```

Class 也存在相同的概念，但在那邊比較不常用。關於裝飾器的更多內容，請參閱函式定義和 class 定義的說明文件。

### descriptor (描述器)

任何定義了 `__get__()`、`__set__()` 或 `__delete__()` method 的物件。當一個 class 屬性是一個描述器時，它的特殊連結行會在屬性查找時被觸發。通常，使用 `a.b` 來取得、設定或刪除某個屬性時，會在 `a` 的 class 字典中查找名稱 `b` 的物件，但如果 `b` 是一個描述器，則相對應的描述器 method 會被呼叫。對描述器的理解是深入理解 Python 的關鍵，因為它們是許多功能的基礎，這些功能包括函式、method、屬性 (property)、class method、狀態 method，以及對 super class (父類) 的參照。

關於描述器 method 的更多資訊，請參閱 descriptors 或描述器使用指南。

### dictionary (字典)

一個關聯陣列 (associative array)，其中任意的鍵會被對映到值。鍵可以是任何帶有 `__hash__()` 和 `__eq__()` method 的物件。在 Perl 中被稱作雜項 (hash)。

### dictionary comprehension (字典綜合運算)

一種緊密的方法，用來處理一個可迭代物件中的全部或部分元素，將處理結果以一個字典回傳。`results = {n: n ** 2 for n in range(10)}` 會生成一個字典，它包含了鍵 `n` 對映到值 `n ** 2`。請參閱 comprehensions。

### dictionary view (字典檢視)

從 `dict.keys()`、`dict.values()` 及 `dict.items()` 回傳的物件被稱作字典檢視。它們提供了字典中項目的動態檢視，這表示當字典有變動時，該檢視會反映這些變動。若要限制將字典檢視轉為完整的 list (串列)，須使用 `list(dictview)`。請參閱字典視圖物件。

### docstring (說明字串)

一個在 class、函式或模組中，作第一個運算式出現的字串文本。雖然它在套件執行時會被忽略，但它會被編譯器辨識，被放入所屬 class、函式或模組的 `__doc__` 屬性中。由於說明字串可以透過自省 (introspection) 來瀏覽，因此它是物件的說明文件存放的標準位置。

### duck-typing (鴨子型)

一種程式設計風格，它不是藉由檢查一個物件的型來確定它是否具有正確的介面；取而代之的是，method 或屬性會單純地被呼叫或使用。（「如果它看起來像一隻鴨子而且叫起來像一隻鴨子，那它一定是一隻鴨子。」）因為調介面而非特定型，精心設計的程式碼能讓多形替代 (polymorphic substitution) 來增進它的靈活性。鴨子型要避免使用 `type()` 或 `isinstance()` 進行測試。（但是請注意，鴨子型可以用抽象基底類 (abstract base class) 來補充。）然而，它通常會用 `hasattr()` 測試，或是 EAFP 程式設計風格。

### EAFP

Easier to ask for forgiveness than permission. (請求寬恕比請求許可更容易。) 這種常見的 Python 編碼風格會先假設有效的鍵或屬性的存在，在該假設被推翻時再捕獲例外。這種乾且快速的風格，其特色是存在許多的 `try` 和 `except` 陳述式。該技術與許多其他語言 (例如 C) 常見的 LBYL 風格形成了對比。

### expression (運算式)

一段可以被評估求值的語法。句話，一個運算式就是文字、名稱、屬性存取、運算子或函式呼叫等運算式元件的累積，而這些元件都能回傳一個值。與許多其他語言不同的是，非所有的 Python 語言構造都是運算式。另外有一些 statement (陳述式) 不能被用作運算式，例如 `while`。賦值 (assignment) 也是陳述式，而不是運算式。

### extension module (擴充模組)

一個以 C 或 C++ 編寫的模組，它使用 Python 的 C API 來與核心及使用者程式碼進行互動。

### f-string (f 字串)

以 'f' 或 'F' 前綴的字串文本通常被稱作「f 字串」，它是格式化的字串文本的縮寫。另請參閱 PEP 498。

**file object (檔案物件)**

一個讓使用者透過檔案導向 (file-oriented) API (如 `read()` 或 `write()` 等 `method`) 來操作底層資源的物件。根據檔案物件被建立的方式，它能協調對真實磁碟檔案或是其他類型的儲存器或通訊裝置 (例如標準輸入 / 輸出、記憶體緩衝區、`socket` (插座)、管 (pipe) 等) 的存取。檔案物件也被稱類檔案物件 (*file-like object*) 或串流 (*stream*)。

實際上，有三種檔案物件：原始的二進位檔案、緩衝的二進位檔案和文字檔案。它們的介面在 `io` 模組中被定義。建立檔案物件的標準方法是使用 `open()` 函式。

**file-like object (類檔案物件)**

*file object* (檔案物件) 的同義字。

**filesystem encoding and error handler (檔案系統編碼和錯誤處理函式)**

Python 所使用的一種編碼和錯誤處理函式，用來解碼來自作業系統的位元組，以及將 Unicode 編碼到作業系統。

檔案系統編碼必須保證能成功解碼所有小於 128 的位元組。如果檔案系統編碼無法提供此保證，則 API 函式會引發 `UnicodeError`。

`sys.getfilesystemencoding()` 和 `sys.getfilesystemcodeerrors()` 函式可用於取得檔案系統編碼和錯誤處理函式。

*filesystem encoding and error handler* (檔案系統編碼和錯誤處理函式) 會在 Python 啟動時由 `PyConfig_Read()` 函式來配置：請參 `filesystem_encoding`，以及 `PyConfig` 的成員 `filesystem_errors`。

另請參 `locale encoding` (區域編碼)。

**finder (尋檢器)**

一個物件，它會嘗試正在被 `import` 的模組尋找 *loader* (載入器)。

有兩種類型的尋檢器：*元路徑尋檢器* (*meta path finder*) 會使用 `sys.meta_path`，而路徑項目尋檢器 (*path entry finder*) 會使用 `sys.path_hooks`。

請參 `finders-and-loaders` 和 `importlib` 以了解更多細節。

**floor division (向下取整除法)**

向下無條件舍去到最接近整數的數學除法。向下取整除法的運算子是 `//`。例如，運算式 `11 // 4` 的計算結果是 `2`，與 `float` (浮點數) 真除法所回傳的 `2.75` 不同。請注意，`(-11) // 4` 的結果是 `-3`，因是 `-2.75` 被向下無條件舍去。請參 [PEP 238](#)。

**free threading (自由執行緒)**

一種執行緒模型，多個執行緒可以在同一直譯器中同時運行 Python 位元組碼。這與全域直譯器鎖形成對比，後者一次只允許一個執行緒執行 Python 位元組碼。請參 [PEP 703](#)。

**free variable (自由變數)**

Formally, as defined in the language execution model, a free variable is any variable used in a namespace which is not a local variable in that namespace. See *closure variable* for an example. Pragmatically, due to the name of the `codeobject.co_freevars` attribute, the term is also sometimes used as a synonym for *closure variable*.

**function (函式)**

一連串的陳述式，它能向呼叫者回傳一些值。它也可以被傳遞零個或多個引數，這些引數可被使用於函式本體的執行。另請參 `parameter` (參數)、`method` (方法)，以及 `function` 章節。

**function annotation (函式釋)**

函式參數或回傳值的一個 *annotation* (釋)。

函式釋通常被使用於型提示：例如，這個函式預期會得到兩個 `int` 引數，會有一個 `int` 回傳值：

```
def sum_two_numbers(a: int, b: int) -> int:
    return a + b
```

函式釋的語法在 `function` 章節有詳細解釋。

請參 [variable annotation](#) 和 [PEP 484](#)，皆有此功能的描述。關於 [釋](#) 的最佳實踐方法，另請參 [annotations-howto](#)。

### `__future__`

`future` 陳述式：`from __future__ import <feature>`，會指示編譯器使用那些在 Python 未來的發布版本中將成 [標準](#) 的語法或語義，來編譯當前的模組。而 `__future__` 模組則記 [了](#) `feature`（功能）可能的值。透過 `import` 此模組 [對](#) 其變數求值，你可以看見一個新的功能是何時首次被新增到此語言中，以及它何時將會（或已經）成 [預設](#) 的功能：

```
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```

### garbage collection (垃圾回收)

當記憶體不再被使用時，將其釋放的過程。Python 執行垃圾回收，是透過參照計數 (reference counting)，以及一個能 [檢測](#) 和 [中斷](#) 參照循環 (reference cycle) 的循環垃圾回收器 (cyclic garbage collector) 來完成。垃圾回收器可以使用 `gc` 模組對其進行控制。

### generator (生成器)

一個會回傳 `generator iterator` (生成器代器) 的函式。它看起來像一個正常的函式，但不同的是它包含了 `yield` 運算式，能 [生](#) 一系列的 [值](#)，這些值可用於 `for` [圈](#)，或是以 `next()` 函式，每次檢索其中的一個值。

這個術語通常用來表示一個 [生成器](#) 函式，但在某些情境中，也可能是表示 [生成器代器](#)。萬一想表達的意思不 [清楚](#)，那就使用完整的術語，以避免歧義。

### generator iterator (生成器代器)

一個由 `generator` (生成器) 函式所建立的物件。

每個 `yield` 會暫停處理程序，[記](#) 住執行狀態 (包括區域變數及擱置中的 `try` 陳述式)。當 [生成器代器](#) 回復時，它會從停止的地方繼續執行 (與那些每次調用時都要重新開始的函式有所不同)。

### generator expression (生成器運算式)

一個會回傳 [代器](#) 的 [運算式](#)。它看起來像一個正常的運算式，後面接著一個 `for` 子句，該子句定義了 [圈](#) 變數、範圍以及一個選擇性的 `if` 子句。該組合運算式會 [外層](#) 函式 [生](#) 多個值：

```
>>> sum(i*i for i in range(10))           # 平方之和 0, 1, 4, ... 81
285
```

### generic function (泛型函式)

一個由多個函式組成的函式，該函式會對不同的型 [實](#) 作相同的運算。呼叫期間應該使用哪種實作，是由調度演算法 (dispatch algorithm) 來 [定](#)。

另請參 [single dispatch](#) (單一調度) 術語表條目、`functools.singledispatch()` 裝飾器和 [PEP 443](#)。

### generic type (泛型型)

一個能 [被](#) 參數化 (parameterized) 的 `type` (型 )；通常是一個 [容器型](#)，像是 `list` 和 `dict`。它被用於 [型](#) [提示](#) 和 [釋](#)。

詳情請參 [泛型](#) [名](#) [型](#)、[PEP 483](#)、[PEP 484](#)、[PEP 585](#) 和 `typing` 模組。

### GIL

請參 [global interpreter lock](#) (全域直譯器鎖)。

### global interpreter lock (全域直譯器鎖)

`CPython` 直譯器所使用的機制，用以確保每次都只有一個執行緒能執行 Python 的 `bytecode` (位元組碼)。透過使物件模型 (包括關鍵的 [建](#) 型 ，如 `dict`) 自動地避免 [行](#) 存取 (concurrent access) 的危險，此機制可以簡化 `CPython` 的實作。鎖定整個直譯器，會使直譯器更容易成 [多](#) 執行緒 (multi-threaded)，但代價是會犧牲掉多處理器的機器能 [提](#) 供的一大部分平行性 (parallelism)。

然而，有些擴充模組，無論是標準的或是第三方的，它們被設計成在執行壓縮或雜 [等](#) 計算密集 (computationally intensive) 的任務時，可以解除 GIL。另外，在執行 I/O 時，GIL 總是會被解除。

從 Python 3.13 開始可以使用 `--disable-gil` 建置設定來停用 GIL。使用此選項建立 Python 後，必須使用 `-X gil=0` 來執行程式碼，或者設定 `PYTHON_GIL=0` 環境變數後再執行程式碼。此功能可以提高多執行緒應用程式的效能，使多核心 CPU 的高效使用變得更加容易。有關更多詳細資訊，請參閱 [PEP 703](#)。

### hash-based pyc (雜架構的 pyc)

一個位元組碼 (bytecode) 暫存檔，它使用雜值而不是對應原始檔案的最後修改時間，來確定其有效性。請參閱 [pyc-invalidation](#)。

### hashable (可雜的)

如果一個物件有一個雜值，該值在其生命期中永不改變（它需要一個 `__hash__()` method），且可與其他物件互相比較（它需要一個 `__eq__()` method），那麼它就是一個可雜物件。比較結果相等的多個可雜物件，它們必須擁有相同的雜值。

可雜性 (hashability) 使一個物件可用作 dictionary (字典) 的鍵和 set (集合) 的成員，因此這些資料結構都在其內部使用了雜值。

大多數的 Python 不可變物件都是可雜的；可變的容器（例如 list 或 dictionary）不是；而不可變的容器（例如 tuple (元組) 和 frozenset），只有當它們的元素是可雜的，它們本身才是可雜的。若物件是使用者自定 class 的實例，則這些物件會被預設為可雜的。它們在互相比較時都是不相等的（除非它們與自己比較），而它們的雜值則是衍生自它們的 `id()`。

### IDLE

Python 的 Integrated Development and Learning Environment (整合開發與學習環境)。*IDLE --- Python editor and shell* 是一個基本的編輯器和直譯器環境，它和 Python 的標準發行版本一起被提供。

### immortal (不滅)

不滅物件 (*Immortal objects*) 是 [PEP 683](#) 引入的 CPython 實作細節。

如果一個物件是不滅的，它的參照計數永遠不會被修改，因此在直譯器運行時它永遠不會被釋放。例如，`True` 和 `None` 在 CPython 中是不滅的。

### immutable (不可變物件)

一個具有固定值的物件。不可變物件包括數字、字串和 tuple (元組)。這類物件是不能被改變的。如果一個不同的值必須被儲存，則必須建立一個新的物件。它們在需要固定雜值的地方，扮演重要的角色，例如 dictionary (字典) 中的一個鍵。

### import path (引入路徑)

一個位置 (或路徑項目) 的列表，而那些位置就是在 import 模組時，會被 *path based finder* (基於路徑的尋檢器) 搜尋模組的位置。在 import 期間，此位置列表通常是來自 `sys.path`，但對於子套件 (subpackage) 而言，它也可能是來自父套件的 `__path__` 屬性。

### importing (引入)

一個過程。一個模組中的 Python 程式碼可以透過此過程，被另一個模組中的 Python 程式碼使用。

### importer (引入器)

一個能尋找及載入模組的物件；它既是 *finder* (尋檢器) 也是 *loader* (載入器) 物件。

### interactive (互動的)

Python 有一個互動式直譯器，這表示你可以在直譯器的提示字元輸入陳述式和運算式，立即執行它們且看到它們的結果。只要敲動 `python`，不需要任何引數（可能藉由從你的電腦的主選單選擇它）。這是測試新想法或檢查模塊和包的非常大的方法（請記住 `help(x)`）。更多互動式模式相關資訊請見 [tut-interac](#)。

### interpreted (直譯的)

Python 是一種直譯語言，而不是編譯語言，不過這個區分可能有些模糊，因為有位元組碼 (bytecode) 編譯器的存在。這表示原始檔案可以直接被運行，而不需明確地建立另一個執行檔，然後再執行它。直譯語言通常比編譯語言有更短的開發 / 除錯期，不過它們的程式通常也運行得較慢。另請參閱 [interactive](#) (互動的)。

### interpreter shutdown (直譯器關閉)

當 Python 直譯器被要求關閉時，它會進入一個特殊階段，在此它逐漸釋放所有被配置的資源，例如模組和各種關鍵部結構。它也會多次呼叫垃圾回收器 (*garbage collector*)。這能觸發使用者自定的解構函式 (destructor) 或弱引用的回呼 (weakref callback)，執行其中的程式碼。在關閉階段被

執行的程式碼會遇到各種例外，因為它所依賴的資源可能不再起作用了（常見的例子是函式庫模組或是警告機制）。

直譯器關閉的主要原因，是 `__main__` 模組或正被運行的腳本已經執行完成。

### iterable (可迭代物件)

An object capable of returning its members one at a time. Examples of iterables include all sequence types (such as *list*, *str*, and *tuple*) and some non-sequence types like *dict*, *file objects*, and objects of any classes you define with an `__iter__()` method or with a `__getitem__()` method that implements *sequence semantics*.

可迭代物件可用於 `for` 圈和許多其他需要一個序列的地方 (`zip()`、`map()`...)。當一個可迭代物件作引數被傳遞給函式 `iter()` 時，它會回傳該物件回傳一個迭代器。此迭代器適用於針對一組值進行一遍 (one pass) 運算。使用迭代器時，通常不一定要呼叫 `iter()` 或自行處理迭代器物件。`for` 陳述式會自動地替你處理這些事，它會建立一個暫時性的未命名變數，用於在圈期間保有該迭代器。另請參 `iterator` (迭代器)、`sequence` (序列) 和 `generator` (生成器)。

### iterator (迭代器)

一個表示資料流的物件。重覆地呼叫迭代器的 `__next__()` method (或是將它傳遞給函式 `next()`) 會依序回傳資料流中的各項目。當不再有資料時，則會引發 `StopIteration` 例外。此時，該迭代器物件已被用盡，而任何對其 `__next__()` method 的進一步呼叫，都只會再次引發 `StopIteration`。迭代器必須有一個 `__iter__()` method，它會回傳迭代器物件本身，所以每個迭代器也都是可迭代物件，且可以用於大多數適用其他可迭代物件的場合。一個明顯的例外，是嘗試多遍迭代 (multiple iteration passes) 的程式碼。一個容器物件 (像是 `list`) 在每次你將它傳遞給 `iter()` 函式或在 `for` 圈中使用它時，都會生成一個全新的迭代器。使用迭代器嘗試此事 (多遍迭代) 時，只會回傳在前一遍迭代中被用過的、同一個已被用盡的迭代器物件，使其看起來就像一個空的容器。

在 `迭代器型` 文中可以找到更多資訊。

CPython 不是始終如一地都會檢查「迭代器有定義 `__iter__()`」這個規定。另請注意，`free-threading` (自由執行緒) CPython 不保證迭代器操作的執行緒安全。

### key function (鍵函式)

鍵函式或理序函式 (collation function) 是一個可呼叫 (callable) 函式，它會回傳一個用於排序 (sorting) 或定序 (ordering) 的值。例如，`locale.strxfrm()` 被用來生成一個了解區域特定排序慣例的排序鍵。

Python 中的許多工具，都接受以鍵函式來控制元素被定序或分組的方式。它們包括 `min()`、`max()`、`sorted()`、`list.sort()`、`heapq.merge()`、`heapq.nsmallest()`、`heapq.nlargest()` 和 `itertools.groupby()`。

有幾種方法可以建立一個鍵函式。例如，`str.lower()` method 可以作不分大小寫排序的鍵函式。或者，一個鍵函式也可以從 `lambda` 運算式被建造，例如 `lambda r: (r[0], r[2])`。另外，`operator.attrgetter()`、`operator.itemgetter()` 和 `operator.methodcaller()` 三個鍵函式的建構函式 (constructor)。關於如何建立和使用鍵函式的範例，請參 `如何排序`。

### keyword argument (關鍵字引數)

請參 `argument` (引數)。

### lambda

由單一 *expression* (運算式) 所組成的一個匿名行函式 (inline function)，於該函式被呼叫時求值。建立 `lambda` 函式的語法是 `lambda [parameters]: expression`

### LBYL

Look before you leap. (三思而後行。) 這種編碼風格會在進行呼叫或查找之前，明確地測試先條件。這種風格與 *EAFP* 方式形成對比，且它的特色是會有許多 `if` 陳述式的存在。

在一個多執行緒環境中，LBYL 方式有在「三思」和「後行」之間引入了競態條件 (race condition) 的風險。例如以下程式碼 `if key in mapping: return mapping[key]`，如果另一個執行緒在測試之後但在查找之前，從 `mapping` 中移除了 `key`，則該程式碼就會失效。這個問題可以用鎖 (lock) 或使用 *EAFP* 編碼方式來解。

### list (串列)

一個 Python 建的 *sequence* (序列)。儘管它的名字是 `list`，它其實更類似其他語言中的一個陣列

(array) 而較不像一個鏈結串列 (linked list), 因存取元素的時間複雜度是  $O(1)$ 。

### list comprehension (串列綜合運算)

一種用來處理一個序列中的全部或部分元素, 將處理結果以一個 list 回傳的簡要方法。 `result = ['{:#04x}'.format(x) for x in range(256) if x % 2 == 0]` 會生一個字串 list, 其中包含 0 到 255 範圍, 所有偶數的十六進位數 (0x..)。 `if` 子句是選擇性的。如果省略它, 則 `range(256)` 中的所有元素都會被處理。

### loader (載入器)

一個能載入模組的物件。它必須定義 `exec_module()` 和 `create_module()` 方法以實作 `Loader` 介面。載入器通常是被 *finder* (尋檢器) 回傳。更多細節請參:

- `finders-and-loaders`
- `importlib.abc.Loader`
- **PEP 302**

### locale encoding (區域編碼)

在 Unix 上, 它是 `LC_CTYPE` 區域設定的編碼。它可以用 `locale.setlocale(locale.LC_CTYPE, new_locale)` 來設定。

在 Windows 上, 它是 ANSI 代碼頁 (code page, 例如 "cp1252")。

在 Android 和 VxWorks 上, Python 使用 "utf-8" 作區域編碼。

`locale.getencoding()` 可以用來取得區域編碼。

也請參考 *filesystem encoding and error handler*。

### magic method (魔術方法)

*special method* (特殊方法) 的一個非正式同義詞。

### mapping (對映)

一個容器物件, 它支援任意鍵的查找, 且能實作 *abstract base classes* (抽象基底類) 中, `collections.abc.Mapping` 或 `collections.abc.MutableMapping` 所指定的 `method`。範例包括 `dict`、`collections.defaultdict`、`collections.OrderedDict` 和 `collections.Counter`。

### meta path finder (元路徑尋檢器)

一種經由搜尋 `sys.meta_path` 而回傳的 *finder* (尋檢器)。元路徑尋檢器與路徑項目尋檢器 (*path entry finder*) 相關但是不同。

關於元路徑尋檢器實作的 `method`, 請參 `importlib.abc.MetaPathFinder`。

### metaclass (元類)

一種 `class` 的 `class`。 `Class` 定義過程會建立一個 `class` 名稱、一個 `class` dictionary (字典), 以及一個 `base class` (基底類) 的列表。 `Metaclass` 負責接受這三個引數, 建立該 `class`。大多數的物件導向程式語言會提供一個預設的實作。Python 的特之處在於它能建立自訂的 `metaclass`。大部分的使用者從未需要此工具, 但是當需要時, `metaclass` 可以提供大且優雅的解方案。它們已被用於記屬性存取、增加執行緒安全性、追物件建立、實作單例模式 (singleton), 以及許多其他的任務。

更多資訊可以在 `metaclasses` 章節中找到。

### method (方法)

一個在 `class` 本體被定義的函式。如果 `method` 作其 `class` 實例的一個屬性被呼叫, 則它將會得到該實例物件成它的第一個 *argument* (引數) (此引數通常被稱 `self`)。請參 *function* (函式) 和 *nested scope* (巢狀作用域)。

### method resolution order (方法解析順序)

方法解析順序是在查找某個成員的過程中, `base class` (基底類) 被搜尋的順序。關於 Python 自 2.3 版直譯器所使用的演算法細節, 請參 `python_2.3_mro`。

### module (模組)

一個擔任 Python 程式碼的組織單位 (organizational unit) 的物件。模組有一個命名空間, 它包含任意的 Python 物件。模組是藉由 *importing* 的過程, 被載入至 Python。

另請參 *package* (套件)。

**module spec (模組規格)**

一個命名空間，它包含用於載入模組的 `import` 相關資訊。它是 `importlib.machinery.ModuleSpec` 的一個實例。

另請參 [module-specs](#)。

**MRO**

請參 [method resolution order](#) (方法解析順序)。

**mutable (可變物件)**

可變物件可以改變它們的值，但維持它們的 `id()`。另請參 [immutable](#) (不可變物件)。

**named tuple (附名元組)**

術語「named tuple (附名元組)」是指從 `tuple` 繼承的任何型 [或 class](#)，且它的可索引 (indexable) 元素也可以用附名屬性來存取。這些型 [或 class](#) 也可以具有其他的特性。

有些 [建型](#) 是 named tuple，包括由 `time.localtime()` 和 `os.stat()` 回傳的值。另一個例子是 `sys.float_info`：

```
>>> sys.float_info[1]           # indexed access
1024
>>> sys.float_info.max_exp     # named field access
1024
>>> isinstance(sys.float_info, tuple) # kind of tuple
True
```

有些 named tuple 是 [建型](#) (如上例)。或者，一個 named tuple 也可以從一個正規的 class 定義來建立，只要該 class 是繼承自 `tuple`，且定義了附名欄位 (named field) 即可。這類的 class 可以手工編寫、可以繼承自 `typing.NamedTuple` 來建立，也可以使用工廠函式 (factory function) `collections.namedtuple()` 來建立。後者技術也增加了一些額外的 method，這些 method 可能是在手寫或 [建](#) 的 named tuple 中，無法找到的。

**namespace (命名空間)**

變數被儲存的地方。命名空間是以 dictionary (字典) 被實作。有區域的、全域的及 [建](#) 的命名空間，而在物件中 (在 method 中) 也有巢狀的命名空間。命名空間藉由防止命名衝突，來支援模組化。例如，函式 `builtins.open` 和 `os.open()` 是透過它們的命名空間來區分彼此。命名空間也藉由明確地區分是哪個模組在實作一個函式，來增進可讀性及可維護性。例如，寫出 `random.seed()` 或 `itertools.islice()` 明確地表示，這些函式分 [是](#) 由 `random` 和 `itertools` 模組在實作。

**namespace package (命名空間套件)**

A *package* which serves only as a container for subpackages. Namespace packages may have no physical representation, and specifically are not like a *regular package* because they have no `__init__.py` file.

Namespace packages allow several individually installable packages to have a common parent package. Otherwise, it is recommended to use a *regular package*.

For more information, see [PEP 420](#) and [reference-namespace-package](#).

另請參 [module](#) (模組)。

**nested scope (巢狀作用域)**

能 [參照](#) 外層定義 (enclosing definition) 中的變數的能力。舉例來 [是](#)，一個函式如果是在另一個函式中被定義，則它便能 [參照](#) 外層函式中的變數。請注意，在預設情 [下](#)，巢狀作用域僅適用於參照，而無法用於賦值。區域變數能在最 [層](#) 作用域中讀取及寫入。同樣地，全域變數是在全域命名空間中讀取及寫入。`nonlocal` 容許對外層作用域進行寫入。

**new-style class (新式類 [是](#))**

一個舊名，它是指現在所有的 class 物件所使用的 class 風格。在早期的 Python 版本中，只有新式 class 才能使用 Python 較新的、多樣的功能，像是 `__slots__`、描述器 (descriptor)、屬性 (property)、`__getattr__()`、class method (類 [方法](#)) 和 static method ([態](#) 方法)。

**object (物件)**

具有狀態 (屬性或值) 及被定義的行 [\(method\)](#) 的任何資料。它也是任何 *new-style class* (新式類 [是](#)) 的最終 base class (基底類 [是](#))。

**optimized scope (最佳化作用域)**

A scope where target local variable names are reliably known to the compiler when the code is compiled, allowing optimization of read and write access to these names. The local namespaces for functions, generators, coroutines, comprehensions, and generator expressions are optimized in this fashion. Note: most interpreter optimizations are applied to all scopes, only those relying on a known set of local and nonlocal variable names are restricted to optimized scopes.

**package (套件)**

一個 Python 的 *module* (模組), 它可以包含子模組 (submodule) 或是遞的子套件 (subpackage)。技術上而言, 套件就是具有 `__path__` 屬性的一個 Python 模組。

另請參 [regular package](#) (正規套件) 和 [namespace package](#) (命名空間套件)。

**parameter (參數)**

在 *function* (函式) 或 *method* 定義中的一個命名實體 (named entity), 它指明該函式能接受的一個 *argument* (引數), 或在某些情況下指示多個引數。共有五種不同的參數類型:

- *positional-or-keyword* (位置或關鍵字): 指明一個可以按照位置或是作關鍵字引數被傳遞的引數。這是參數的預設類型, 例如以下的 *foo* 和 *bar*:

```
def func(foo, bar=None): ...
```

- *positional-only* (僅限位置): 指明一個只能按照位置被提供的引數。在函式定義的參數列表中包含一個 `/` 字元, 就可以在該字元前面定義僅限位置參數, 例如以下的 *posonly1* 和 *posonly2*:

```
def func(posonly1, posonly2, /, positional_or_keyword): ...
```

- *keyword-only* (僅限關鍵字): 指明一個只能以關鍵字被提供的引數。在函式定義的參數列表中, 包含一個任意數量位置參數 (var-positional parameter) 或是單純的 `*` 字元, 就可以在其後方定義僅限關鍵字參數, 例如以下的 *kw\_only1* 和 *kw\_only2*:

```
def func(arg, *, kw_only1, kw_only2): ...
```

- *var-positional* (任意數量位置): 指明一串能以任意序列被提供的位置引數 (在已被其他參數接受的任何位置引數之外)。這類參數是透過在其參數名稱字首加上 `*` 來定義的, 例如以下的 *args*:

```
def func(*args, **kwargs): ...
```

- *var-keyword* (任意數量關鍵字): 指明可被提供的任意數量關鍵字引數 (在已被其他參數接受的任何關鍵字引數之外)。這類參數是透過在其參數名稱字首加上 `**` 來定義的, 例如上面範例中的 *kwargs*。

參數可以指明引數是選擇性的或必需的, 也可以一些選擇性的引數指定預設值。

另請參 [術語表的 argument \(引數\) 條目](#)、常見問題中的 [引數和參數之間的差別](#)、[inspect.Parameter](#) class、[function](#) 章節, 以及 [PEP 362](#)。

**path entry (路徑項目)**

在 *import path* (引入路徑) 中的一個位置, 而 *path based finder* (基於路徑的尋檢器) 會參考該位置來尋找要 import 的模組。

**path entry finder (路徑項目尋檢器)**

被 `sys.path_hooks` 中的一個可呼叫物件 (callable) (意即一個 *path entry hook*) 所回傳的一種 *finder*, 它知道如何以一個 *path entry* 定位模組。

關於路徑項目尋檢器實作的 *method*, 請參 `importlib.abc.PathEntryFinder`。

**path entry hook (路徑項目)**

在 `sys.path_hooks` 列表中的一個可呼叫物件 (callable), 若它知道如何在一個特定的 *path entry* 中尋找模組, 則會回傳一個 *path entry finder* (路徑項目尋檢器)。

**path based finder (基於路徑的尋檢器)**

預設的元路徑尋檢器 (*meta path finder*) 之一, 它會在一個 *import path* 中搜尋模組。

**path-like object (類路徑物件)**

一個表示檔案系統路徑的物件。類路徑物件可以是一個表示路徑的 `str` 或 `bytes` 物件，或是一個實作 `os.PathLike` 協定的物件。透過呼叫 `os.fspath()` 函式，一個支援 `os.PathLike` 協定的物件可以被轉成 `str` 或 `bytes` 檔案系統路徑；而 `os.fsdecode()` 及 `os.fsencode()` 則分別可用於確保 `str` 及 `bytes` 的結果。由 **PEP 519** 引入。

**PEP**

Python Enhancement Proposal (Python 增進提案)。PEP 是一份設計明文件，它能向 Python 社群提供資訊，或是描述 Python 的一個新功能或該功能的程序和環境。PEP 應該要提供簡潔的技術規範以及被提案功能的運作原理。

PEP 的存在目的，是要成重大新功能的提案、社群中關於某個問題的意見收集，以及已納入 Python 的設計策略的記錄，這些過程的主要機制。PEP 的作者要負責在社群建立共識並反對意見。

請參 **PEP 1**。

**portion (部分)**

在單一目錄中的一組檔案(也可能儲存在一個 zip 檔中)，這些檔案能對一個命名空間套件(namespace package) 有所貢獻，如同 **PEP 420** 中的定義。

**positional argument (位置引數)**

請參 `argument` (引數)。

**provisional API (暫行 API)**

暫行 API 是指，從標準函式庫的向後相容性(backwards compatibility) 保證中，故意被排除的 API。雖然此類介面，只要它們被標示暫行的，理論上不會有重大的變更，但如果核心開發人員認為有必要，也可能會出現向後不相容的變更(甚至包括移除該介面)。這種變更不會無端地發生——只有 API 被納入之前未察覺的嚴重基本缺陷被揭露時，它們才會發生。

即使對於暫行 API，向後不相容的變更也會被視為「最後的解決方案」——對於任何被發現的問題，仍然會盡可能找出一個向後相容的解決方案。

這個過程使得標準函式庫能隨著時間不斷進化，而避免耗費過長的時間去鎖定有問題的設計錯誤。請參 **PEP 411** 了解更多細節。

**provisional package (暫行套件)**

請參 `provisional API` (暫行 API)。

**Python 3000**

Python 3.x 系列版本的稱(很久以前創造的，當時第 3 版的發布是在遠的未來。)也可以縮寫為 [Py3k]。

**Pythonic (Python 風格的)**

一個想法或一段程式碼，它應用了 Python 語言最常見的慣用語，而不是使用其他語言常見的概念來實作程式碼。例如，Python 中常見的一種習慣用法，是使用一個 `for` 陳述式，對一個可迭代物件的所有元素進行遍歷。許多其他語言也有這種類型的架構，所以不熟悉 Python 的人有時會使用一個數值計數器來代替：

```
for i in range(len(food)):
    print(food[i])
```

相較之下，以下方法更簡潔、更具有 Python 風格：

```
for piece in food:
    print(piece)
```

**qualified name (限定名稱)**

一個「點分隔名稱」，它顯示從一個模組的全域作用域到該模組中定義的 `class`、函式或 `method` 的「路徑」，如 **PEP 3155** 中的定義。對於頂層的函式和 `class` 而言，限定名稱與其物件名稱相同：

```
>>> class C:
...     class D:
...         def meth(self):
```

(繼續下一頁)

(繼續上一頁)

```

...         pass
...
>>> C.__qualname__
'C'
>>> C.D.__qualname__
'C.D'
>>> C.D.meth.__qualname__
'C.D.meth'

```

當用於引用模組時，完全限定名彙 (*fully qualified name*) 是表示該模組的完整點分隔路徑，包括任何的父套件，例如 `email.mime.text`：

```

>>> import email.mime.text
>>> email.mime.text.__name__
'email.mime.text'

```

### reference count (參照計數)

對於一個物件的參照次數。當一個物件的參照計數下降到零時，它會被解除配置 (*deallocated*)。有些物件是「不滅的 (*immortal*)」擁有不會被改變的參照計數，也因此永遠不會被解除配置。參照計數通常在 Python 程式碼中看不到，但它是在 *CPython* 實作的一個關鍵元素。程式設計師可以呼叫 `getrefcount()` 函式來回傳一個特定物件的參照計數。

### regular package (正規套件)

一個傳統的 *package* (套件)，例如一個包含 `__init__.py` 檔案的目錄。

另請參閱 *namespace package* (命名空間套件)。

### REPL

「read-eval-print 圈 (read-eval-print loop)」的縮寫，是互動式直譯器 shell 的另一個名稱。

### \_\_slots\_\_

在 `class` 部的一個宣告，它藉由預先宣告實例屬性的空間，以及消除實例 *dictionary* (字典)，來節省記憶體。雖然該技術很普遍，但它有點難以正確地使用，最好保留給那種在一個記憶體關鍵 (*memory-critical*) 的應用程式中存在大量實例的罕見情況。

### sequence (序列)

一個 *iterable* (可代物件)，它透過 `__getitem__()` *special method* (特殊方法)，使用整數索引來支援高效率的元素存取，定義了一個 `__len__()` *method* 來回傳該序列的長度。一些建序列表包括 *list*、*str*、*tuple* 和 *bytes*。請注意，雖然 *dict* 也支援 `__getitem__()` 和 `__len__()`，但它被視對映 (*mapping*) 而不是序列，因其查找方式是使用任意的 *hashable* 鍵，而不是整數。

抽象基底類 (*abstract base class*) `collections.abc.Sequence` 定義了一個更加豐富的介面，不僅止於 `__getitem__()` 和 `__len__()`，還增加了 `count()`、`index()`、`__contains__()` 和 `__reversed__()`。實作此擴充介面的型別，可以使用 `register()` 被明確地。更多關於序列方法的文件，請見常見序列操作。

### set comprehension (集合綜合運算)

一種緊密的方法，用來處理一個可代物件中的全部或部分元素，將處理結果以一個 *set* 回傳。`results = {c for c in 'abracadabra' if c not in 'abc'}` 會生一個字串 *set*: {'r', 'd'}。請參閱 *comprehensions*。

### single dispatch (單一調度)

*generic function* (泛型函式) 調度的一種形式，在此，實作的選擇是基於單一引數的型別。

### slice (切片)

一個物件，它通常包含一段 *sequence* (序列) 的某一部分。建立一段切片的方法是使用下標符號 (*subscript notation*) `[]`，若要給出多個數字，則在數字之間使用冒號，例如 `variable_name[1:3:5]`。在括號 (下標) 符號的部，會使用 *slice* 物件。

### soft deprecated (軟性用)

被軟性用的 API 代表不應再用於新程式碼中，但在現有程式碼中繼續使用它仍會是安全的。API 仍會以文件記會被測試，但不会被繼續改進。

與正常用不同，軟性用有除 API 的規劃，也不會發出警告。

請參 PEP 387：軟性用。

### special method (特殊方法)

一種會被 Python 自動呼叫的 method，用於對某種型執行某種運算，例如加法。這種 method 的名稱會在開頭和結尾有兩個下底。Special method 在 specialnames 中有詳細明。

### statement (陳述式)

陳述式是一個套組 (suite, 一個程式碼「區塊」) 中的一部分。陳述式可以是一個 *expression* (運算式)，或是含有關鍵字 (例如 `if`、`while` 或 `for`) 的多種結構之一。

### static type checker (態型檢查器)

會讀取 Python 程式碼分析的外部工具，能找出錯誤，像是使用了不正確的型。另請參提示 (*type hints*) 以及 *typing* 模組。

### strong reference (參照)

在 Python 的 C API 中，參照是對物件的參照，該物件持有該參照的程式碼所擁有。建立參照時透過呼叫 `Py_INCREF()` 來獲得參照、除參照時透過 `Py_DECREF()` 釋放參照。

`Py_NewRef()` 函式可用於建立一個對物件的參照。通常，在退出參照的作用域之前，必須在該參照上呼叫 `Py_DECREF()` 函式，以避免漏一個參照。

另請參 *borrowed reference* (借用參照)。

### text encoding (文字編碼)

Python 中的字串是一個 Unicode 碼點 (code point) 的序列 (範圍在 `U+0000` -- `U+10FFFF` 之間)。若要儲存或傳送一個字串，它必須被序列化一個位元組序列。

將一個字串序列化位元組序列，稱「編碼」，而從位元組序列重新建立該字串則稱「解碼 (decoding)」。

有多種不同的文字序列化編解碼器 (*codecs*)，它們被統稱「文字編碼」。

### text file (文字檔案)

一個能讀取和寫入 *str* 物件的一個 *file object* (檔案物件)。通常，文字檔案實際上是存取位元組導向的資料流 (*byte-oriented datastream*) 會自動處理 *text encoding* (文字編碼)。文字檔案的例子有：以文字模式 ('`r`' 或 '`w`') 開的檔案、`sys.stdin`、`sys.stdout` 以及 `io.StringIO` 的實例。

另請參 *binary file* (二進位檔案)，它是一個能讀取和寫入類位元組串物件 (*bytes-like object*) 的檔案物件。

### triple-quoted string (三引號字串)

由三個雙引號 (") 或單引號 (') 的作邊界的一個字串。雖然它們有提供於單引號字串的任何額外功能，但基於許多原因，它們仍是很有用的。它們讓你可以在字串中包含未跳 (unescaped) 的單引號和雙引號，而且它們不需使用連續字元 (continuation character) 就可以跨越多行，這使得它們在編寫明字串時特有用。

### type (型)

一個 Python 物件的型定了它是什類型的物件；每個物件都有一個型。一個物件的型可以用它的 `__class__` 屬性來存取，或以 `type(obj)` 來檢索。

### type alias (型名)

一個型的同義詞，透過將型指定給一個識符 (identifier) 來建立。

型名對於簡化型提示 (*type hint*) 很有用。例如：

```
def remove_gray_shades (
    colors: list[tuple[int, int, int]]) -> list[tuple[int, int, int]]:
    pass
```

可以寫成這樣，更具有可讀性：

```
Color = tuple[int, int, int]

def remove_gray_shades(colors: list[Color]) -> list[Color]:
    pass
```

請參 [typing](#) 和 [PEP 484](#)，有此功能的描述。

### type hint (型提示)

一種 *annotation* (釋)，它指定一個變數、一個 class 屬性或一個函式的參數或回傳值的預期型。

型提示是選擇性的，而不是被 Python 制的，但它們對 *態型檢查器* (*static type checkers*) 很有用，能協助 IDE 完成程式碼的補全 (completion) 和重構 (refactoring)。

全域變數、class 屬性和函式 (不含區域變數) 的型提示，都可以使用 `typing.get_type_hints()` 來存取。

請參 [typing](#) 和 [PEP 484](#)，有此功能的描述。

### universal newlines (通用行字元)

一種解譯文字流 (text stream) 的方式，會將以下所有的情識一行的結束：Unix 行尾慣例 '\n'、Windows 慣例 '\r\n' 和舊的 Macintosh 慣例 '\r'。請參 [PEP 278](#) 和 [PEP 3116](#)，以及用於 `bytes.splitlines()` 的附加用途。

### variable annotation (變數釋)

一個變數或 class 屬性的 *annotation* (釋)。

釋變數或 class 屬性時，賦值是選擇性的：

```
class C:
    field: 'annotation'
```

變數釋通常用於型提示 (*type hint*)：例如，這個變數預期會取得 `int` (整數) 值：

```
count: int = 0
```

變數釋的語法在 [annassign](#) 章節有詳細的解釋。

請參 [function annotation](#) (函式釋)、[PEP 484](#) 和 [PEP 526](#)，皆有此功能的描述。關於釋的最佳實踐方法，另請參 [annotations-howto](#)。

### virtual environment (擬環境)

一個協作隔離 (cooperatively isolated) 的執行環境，能讓 Python 的使用者和應用程式得以安裝和升級 Python 發套件，而不會對同一個系統上運行的其他 Python 應用程式的行生干擾。

另請參 [venv](#)。

### virtual machine (擬機器)

一部完全由軟體所定義的電腦 (computer)。Python 的擬機器會執行由 *bytecode* (位元組碼) 編譯器所發出的位元組碼。

### Zen of Python (Python 之)

Python 設計原則與哲學的列表，其容有助於理解和使用此語言。此列表可以透過在互動式提示字元後輸入 `import this` 來找到它。

---

## 關於這份📖明文件

---

Python 📖明文件是透過使用 [Sphinx](#)（一個原📖 Python 而生的文件📖生器、目前是以獨立專案形式來維護）將使用 [reStructuredText](#) 撰寫的原始檔轉📖而成。

如同 Python 自身，透過自願者的努力下📖出文件與封裝後自動化執行工具。若想要回報臭蟲，請見 [reporting-bugs](#) 頁面，📖含相關資訊。我們永遠歡迎新的自願者加入！

致謝：

- Fred L. Drake, Jr., 原始 Python 文件工具集的創造者以及一大部份📖容的作者；
- 創造 [reStructuredText](#) 和 [Docutils](#) 工具組的 [Docutils](#) 專案；
- Fredrik Lundh 先生，[Sphinx](#) 從他的 [Alternative Python Reference](#) 計劃中獲得許多的好主意。

### B.1 Python 文件的貢獻者們

許多人都曾📖 Python 這門語言、Python 標準函式庫和 Python 📖明文件貢獻過。Python 所發📖的原始碼中含有部份貢獻者的清單，請見 [Misc/ACKS](#)。

正因📖 Python 社群的撰寫與貢獻才有這份這📖棒的📖明文件 -- 感謝所有貢獻過的人們！

---

 沿革與授權
 

---

## C.1 軟體沿革

Python 是由荷蘭數學和計算機科學研究學會 (CWI, 見 <https://www.cwi.nl>) 的 Guido van Rossum 於 1990 年代早期所創造, 目的是作一種稱 ABC 語言的後繼者。儘管 Python 包含了許多來自其他人的貢獻, Guido 仍是其主要作者。

1995 年, Guido 在維吉尼亞州雷斯頓的國家創新研究公司 (CNRI, 見 <https://www.cnri.reston.va.us>) 繼續他在 Python 的工作, 在那發了該軟體的多個版本。

2000 年五月, Guido 和 Python 核心開發團隊轉移到 BeOpen.com 成立了 BeOpen PythonLabs 團隊。同年十月, PythonLabs 團隊轉移到 Digital Creations, 後來成 Zope Corporation。2001 年, Python 軟體基金會 (PSF, 見 <https://www.python.org/psf/>) 成立, 這是一個專擁有 Python 相關的智慧財產權而創立的非營利組織。Zope Corporation 過去是 PSF 的一個贊助會員。

所有的 Python 版本都是開源的 (有關開源的定義, 參 <https://opensource.org>)。歷史上, 大多數但非全部的 Python 版本, 也是 GPL 相容的; 以下表格總結各個版本的差異。

發版本	源自	年份	擁有者	GPL 相容性? (1)
0.9.0 至 1.2	不適用	1991-1995	CWI	是
1.3 至 1.5.2	1.2	1995-1999	CNRI	是
1.6	1.5.2	2000	CNRI	否
2.0	1.6	2000	BeOpen.com	否
1.6.1	1.6	2001	CNRI	是 (2)
2.1	2.0+1.6.1	2001	PSF	否
2.0.1	2.0+1.6.1	2001	PSF	是
2.1.1	2.1+2.0.1	2001	PSF	是
2.1.2	2.1.1	2002	PSF	是
2.1.3	2.1.2	2002	PSF	是
2.2 以上	2.1.1	2001 至今	PSF	是

### 備

- (1) GPL 相容不表示我們是在 GPL 下發 Python。不像 GPL, 所有的 Python 授權都可以讓你發修改後的版本, 但不一定要使你的變更成開源。GPL 相容的授權使得 Python 可以結合其他

在 GPL 下發的軟體一起使用；但其它的授權則不行。

- (2) 根據 Richard Stallman 的 法，1.6.1 不是 GPL 相容的，因其授權有一個法律選擇條款。然而根據 CNRI 的 法，Stallman 的律師告訴 CNRI 的律師，1.6.1 與 GPL 「不相容」。

感謝許多的外部志工，在 Guido 指導下的付出，使得這些版本的發成可能。

## C.2 關於存取或以其他方式使用 Python 的合約條款

Python 軟體和 明文件的授權是基於 Python 軟體基金會授權第二版 (Python Software Foundation License Version 2)。

從 Python 3.8.6 開始， 明文件中的範例、程式庫和其他程式碼，是被雙重授權 (dual licensed) 於 PSF 授權第二版以及 *Zero-Clause BSD* 授權。

有些被納入 Python 中的軟體是基於不同的授權。這些授權將會與其授權之程式碼一起被列出。關於這些授權的不完整清單，請參 被收 軟體的授權與致謝。

### C.2.1 PYTHON SOFTWARE FOUNDATION LICENSE VERSION 2

1. This LICENSE AGREEMENT is between the Python Software Foundation ("PSF"), and the Individual or Organization ("Licensee") accessing and otherwise using this software ("Python") in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python alone or in any derivative version, provided, however, that PSF's License Agreement and PSF's notice of copyright, i.e., "Copyright © 2001-2024 Python Software Foundation; All Rights Reserved" are retained in Python alone or in any derivative version prepared by Licensee.
3. In the event Licensee prepares a derivative work that is based on or incorporates Python or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python.
4. PSF is making Python available to Licensee on an "AS IS" basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By copying, installing or otherwise using Python, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.2 BEOPEN.COM LICENSE AGREEMENT FOR PYTHON 2.0

### BEOPEN PYTHON OPEN SOURCE LICENSE AGREEMENT VERSION 1

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization ("Licensee") accessing and otherwise using this software in source or binary form and its associated documentation ("the Software").
2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.
3. BeOpen is making the Software available to Licensee on an "AS IS" basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF USING, MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
6. This License Agreement shall be governed by and interpreted in all respects by the law of the State of California, excluding conflict of law provisions. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between BeOpen and Licensee. This License Agreement does not grant permission to use BeOpen trademarks or trade names in a trademark sense to endorse or promote products or services of Licensee, or any third party. As an exception, the "BeOpen Python" logos available at <http://www.pythonlabs.com/logos.html> may be used according to the permissions granted on that web page.
7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.3 CNRI LICENSE AGREEMENT FOR PYTHON 1.6.1

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 ("CNRI"), and the Individual or Organization ("Licensee") accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.
2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI's License Agreement and CNRI's notice of copyright, i.e., "Copyright © 1995-2001 Corporation for National Research Initiatives; All Rights Reserved" are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI's License Agreement, Licensee may substitute the following text (omitting the quotes): "Python 1.6.1 is made available subject to the terms and conditions in CNRI's License Agreement. This Agreement together with Python 1.6.1 may be located on the

(繼續下一頁)

(繼續上一頁)

internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the internet using the following URL: <http://hdl.handle.net/1895.22/1013>".

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.
4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS" basis. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.
5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.
6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.
7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the law of the Commonwealth of Virginia, excluding Virginia's conflict of law provisions. Notwithstanding the foregoing, with regard to derivative works based on Python 1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.
8. By clicking on the "ACCEPT" button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

## C.2.4 CWI LICENSE AGREEMENT FOR PYTHON 0.9.0 THROUGH 1.2

Copyright © 1991 - 1995, Stichting Mathematisch Centrum Amsterdam, The Netherlands. All rights reserved.

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Stichting Mathematisch Centrum or CWI not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

STICHTING MATHEMATISCH CENTRUM DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL STICHTING MATHEMATISCH CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS

(繼續下一頁)

(繼續上一頁)

ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

## C.2.5 ZERO-CLAUSE BSD LICENSE FOR CODE IN THE PYTHON DOCUMENTATION

Permission to use, copy, modify, and/or distribute this software for any purpose with or without fee is hereby granted.

THE SOFTWARE IS PROVIDED "AS IS" AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL THE AUTHOR BE LIABLE FOR ANY SPECIAL, DIRECT, INDIRECT, OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

## C.3 被收 軟體的授權與致謝

本節是一個不完整但持續增加的授權與致謝清單，對象是在 Python 版本中所收的第三方軟體。

### C.3.1 Mersenne Twister

*random* 模組底下的 `_random` C 擴充程式包含了以 <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html> 的下載內容基礎的程式碼。以下是原始程式碼的完整聲明：

A C-program for MT19937, with initialization improved 2002/1/26.  
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using `init_genrand(seed)`  
or `init_by_array(init_key, key_length)`.

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura,  
All rights reserved.

Redistribution and use in source and binary forms, with or without  
modification, are permitted provided that the following conditions  
are met:

1. Redistributions of source code must retain the above copyright  
notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright  
notice, this list of conditions and the following disclaimer in the  
documentation and/or other materials provided with the distribution.
3. The names of its contributors may not be used to endorse or promote  
products derived from this software without specific prior written  
permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS  
"AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT  
LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR  
A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR  
CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL,  
EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO,  
PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR  
PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF

(繼續下一頁)

(繼續上一頁)

```
LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
```

Any feedback is very welcome.

<http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html>

email: m-mat @ math.sci.hiroshima-u.ac.jp (remove space)

## C.3.2 Sockets

`socket` 模組使用 `getaddrinfo()` 和 `getnameinfo()` 函式，它們在 WIDE 專案 (<https://www.wide.ad.jp/>) 中，於不同的原始檔案中被編碼：

```
Copyright (C) 1995, 1996, 1997, and 1998 WIDE Project.  
All rights reserved.
```

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the project nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

```
THIS SOFTWARE IS PROVIDED BY THE PROJECT AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PROJECT OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
```

## C.3.3 非同步 socket 服務

`test.support.asyncchat` 和 `test.support.asyncore` 模組包含以下聲明：

```
Copyright 1996 by Sam Rushing
```

```
All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Sam Rushing not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.
```

```
SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN
```

(繼續下一頁)

(繼續上一頁)

```
NO EVENT SHALL SAM RUSHING BE LIABLE FOR ANY SPECIAL, INDIRECT OR
CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS
OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT,
NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN
CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.
```

### C.3.4 Cookie 管理

`http.cookies` 模組包含以下聲明：

```
Copyright 2000 by Timothy O'Malley <timo@alum.mit.edu>
```

```
All Rights Reserved
```

```
Permission to use, copy, modify, and distribute this software
and its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that that copyright notice and this permission
notice appear in supporting documentation, and that the name of
Timothy O'Malley not be used in advertising or publicity
pertaining to distribution of the software without specific, written
prior permission.
```

```
Timothy O'Malley DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS
SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY
AND FITNESS, IN NO EVENT SHALL Timothy O'Malley BE LIABLE FOR
ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR
PERFORMANCE OF THIS SOFTWARE.
```

### C.3.5 執行追 F

`trace` 模組包含以下聲明：

```
portions copyright 2001, Autonomous Zones Industries, Inc., all rights...
err... reserved and offered to the public under the terms of the
Python 2.2 license.
Author: Zooko O'Whielacronx
http://zooko.com/
mailto:zooko@zooko.com
```

```
Copyright 2000, Mojam Media, Inc., all rights reserved.
Author: Skip Montanaro
```

```
Copyright 1999, Bioreason, Inc., all rights reserved.
Author: Andrew Dalke
```

```
Copyright 1995-1997, Automatrix, Inc., all rights reserved.
Author: Skip Montanaro
```

```
Copyright 1991-1995, Stichting Mathematisch Centrum, all rights reserved.
```

```
Permission to use, copy, modify, and distribute this Python software and
its associated documentation for any purpose without fee is hereby
granted, provided that the above copyright notice appears in all copies,
and that both that copyright notice and this permission notice appear in
supporting documentation, and that the name of neither Automatrix,
```

(繼續下一頁)

(繼續上一頁)

Bioreason or Mojama Media be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

### C.3.6 UUencode 與 UUdecode 函式

uu 編解碼器包含以下聲明:

```
Copyright 1994 by Lance Ellinghouse
Cathedral City, California Republic, United States of America.
    All Rights Reserved
Permission to use, copy, modify, and distribute this software and its
documentation for any purpose and without fee is hereby granted,
provided that the above copyright notice appear in all copies and that
both that copyright notice and this permission notice appear in
supporting documentation, and that the name of Lance Ellinghouse
not be used in advertising or publicity pertaining to distribution
of the software without specific, written prior permission.
LANCE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO
THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND
FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE
FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN
ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT
OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Modified by Jack Jansen, CWI, July 1995:
- Use binascii module to do the actual line-by-line conversion
  between ascii and binary. This results in a 1000-fold speedup. The C
  version is still 5 times faster, though.
- Arguments more compliant with Python standard
```

### C.3.7 XML 遠端程序呼叫

xmlrpc.client 模組包含以下聲明:

```
The XML-RPC client interface is

THIS SOFTWARE IS PROVIDED BY THE AUTHOR AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

### C.3.10 SipHash24

Python/pyhash.c 檔案包含 Marek Majkowski 基於 Dan Bernstein 的 SipHash24 演算法的實作。它包含以下聲明：

```
<MIT License>
Copyright (c) 2013 Marek Majkowski <marek@popcount.org>

Permission is hereby granted, free of charge, to any person obtaining a copy
of this software and associated documentation files (the "Software"), to deal
in the Software without restriction, including without limitation the rights
to use, copy, modify, merge, publish, distribute, sublicense, and/or sell
copies of the Software, and to permit persons to whom the Software is
furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in
all copies or substantial portions of the Software.
</MIT License>

Original location:
  https://github.com/majek/csiphash/

Solution inspired by code from:
  Samuel Neves (supercop/crypto_auth/siphhash24/little)
  djb (supercop/crypto_auth/siphhash24/little2)
  Jean-Philippe Aumasson (https://131002.net/siphhash/siphhash24.c)
```

### C.3.11 strtod 與 dtoa

Python/dtoa.c 檔案提供了 C 的 `dtoa` 和 `strtod` 函式，用於將 C 的雙精度浮點數和字串互相轉。該檔案是衍生自 David M. Gay 建立的同名檔案，後者現在可以從 <https://web.archive.org/web/20220517033456/http://www.netlib.org/fp/dtoa.c> 下載。於 2009 年 3 月 16 日所檢索的原始檔案包含以下版權與授權聲明：

```
/*
 *
 * The author of this software is David M. Gay.
 *
 * Copyright (c) 1991, 2000, 2001 by Lucent Technologies.
 *
 * Permission to use, copy, modify, and distribute this software for any
 * purpose without fee is hereby granted, provided that this entire notice
 * is included in all copies of any software which is or includes a copy
 * or modification of this software and in all copies of the supporting
 * documentation for such software.
 *
 * THIS SOFTWARE IS BEING PROVIDED "AS IS", WITHOUT ANY EXPRESS OR IMPLIED
 * WARRANTY. IN PARTICULAR, NEITHER THE AUTHOR NOR LUCENT MAKES ANY
 * REPRESENTATION OR WARRANTY OF ANY KIND CONCERNING THE MERCHANTABILITY
 * OF THIS SOFTWARE OR ITS FITNESS FOR ANY PARTICULAR PURPOSE.
 */
```

### C.3.12 OpenSSL

如果 OpenSSL 函式庫可被作業系統使用，則 `hashlib`、`posix`、`ssl` 模組會使用它來提升效能。此外，因 Windows 和 macOS 的 Python 安裝程式可能包含 OpenSSL 函式庫的副本，所以我們也在此收 OpenSSL 授權的副本。對於 OpenSSL 3.0 版本以及由此衍生的更新版本則適用 Apache 許可證 v2：

```
Apache License
Version 2.0, January 2004
https://www.apache.org/licenses/
```

## TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

## 1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

(繼續下一頁)

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.
3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.
4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
  - (a) You must give any other recipients of the Work or Derivative Works a copy of this License; and
  - (b) You must cause any modified files to carry prominent notices stating that You changed the files; and
  - (c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
  - (d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or

(繼續上一頁)

for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.
6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.
7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

### C.3.13 expat

除非在建置 `pyexpat` 擴充時設定 `F --with-system-expat`，否則該擴充會用一個 `F` 含 `expat` 原始碼的副本來建置：

Copyright (c) 1998, 1999, 2000 Thai Open Source Software Center Ltd  
and Clark Cooper

(繼續下一頁)

(繼續上一頁)

```
Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:
```

```
The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.
```

```
THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY
CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT,
TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE
SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.
```

### C.3.14 libffi

除非在建置 `_ctypes` 模組底下 `_ctypes` 擴充程式時設定 `--with-system-libffi`，否則該擴充會用一個含 `libffi` 原始碼的副本來建置：

```
Copyright (c) 1996-2008 Red Hat, Inc and others.
```

```
Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:
```

```
The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.
```

```
THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND
NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT
HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY,
WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM,
OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER
DEALINGS IN THE SOFTWARE.
```

### C.3.15 zlib

如果在系統上找到的 `zlib` 版本太舊以致於無法用於建置 `zlib` 擴充，則該擴充會用一個含 `zlib` 原始碼的副本來建置：

```
Copyright (C) 1995-2011 Jean-loup Gailly and Mark Adler
```

```
This software is provided 'as-is', without any express or implied
warranty. In no event will the authors be held liable for any damages
arising from the use of this software.
```

```
Permission is granted to anyone to use this software for any purpose,
including commercial applications, and to alter it and redistribute it
```

(繼續下一頁)

(繼續上一頁)

```
freely, subject to the following restrictions:
```

1. The origin of this software must not be misrepresented; you must not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.
2. Altered source versions must be plainly marked as such, and must not be misrepresented as being the original software.
3. This notice may not be removed or altered from any source distribution.

```
Jean-loup Gailly      Mark Adler
jloup@gzip.org        madler@alumni.caltech.edu
```

### C.3.16 cfuhash

`tracemalloc` 使用的雜表 (hash table) 實作，是以 `cfuhash` 專案基礎：

```
Copyright (c) 2005 Don Owens
All rights reserved.
```

```
This code is released under the BSD license:
```

```
